1 **1 Introduction**

2 Hip fracture is the plain English term for a proximal femoral fracture or PFF. It refers to a 3 fracture occurring in the area between the edge of the femoral head and 5 centimetres 4 below the lesser trochanter (Figure 1). These fractures are generally divided into two main 5 groups depending on their relationship to the capsule of the hip joint. Those above the 6 insertion of the capsule are termed intracapsular, subcapital or femoral neck fractures. 7 Those below the insertion are extracapsular. The extracapsular group is then further split 8 into trochanteric (inter or per-trochanteric and reverse oblique) and subtrochanteric as 9 shown. The division into intra and extracapsular fractures. This relates to both the blood 10 supply of the femoral head and the mechanics of fixation.

11 Hip fracture is a major issue due to an ever increasing ageing population. About 70–75,000 12 hip fractures (proximal femoral fractures) occur annually in the UK³⁸, with a cost (including 13 medical and social care) amounting to about £2 billion a year. Demographic projections 14 indicate that the UK annual incidence will rise to 91,500 by 2015 and 101,000 in 2020³⁸, 15 with an associated increase in annual expenditure. The majority of this expenditure will be 16 accounted for by hospital bed days and a further substantial contribution will come from 17 health and social aftercare. At present about a quarter of patients with hip fracture are 18 admitted from institutional care, and about 10-20% of those admitted from home 19 ultimately move to institutional care.

20 Hip fracture is the commonest reason for admission to an orthopaedic trauma ward and is 21 usually a 'fragility' fracture¹ caused by a fall affecting an older person with osteoporosis or 22 osteopaenia (a condition in which bones lose calcium and become thinner, but not as much 23 as in osteoporosis). The average age of a person with hip fracture is 77 years, and most are 24 women. Mortality is high – about 10% of people with a hip fracture die within 1 month and 25 about one third within 12 months. Most of the deaths are due to associated co morbidities 26 (including bronchopneumonia) and not just to the fracture itself reflecting the high 27 prevalence of comorbidity in people with hip fracture. It is often the occurrence of a fall 28 and fracture that signals underlying ill health. Thus, hip fracture is by no means an 29 exclusively surgical concern. Its effective management requires the co-ordinated 30 application of medical, surgical, anaesthetic and multidisciplinary rehabilitation skills and a 31 comprehensive approach covering the full time course of the condition from presentation 32 to subsequent follow-up, including the transition from hospital to community.

¹ The strict definition of a fragility fracture is one caused by a fall from standing height or less. For the purposes of this guidance, the definition is slightly more flexible to encompass all hip fractures judged to have an osteoporotic or osteopaenic basis

Although hip fracture is predominantly a phenomenon of later life, it may occur at any age
 in people with osteoporosis or osteopenia, and this guidance is applicable to adults across
 the age spectrum. Skills in its management have, however been accrued, researched and
 reported especially by collaborative teams specialising in the care of older people (using the
 general designation orthogeriatrics). These skills are applicable in hip fracture irrespective
 of age, and the guidance includes recommendations that cover the needs of younger
 patients by drawing on such skills in an organised manner.

8 This guidance covers the management of hip fracture from the point of admission to 9 secondary care through to final return to the community and discharge from specific 10 follow-up. It assumes that anyone clinically suspected of having a hip fracture will be 11 referred for immediate hospital assessment other than in exceptional circumstances. It 12 excludes (other than by cross-reference) aspects covered by parallel NICE guidance, most 13 notably primary and secondary prevention of fragility fractures, but recognises the 14 importance of effective linkage to these closely related elements of comprehensive care.

- The diagnosis of hip fracture is easily missed and in a small minority of patients the fracture
 may not be apparent on a plain X-ray. In view of the serious nature of hip fracture the
 guidance has sought to identify the most cost-effective imaging strategies to ensure this
 does not happen.
- 19 Although not a structured service delivery evaluation, the Guideline Group was required to 20 extend its remit to cover essential implications for service organisation within the NHS 21 where these are fundamental to hip fracture management, and this has been done. In 22 general it is the case that suboptimal care and/or fragmentation of care result in longer 23 periods of dependency and/or hospitalisation leading to greater cost as well as inferior 24 outcome. There is substantial variation and lack of clarity in the UK in the extent, timing, 25 manner and organisation of the necessary collaborative and multidisciplinary elements of 26 effective management, including the timely achievement of rehabilitation after surgery 27 according to individual need. A further concern is the occurrence of delay before necessary 28 surgery is carried out. Prompt surgery has been generally recognised to be important, but 29 surgery is sometimes delayed for administrative or clinical reasons. Emerging evidence from 30 the National Hip Fracture database indicates substantial variation across centres in England 31 and Wales in this and other indicators of clinical and service quality. Such variation has 32 potentially profound economic implications, and priority has been given where appropriate 33 to underpinning recommendations with any available evidence of cost-effectiveness in the 34 NHS. Since work began on the guideline the Department of Health in England has launched 35 a high priority Best Practice Tariff initiative targeting a range of performance variables for 36 hip fracture, and the GDG have been aware of this contextual change as well as of 37 humanitarian issues in evaluating the evidence and formulating recommendations.
- At all stages of hip fracture management, the importance of optimal communication with,
 and support for, patients themselves and those who provide or will provide care –
 including unpaid care family members or others has been a fundamental tenet of
 guidance development.

The view of the GDG is that an exceptional contemporary window of opportunity exists in
the NHS to achieve major improvements in the delivery of hip fracture care, to the benefit
not only of patients but of the system as a whole in terms of efficiency and cost. It is hoped
that implementation of this guidance will be instrumental to that end.

8

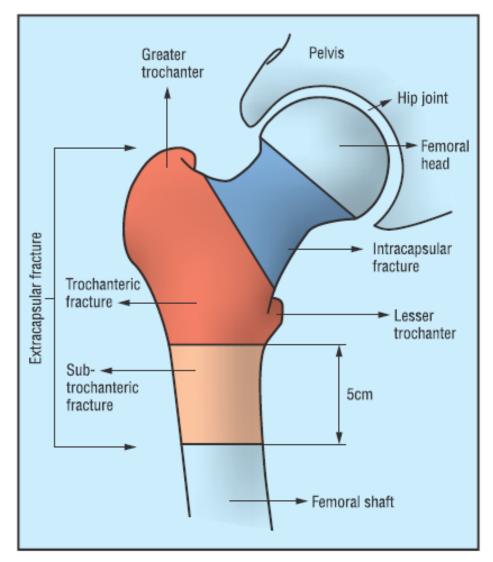

Figure 1: Types of hip fracture (Parker M & Johansen A, 2006)^{251,262}

Classification of hip fractures. Fractures in the blue area are intracapsular and those in the red and orange areas are extracapsular

1 2 Development of the guideline

2 2.1 What is a NICE clinical guideline?

NICE clinical guidelines are recommendations for the care of individuals in specific clinical
 conditions or circumstances within the NHS – from prevention and self-care through
 primary and secondary care to more specialised services. We base our clinical guidelines on
 the best available research evidence, with the aim of improving the quality of health care.
 We use predetermined and systematic methods to identify and evaluate the evidence
 relating to specific review questions.

9 NICE clinical guidelines can:

10

11

15

16

20

21

22

24

25

26

- provide recommendations for the treatment and care of people by health professionals
- be used to develop standards to assess the clinical practice of individual health
 professionals
- be used in the education and training of health professionals
 - help patients to make informed decisions
 - improve communication between patient and health professional
- While guidelines assist the practice of healthcare professionals, they do not replace theirknowledge and skills.
- 19 We produce our guidelines using the following steps:
 - Guideline topic is referred to NICE from the Department of Health
 - Stakeholders register an interest in the guideline and are consulted throughout the development process.
- The scope is prepared by the National Clinical Guideline Centre (NCGC)
 - The NCGC establishes a guideline development group
 - A draft guideline is produced after the group assesses the available evidence and makes recommendations

- There is a consultation on the draft guideline. The final guideline is produced. The NCGC and NICE produce a number of versions of this guideline: 5 the **full guideline** contains all the recommendations, plus details of the methods 6 used and the underpinning evidence the NICE guideline lists the recommendations the quick reference guide (QRG) presents recommendations in a suitable format for health professionals 10 information for the public ('understanding NICE guidance' or UNG) is written using suitable language for people without specialist medical knowledge.
- 12 This version is the full version. The other versions can be downloaded from NICE 13 www.NICE.org.uk and the NCGC website www.ncgc.ac.uk.

2.2 Remit 14

1

2

3

4

7

8

9

11

- 15 NICE received the remit for this guideline from the Department of Health. They 16 commissioned the NCGC to produce the guideline.
- 17 The remit for this guideline is:
- 18 To prepare a clinical guideline on the management of fractured neck of femur.

19 2.3 Who developed this guideline?

- 20 A multidisciplinary Guideline Development Group (GDG) comprising professional group 21 members and consumer representatives of the main stakeholders developed this guideline 22 (see section on Guideline Development Group Membership and acknowledgements).
- 23 The National Institute for Health and Clinical Excellence funds the National Clinical 24 Guideline Centre (NCGC) and thus supported the development of this guideline. The GDG 25 was convened by the NCGC and chaired by Professor Cameron Swift in accordance with 26 guidance from the National Institute for Health and Clinical Excellence (NICE).
- 27 The group met every 6-8 weeks during the development of the guideline. At the start of the 28 guideline development process all GDG members declared interests including 29 consultancies, fee-paid work, share-holdings, fellowships and support from the healthcare 30 industry. At all subsequent GDG meetings, members declared arising conflicts of interest, 31 which were also recorded.
- 32 Members were either required to withdraw completely or for part of the discussion if their 33 declared interest made it appropriate. The details of declared interests and the actions 34 taken are shown in Appendix B.

1 2 3 4 5 6		proces review searche	om the NCGC provided methodological support and guidance for the development s. The team working on the guideline included a project manager, systematic ers, health economists and information scientists. They undertook systematic es of the literature, appraised the evidence, conducted meta analysis and cost veness analysis where appropriate and drafted the guideline in collaboration with the
7			
8	2.4	What	this guideline covers
9		The p	oopulation of this guideline covers:
10 11		a)	Adults aged 18 years and older presenting to the health service with a clinical diagnosis (firm or provisional) of fragility fracture of the hip.
12		b)	People with the following types of hip fracture:
13			 intracapsular (undisplaced and displaced)
14			• extracapsular (trochanteric and subtrochanteric).
15 16 17		c)	Those with comorbidity strongly predictive of outcome, and those without such comorbidity. The influence (if any) of advanced age or gender on clinical decision-making, management and outcome will be specifically evaluated.
18 19			urther details please refer to the scope in Appendix A and review protocols in ndix C.
20		Key c	linical areas in this guideline are:
21 22		a)	Using alternative radiological imaging to confirm or exclude a suspected hip fracture in patients with a normal X-ray.
23 24		b)	Involving a physician or orthogeriatrician in the care of patients presenting with hip fracture.
25		c)	Early surgery (within 48 hours).
26 27		d)	Optimal preoperative and postoperative analgesia (pain relief), including the use of nerve blockade.
28 29		e)	Regional (spinal – also known as 'epidural') versus general anaesthesia in patients undergoing surgery for hip fracture.
30		f)	Surgeon experience and seniorityFor displaced intracapsular fracture:
31		g)	Internal fixation versus arthroplasty (hip replacement surgery)
32 33		h)	Total hip replacement versus hemiarthroplasty (replacing the head of the femur only).

1 2		i)	Choice of surgical implants - Sliding hip screw versus intramedullary nail for trochanteric extracapsular fracture.
3 4		j)	Choice of surgical implants - Sliding hip screw versus intramedullary nail for subtrochanteric extracapsular fracture.
5		k)	Cemented versus non-cemented arthroplasty implants.
6 7		I)	Hospital-based multidisciplinary rehabilitation for patients who have undergone hip fracture surgery.
8 9		m)	Early transfer to community-based multidisciplinary rehabilitation for patients who have undergone hip fracture surgery.
10	2.5	What	this guideline does not cover
11		The p	opulation of this guideline does not cover:
12		a)	People younger than 18 years.
13 14		b)	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia (because these would require more condition-specific guidance).
15		Clinica	al areas not included in this guideline are:
16		a)	Primary and secondary prevention of fragility fracture.
17		b)	Prevention and management of pressure sores.
18		c)	Prophylaxis for venous thromboembolism.
19		d)	Prevention and management of infection at the surgical site.
20		e)	Nutritional support.
21		f)	Selection of prostheses for hip replacement.
22		g)	Complementary and alternative therapies.
23	2.6	Relati	onships between the guideline and other NICE guidance
24		Related	INICE Health Technology Appraisals:

1 3 Methods

This guidance was developed in accordance with the methods outlined in the NICE
 Guidelines Manual 2009²²⁷

4 **3.1** Developing the review questions and outcomes

5 Review questions were developed in a PICO framework (patient, intervention, comparison 6 and outcome) for intervention reviews, and with a framework of population, index tests, 7 reference standard and target condition for reviews of diagnostic test accuracy. This was to 8 guide the literature searching process and to facilitate the development of 9 recommendations by the guideline development group (GDG). They were drafted by the 10 NCGC technical team and refined and validated by the GDG. The questions were based on 11 the key clinical areas identified in the scope (Appendix A). Further information on the 12 outcome measures examined follows this section.

Chap Review question		Outcomes	
ter			
Radiology	In patients with a continuing clinical suspicion of hip fracture, despite negative radiographic findings, what is the clinical and cost-effectiveness of additional imaging (radiography after at least 48 hours), Radionuclide scanning (RNS), ultrasound (US) and computed tomography (CT), compared to magnetic resonance imaging (MRI), in confirming, or excluding, a hip fracture?	 Sensitivity Specificity Positive and negative predictive values Positive and negative likelihood ratios 	
Timing of surgery	In patients with hip fractures what is the clinical and cost effectiveness of early surgery (within 24, 36 or 48 hours) on the incidence of complications such as mortality, pneumonia, pressure sores, cognitive dysfunction and increased length of hospital stay?	 Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Length of time before community resettlement/discharge Place of residence (compared with baseline) 12 months after fracture Functional status (30 days, 3 months, 1 year) Quality of life (30 days, 3 months, 1 year) Complications (including pressure ulcers) 	
Analgesia	In patients who have or are suspected of having a hip fracture, what is the clinical and cost effectiveness of nerve blocks compared to other forms of analgesia in providing adequate pain relief and reducing side effects and mortality?	 Pain Need for 'breakthrough' analgesia Mortality Adverse effects 	
Anaesthesia	In patients undergoing surgical repair for hip fractures, what is the clinical and cost effectiveness of regional (spinal/epidural) anaesthesia compared to general anaesthesia in reducing complications such as mortality, cognitive dysfunction thromboembolic events, post operative respiratory morbidity, renal failure and length of stay in hospital?	 Patient preference Early mortality up to 1 month Functional status up to 1 year Pain Adverse effects 	

		Methods	17
Surgeon seniority	Does surgeon seniority (consultant or equivalent) reduce the incidence of mortality, operative revision and poor functional outcome?	1 year)	าร
Cement	In hip fracture patients undergoing total hip replacement what is the clinical and cost effectiveness of cemented total hip replacement versus uncemented total hip replacement on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?	 Mortality a months & Functional Pain (generic visual analirating) Quality of Requirement Length of a hospital/a Length of a communit (i.e. supera Place of readter fract 	ent for reoperation stay in cute care stay in to y or resettlement spell) sidence 12 months
Intracapsular fractures	In patients undergoing repair for intracapsular hip fractures what is the clinical and cost effectiveness of internal fixation compared to hemiarthroplasty compared to total hip replacement on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?	months & Functional Pain (generic visual analic rating) Quality of Requirement Length of hospital/a Length of communit (i.e. supersident)	ent for reoperation stay in cute care stay in to y or resettlement spell) sidence 12 months
Surgical approach	In patients having surgical treatment for intracapsular hip fracture with hemiarthroplasty what is the clinical and cost effectiveness of anterolateral compared to posterior surgical approach on mortality, number of reoperations, dislocation, functional status, length of hospital stay, quality of life and pain?	1 year)	ns status

Hemiarthrop lasty stem design	In patients undergoing surgery for hip fracture what is the clinical and cost effectiveness of 'OEDP 10A rating' designs of stems in preference to Austin Moore or Thompson stems when inserting a hemiarthroplasty on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?	 Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell) Place of residence 12 months after fracture
Extracapsula r fractures	In patients undergoing repair for trochanteric extracapsular hip fractures what is the clinical and cost effectiveness of extramedullary sliding hip screws compared to intramedullary nails on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?	 Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation (operative or postoperative fracture of the femur, cut-out and non-union) Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell) Wound healing complications
Extracapsula r fractures	In patients undergoing repair for subtrochanteric extracapsular hip fractures, what is the effectiveness of extramedullary sliding hip screws compared to intramedullary nails on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?	 Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation (operative or postoperative fracture of the femur, cut-out and non-union) Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell) Wound healing complications

	Methods	19
Mobilisation strategies In patients who have undergone surgery for hip fracture, what is the clinical and cost effectiveness of early mobilisation (<48 hours after surgery) compared to late mobilisation on functional status, mortality, place of residence/discharge, pain and quality of life?	months & Functiona Pain (gene visual ana rating) Quality of	at 30 days, 3 1 year or longer I status up to 1 year erally measured by logue scale or verbal life destination
Mobilisation strategies In patients who have undergone surgery for hip fracture, what is the clinical and cost effectiveness of intensive physiotherapy compared to non intensive physiotherapy on functional status, mortality, place of residence/discharge, pain and quality of life?	months & Functiona Pain (gene visual ana rating) Quality of	at 30 days, 3 1 year or longer I status up to 1 year erally measured by logue scale or verbal life destination
Multidiscipli nary rehabilitatio n N Hutidiscipli n N Hutidiscipli n Hutidiscipli n Hutical and cost effectiveness of 'orthogeriatrician' involvement in the whole pathway of assessment, peri- operative care and rehabilitation on functional status, length of stay in secondary care, mortality, place of residence/discharge, hospital readmission and quality of life?	 Mortality 1 year) Length of care Length of communit resettlem Place of re with base after fract Functiona months, 1 Hospital re 	ent/discharge esidence (compared line) 12 months cure I status (30 days, 3 year) eadmission life (30 days, 3
Multidiscipli nary rehabilitatio n	 Mortality 1 year) Length of care Length of communit resettlem Place of re with base after fract Functiona months, 1 Hospital re 	(30 days, 3 months, stay in secondary time before ty ent/discharge esidence (compared line) 12 months ture I status (30 days, 3 year) eadmission life (30 days, 3

Multidiscipli nary rehabilitatio n	In patients with hip fracture what is the clinical and cost effectiveness of community-based multidisciplinary rehabilitation on functional status, length of stay in secondary care, mortality, place of residence/discharge, hospital readmission and quality of life?	 Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Length of time before community resettlement/discharge Place of residence (compared with baseline) 12 months after fracture Functional status (30 days, 3 months, 1 year) Hospital readmission Quality of life (30 days, 3 months, 1 year)
Carer involvement	In patients who have been discharged after hip fracture repair, what is the clinical and cost effectiveness of having a non paid carer (e.g. spouse, relative, friends) on mortality, length of stay, place of residence/discharge, functional status, hospital readmission and quality of life?	 Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Length of time before community resettlement/discharge Place of residence (compared with baseline) 12 months after fracture Functional status (30 days, 3 months, 1 year) Hospital readmission Quality of life (30 days, 3 months, 1 year)

2

3 3.2 Searching for evidence

4 3.2.1 Clinical literature search

5 Systematic literature searches were undertaken to identify evidence within published 6 literature in order to answer the review questions as per The Guidelines Manual²²⁷. 7 Clinical databases were searched using relevant medical subject headings, free-text 8 terms and study type filters where appropriate. Studies published in languages other 9 than English were not reviewed. Where possible, searches were restricted to articles 10 published in English language. All searches were conducted on core databases, 11 MEDLINE, Embase and The Cochrane Library. Additional subject specific databases were 12 used for some questions: PsycInfo for patient views and patient education questions; 13 Cinahl for every question except those on anaesthesia, analgesia and the surgical procedures. All searches were updated on the 31st August 2010. No papers after this 14 15 date were considered.

- Search strategies were checked by looking at reference lists of relevant key papers,
 checking search strategies in other systematic reviews and asking the GDG for known
 studies. The questions, the study types applied, the databases searched and the years
 covered can be found in Appendix D.
- 5 During the scoping stage, a search was conducted for guidelines and reports on the 6 websites listed below and on organisations relevant to the topic. Searching for grey 7 literature or unpublished literature was not undertaken. All references sent by 8 stakeholders were considered.
 - Guidelines International Network database (www.g-i-n.net)
- 10 National Guideline Clearing House (www.guideline.gov/)
 - National Institute for Health and Clinical Excellence (NICE) (www.nice.org.uk)
 - National Institutes of Health Consensus Development Program (consensus.nih.gov/)
- 13 NHS Evidence (<u>www.evidence.nhs.uk/</u>)
- 14

11

12

15 **3.2.2 Health economic literature search**

16 Systematic literature searches were also undertaken to identify health economic evidence 17 within published literature relevant to the review questions. The evidence was identified by 18 conducting a broad search relating to the guideline population in the NHS economic 19 evaluation database (NHS EED) and health technology assessment (HTA) database with no 20 date restrictions. Additionally, the search was run on MEDLINE and Embase, with a specific 21 economic filter, to ensure recent publications that had not yet been indexed by these 22 databases were identified. This was supplemented by additional searches that looked for 23 economic papers specifically relating to the radiological imaging question on MEDLINE, 24 Embase, NHS EED and HTA databases, and the Health Economic Evaluations Database 25 (HEED) as it became apparent that some papers in this area were not being identified 26 through the first search. Studies published in languages other than English were not 27 reviewed. Where possible, searches were restricted to articles published in English 28 language.

- The search strategies for health economics are included in Appendix D. All searches were updated on the 31st August 2010. No papers published after this date were considered.
- 31

32 **3.3 Evidence of effectiveness**

- 33 The Research Fellow
- Identified potentially relevant studies for each review question from the relevant search
 results by reviewing titles and abstracts full papers were then obtained.
- Reviewed full papers against pre-specified inclusion / exclusion criteria to identify studies
 that addressed the review question in the appropriate population and reported on
 outcomes of interest (review protocols are included in Appendix C).

HIP FRACTURE (1st draft October 2010)

1 2	• Critically appraised relevant studies using the appropriate checklist as specified in The Guidelines Manual ²²⁷ .
3 4	• Extracted key information about the study's methods and results into evidence tables (evidence tables are included in Appendix E).
5 6	 Generated summaries of the evidence by outcome (included in the relevant chapter write-ups):
7 8	 Randomised studies: meta analysed, where appropriate and reported in GRADE profiles (for clinical studies) – see below for details
9	• Observational studies: data presented as a range of values in GRADE profiles
10	 Diagnostic studies: data presented as a range of values in adapted GRADE profiles
11 12	 Qualitative studies: each study summarised in a table where possible, otherwise presented in a narrative.
13	
14	3.3.1 Inclusion/exclusion
15	See the review protocols in Appendix C for full details.
16	
17	3.3.2 Methods of combining clinical studies
18	Data synthesis for intervention reviews
19 20 21 22 23 24	Where possible, meta-analyses were conducted to combine the results of studies for each review question using Cochrane Review Manager (RevMan5) software. Fixed-effects (Mantel-Haenszel) techniques were selected to calculate risk ratios (relative risk) for the binary outcomes. The continuous outcomes were analysed using an inverse variance method for pooling weighted mean differences and where the studies had different scales, standardised mean differences were used.
25 26 27	Statistical heterogeneity was assessed by considering the chi-squared test for significance at p<0.05 or an I-squared inconsistency statistic of >50% to indicate significant heterogeneity. Where significant heterogeneity was present, we carried out predefined

- subgroup analyses as defined in the protocol for each question (Appendix C). Sensitivity
 analysis based on the quality of studies was also carried out if there were differences, with
 particular attention paid to allocation concealment, blinding and loss to follow-up (missing
 data).
- Assessments of potential differences in effect between subgroups were based on the chi squared tests for heterogeneity statistics between subgroups. If no sensitivity analysis was
 found to completely resolve statistical heterogeneity then a random effects (DerSimonian
 and Laird) model was employed to provide a more conservative estimate of the effect.
- For binary outcomes, absolute event rates were also calculated using the GRADEprosoftware using event rate in the control arm of the pooled results.

1 Data synthesis for diagnostic test accuracy review

For diagnostic test accuracy studies, the following outcomes were reported: sensitivity,
specificity, positive predictive value, negative predictive value and positive and negative
likelihood ratios. In cases where the outcomes were not reported, 2 by 2 tables were
constructed from raw data to allow calculation of these accuracy measures. Summary
receiver operative characteristic (ROC) curves were not generated as we did not explore the

- 7 effect of different cut-off thresholds on sensitivity and specificity for the imaging questions.
- 8

9 3.3.3 Appraising the quality of evidence by outcomes

10 The evidence for outcomes from the included RCT and observational studies were 11 evaluated and presented using an adaptation of the 'Grading of Recommendations 12 Assessment, Development and Evaluation (GRADE) toolbox' developed by the international 13 GRADE working group (http://www.gradeworkinggroup.org/). The software (GRADEpro) 14 developed by the GRADE working group was used to assess the quality of each outcome, 15 taking into account individual study quality and the meta-analysis results. The summary of 16 findings was presented as two separate tables in this guideline. The "Clinical/Economic 17 Study Characteristics" table includes details of the quality assessment while the "Clinical 18 /Economic Summary of Findings" table includes pooled outcome data, where appropriate, 19 an absolute measure of intervention effect and the summary of quality of evidence for that 20 outcome. In this table, the columns for intervention and control indicate the sum of the 21 sample size for continuous outcomes. For binary outcomes such as number of patients with 22 an adverse event, the event rates (n/N: number of patients with events divided by sum of 23 number of patients) are shown with percentages. Reporting or publication bias was only 24 taken into consideration in the quality assessment and included in the Clinical Study 25 Characteristics table if it was apparent. Each outcome was examined separately for the 26 quality elements listed and defined in Table 3-1 and each graded using the quality levels 27 listed in

- Table 3-2. The main criteria considered in the rating of these elements are discussed below
 (see section 3.3.4 Grading of Evidence). Footnotes were used to describe reasons for
 grading a quality element as having serious or very serious problems. The ratings for each
 component were summed to obtain an overall assessment for each outcome.
- Table 3-3. The GRADE toolbox is currently designed only for randomised trials and
 observational studies but we adapted the quality assessment elements and outcome
 presentation for diagnostic accuracy studies.

1 Table 3-1: Descriptions of quality elements in GRADE for intervention studies

Quality element	Description
Limitations	Limitations in the study design and implementation may bias the estimates of the treatment effect. Major limitations in studies decrease the confidence in the estimate of the effect
Inconsistency	Inconsistency refers to an unexplained heterogeneity of results
Indirectness	Indirectness refers to differences in study population, intervention, comparator and outcomes between the available evidence and the review question, or recommendation made
Imprecision	Results are imprecise when studies include relatively few patients and few events and thus have wide confidence intervals around the estimate of the effect relative to the clinically important threshold
Publication bias	Publication bias is a systematic underestimate or an overestimate of the underlying beneficial or harmful effect due to the selective publication of studies

2 3

Table 3-2: Levels for quality elements in GRADE

Level	Description
None	There are no serious issues with the evidence
Serious	The issues are serious enough to downgrade the outcome evidence by one level
Very serious	The issues are serious enough to downgrade the outcome evidence by two levels

4

5 Table 3-3: Overall quality of outcome evidence in GRADE

Level	Description
High	Further research is <i>very unlikely</i> to change our confidence in the <i>estimate of effect</i>
Moderate	Further research is <i>likely</i> to have an important impact on our confidence in the <i>estimate of effect</i> and may change the estimate
Low	Further research is <i>very likely</i> to have an important impact on our confidence in the estimate of effect and is likely to change the estimate
Very low	Any estimate of effect is very uncertain

15

16

7 3.3.4 Grading the quality of clinical evidence

8 After results were pooled, the overall quality of evidence for each outcome was considered.
 9 The following procedure was adopted when using GRADE:

- 1. A quality rating was assigned, based on the study design. RCTs start HIGH and observational studies as LOW, uncontrolled case series as LOW or VERY LOW
- 2. The rating was then downgraded for the specified criteria: Study limitations, inconsistency, indirectness, imprecision and reporting bias. These criteria are detailed below. Observational studies were upgraded if there was: a large magnitude of effect, dose-response gradient, and if all plausible confounding would reduce a demonstrated effect or suggest a spurious effect when results showed no effect. Each

- 1 quality element considered to have "serious" or "very serious" risk of bias were rated 2 down -1 or -2 points respectively.
- 3
- 4 3. The downgraded/upgraded marks were then summed and the overall quality rating 5 was revised. For example, all RCTs started as HIGH and the overall quality became 6 MODERATE, LOW or VERY LOW if 1, 2 or 3 points were deducted respectively.
- 7 4. The reasons or criteria used for downgrading were specified in the footnotes.
- 8 The details of criteria used for each of the main quality element are discussed further in the 9 following sections 4.3.5 to 4.3.8.

10 3.3.5 Study limitations

- 11 The main limitations for randomised controlled trials are listed in Table 3-4.
- 12 The GDG accepted that investigator blinding in surgical intervention studies was impossible
- 13 and participant blinding was also impossible to achieve in most situations. Therefore, open-
- 14 label studies for surgery were not downgraded in the quality rating across the guideline.
- 15 Studies were downgraded for unclear or inadequate allocation concealment. .
- 16 Table 3-4 lists the limitations considered for randomised controlled trials.

17 Table 3-4: Study limitations of randomised controlled trials

Limitation	Explanation			
Allocation concealment	Those enrolling patients are aware of the group to which the next enrolled patient will be allocated (major problem in "pseudo" or "quasi" randomised trials with allocation by day of week, birth date, chart number etc.)			
Lack of blinding	Patient, caregivers, those recording outcomes, those adjudicating outcomes, or data analysts are aware of the arm to which patients are allocated			
Incomplete accounting of patients and outcome events	Loss to follow-up not accounted and failure to adhere to the intention to treat principle when indicated			
Selective outcome reporting	Reporting of some outcomes and not others on the basis of the results			
Other limitations	 For example: stopping early for benefit observed in randomised trials, in particular in the absence of adequate stopping rules use of unvalidated patient-reported outcomes carry-over effects in cross-over trials recruitment bias in cluster-randomised trials 			

18

19 3.3.6 Inconsistency

- 20 Inconsistency refers to an unexplained heterogeneity of results. When estimates of the 21 treatment effect across studies differ widely (i.e. heterogeneity or variability in results), this suggests true differences in underlying treatment effect. When heterogeneity was 22

1 measured at either Chi square p<0.05 or I- squared inconsistency statistic of >50%, but no 2 plausible explanation can be found, the quality of evidence was downgraded by one or two 3 levels, depending on the extent of uncertainty to the results contributed by the 4 inconsistency in the results. In addition to the I- square and Chi square values, the decision 5 for downgrading was also dependent on factors such as whether the intervention is 6 associated with benefit in all other outcomes or whether the uncertainty about the 7 magnitude of benefit (or harm) of the outcome showing heterogeneity would influence the 8 overall judgment about net benefit or harm (across all outcomes).

9 If inconsistency could be explained based on prespecified subgroup analysis, the GDG took
 10 this into account and considered whether to make separate recommendations based on
 11 the identified explanatory factors, i.e. population and intervention. Where subgroup
 12 analysis gives a plausible explanation of heterogeneity, the quality of evidence would not
 13 be downgraded.

14 3.3.7 Indirectness

15 Directness refers to the extent to which the populations, intervention, comparisons and

- 16 outcome measures are similar to those defined in the inclusion criteria for the reviews.
- 17 Indirectness is important when these differences are expected to contribute to a difference
- 18 in effect size, or may affect the balance of harms and benefits considered for an
- 19 intervention.

20 3.3.8 Imprecision

21The sample size, event rates and the resulting width of confidence intervals were the main22criteria considered. Where the minimal important difference (MID) of an outcome is23known, the optimal information size (OIS), i.e. the sample size required to detect the24difference with 80% power and p≤0.05 was calculated and used as the criteria. The criteria25applied for imprecision are based on the confidence intervals for pooled or the best26estimate of effect as illustrated in Figure 3-1 and outlined in Error! Reference source not27found..

28

Figure 3-1: Illustration of precise and imprecise outcomes based on the confidence interval ofoutcomes in a forest plot

2 3 4 5 6 7 8 9	MID = minimal important difference determined for each outcome. The MIDs are the threshold for appreciable benefits and harms. The confidence intervals of the top three points of the diagram were considered precise because the upper and lower limits did not cross the MID. Conversely, the bottom three points of the diagram were considered imprecise because all of them crossed the MID and reduced our certainty of the results. Figure adapted from GRADEPro software. The following are the MID for the outcomes and the methods used to calculate the OIS in this guideline:				
10	Any statistically significant difference in mortality				
11	 The default confidence intervals in GRADE of 0.75 and 1.25 for all other outcomes. 				
12					
13	3.4 Evidence of cost-effectiveness				
14 15	Evidence on cost-effectiveness related to the key clinical issues being addressed in the guideline was sought. The health economist:				
16	Undertook a systematic review of the economic literature				
17	Undertook new cost-effectiveness analysis in priority areas				
18					
19	3.4.1 Literature review				
20	The Health Economist:				
21 22	 Identified potentially relevant studies for each review question from the economic search results by reviewing titles and abstracts – full papers were then obtained. 				
23 24	 Reviewed full papers against pre-specified inclusion / exclusion criteria to identify relevant studies (see below for details). 				
25 26	• Critically appraised relevant studies using the economic evaluations checklist as specified in The Guidelines Manual ²²⁷ .				
27 28	 Extracted key information about the study's methods and results into evidence tables (evidence tables are included in Appendix F). 				
29 30	 Generated summaries of the evidence in NICE economic evidence profiles – see below for details. 				
31					
32	3.4.1.1 Inclusion/exclusion				
33 34	Full economic evaluations (cost-effectiveness, cost–utility, cost-benefit and cost- consequence analyses) and comparative costing studies that addressed the review				

question in the relevant population were considered potentially applicable as economic
 evidence.

Studies that only reported cost per hospital (not per patient), or only reported average
cost effectiveness without disaggregated costs and effects, were excluded. However,
studies reporting the cost per hospital were included when it was possible to ascertain the
cost per patient of each intervention. Abstracts, posters, reviews, letters/editorials,
foreign language publications and unpublished studies were excluded. Studies judged to
have had an applicability rating of 'not applicable' were excluded (this included studies
that took the perspective of a non-OECD country).

- Remaining studies were prioritised for inclusion based on their relative applicability to the
 development of this guideline and the study limitations. For example, if a high quality,
 directly applicable UK analysis was available other less relevant studies may not have
 been included. Where exclusions occurred on this basis, this is noted in the relevant
 section.
- For more details about the assessment of applicability and methodological quality see the
 economic evaluation checklist (The Guidelines Manual, Appendix H²²⁷ and the health
 economics research protocol in Appendix C.
- When no relevant economic analysis was found from the economic literature review,
 relevant UK NHS unit costs related to the compared interventions were presented to the
 GDG to inform the possible economic implication of the recommendation to make.
- 21

22 3.4.2 NICE economic evidence profiles

23 The NICE economic profile has been used to summarise cost and cost-effectiveness 24 estimates. The economic evidence profile shows, for each economic study, an assessment 25 of applicability and methodological quality, with footnotes indicating the reasons for the 26 assessment. These assessments were made by the health economist using the economic evaluation checklist from The Guidelines Manual, Appendix H²²⁷. It also shows 27 28 incremental costs, incremental outcomes (e.g. QALYs) and the incremental cost-29 effectiveness ratio from the primary analysis, as well as information about the assessment 30 of uncertainty in the analysis. See Table 3-5 for more details.

- 31 If a non-UK study was included in the profile, the results were converted into pounds
 32 sterling using the appropriate purchasing power parity²³⁸.
- 33 Table 3-5: Content of NICE economic profile

Item	Description		
Study	First author name, reference, date of study publication and country perspective.		
Limitations	An assessment of methodological quality of the study*:		
	• Minor limitations – the study meets all quality criteria, or the study fails to meet one or more quality criteria, but this is unlikely to change the conclusions about cost effectiveness.		
	 Potentially serious limitations – the study fails to meet one or more quality criteria, and this could change the conclusion about cost effectiveness New serious limitations – the study fails to meet one or more quality. 		
	 Very serious limitations – the study fails to meet one or more quality 		

	criteria and this is very likely to change the conclusions about cost effectiveness. Studies with very serious limitations would usually be excluded from the economic profile table.	
Applicability	 An assessment of applicability of the study to the clinical guideline, the current NHS situation and NICE decision-making*: Directly applicable – the applicability criteria are met, or one or more criteria are not met but this is not likely to change the conclusions about cost effectiveness. Partially applicable – one or more of the applicability criteria are not met, and this might possibly change the conclusions about cost effectiveness. Not applicable – one or more of the applicability criteria are not met, and this is likely to change the conclusions about cost effectiveness. 	
Other comments	Particular issues that should be considered when interpreting the study.	
Incremental cost	The mean cost associated with one strategy minus the mean cost of a comparator strategy.	
Incremental effects	The mean QALYs (or other selected measure of health outcome) associated with one strategy minus the mean QALYs of a comparator strategy.	
ICER	Incremental cost-effectiveness ratio: the incremental cost divided by the respective QALYs gained	
Uncertainty	A summary of the extent of uncertainty about the ICER reflecting the results of deterministic or probabilistic sensitivity analyses, or stochastic analyses of trial data, as appropriate.	
*Limitations and applicability were assessed using the economic evaluation checklist from The Guidelines		

1 *Limitations and applicability were assessed using the economic evaluation checklist from The Guidelines

2 Manual, Appendix H²²⁷

When no cost-effectiveness evidence was available, the cost of the interventions being
evaluated has in some cases been determined by conducing original cost analyses there
were reported in Appendix H. Alternatively, the GDG was presented with the cost figures

6 from relevant sources, such as the NHS reference cost for England and Wales.

7 3.4.3 Undertaking new health economic analysis

- 8 As well as reviewing the published economic literature for each review question, as 9 described above, new economic analyses were undertaken by the Health Economist in 10 priority areas. Priority areas for new health economic analysis were agreed by the GDG 11 after formation of the review questions and consideration of the available health 12 economic evidence.
- Additional data for the analysis was identified as required through additional literature
 searches undertaken by the Health Economist, and discussion with the GDG. Model
 structure, inputs and assumptions were explained to and agreed by the GDG members
 during meetings, and they commented on subsequent revisions.
- 17 See Appendix H for details of the health economic analyses undertaken for the guideline.
- 18

HIP FRACTURE (1 st	DRAFT	OCTOBER	2010)
----------------	-----------------	-------	---------	-------

1	3.4.4	Cost-effectiveness criteria
2 3 4 5 6		NICE's report 'Social value judgements: principles for the development of NICE guidance' ²²⁶ sets out the principles that GDGs should consider when judging whether an intervention offers good value for money. In general, an intervention was considered to be cost effective if either of the following criteria applied (given that the estimate was considered plausible):
7 8 9		 a) The intervention dominated other relevant strategies (that is, it was both less costly in terms of resource use and more clinically effective compared with all the other relevant alternative strategies), or
10 11		b) The intervention cost less than £20,000 per quality-adjusted life-year (QALY) gained compared with the next best strategy.
12 13 14 15 16 17		If the GDG recommended an intervention that was estimated to cost more than £20,000 per QALY gained, or did not recommend one that was estimated to cost less than £20,000 per QALY gained, the reasons for this decision are discussed explicitly in the 'from evidence to recommendations' section of the relevant chapter. This is written with reference to the issues regarding the plausibility of the estimate or to the factors set out in the Social value judgements report ²²⁶ .
18		
19		
20	3.5	Developing recommendations
21		Over the course of the guideline development process, the GDG was presented with:
22 23		• Evidence tables of the clinical evidence (Appendix E) and economic evidence (Appendix F) reviewed from the literature.
24 25		• Summary of clinical and economic evidence and quality (as presented in chapters 5 to 13).
26		• Forest plots (Appendix G)
27 28		• A description of the methods and results of the cost-effectiveness analysis undertaken for the guideline (Appendix H)
29 30 31 32 33 34 35		Recommendations were drafted on the basis of the GDG interpretation of the available evidence, taking into account the balance of benefits, harms and costs. When clinical and economic evidence was of poor quality, conflicting or absent, the GDG drafted recommendations based on their expert opinion. The considerations for making consensus based recommendations include the balance between potential harms and benefits, economic or implications compared to the benefits, current practices, recommendations made in other relevant guidelines, patient preferences and equality issues. The consensus recommendations were done through discussions in the GDG.

1 **3.5.1** Research recommendations

- When areas were identified for which good evidence was lacking, the guideline development
 group considered making recommendations for future research. Decisions about inclusion
 were based on factors such as:
- the importance to patients or the population
- 6 national priorities
- 7 potential impact on the NHS and future NICE guidance
- 8 ethical and technical feasibility
- 9

10 3.6 Validation process

The guidance is subject to an eight week public consultation and feedback as part of the
 quality assurance and peer review of the document. All comments received from registered
 stakeholders are responded to in turn and posted on the NICE website when the pre publication check of the full guideline occurs.

15

16 **3.7 Updating the guideline**

- Following publication, and in accordance with the NICE guidelines manual, NICE will ask a
 National Collaborating Centre or the National Clinical Guideline Centre to advise NICE's
 Guidance executive whether the evidence base has progressed significantly to alter the
 guideline recommendations and warrant an undate
- 20 guideline recommendations and warrant an update.
- 21

22 3.8 Disclaimer

Health care providers need to use clinical judgement, knowledge and expertise when deciding whether
 it is appropriate to apply guidelines. The recommendations cited here are a guide and may not be
 appropriate for use in all situations. The decision to adopt any of the recommendations cited here
 must be made by the practitioners in light of individual patient circumstances, the wishes of the
 patient, clinical expertise and resources.

The National Clinical Guideline Centre disclaim any responsibility for damages arising out of the use or
 non-use of these guidelines and the literature used in support of these guidelines.

30

31 **3.9 Funding**

The National Clinical Guideline Centre was commissioned by the National Institute for Healthand Clinical Excellence to undertake the work on this guideline.

1 **4 Guideline summary**

2 4.1 Map of recommendations

3 An algorithm will be added before publication.

1	Key priorities for implementation
2 3	The GDG identified ten key priorities for implementation. The decision was made after discussion and voting by the GDG. They selected recommendations that would:
4	• Have a high impact on outcomes that are important to patients (A)
5	• Have a high impact on reducing variation in care and outcomes (B)
6	• Lead to a more efficient use of NHS resources (C)
7	Promote patient choice (D)
8	Promote equalities.(E)
9 10	In doing this the GDG also considered which recommendations were particularly likely to benefit from implementation support. They considered whether a recommendation:
11	• Requires changes in service delivery (W)
12 13	 Requires retraining of professionals or the development of new skills and competencies (X)
14 15	 Affects and needs to be implemented across various agencies or settings (complex interactions) (Y)
16 17	 May be viewed as potentially contentious, or difficult to implement for other reasons (Z)
18 19 20	For each key recommendation listed below, the selection criteria and implementation support points are indicated by the use of the letters shown in brackets above and are shown in the linking evidence to recommendations sections in the relevant chapters.
21	Perform surgery on the day of, or the day after, admission. (A, B, C, F, W, Y and Z).
22 23	Identify and treat correctable comorbidities immediately so that surgery is not delayed by:
24	• anaemia
25	anticoagulation
26	volume depletion
27	electrolyte imbalance
28	uncontrolled diabetes
29	uncontrolled heart failure
30	correctable cardiac arrhythmia or ischaemia
31	acute chest infection

	34	HIP FRACTURE (1 st draft October 2010)					
1		• exacerbation of chronic chest conditions (A, B, C, F, Y and Z).					
2 3	Scher Z).	edule surgery for hip fracture patients on a planned trauma list (A, B, C, F, W, and					
4 5		Offer replacement arthroplasty to patients with a displaced intracapsular fracture (A, B, C, F and Z).					
6	➢ Offe	er total hip replacement to patients with a displaced intracapsular fracture who:					
7		were independently mobile before fracture and					
8		 are not cognitively impaired and 					
9		• are medically fit for anaesthesia and the operation (A, B, C, X, and Z).					
10 11 12	intra	er extramedullary implants such as a sliding hip screw in preference to an amedullary nail to patients with trochanteric fractures above and including the er trochanter (AO classification types A1 and A2) (A, B, C, and Z).					
13 14		er patients physiotherapy assessment and, unless medically or surgically traindicated, mobilisation on the day after surgery (A, B, C, D, E, F, W, X, Y and Z).					
15 16		er patients mobilisation at least once a day and ensure regular physiotherapy ew (A, B, F, and W).					
17 18		m admission, offer all hip fracture patients a formal, acute orthogeriatric or nopaedic ward-based Hip Fracture Programme that includes all of the following:					
19		orthogeriatric assessment					
20		 rapid optimisation of fitness for surgery 					
21 22 23		 early identification of individual goals for multidisciplinary rehabilitation to recover mobility and independence, and to facilitate return to prefracture residence and long-term well-being. 					
24		 continued co-ordinated orthogeriatric and multidisciplinary review 					
25		• communication with the primary care team (A,B,C,D,E,F,W,X,Y and Z).					
26		• (A,B,C,D,E,F,W,X,Y and Z).					
27 28 29	Pro	sider offering early supported discharge (ESD) as part of the Hip Fracture gramme (HFP) provided the HFP multidisciplinary team (MDT) remain involved the patient meets all of the following criteria:					
30		medically stable					
31		no cognitive impairment					
32		able to transfer and mobilise short distances					

1	• rehabilitation potential not yet achieved (A,B,C, E,F,W, and Z).
2	
3	4.2 Full list of recommendations
4	4.2.1 Imaging options in occult hip fracture
5 6 7	Offer magnetic resonance imaging (MRI) if hip fracture is suspected despite negative anteroposterior pelvis and lateral hip X-rays. If MRI is not available within 24 hours or is contraindicated, consider computed tomography (CT).
8	
9	4.2.2 Timing of surgery
10	Perform surgery on the day of, or the day after, admission.
11 12	Identify and treat correctable comorbidities immediately so that surgery is not delayed by:
13	• anaemia
14	anticoagulation
15	volume depletion
16	electrolyte imbalance
17	uncontrolled diabetes
18	uncontrolled heart failure
19	correctable cardiac arrhythmia or ischaemia
20	acute chest infection
21	exacerbation of chronic chest conditions.
22	4.2.3 Analgesia
23 24	Offer immediate analgesia to patients presenting at hospital with suspected hip fracture, including people with cognitive impairment.
25	Assess pain:
26	• within 30 minutes of administering initial analgesia and
27	hourly until settled on the ward and
28	• regularly as part of routine nursing observations throughout admission.

	Hip Fracture (1 st draft October 2010)
--	---

1 2 3	4	Ensure analgesia is sufficient to allow movements necessary for investigations (as indicated by the ability to tolerate passive external rotation of the leg), and for nursing care and rehabilitation.
4	\blacktriangleright	Offer paracetamol every 6 hours preoperatively unless contraindicated.
5 6		Offer additional opioids if paracetamol alone does not provide sufficient preoperative pain relief.
7 8 9	>	Consider adding nerve blocks if paracetamol and opioids do not provide sufficient preoperative pain relief or to limit opioid dosage. Do not use nerve blocks as a substitute for early surgery.
10		Offer paracetamol every 6 hours postoperatively unless contraindicated.
11 12	>	Offer additional opioids if paracetamol alone does not provide sufficient postoperative pain relief.
13	\triangleright	Non steroidal anti-inflammatory drugs (NSAIDs) are not recommended.
14		
15	4.2.4 Ana	esthesia
16 17	4	Offer patients a choice of spinal or general anaesthesia after discussing the risks and benefits.
18	\triangleright	Consider intraoperative nerve blocks for all patients undergoing surgery.
19	4.2.5 Surg	eon seniority
20	\triangleright	Schedule surgery for hip fracture patients on a planned trauma list.
21 22	4	Unsupervised trainees should not undertake surgery or anaesthesia on patients with hip fracture.
23	4.2.6 Surg	ical procedures
24 25	>	Operate on patients with the aim to allow them to fully weight bear (without restriction) in the immediate post operative period.
26	\blacktriangleright	Offer replacement arthroplasty to patients with a displaced intracapsular fracture.
27	\blacktriangleright	Offer total hip replacement to patients with a displaced intracapsular fracture who:
28		were independently mobile before fracture and
29		are not cognitively impaired and
30		• are medically fit for anaesthesia and the operation.
31 32 33	\checkmark	Consider using a proven femoral stem design rather than Austin Moore or Thompson stems for arthroplasties. Suitable designs include those with an Orthopaedic Data Evaluation Panel rating of 10A, 10B, 10C, 7A, 7B, 5A, 5B, 3A or 3B.

1	\checkmark	Offer cemented implants to patients undergoing surgery with arthroplasty.
2 3		Consider an anterolateral approach in favour of posterior approach when inserting a hemiarthroplasty.
4 5 6	4	Offer extramedullary implants such as a sliding hip screw in preference to an intramedullary nail to patients with trochanteric fractures above and including the lesser trochanter (AO classification types A1 and A2).
7	\triangleright	Offer an intramedullary nail to patients with a subtrochanteric fracture.
8	4.2.7 Mot	pilisation strategies
9 10		Offer patients physiotherapy assessment and, unless medically or surgically contraindicated, mobilisation on the day after surgery.
11 12	~	Offer patients mobilisation at least once a day and ensure regular physiotherapy review.
13	4.2.8 Mul	tidisciplinary management
14 15		From admission, offer all hip fracture patients a formal, acute orthogeriatric or orthopaedic ward-based Hip Fracture Programme that includes all of the following:
16		orthogeriatric assessment
17		rapid optimisation of fitness for surgery
18 19 20		 early identification of individual goals for multidisciplinary rehabilitation to recover mobility and independence, and to facilitate return to prefracture residence and long-term well-being.
21		continued co-ordinated orthogeriatric and multidisciplinary review
22		• communication with the primary care team.
23		
24 25 26	$\mathbf{\lambda}$	If a hip fracture complicates or precipitates a terminal illness, the multidisciplinary team should still consider the role of surgery, as part of a palliative care approach that:
27		minimises pain and other symptoms and
28		establishes patients' own priorities for rehabilitation and
29		• considers patients' wishes about their end-of-life care.
30 31 32	>	Actively look for cognitive impairment in all patients presenting with hip fracture and offer individualised care in line with 'Delirium' (NICE clinical guideline 103) to minimise the risk of delirium and maximise independence.

1 2 3	Consider offering early supported discharge (ESD) as part of the Hip Fracture Programme (HFP) provided the HFP multidisciplinary team (MDT) remain involved and the patient meets all of the following criteria:
4	medically stable
5	no cognitive impairment
6	able to transfer and mobilise short distances
7	rehabilitation potential not yet achieved.
8 9	Only consider intermediate care (continued rehabilitation in a community hospital o residential care unit) if all the following criteria are met:
10	• intermediate care is included in the Hip Fracture Programme
11 12	 the Hip Fracture Programme leads clinically; on patient selection, and in agreeing length of stay and objectives for intermediate care
13 14 15	 the Hip Fracture Programme leads managerially; ensuring that intermediate care is not resourced at the expense of the acute hospital's multidisciplinary team.
16 17 18	Patients admitted from care or nursing homes should not be denied the benefits of a rehabilitation programme in the community, hospital or as part of an early supporte discharge programme.
19	4.2.9 Patient and carer views and information
20 21	Offer patients and their families and carers verbal and written information about treatment and care including:
22	• diagnosis
23	choice of anaesthesia
24	choice of analgesia and other medications
25	surgical procedures
26	possible complications
27	post-operative care
28	rehabilitation programme
29	likely long-term outcome
30	healthcare professionals involved.
31	

1	4.3	Research recommendations
2		The GDG identified the following priority areas for research:
3		Imaging options in occult hip fracture
4		Anaesthesia
5		Displaced intracapsular hip fracture
6		Early supported discharge
7		Physiotherapy
8	4.3. 1	L Research recommendation on imaging options in occult hip fracture
9 10 11		In patients with a continuing suspicion of a hip fracture but whose radiographs are normal, what is the effectiveness of computed tomography compared to magnetic resonance imaging, in confirming or excluding the fracture?
12		Why this is important
13 14 15 16 17 18 19 20 21 22 23		The GDG's consensus decision to recommend CT over radionuclide bone scan as an alternative to MRI to detect occult hip fractures reflects current NHS practice but assumes that advances in technology have made the reliability of CT comparable to that of MRI. If modern CT indeed can be shown to have similar reliability and accuracy to MRI, then this has considerable implications because of its widespread availability out of hours and lower cost. It is a high priority, therefore, to confirm or refute this assumption by direct randomised comparison. The study design would need to retain MRI as the 'gold standard' for cases of uncertainty and would clearly need to standardise the criteria, expertise and procedures for radiological assessment. Numbers required would depend on the degree of sensitivity and specificity (the key outcome criteria) set as target requirement for comparability, but need not necessarily be very large.
0.4		

24 **4.3.2** Research recommendation on anaesthesia

What is the clinical and cost effectiveness of regional versus general anaesthesia on postoperative morbidity in patients with hip fracture?

27 Why this is important

28 No recent randomised controlled trials were identified that fully address this question. The 29 evidence is old and does not reflect current practice. In addition, in most of the studies the 30 patients are sedated before regional anaesthesia is administered and this is not taken into 31 account when analysing the results. The study design for the proposed research would be 32 best addressed by an randomised controlled trial. This would ideally be a multi-centred trial 33 including 3,000 participants in each arm. This is achievable if one considers that there are 70, 000 hip fractures a year in the UK³⁸. The study should have three arms which look at 34 35 spinal anaesthesia versus spinal anaesthesia plus sedation versus general anaesthesia, this 36 would separate those with regional anaesthesia from those with regional anaesthesia plus 37 sedation. The study would also need to control for surgery, especially type of fracture, 38 prosthesis and grade of surgeon.

- A qualitative research component would also be helpful to study patient preference for
 type of anaesthesia.
- 3

5

6

7

4.3.3 Research recommendation on displaced intracapsular hip fracture

What is the clinical and cost effectiveness of large head total hip replacement versus hemiarthroplasty on functional status, reoperations and quality of life in patients with displaced intracapsular hip fracture?

8 Why this is important

9 Large head total hip replacement is a development of traditional total hip replacement 10 where a larger head makes the joint more stable and hence reduces the risks of dislocation. 11 Previously, three small trials have shown that traditional small head total hip replacement 12 have shown improved outcomes and function yet with an increased dislocation rate in 13 selected groups of patients. The drawback with the large head arthroplasty is the additional 14 implant cost and theatre time. This cost can account for up to 20% of current NHS tariff (up 15 to £2000) and the study aims to address whether this translates to improved patient 16 outcome. The study design for the proposed research would be best addressed by an 17 randomised controlled trial. This would have two arms to compare current standard care 18 (using hemiarthroplasty) with using large head total hip replacement for patients sustaining 19 displaced intracapsular hip fractures. Primary outcome would be patient mobility at 1 year 20 and secondary outcomes would include functional outcomes, quality of life and cost 21 effectiveness of the intervention.

It would be expected that a sample size of approximately 500 patients would be required to
 show a significant difference in the mobility, hip function and quality of life (assuming 80%
 power p<0.05). Recruiting centres through a trauma research network it is estimated that
 10 centres would be able to recruit 20 patients per month (from 45 eligible patients) giving
 a recruitment period of 25 months.

27 4.3.4 Research recommendation on early supported discharge

What is the clinical and cost effectiveness of early supported discharge on mortality, quality of life and functional status in patients with hip fracture who are admitted from a care home?

31 Why this is important

28

29

30

32 Care and nursing homes residents account for 30% of all hip fracture patients admitted to 33 hospital. Two-thirds of these come from care homes and the remainder from nursing 34 homes. These patients are frailer, more functionally dependent and have a higher 35 prevalence of cognitive impairment than patients admitted from their own homes. One 36 third of those admitted from a care home are discharged to a nursing home and a fifth are 37 readmitted to hospital within 3 months. There are no clinical trials to define the optimal 38 rehabilitation pathway following hip fracture for these patients and they therefore 39 represent a discrete cohort where the existing meta-analyses do not apply. As a 40 consequence, many are denied structured rehabilitation and are returned back to their care 41 home ornursing home with very little or no rehabilitation input.

Given the patient frailty and comorbidities, rehabilitation may have a limited effect on clinical outcomes for this group. The fact that they already live in a home where they are supported by trained care staff, however, clearly provides an opportunity for a systematic approach to rehabilitation. Early multidisciplinary rehabilitation based in care homes ornursing homes would take advantage of the day-to-day care arrangements already in place and provide additional NHS support to deliver naturalistic rehabilitation, where problems are tackled in the patient's residential setting.

- 8 Early supported multidisciplinary rehabilitation could reduce hospital stay, improve early
 9 return to function, and affect both readmission rates and the level of NHS-funded nursing
 10 care required.
- 11 The research would follow a two-stage design: (1) an initial feasibility study to refine the 12 selection criteria and process for reliable identification and characterisation of those 13 considered most likely to benefit, together with the intervention package and measures for 14 collaboration between the Hip Fracture Programme team, care-home staff and other 15 community-based professionals, and (2) a cluster randomized controlled comparison (with, 16 say, two or more intervention units and matched control units) set against agreed outcome 17 criteria. The latter should include those specified above, together with measures of the 18 impact on care-home staff activity and cost, as well as qualitative data from patients on 19 relevant quality-of-life variables.

20 4.3.5 Research recommendation on physiotherapy

What is the clinical and cost effectiveness of additional intensive physiotherapy
 and/or occupational therapy (for example progressive, resistance training) after hip
 fracture?

24 Why this is important

- 25 The rapid restoration of physical and self care functions is a critical to recovery from hip
- 26 fracture, particularly where the goal is to return to the patient to pre-operative levels of
- function and residence. Approaches that are worthy of future development and
- 28 investigation include progressive resistance training, progressive balance and gait training,
- supported treadmill gait re-training, dual task training, and Activities of Daily Living training.
 The optimal time point at which these interventions should be started requires clarification.
- 31 The ideal study design is a randomised controlled trial. Initial studies may have to focus on 32 proof of concept and be mindful of costs. A phase III randomised controlled trial is required 33 to determine effectiveness and cost-effectiveness. The ideal sample size will be around 400 34 - 500 patients, and the primary outcome should be physical function and health related 35 quality of life. Outcomes should also include falls. A formal sample size calculation will need 36 to be undertaken. Outcomes should be followed over a minimum of 1 year, and compare if 37 possible, either the recovery curve for restoration of function or time to attainment of 38 functional goals.

39 4.3.6 Additional research recommendations

The following research questions were selected by the GDG but were not prioritised in thetop five recommendations for research.

1 4.3.6.1 Analgesia

3

4

5

16

17

18

- 2 The GDG recommended the following research question:
 - What is the clinical and cost effectiveness of preoperative and postoperative nerve blocks in reducing pain and achieving mobilisation and physiotherapy goals sooner in patients with hip fracture?

6 Why this is important

Nerve blocks may potentially find an important role in the management of hip fracture
pain, both pre- and post-operatively, because of their potential to reduce the requirement
for opioids and their associated unwanted effects. Economically there are considerations
for staff training, but also for the potential benefits in terms of duration of stay and early
mobilisation. It is not possible from the existing literature to determine this with any
confidence and there is a pressing need for a definitive trial comparing these outcomes
with nerve blocks against a defined protocol of systemic opioid use.

14 4.3.6.2 Timing of surgery

- 15 The GDG recommended the following research question:
 - What is the clinical and cost effectiveness of surgery within 36 hours of admission compared to surgery later than 36 hours from admission in mortality, morbidity and quality of life in patients with hip fracture?

19 Why this is important

20 Early and appropriate surgery for hip fractures is the most effective form of pain relief, 21 potentially quickening the rehabilitation and reducing complications. Within the current 22 literature no specific time interval threshold has been identified (up to 24hr) below which a 23 reduction in delay has shown no benefit. In addition to the evidence of the cost 24 effectiveness below 48hr, pragmatic, organisational and humanitarian considerations have 25 been utilised to arrive at the recommendation to operate not later than the day after 26 admission. A formal study within the NHS based on an arbitrary but realistic 36hr threshold 27 would provide additional important data to that already available, in order to inform more 28 precisely the forward clinical and cost-effectiveness of the strategy. For ethical reasons, the 29 research design would be an observational cohort study, correcting for confounding 30 variables, possibly set in the context of the National Hip Fracture Database and examining 31 the effect of the time to surgery and its cost on key outcomes, including mortality, 32 complications, length of stay, time taken to rehabilitate and qualitative aspects of the 33 experiences of patients.

34 **4.3.6.3** Reverse oblique trochanteric fractures

- 35 The GDG recommended the following research question:
- What is the clinical and cost effectiveness of intramedullary versus extramedullary
 total hip replacement on mortality, functional status and quality of life in patients
 with reverse oblique trochanteric hip fracture?

39 Why this is important

GUIDELINE SUMMARY

Reverse oblique trochanteric fractures account for approximately 5 % of all trochanteric hip fractures. This means it affects approximately over 1000 patients per year in the UK. Presently there is little evidence as to which is the preferable implant (which can be either extramedullary – outside the bone, or intramedullary - inside the bone). The potential biomechanical advantage of intramedullary advantage may be offset by increased cost (which can be over £1000 more expensive). A randomised trial comparing the two implants using patient mobility, function and re-operation would allow a more informed choice of treatment for this injury.

- 9 **4.3.6.4 Designated hip fracture units**
- 10 The GDG recommended the following research question:

What is the clinical and cost effectiveness of a designated hip fracture unit within
 the trauma ward compared to units integrated into acute trusts on mortality,
 quality of life and functional status in patients with hip fracture?

14 Why this is important

1

2

3

4

5

6

7

- The increasingly structured approach to hip fracture care has led to a number of UK units
 considering or establishing a specific 'hip fracture ward' as a specialist part of their acute
 orthopaedic service.
- Designated hip fracture wards may prove an effective means of delivering the whole
 programme of coordinated perioperative care and multidisciplinary rehabilitation which
 this NICE Guidance has proposed, but at present there is no high quality evidence of their
 clinical effectiveness when compared to such care within general orthopaedic or trauma
 beds.
- It may not be practical to run an RCT within a trauma unit, but there is certainly potential
 for cohort studies to explore the effect of such units on individual patients' mobility,
 discharge residence, mortality and length of stay. Units considering the establishment of
- 26 hip fracture wards should be encouraged to consider performing such trials.
- 27 4.3.6.5 Care/nursing home residents
- 28 The GDG recommended the following research question:
- 29 Do patients admitted to hospital with a fractured hip who live permanently in a
 30 care/nursing home have equal access to multidisciplinary rehabilitation as patients
 31 admitted from home?
- 32 Why this is important
- 33 The existing literature on the effectiveness of multidisciplinary rehabilitation typically 34 excludes patients who live in care/nursing homes. From an equality perspective it 35 hypothesised that this group of people do not have access to the same multidisciplinary 36 rehabilitation as patients who are returning home as it is assumed patients returning to 37 care/nursing homes will have their care needs met by the home. The research design would 38 be a prospective observational cohort study to determine the extent and quality of 39 rehabilitation services available to this group in comparison to patients returning to their 40 own homes.

1	4.3.6.6 Patient and carer quality of life
2	The GDG recommended the following research question:
3 4	What quality of life value do individual patients and their carers place on different mobility, independence and residence states following rehabilitation?
5	Why this is important
6 7 8 9 10	It is important in evaluating future priorities for intervention to determine whether the perceived clinical and health economic benefits of rehabilitation outcomes in the research literature are matched over the same time-frame by the quality of life judgements, aspirations and expectations of patients themselves and their carers. There is currently no evidence.
11	4.3.6.7 Patient experience
12	The GDG recommended the following research question:
13 14 15	What is the patient's experience of being admitted to hospital with a hip fracture in relation to surgery, pain management, timeliness of information given, and rehabilitation?
16	Why this is important
17	No studies from NHS populations were identified where patients commented specifically or

No studies from NHS populations were identified where patients commented specifically on 17 18 their surgery, their pain management and rehabilitation programme. There were comments 19 in the patient views studies about not being kept informed about the management of their 20 condition, however there was no information identified about the appropriate time to be 21 told. It may be that different patients want the information at different times. The studies 22 suggest that patients suffer from fear, pain and delirium until after surgery and it is 23 important to learn what (if anything) can be done to alleviate this which for many will be 24 considered the worst stage in their treatment.

1 5 Imaging options in occult hip fracture

2 5.1 Introduction

The occult, or 'hidden', hip fracture is one in which the clinical findings are suggestive of a
fracture but this is not confirmed by radiographs.

5 Most hip fractures can be readily diagnosed using radiographs, consisting of an antero-6 posterior (AP) and a lateral projection of the hip, whenever the clinical suspicion of a 7 fracture first arises. Importantly, no clinical decision rule has yet become available that 8 would allow clinicians to exclude a hip fracture without imaging. To avoid misdiagnosis 9 with hip pain being attributed erroneously to soft tissue injury and the patient being 10 discharged, a high index of clinical suspicion of hip fracture is required. This applies in all 11 patients presenting with a typical history - usually hip pain following trauma, e.g. a fall - as 12 certain typical features, such as the inability to bear weight or a shortened, abducted and 13 externally rotated leg, may be absent.

14 Achieving an accurate diagnosis as soon as possible is advantageous for a variety of 15 reasons. The primary reason is that without an accurate diagnosis it is not possible to 16 formulate a proper management plan. A fracture which is not obviously evident on 17 radiographs is likely to be undisplaced. Once the hip fracture is demonstrated early 18 diagnosis may allow for a simple procedure to fix the fracture in situ. Should it be confirmed 19 that no hip fracture is present then other diagnoses may be sought, there is less chance of 20 the patient being kept unnecessarily immobile and the patient may not need to stay in 21 hospital.

22 Hip radiographs have an estimated sensitivity of between 90% and 98%, and the initial films 23 will therefore miss only a small proportion of hip fractures. It is, however, essential to 24 ensure that the radiographs are of satisfactory quality. In particular, if the initial AP film of 25 the entire pelvis together with the lateral hip projection (taken in the position of comfort) 26 show no fracture, a third film should be taken centred on the hip with the hip in 10 degrees 27 of internal rotation to position the femoral neck at 90 degrees to the x-ray beam and 28 ensure an optimum view of this area. All subsequent discussion and recommendations 29 assume radiographs of this standard to have been obtained before characterising a 30 suspected but undetected fracture as occult.

The prevalence of occult hip fractures is estimated to be around 3 – 4%; up to 9% in some
 series (though a proportion of this may reflect radiographs of inadequate standard as
 discussed above). Bone resorption around the fracture site, or cortical displacement, will
 render most occult hip fractures visible if radiographs are repeated after a few days. This is
 due to bone resorption occurring along the fracture line making it radiographically more

obvious, but displacement or impaction may occur during this interval due to the patient
 having walked with the fracture. Delays in surgery due to late diagnosis are associated with
 prolonged suffering and poorer health outcomes for patients, and expose clinicians to the
 risk of litigation.

5 Optimal strategy for patient selection and timing of secondary imaging strategies to ensure 6 early diagnosis of occult hip fractures, while avoiding over investigation of patients with 7 soft tissue injury only, is yet to be determined. However, the inability to weight bear on the 8 day following the injury, in spite of adequate analgesia, should prompt clinicians to re-9 evaluate the patient and have a high index of suspicion of hip fracture.

10 Imaging modalities used to assist in the early detection of occult hip fractures include 11 computed tomography (CT), radionuclide scan (RNS), magnetic resonance imaging (MRI) 12 and, rarely, ultrasound scanning (US). The type of secondary imaging modalities used locally 13 is often determined by considerations of access, particularly outside normal working hours, 14 and radiological expertise available. MRI is usually considered to be the reference standard, 15 as numerous studies have found MRI to have the highest accuracy (100% sensitivity and 16 between 93% and 100% specificity, depending on experience and skill of radiologist 17 interpreting the images).

In this chapter we consider the clinical and cost-effectiveness of a number of alternative
 imaging modalities that can be used to detect an occult hip fracture when MRI is
 unavailable or precluded for safety or technical reasons.

21

22 5.2 Review question

In patients with a continuing clinical suspicion of hip fracture, despite negative radiographic
 findings, what is the clinical and cost-effectiveness of additional imaging (radiographs after
 at least 48 hours, RNS, US and CT, compared to MRI, in confirming, or excluding, a hip
 fracture?

27 5.3 Radiographs

28 5.3.1 What is the diagnostic accuracy of additional radiographs (X-Rays) after 48 hours

29 compared to MRI in the diagnosis of occult hip fractures

Radiographs are the most widely available imaging technique (in- and out-of hours) utilised
 for diagnosis of hip fracture. They can be acquired quickly (5 minutes) and experience in
 image interpretation is widespread.

A hip fracture not visible on the original radiographs may become evident on films taken a
 few days later because of bone resorption (reduced bone density) along the fracture line,
 impaction (fracture line becomes more dense) or displacement.

36 5.3.1.1 Clinical evidence

- 37 No studies were identified.
- 38 5.3.1.2 Economic evidence.

1 No studies were identified.

2 **5.3.1.3** Recommendations and link to evidence

3 See Section 5.6.2

4 5.4 Radionuclide bone scan (RNS)

5 For a RNS of the skeleton a short-life radio-isotope (technetium 99m) is linked to methylene 6 diphosphonate (MDP) which is taken up in areas of bone formation (osteoblastic activity) 7 resulting in 'hot spots'. The isotope is injected intravenously and then there has to be a 8 delay of three hours before scanning, using a gamma camera and which takes 30 minutes, 9 will detect increased uptake in the skeleton. Other causes of high bone turnover such as 10 arthritis, synovitis and tumor may lead to false positive results and these are more frequent 11 in patients over the age of 70. It is common practice to defer RNS until 72 hours after injury 12 to avoid false negative scans but some authors suggest that the modern three-phase 13 technique may give accurate results after only 24 hours.

14 5.4.1 What is the diagnostic accuracy of RNS compared to MRI in the diagnosis of occult

- 15 hip fractures
- 16 See Evidence Table 1, Appendix E.
- 17

18 **5.4.1.1** Clinical evidence

26

27 5.4.2 Economic evidence

No studies were identified. The cost of the procedures in England and Wales were
 presented to the GDG: a category 3 RNS costs £205, and an MRI (one area, no contrast)

1	costs £206 (source: National schedule of reference costs 2008-09; NHS trusts and PCTs
2	combined).

4 5.4.2.1 Evidence statement(s)

- **Clinical** The sensitivity of bone RNS compared to MRI ranged from 75% to 98% and specificity was 100%. This means that between 2% and 25% of those who have a fracture, the fracture will have been missed. However, all patients who tested positively do actually have a fracture. (LOW QUALITY)
- **Economic** No studies were identified on the cost-effectiveness of the diagnostic accuracy of RNS compared to MRI in the diagnosis of occult hip fractures.

5

6 5.4.3 Recommendations and link to evidence

- 7 See section 5.6.2
- 8

9 5.5 Ultrasound (US)

- 10 In ultrasound (US) imaging a probe emits ultrasound waves which are reflected off surfaces 11 and recored to form the image. Good contact is required between skin and probe 12 (coupling), generally achieved with gel, but may be problematic if there is pain or soft tissue 13 swelling in the site being scanned, which may be the case in hip fracture. US is widely 14 available, both in- and out-of-hours, does not use ionising radiation and is relatively 15 inexpensive. However, it takes considerable skill and expertise to acquire optimum images 16 and for interpretation of the appearances. Currently this kind of US scanning is performed 17 by a minority of specialised musculo-skeletal radiologists in the UK.
- Ultrasound scanning of the hip may detect bone surface changes, effusions or haemorrhage
 in patients with fractures but the results are non-specific and usually require confirmation
- 20 by MRI or CT. The technique is highly operator-dependent.
- 21 5.5.1 Diagnostic accuracy of ultrasound (US) compared to MRI in the diagnosis of occult hip
- 22 fractures

3

4 5.5.1.2 Economic evidence

5	No studies were identified. The costs of the procedures in England and Wales were
6	presented to the GDG: ultrasound (US) costs £48 for a procedure lasting less than 20
7	minutes, and £62 for a procedure lasting more than 20 minutes. The cost of an MRI (one
8	area, no contrast) is £206 (source: National schedule of reference costs 2008-09; NHS trusts
9	and PCTs combined)

10 5.5.1.3 Evidence statement(s)

- **Clinical** The sensitivity of ultrasound (US) compared to MRI was 100% and specificity was 65%. This means that none of the patients who had a fracture have been missed. However, of those who tested positive 35% do not actually have a fracture i.e. there is a high percentage of false positives (sonographic abnormalities indistinguishable from those attributable to conditions other than fracture) (LOW QUALITY)
- **Economic** No studies were identified on the cost-effectiveness of the diagnostic accuracy of ultrasound (US) compared to MRI in the diagnosis of occult hip fractures.

11 5.5.2 Recommendations and link to evidence

- 12 See section 5.6.2
- 13

14 5.6 Computed tomography (CT)

15 CT uses rings of sensitive detectors and an X-ray tube which rotates around the patient to
 acquire transverse axial images through the body. CT is a readily available imaging
 modality but its value for the detection of occult hip fractures has not been extensively
 evaluated. There is evidence that undisplaced fractures running parallel to the axial plane

- 19 can be missed and limited resolution of osteoporotic trabecular bone may make the
- 20 technique less reliable for the detection of fractures of the hip than of other areas of the

1 body. However, technical developments in CT (spiral, multi-detector referred to as MDCT) 2 have enabled thin 2 dimensional (2D) sections to be acquired very rapidly and from which 3 3D volumetric reconstructions can be acquired and displayed at bone, or a variety of soft 4 tissue, settings. This has greatly enhanced the potential application of CT to imaging occult 5 hip fractures. The scan is rapid (2minutes)(slice thickness 1.25mm; MAs between 100 to 6 355 depending on patient size/weight; field of view 36cm) and from which coronal, sagittal 7 and other planar/3D reformations can be generated. CT is particularly good for imaging 8 bone, but does not show the marrow changes (oedema) which occur in hip fracture 9 adjacent to the fracture line.

10 5.6.1.1 Clinical evidence

11 No studies that meet our inclusion criteria were identified.

12 **5.6.1.2** Economic evidence

- 13 No studies were identified. The costs of the procedures in England and Wales were
- presented to the GDG: the cost for a CT scan (one area, no contrast) is £101. The cost of an
- 15 MRI (one area, no contrast) is £206 (source: National schedule of reference costs 2008-09;
- 16 NHS trusts and PCTs combined)

17 5.6.1.3 Evidence statement(s)

- **Clinical** No studies were identified directly comparing the diagnostic accuracy of CT with MRI and that meet our inclusion criteria.
- **Economic** No studies were identified on the cost-effectiveness of the diagnostic accuracy of CT compared to MRI in the diagnosis of occult hip fracture.

18

19 5.6.2 Recommendations and link to evidence

<i>Recommendation</i>	Offer magnetic resonance imaging (MRI) if hip fracture is suspected despite negative anteroposterior pelvis and lateral hip X-rays. If MRI is not available within 24 hours or is contraindicated, consider computed tomography (CT).
Relative values of different outcomes	Reliability (in terms of diagnostic accuracy) was considered the primary outcome of interest. A false positive diagnosis carries the risks either of unnecessary surgery or of delay and increased cost caused by the need for additional radiographic investigation; a false negative result carries the risks associated with subsequent fracture displacement and its consequences as well as avoidable prolonged immobility and pain. It is therefore important for the selected method to minimise both false positives and false negatives.
Trade off between clinical benefits and harms	MRI cannot be used in patients with certain types of metallic implants but does not otherwise have known harmful effects other than the potential to cause claustrophobia due to the need for patients to remain in a confined space for a considerable length of

	time. MRI was considered to be the first choice option in view of its superior diagnostic accuracy (up to 100% specificity and sensitivity).
	If limitations in the local availability of MRI otherwise lead to unacceptably prolonged delay to diagnosis offering an RNS or CT may have a net benefit to the patient even though both carry the risks of exposure to ionising radiation. A delay of several days may, however, be required for RNS to achieve the required sensitivity, it is also generally unavailable out-of-hours (a further cause of delay), and may provide less precise information for surgical planning.
	Repeat radiographs after 48 hours have limited sensitivity and carry the risks of displacement during the intervening period, as well as those of delay to surgery.
	Ultrasound (US) has no known harms but it's low specificity means that further imaging confirmation (with resulting delay) is required to determine whether a positive US represents a fracture, thus limiting its use. Conversely, a negative US reliably excludes fracture and could in theory enable immediate discharge of this small subset of patients from Emergency departments.
	The advent of MRI has enabled the accurate early identification of occult hip fractures that would previously have been missed. The precise natural history of such occult fractures (and therefore the precise place of surgical intervention) has therefore only begun to be fully clarified. It is at least theoretically possible that a proportion of occult fractures might not require surgery. At the same time techniques of fracture fixation have also become less traumatic and invasive. Unless and until these issues of benefit/harm are fully resolved, precise and reliable early diagnosis as a basis for surgical decision making remains a clinical priority.
Economic considerations	In England and Wales, the cost of a radionuclide scan (RNS) and of an MRI is very similar: a category 3 RNS costs £205, and an MRI (one area, no contrast) costs £206. However, an MRI is cost saving compared to an RNS, as the latter may result in a longer length of hospital stay (and the possible consequences of delay to surgery) before the fracture is diagnosed.
	The GDG also considered MRI to be cost-effective compared to US, since in the case of a positive US, its low specificity would still necessitate additional imaging (notably MRI or CT) to confirm the diagnosis. The possible consequences of delay to surgery would need to be added to those of additional imaging.
Quality of evidence	Two cross sectional studies comparing RNS to MRI were identified. These studies had serious methodological limitations due to the limited reporting of patient demographics and lack of clarity as to whether the assessors were blinded to the results of the index test when interpreting the results of the reference standard and vice versa.
	One cross sectional study comparing ultrasound (US) to MRI was

One cross sectional study comparing ultrasound (US) to MRI was identified. This study was of moderate quality. The GDG considered

51

IMAGING

that the reproducibility was a potential limitation as the sonographic readings were performed by highly experienced muskuloskeletal radiologists. There were no serious inconsistencies or indirectness in any of the identified studies.

The assumption that MRI is the gold standard for detecting occult hip fracture and the recommendation advising use of CT as an alternative to MRI were based on unanimous GDG consensus.

Other considerations The diagnosis and management of occult hip fracture is still very much an evolving area of practice. In the absence of an evidencebased clinical decision rule clinicians must exert clinical judgement to decide when suspicion of hip fracture after normal plain radiographs is great enough to warrant additional imaging.

> Before radiographs are regarded as excluding a hip fracture one should ensure that radiographic quality is optimized. When AP pelvic or hip radiographs are performed the leg should be a little internally rotated with the great toes of the feet overlapping so as to bring the anteverted femoral neck parallel to the X-ray table. In this position little of the lesser trochanter should be visible medial to the femoral cortex (the more externally rotated is the leg the more obvious is the lesser trochanter). Optimising the positioning enables the greater trochanter to be better visualized and not obscured behind the femur. When a hip fracture is present it may prove impossible to position the leg in this optimum position because of pain, but this may be compensated for by appropriate X-ray tube angulation. It should also be ensured that the X-ray exposure factors are optimum to demonstrate both the entire pelvis, to check that fractures are not present in sites additional to the hip, and also for the hip suspected of fracture. To attain this separate exposures and radiographs may be required.

> Whilst the GDG considered that MRI was the best test to use to detect occult hip fracture and that this should be the first choice, they noted that there may be occasions where MRI is not available and thought it was important to give guidance as to which test to use in these circumstances. The GDG's consensus decision to recommend CT over RNS is based on greater availability, especially outside the working week, and shorter delay to diagnosis. It also reflects current NHS practice.

In addition, the technical aspects of RNS of bone (3 hour delay after radionuclide is give when gamma emission can be recorded; also increased uptake of radionuclide depends on creased osteoblastic activity which may take several days to occur following fracture; lack of availability out of hours) makes this the least appropriate now for imaging occult hip fractures and I believe is now not often used in this scenario, since the advent of CT and MRI.

The GDG were also aware that rapid advances in CT technology, such as 64-slice scanners and sophisticated 3 dimensional reconstruction algorithms, may well overcome the limitations of CT reported in the published literature about its value for detection of occult hip fractures.

2 5.7 Research recommendation on imaging options in occult hip fracture

- 3 The GDG recommended the following research question:
- In patients with a continuing suspicion of a hip fracture but whose radiographs are normal,
 what is the effectiveness of computed tomography compared to magnetic resonance
 imaging, in confirming or excluding the fracture?

7 Why this is important

1

8 The GDG's consensus decision to recommend CT over a radionuclide bone scan as an 9 alternative to MRI to detect occult hip fractures reflects current NHS practice but assumes 10 that advances in technology have made the reliability of CT comparable to that of MRI. If 11 modern CT indeed can be shown to have similar reliability and accuracy to MRI, then this 12 has considerable implications because of its widespread availability out of hours and lower 13 cost. It is a high priority, therefore, to confirm or refute this assumption by direct 14 randomised comparison. The study design would need to retain MRI as "gold standard" for 15 cases of uncertainty and would clearly need to standardise the criteria, expertise and 16 procedures for radiological assessment. Numbers required would depend on the degree of 17 sensitivity/specificity (the key outcome criteria) set as target requirement for comparability, 18 but need not necessarily be very large.

1 6 Timing of surgery

2 6.1 Introduction

3 The timing of treatment for patients sustaining fractures of the proximal femur remains one 4 of the biggest challenges to a health care system. It involves multidisciplinary co-ordination 5 between accident and emergency departments, acute orthopaedic trauma services, 6 orthogeriatricians, anaesthetists, as well as the availability of appropriate theatre space 7 with trained staff and relevant equipment. In the past these patients were given low 8 priority in the hospital system, which led to many delays and repeated periods of 9 starvation. It is recognised that it is not only the time a patient takes to get to surgery that 10 is important, but that the patient has to be medically optimised, with the anaesthetic, 11 surgical and theatre team being appropriately experienced. When planning any emergency 12 care it is not always possible to predict the number of cases which can present, so any 13 system which is set up must have the flexibility to adapt to the peaks and troughs of 14 admissions. This can lead to potential free theatre capacity in quieter periods.

- As it would be unethical to enforce an unnecessary delay for patients sustaining fractures of
 the proximal femur, all studies reported are retrospective cohort studies. As such the level
 and quality of the evidence is poor.
- 18 The timing of surgery is an early marker of a patient's progress following a hip fracture. The 19 surgery does not stand alone. The pathway to safe, timely surgery includes proper 20 organisation and expertise in diagnosis, medical optimisation and anaesthesia. In the last 21 decade many orthopaedic trauma emergencies are now treated on dedicated planned 22 trauma lists. A planned trauma list is one with a rostered senior anaesthetist, senior 23 surgeon and dedicated theatre time. These by their nature usually concentrate the 24 expertise required.
- There are sometimes legitimate reasons for delay and it is important to look at the
 excluded patients in these studies. In a few patients delay to surgery is unavoidable.
 However, it should be anticipated that many patients with hip fractures will be frail and
 have comorbidities. The following would be common findings in patients presenting with
 hip fractures:
- 30 Anaemia
- 31 Anticoagulation
- Volume depletion
- Electrolyte imbalance

1 Uncontrolled diabetes 2 Uncontrolled heart failure 3 Correctable cardiac arrhythmia or ischaemia 4 Acute chest infection 5 Exacerbation of chronic chest conditions 6 7 Provided these problems are sought and measures initiated to correct them are taken 8 promptly the majority can be optimised within 24 hours. 9 When looking at the timings measured it is generally accepted the time of diagnosis should 10 be the initial time recorded and the time to the start of the anaesthetic procedure be the 11 index time measured. Objective outcomes used to compare timing of surgery include early 12 and late mortality, length of hospital stay, return to mobility, complications including chest 13 infections and pressure sores, change of residence and other surgical complications. What 14 has not been measured in the past is the pain and suffering experienced with prolonged 15 delay and what is the ethical time period the elderly, who are often very frail, should wait 16 for treatment.

17 6.1.1 Review question

- In patients with hip fractures what is the clinical and cost effectiveness of early surgery
 (within 24, 36 or 48 hours) on the incidence of complications such as mortality, pneumonia,
 pressure sores, cognitive dysfunction and increased length of hospital stay?
- Data are given for studies where outcomes have been adjusted for confounding factors such as comorbidity and age using logistic regression. A separate subgroup is given which excludes patients who are unfit for surgery i.e. reason for delay is due to unavailability of staff, theatres or equipment. Delay to surgery in the identified studies was from time to admission. All studies report surgical delay versus early surgery to investigate the harm of delaying surgery.
- 27 The cut-off for delay to surgery in this analysis is 24, 36 and 48 hours.
- 28 See evidence table 2, Appendix E and forest plots G2 to G22 in Appendix G.
- 29

13 6.1.1.2 Economic evidence

One study^{296,296} was found which calculated the mean hospital costs for hip fracture 14 15 patients who had received surgery at different points in time from admission. This study 16 was excluded because of serious methodological limitations, as no reason was given as to 17 why patients had faced delays before receiving surgery (whether it was because of medical 18 or administrative reasons)

19 An original decision analytical model was developed to compare the cost-effectiveness of a 20 strategy consisting in adding extra half-day operating lists to increase the proportion of 21 patients operated within 48 hours from admission against a non-investment strategy.

22 Please see Appendix H, section 8.5 for further details.

23 Table 6-22: Early versus late (>48h) surgery for hip fracture - Economic study characteristics

	Study	Limitations	Applicability	Other Comments	
	NCGC decision model	Minor limitations ^(a)	Partial applicability ^(b)		
24	(a) Cost-effectiveness analysis based on a Markov model				

Cost-effectiveness analysis based on a Markov model.

(b) The findings of the model may not be generalized to the whole UK NHS because its treatment effects and cost data are based on evidence from two specific hospital settings. The addition of extra operating lists may not be feasible for those providers where no spare theatre capacity is available.

 - (b) For the second year, the mean costs associated with the strategy of investment for early surgery were £47.3, and for the non-investment strategy £46.4.
 - (c) In the first year of implementation of extra operating lists, the mean effectiveness for the strategy of investment for early surgery was 2.3637, and for the non-investment strategy 2.3212. In the second year, they corresponded to 2.415 and 2.321 respectively.
 - (d) 95% CI of ICERs calculated from the 10,000 Monte Carlo simulations.

15 6.1.1.3 Evidence statement (s)

Clinical All patients

Early surgery (<24h) shows a statistically significant and clinically significant reduction in mortality (in 4 out of 7 studies) (VERY LOW QUALITY) and reduction in pressure ulcers (LOW QUALITY) with early surgery compared to late surgery. No statistically significant difference shown for return to independent living or major complications (LOW QUALITY).

Early surgery (<36h) – statistically significant and clinically significant reduction in pressure ulcers with early surgery compared to late surgery (LOW QUALITY). Statistically significant, but not clinically significant increased return to independent living (VERY LOW QUALITY). No statistically significant difference in mortality at 4 months (VERY LOW QUALITY).

Early surgery (<48h) shows a statistically significant and clinically significant reduction in mortality (in 4 out of 8 studies) (VERY LOW QUALITY), increased return to independent living (VERY LOW QUALITY), reduced pressure ulcers (LOW QUALITY), reduced major and minor complications with early surgery compared to late surgery (VERY LOW QUALITY).

Exclusion of patients unfit for surgery

Early surgery (<24h) – Statistically significant, but not clinically significant reduction in major post operative complications with early surgery compared to late surgery. No statistically significant difference in mortality, with early

surgery compared to late surgery. (VERY LOW QUALITY)

Early surgery (<48h) – Statistically significant, and clinically significant reduction in mortality at 1 year and patients changing residence (more dependent) and increased return to original residence (VERY LOW QUALITY). No statistically significant difference in mortality at 30 days with early surgery compared to late surgery. (VERY LOW QUALITY).

Economic Investing in adding extra operating lists as a way to increase the proportion of patients operated within 48 hours from admission is only marginally above the £20k/QALYs threshold in the first year of implementation, but becomes clearly cost-effective from the second year onwards.

This evidence has minor limitations and partial applicability.

1

2 6.1.2 Recommendations and link to evidence

Recommendation	Perform surgery on the day of, or the day after, admission.
Relative values of different outcomes	The GDG recognised that hip fracture surgery was often disproportionately delayed in comparison with other operations, and that this in part reflected a lack of sufficient priority afforded to this group of patients.
	On humanitarian criteria alone, initiatives to avoid delay were considered to be of high priority in developing the guidance. It was considered that surgery was the best form of pain relief, and that to spend more than one night in hospital without operation was generally unacceptable.
	Postponement of surgery carries increased risk of complications, as well as prolongation of pain, and the need for repeated pre- operative fasting.
	Of the outcomes derived from the literature, mortality, return to independent living, occurrence of specific complications (notably pressure ulcers) and duration of hospital stay were all considered of parallel and inter-related importance as indicators of care standard and efficacy.
Trade off between clinical benefits and harms	There was no instance in the literature of any advantage in delaying surgery, nor of disadvantage in reducing delay.
	Although the range of studies utilised a range of arbitrary or pragmatic time thresholds (governed to some degree by service context and organisation), there was no definitive cut-off point (up to and including 24 hours) beyond which further reduction of delay ceased to confer measurable benefit in one or more outcomes.
	Therefore the GDG considered it could not be prescriptive about the precise time threshold from the literature alone.
	The trade off between early surgery and harms relate to the difficulties and infrastructure required to treat this population who present as emergencies. It is recognized surgery is the best form of analgesia and as over 30% present with cognitive impairment, it

	can be otherwise difficult to assess patients suffering. It is also considered humane not to leave this frail patient group waiting treatment (often being repeatedly starved). The potential harm of earlier surgery include the risks of not medically resuscitating and optimizing the patients health prior to a further surgical insult and ensuring the surgical team is experienced and available. A delay up to 36 hours allows for appropriate assessment and planning. It allows patients to be operated on in planned trauma lists and should allow most hospitals to cope with peaks in emergency admissions.
	Only one study ⁴ looked at complications, return to independent living and pressure sores. Whilst this study did report a small benefit in protecting against pressure sores it did not demonstrate any additional benefits. Regarding mortality one study ³⁴² showed a small difference in mortality at one year, though again the difference and numbers were small.
	Alani et al., 2008 ⁴ is the only study which looked at the 36 hour time frame. It failed to show improvement in mortality at four months yet showed a slight benefit in return to independent living and avoidance of pressure ulcers.
	When comparing surgery at 48 hours, again the data is limited. The overall number of patients included is small and there is a reported decrease in mortality in two out of the five studies included ^{30,342} . Apart from the benefits already reported in Alani's study, other outcomes were either not reported or did not show any difference.
Economic considerations	To be able to offer surgery for hip fracture patients by an experienced surgical team, within the recommended time period, it is recognized there may have to be an investment in infrastructure. Specifically planned trauma operating lists with experienced surgical, anaesthetic and theatre team. Generally these should occur in the normal working day. As admission numbers, including peaks and troughs, cannot be always predicted then this capacity may not always be utilised.
	The potential costs of reducing delay to surgery were recognised- such as additional theatre time, out-of-hours staffing (including senior staff), out of-hours lists and planned trauma lists.
	These costs will be at least partially offset by potential savings from reduced length of stay, reduced complications and enhanced return to independent living.
	There was no definitive health economic study for any time threshold in the literature. The guideline group therefore considered that an original decision model was crucial to inform the broad economic feasibility of any recommendation on reducing surgical delay. As discussed in Appendix H, the GDG agreed that, out of the evidence included in the clinical review, the outcome data to undertake this analysis were adequate only to provide a model based on a 48hr threshold, and as a consequence this specific cut-off point was selected for the economic analysis.

	The economic model demonstrates that investing to add extra operating lists in order to undertake surgery within 48 hours from admission is only marginally above the £20k/QALYs threshold in the first year of implementation, but becomes clearly cost-effective in the following years.
	Furthermore, the implementation of extra operating lists will also achieve a more equitable distribution of health care resources in favour of patients that had previously been made to wait for surgery as other cases were given higher priority.
	However, the model does not capture the possibility that the extra operating lists could potentially be used to treat cases in addition to hip fracture patients (thus resulting in an increase of activity for the hospital trust and subsequent QALYs gains for the patients treated).
	In addition, our cost-effectiveness estimates are also conservative in that we do not look at the impact that early surgery has on the pain relief of our population.
Quality of evidence	The available clinical evidence covering this issue is of low quality, but in aggregate supports the avoidance of surgical delay.
	For this reason there is an element of consensus in the wording of the recommendation which, in addition to the evidence of clinical benefit and NHS economic feasibility, also reflects a strong humanitarian case. The consensus was unanimous within the GDG.
	However, the health economic analysis reported in Appendix H showed that surgery performed with 48 hours was cost effective.
	Although the evidence base for this question is predominantly retrospective, cohort studies of low quality (all low or very low) it is not considered ethical to conduct an RCT to answer this question.
	The main studies included were cohort studies that adjusted for confounding factors by logistic regression, which although were low quality were considered higher quality than cohort studies without any adjustment. The subgroup studies did not adjust for confounding factors, but were considered as similar quality to those studies using logistic regression as the population excluded those unfit for surgery.
Other considerations	The context of implementation has changed during guideline development in such a way as to highlight the relevance and feasibility of the recommendation, in that the Department of Health has introduced a Best Practice Tariff initiative to achieve hip fracture surgery within 36 hours of admission.

Recommendation	Identify and treat correctable comorbidities immediately so that surgery is not delayed by: anaemia anticoagulation volume depletion electrolyte imbalance uncontrolled diabetes uncontrolled heart failure correctable cardiac arrhythmia or ischaemia acute chest infection exacerbation of chronic chest conditions.
Relative values of different outcomes	The most important outcomes considered here were mortality, length of stay in hospital and post operative complications.
Trade off between clinical benefits and harms	Patients should not be delayed for routine tests which will not affect the surgical or anaesthetic procedure. It has been shown in the majority of patients that longer delay leads to an increase in complications and length of stay in those medically fit. A number of medical conditions that might pose a concern to the surgeon or the anaesthetist are so commonly encountered among patients presenting with hip fracture that their occurrence should be anticipated, and admission assessment and management protocols designed that will expedite their management and so prevent their delaying surgery. The process of pro-actively seeking to identify such conditions will also help in identifying other less common potential concerns that might need more individual assessment - by experienced physicians (often orthogeriatricians) or anaesthetists - when a medical delay may be required.
Economic considerations	The early identification and treatment of patients' comorbidities may require additional resources in terms of personnel's rounds and ad-hoc tests. These costs would be at least partially off-set by savings linked with a lower length of hospital stay associated with the possibility of performing surgery at an earlier stage.
Quality of evidence	The evidence included in this chapter did not cover treatment of comorbidities. The main studies adjusted for these factors and the subgroup excluded patients unfit for surgery.
Other considerations	There should be the availability of experienced orthogeriatricians / physicians and anaesthetists to assess patients who may require further optimization. Regular review and communication with the surgical team is essential.

1 6.2 Research recommendations on timing of surgery

2 6.2.1 Surgery within 36 hours

- 3 The GDG recommended the following research question:
 - What is the clinical and cost effectiveness of surgery within 36 hours of admission compared to surgery later than 36 hours from admission in mortality, morbidity and quality of life in patients with hip fracture?

7 Why this is important

8 Early and appropriate surgery for hip fractures is the most effective form of pain relief, 9 potentially quickening the rehabilitation and reducing complications. Within the current 10 literature no specific time interval threshold has been identified (up to 24hr) below which a 11 reduction in delay has shown no benefit. In addition to the evidence of the cost 12 effectiveness below 48hr, pragmatic, organisational and humanitarian considerations have 13 been utilised to arrive at the recommendation to operate not later than the day after 14 admission. A formal study within the NHS based on an arbitrary but realistic 36hr threshold 15 would provide additional important data to that already available, in order to inform more 16 precisely the forward clinical and cost-effectiveness of the strategy. For ethical reasons, the 17 research design would be an observational cohort study, correcting for confounding 18 variables, possibly set in the context of the National Hip Fracture Database and examining 19 the effect of the time to surgery and its cost on key outcomes, including mortality, 20 complications, length of stay, time taken to rehabilitate and qualitative aspects of the 21 experiences of patients.

5

1 7 Analgesia

2 7.1 Introduction

Pain is a major component of the patient experience following a hip fracture. Fracture and
 post-operative pain, along with fracture and surgical site blood loss, constitute the major
 physiological stresses facing these patients. Fear of pain is a major concern to them and
 their relatives. The best form of analgesia is surgical repair, but there will usually be a
 period when assessment is taking place when some analgesia is needed. Prompt and
 adequate relief of pain has long been identified as a major priority in the management of
 hip fracture, and one that has not always historically been achieved.

Pain relief is obviously important for simple humanitarian reasons and for acute nursing
 care, but also improves patients' wellbeing, reduces the risk of delirium, and facilitates the
 return to mobility and independence.

13 It is often difficult to assess the need for analgesia when the patients are lying still. They
 may require more pain relief when moved passively for investigations, such as radiological
 procedures and subsequently for the active mobilisation essential to their successful
 recovery. Many patients with hip fracture may be unable to express their pain, either
 because of cognitive impairment, acute delirium or an underlying expressive dysphasia.

Systemic analgesics act through the bloodstream on the whole body rather than on a
localised area or region. They are still the most widely used drugs for providing pain relief in
acute painful situations. Systemic analgesics used for pain relief in hip fracture include
simple analgesics such as paracetamol, and a wide range of opioids. Non-steroidal antiinflammatory drugs are usually avoided or used with caution because of their side effects.
These include upper gastrointestinal bleeding, nephrotoxicity and fluid retention – to all of
which the older population and are well known to exhibit increased susceptibility.

The nerves supplying the proximal femur may also be blocked by injecting local anaesthetic
around the femoral nerve. These injections are referred to as nerve blocks and are
sometimes administered to patients to reduce pain if simple analgesics and opioids have
not proven to be sufficient. They are also thought to improve pain scores and mobility and
to help avoid excessive opioid usage.

The aim of this chapter is to identify optimal preoperative and postoperative analgesia
 including the use of nerve blocks as adjuncts or alternatives to simple analgesics such as
 paracetamol and opioids.

The use of nerve blocks as with anaesthesia is covered in Chapter 8 on regional compared
 to general anaesthesia.

3 7.2 Systemic analgesia

4 7.2.1 Review question

In patients who have or are suspected of having a hip fracture, what is the comparative
effectiveness and cost effectiveness of systemic analgesics in providing adequate pain relief
and reducing side effects and mortality?

8 7.2.1.1 Clinical evidence

9 No studies on the effectiveness of these drugs in hip fracture patients were identified.

10 7.2.1.2 Economic evidence

11No relevant studies were identified. We conducted a cost analysis of a nerve block, non-12opioids and other analgesics. We found that a nerve block would cost approximately13£54.66. The average cost for opioids controlled drugs is £11.84 (where £1.34 is the average14cost per dose of the drugs and £10.50 the personnel cost of two trained nurses required for15the administration of the drugs). The price of opioids non-controlled drugs is estimated at16£1.96 per doses. The cost of non-opioids analgesics is less than £0.1p per dose. Please see17Appendix H section 8.1 for further details.

18 **7.2.2 Recommendations and link to evidence**

- 19 In order to present the recommendations in a logical manner and retain their sequential20 order, the recommendations for this section are presented below in section 7.3.2
- 21

22 7.3 Nerve blocks compared to systemic analgesia

23 7.3.1 Review question

- In patients who have or are suspected of having a hip fracture, what is the clinical and cost
 effectiveness of nerve blocks compared to other forms of analgesia in providing adequate
 pain relief and reducing side effects and mortality?
- 27 See evidence table 3, Appendix E and forest plots G23 to G37 in Appendix G.
- 28

29 **7.3.1.1** Clinical evidence

30The review considered any nerve block that affects the nerves supplying the proximal31femur. These include the subcostal nerve, the lateral cutaneous nerve of the thigh, the32femoral nerve, psoas (lumbar plexus), fascia iliaca compartment block (FICB) and triple33(femoral, obturator and sciatic) nerve.

The literature search retrieved one Cochrane review (Parker et al 2002)²⁵⁴. A further update
 search was then conducted to look for any papers that may have been published since the
 publication of this review. No additional studies were retrieved and therefore the clinical
 evidence presented in this chapter is based on the Parker et al results with the addition of

- 5 the GRADE analysis.
- 6

Confusional state	15/77 (19.5%)	34/101 (33.7%)	RR 0.63 (0.37-1.06)	125 fewer per 1000 (212 fewer to 20 more)	Low

2 7.3.1.2 Economic evidence

No relevant studies were identified. We conducted a cost analysis of a nerve block, non-opioids and other analgesics. We found that a nerve block would cost approximately
£54.66. The average cost for opioids controlled drugs is £11.84 (where £1.34 is the average
cost per dose of the drugs and £10.50 the personnel cost of two trained nurses required for
the administration of the drugs). The price of opioids non-controlled drugs is estimated at
£1.96 per doses. The cost of non-opioids analgesics is less than £0.1p per dose. Please see
Appendix H section 8.1 for further details.

10 7.3.1.3 Evidence statement (s)

Clinical There is a statistically significant but not clinically significant reduction in pain when using nerve blocks compared to other forms of analgesia. (LOW QUALITY). There is a statistically significant but not clinically significant reduction in pneumonia when using nerve blocks compared to other forms of analgesia (MODERATE QUALITY).

There is no statistically significant difference between nerve blocks and other forms of analgesia in all other outcomes (LOW QUALITY).

Economic No studies on the cost-effectiveness of nerve blocks for hip fracture patients

were identified.

1 7.3.2 Recommendations and link to evidence

Recommendation	Offer immediate analgesia to patients presenting at hospital with suspected hip fracture, including people with cognitive impairment.	
Relative values of different outcomes	This group of patients is most commonly elderly and frail and pain is one of the main physiological and psychological stresses they face. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important.	
Trade off between clinical benefits and harms	Immediate pain control not only improves patients' wellbeing but may reduce the risk of delirium, and facilitate rehabilitation and a return to mobility and independence. The risks of pain relief are the side effects of the individual agents used to achieve it (see below).	
Economic considerations	The GDG agrees that the costs of providing immediate and adequate analgesia are likely to be offset by the improvement in patients' wellbeing.	
Quality of evidence	There have been no studies on the timing of analgesia on patient outcome. The evidence for efficacy is that of each agent. The recommendation is based on GDG consensus.	
Other considerations	It is a humanitarian necessity that these patients receive adequate analgesia, even if cognitively impaired, or limited in their ability to express pain.	
	Particular skill and sensitivity may be required in the management of pain in those who also show signs of delirium (see NICE delirium Guideline ²²²)	
	It must be remembered that patients may require more analgesia for investigations such as X Rays.	
Recommendation	Assess pain:	
	within 30 minutes of administering initial analgesia and	
	hourly until settled on the ward and	
	 regularly as part of routine nursing observations throughout admission 	
Relative values of different outcomes	This group of patients is most commonly elderly and frail and pain is one of the main physiological and psychological stresses they face. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most	

74

important outcome. The GDG also considered adverse events outcomes to be important.

Trade off between clinical
benefits and harmsRegular assessments mean that the patients benefit from analgesia
that is tailored to their needs and ensure that the analgesic agents
have taken effect. There are no identifiable harms associated with
this.

Economic considerations The GDG agrees that the additional costs linked with the staff time required for regular pain assessment are likely to be offset by the beneficial outcomes of ensuring adequate analgesia.

Quality of evidenceThere have been no studies of this approach to achieving adequate
analgesia. The recommendation is based on GDG consensus.

Other considerationsSatisfactory and timely pain relief can only be ensured by regular
re-assessment.

To maintain an adequate level of pain relief, analgesia should be administered routinely and not 'on demand'. It is good practice to re-assess a patient in severe pain after 30 minutes, as analgesia will have taken effect in this time and the need (or not) for additional analgesia can be determined. If further analgesia is required, the need for subsequent hourly reassessment is justified not only by the need to ensure a satisfactory response, but also to assess any unwanted effects.

Some patients may be unable to express their need for pain relief to health care professionals. Regular assessment of pain and tailoring of medication accordingly will reduce the risk of these patients suffering because of inadequate pain control.

The GDG also considered evidence on patient views. Two studies in which patients mentioned pain management were identified (Section 13.2). In one, pain management did not seem to be a problem³⁰⁶. However, in the other the patient had to keep asking for pain relief after surgery²⁶⁶. This highlights the importance of regular assessment.

Recommendation	Ensure analgesia throughout the patient's stay is sufficient to allow movements necessary for investigations (as indicated by the ability to tolerate passive external rotation of the leg), and for nursing care and subsequent rehabilitation.
Relative values of different outcomes	This group of patients is most commonly elderly and frail and pain is one of the main physiological and psychological stresses they face. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important.
Trade off between clinical benefits and harms	Providing adequate levels of analgesia is essential in improving the patients' wellbeing and minimising their discomfort whilst clinical investigations are being carried out. There are no identifiable

harms from carrying out this assessment.

Economic considerations	The beneficial outcomes of ensuring that adequate analgesia is provided to allow patients' movements are likely to offset the staff time required).
Quality of evidence	There have been no studies of this approach to achieving adequate analgesia. The recommendation is based on GDG consensus.
Other considerations	In both the pre and post operative periods if the patient can tolerate passive rotation of the leg then this gives an indication they will be comfortable for pre-operative radiographs as well as initial post operative mobilisation. This procedure should adequately predict the adequacy of analgesia when patients subsequently have to be moved (e.g. on and off examination surfaces) for investigational procedures, such as X-rays.
Recommendation	Offer paracetamol every 6 hours preoperatively unless contraindicated
Relative values of different	This group of patients is most commonly elderly and frail and pain
outcomes	is one of the main physiological and psychological stresses they face. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important.
outcomes Trade off between clinical benefits and harms	face. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events
Trade off between clinical	face. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important. Simple regular prescribed analgesia such as paracetamol is not associated with any significant harm or side effects. However, it should be avoided or used with caution in patients with known

Other considerationsComplications are especially more likely to develop when stronger
analgesia is administered in the elderly. Regular paracetamol is
first-line unless contra-indicated

This and subsequent recommendations follow a logical hierarchy for the use of analgesic agents as indicated in the World Health Organisation pain relief ladder.

these are unethical. However, in a randomised controlled trial, Cuvillion et al 2007⁶⁰ have shown that intravenous paracetamol (2mg) can be as effective as nerve blocks or morphine in the post-

Recommendation	Offer additional opioids if paracetamol alone does not provide sufficient preoperative pain relief
Relative values of different outcomes	This group of patients is most commonly elderly and frail and pain is one of the main physiological and psychological stresses they face. Therefore, the GDG considered pain relief (for example as indicated or by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important.
Trade off between clinical benefits and harms	Repeated use of opioids may cause dependence and tolerance but this should not be a deterrent in the control of pain in patients who may have a terminal illness.
	Many older patients may have impaired respiratory function and opioids should be used with caution in these patients. Smaller doses may be required in older patients.
	Harm may come from excessive opioid administration:
	Some patients may develop nausea and constipation from stronger opioidsopiods and codeine. Regular laxatives may need to be administered.
	Severe constipation may exacerbate other chronic conditions like diverticulitis.
	The significant sedation from even mild opioids in this vulnerable group may slow down their post-operative mobilisation, and upset their balance.
	There is a trade off between using stronger analgesia with more side effects and the benefit of better pain relief. Elderly patients are more susceptible to the harmful effects of opioid analgesics.
	Opioids and NSAIDs can both cause harm in elderly patients with comorbidities. Most elderly hip fracture patients do have multiple chronic conditions such as decreased renal function, hiatus hernia or previous gastric or duodenal erosions, vertigo, diverticulitis, or mild cognitive problems that may be exacerbated by these forms of analgesia.
Economic considerations	The administration of some opioids requires two trained nurses for approximately 15 minutes. Please see Appendix H section 8.1 for further details. The GDG agrees that the additional costs are likely to be offset by the beneficial outcomes of ensuring adequate analgesia (see Recommendation 1).
Quality of evidence	No studies on the effectiveness of opioids compared to placebo or to other drugs in hip fracture patients were identified.
Other considerations	None

Recommendation	Consider adding nerve blocks if paracetamol and opioids do not provide sufficient preoperative pain relief or to limit opioid dosage. Nerve blocks should be administered by trained personnel. Do not use nerve blocks as a substitute for early surgery.
Relative values of different outcomes	This group of patients is most commonly elderly and frail and pain is one of the main physiological and psychological stresses they face. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important. Adequate pain relief is beneficial. Reduction in the required administration of opioids and the associated side effects may also be an important outcome.
Trade off between clinical benefits and harms	Local nerve blocks are effective and may serve as a means of reducing the need for, and side effects of, opioids and other analgesia. However, as there they are associated with a very rare incidence of nerve damage, administering them in a busy casualty department may require a rolling programme of training junior doctors or nurses to be competent with this technique.
Economic considerations	The additional cost of nerve blocks versus the cost of opioid drugs may be offset by savings in the resources that would be required to treat the side effects of opioids. The GDG agrees that the additional costs are likely to be offset by the beneficial outcomes of ensuring adequate analgesia.
Quality of evidence	There are a limited number of clinical trials that have examined the effectiveness of nerve blocks in conjunction with general anaesthesia. Some studies have looked at the impact of inserting nerve blocks before the surgical procedure, to see if this may reduce analgesic requirements and improve pain management. These studies show that nerve blocks reduce the degree of pain compared to other forms of analgesia alone and that they may have fewer side effects compared to systemic analgesia.
Other considerations	Although studies have shown that nerve blocks are better than other forms of analgesia at relieving pain, the GDG considered that this should not be the be first line treatment. The GDG wished to ensure that the administration of analgesics is done in a step wise approach as some patients may benefit from simple analgesics such as paracetamol and therefore avoid the more serious side effects of stronger analgesics.

Recommendation	Offer paracetamol every 6 hours postoperatively unless contraindicated.
Relative values of different outcomes	This group of patients is most commonly elderly and frail and pain is one of the main physiological and psychological stresses they face. It is also of central importance in achieving early mobilisation post-operatively. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important.
Trade off between clinical benefits and harms	Paracetamol administered first-line and regularly in standard dosage at this frequency is commonly effective and lacks the unwanted effects of second-line systemic agents (see below). It should be avoided or used with caution in patients with known hypersensitivity to paracetamol and in liver and renal disease.
Economic considerations	The cost of paracetamol is minimal. The administration of paracetamol would be part of routine drug rounds, and therefore it will not involve additional staff or administrative costs. (Appendix H, section 8.1).
Quality of evidence	Cuvillion et al have shown that intravenous paracetamol is as effective as nerve blocks or morphine in the post-operative phase.
Other considerations	Paracetamol should be the first option as opioids often sedate patients when they need to be alert to understand and remember important instructions from the physiotherapist on early effective mobilisation. Also opioids may make patients feel dizzy and unconfident about their balance.
	Post-operatively active mobilisation may require additional pain relief. Pain may be a critical barrier to be overcome for effective early mobilisation.
Recommendation	Offer additional opioids if paracetamol alone does not provide sufficient postoperative pain relief.
Relative values of different outcomes	This group of patients is most commonly elderly and frail and pain is one of the main physiological and psychological stresses they face. It is also of central importance in achieving early mobilisation post-operatively. Therefore, the GDG considered pain relief (for example as indicated by Visual Analogue Scales or by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important.
Trade off between clinical benefits and harms	Opioids do have significant side effects of sedation, nausea, dizziness and constipation. However, pain is also a significant barrier to early mobilisation. Getting the analgesia right at each step of the hip fracture pathway is a skilled judgement for each individual patient until they are discharged.

	Often opioids sedate patients when they need to be alert to understand and remember important instructions from the physiotherapist on early effective mobilisation. Also opioids may make patients feel dizzy and unconfident about their balance.
Economic considerations	The GDG believe that the side-effects of opioids and additional costs are likely to be offset by the benefits of pain relief.
Quality of evidence	No studies on the effectiveness of opioids compared to placebo or to other drugs in hip fracture patients were identified. This recommendation is based on GDG consensus.
Other considerations	None.

Recommendation	Non steroidal anti-inflammatory drugs (NSAIDs) are not recommended.
Relative values of different outcomes	This group of patients is most commonly elderly and frail and pain is one of the main physiological and psychological stresses they face. It is also of central importance in achieving early mobilisation post-operatively. Therefore, the GDG considered pain relief (for example as indicated by the need for 'breakthrough analgesia') to be the most important outcome. The GDG also considered adverse events outcomes to be important.
Trade off between clinical benefits and harms	The benefits of pain relief are outweighed by the potential side effects of these drugs particularly (but not exclusively) in the elderly population. There is a known age-related increase in susceptibility to the harmful effects of NSAIDs including upper gastrointestinal bleeding, nephrotoxicity and fluid retention.
Economic considerations	None
Quality of evidence	No RCTs on the effectiveness of NSAIDs compared to placebo or to other drugs in hip fracture patients were identified. This recommendation is based on GDG consensus.
Other considerations	The side effects of these drugs are too great in the elderly. Therefore, the GDG decided that they should be avoided as there are other safer alternatives are available such as paracetamol and opioids.
	As discussed, many of these patients have comorbidities of hiatus hernia, gastric or duodenal erosions, or chronic renal impairment, which can all be made worse by regular use of NSAIDs.

2 7.4 Research recommendations on analgesia

3 The GDG recommended the following research question:

- What is the clinical and cost effectiveness of preoperative and postoperative nerve blocks in reducing pain and achieving mobilisation and physiotherapy goals sooner
 - in patients with hip fracture?

4 Why this is important

- Nerve blocks may potentially find an important role in the management of hip fracture
 pain, both pre- and post-operatively, because of their potential to reduce the requirement
 for opioids and their associated unwanted effects. Economically there are considerations
 for staff training, but also for the potential benefits in terms of duration of stay and early
 mobilisation. It is not possible from the existing literature to determine this with any
 confidence and there is a pressing need for a definitive trial comparing these outcomes
- 11 with nerve blocks against a defined protocol of systemic opioid use.

8 Regional (spinal or epidural) versus general anaesthesia

3 8.1 Introduction

Patients who have a proximal femoral fracture are usually offered surgery to treat the
injury. The vast majority of these operations will require some type of anaesthesia.
Anaesthesia may be general anaesthesia or regional anaesthesia.

- 7 General anaesthesia involves complete loss of consciousness. This may be achieved by 8 either inhalational agents or intravenous anaesthetic agents. Regional anaesthesia is 9 conducted by numbing the nerves that supply sensation to the lower limbs, with the 10 injection of local anaesthetic solution into the fluid surrounding the spinal cord. There are 11 two types of regional anaesthesia, spinal and epidural. During a spinal, local anaesthetic 12 drugs, sometimes in combination with opioid painkillers are injected directly into the 13 cerebro-spinal fluid of the spinal cord. The majority regional anaesthesia administered to 14 hip fracture patients is spinal anaesthesia rather than epidural.
- Hip fracture patients are generally elderly and have significant comorbidities. This increases
 the risks from all types of anaesthesia. At present both regional and general anaesthesia are
 administered but the eventual choice is the preference and experience of the anaesthetist
 in discussion with the patient and their carers.
- The aim of this review is to identify whether regional anaesthesia confers any benefit
 compared to general anaesthesia with regards to reducing complications and improving
 patient outcomes after surgery.

22 8.2 Regional versus general anaesthesia

23 8.2.1 Review question

In patients undergoing surgical repair or replacement for hip fractures, what is the clinical
 and cost-effectiveness of regional (spinal/epidural) anaesthesia compared to general

- 26 anaesthesia in reducing complications such as mortality, cognitive dysfunction,
- 27 thromboembolic events, post operative respiratory morbidity, renal failure and length of
- 28 stay in hospital?

29 8.2.1.1 Clinical evidence

- The literature search retrieved one Cochrane review (Parker et al 2004)²⁵⁸. A further update 1
- 2 search was then conducted to search for any papers that may have been published since
- 3 the publication of this review. No additional studies were retrieved and therefore the
- 4 clinical evidence presented in this chapter are based on the Parker et al results with the 5
- addition of the GRADE analysis.
- 6 In addition, we conducted a systematic review on patient views to look for evidence on 7 patient preference as this was one of the main outcomes.
- 8 See evidence table 5.4, Appendix E, forest plots G38 to G49.

Outcome	Number of studies	Design	Limitations	Inconsistency	Indirectness	Other considerations/ imprecision
Mortality (early up to 1 month) ^{1,20,23,63,64,1} 65,208,209,269,326,330	11	RCT	Serious limitations (a), (b)	No serious inconsistency	No serious indirectness	Serious Imprecision ^(c)

Deep vein thrombosis ^{36,63,208}	4	RCT	Serious limitations (a), (b)	No serious inconsistency	No serious indirectness	Serious Imprecision ^(c)

9 Table 8-26: General vs. regional anaesthesia – Clinical study characteristics

10 (a) Some of the studies did not report definite allocation concealment

11 (b) None of the trials clearly stated whether it was an intention to treat analysis

12 (c) The relatively few events and few patients give wide confidence intervals around the estimate of effect. 13 This makes it difficult to know the true effect size for this outcome.

14 (d) Pooling of the results showed some but not statistically significant heterogeneity: $l^2 = 31\%$ (p= 0.18)

15 (e) The results of pooling all pulmonary embolism events showed statistical heterogeneity $I^2 = 47\%$ (p=

16 0.06). The authors suggest this is mainly due to the significantly different in trials presenting results for 17 fatal and non fatal pulmonary embolism. These were subsequently analysed in separate meta-analyses.

18

19

Table 8-27: General vs. regional anaesthesia - Clinical summary of findings

Intervention	Control	Relative risk (95% CI)	Absolute effect	Quality

			, .	
Study	Incremental cost (£)	Incremental effects	ICER	Uncertainty
Chakladar 2010 ⁴⁶	76.77 ^(a)	NA	NA	NR

2 3 (a) General anaesthesia more costly than regional anaesthesia (SD):£270.58 (44.68) vs 193.81

(44.68); p<0.0001

4 8.2.1.3 Evidence statement (s)

Clinical There is a statistically and clinically significant reduction in early mortality (up to 1 month) in patients having regional anaesthesia compared to those having general anaesthesia (LOW QUALITY).

There is no statistically significant difference in mortality when data at 1, 3, 6 and 12 months are combined (LOW QUALITY).

There is a statistically significant but not clinically significant improvement in postoperative confusion and reduction in incidence of deep vein thrombosis in patients receiving regional compared to general anaesthesia (LOW QUALITY).

There were no statistically significant differences in length of stay in hospital, vomiting, pneumonia, myocardial infarction and pulmonary embolism (LOW QUALITY).

Economic One study found general anaesthesia to be more costly than spinal anaesthesia. This evidence has very serious limitations since it did not evaluate effectiveness and may not have included all important cost differences.

5 8.2.2 Recommendations and link to evidence

Recommendation	Offer patients a choice of spinal or general anaesthesia after discussing the risks and benefits.
Relative values of different outcomes	The GDG considered early mortality (up to 1 month) and patient preference to be the most important outcomes.
Trade off between clinical benefits and harms	Most clinical benefit was seen in patients undergoing regional anaesthesia. However, there is a small chance of nerve damage following regional anaesthesia.
	Potential benefits with regional also include, reduction in Venous Thromboembolism (VTE) complications but studies were conducted in patients not receiving VTE prophylaxis (chance of a false positive). However, this finding is supported by a more comprehensive review of DVT and PE across all surgical patients in the NICE guideline on venous thromboembolism prophylaxis ²²³ .
	Some patients perceive unconsciousness during general anaesthesia as a benefit, but others fear the loss of control. In addition. a potential benefit with general anaesthesia includes lack of awareness throughout the surgical procedure. However,

recovery on the first post-operative day may be slower.

Economic considerations The GDG felt that because of the potentially serious limitations of the study included as economic evidence there were insufficient data to claim that the overall costs of the general and regional anaesthesia are substantially different.

However, there was agreement in acknowledging that spinal anaesthesia usually involves lower costs for drugs, anaesthesia equipment and airway equipment than general anaesthesia.

Nevertheless, these lower costs of regional anaesthesia could be offset by its longer administration time. The GDG debated at length whether regional anaesthesia required more time to be administered compared to general anaesthesia, but no agreement was reached.

Quality of evidence The studies comparing the two types of anaesthesia were mainly of low methodological quality. They included small numbers of participants and only reported a few outcome measures. These varied between studies making pooling of the data difficult. The studies lacked methodological rigour in particular regarding allocation concealment, assessor blinding and intention to treat analysis. The studies are now considered to be out of date and no longer relevant to current anaesthesia and perioperative care. In addition, they do not account for the advances in safety in the field of anaesthesia. For example in some of the studies patients allocated to general anaesthesia did not receive thromboprophylaxis as part of routine care.

> The economic evidence has very serious limitations, as it is based on responses to a questionnaire on a hypothetical anaesthetic technique, and not a direct audit of actual equipment usage. Moreover, the analysis did not look at whether there are any potential savings linked to a reduction in the cases of confusion when regional anaesthesia is used.

Other considerationsThe GDG also considered the evidence for other outcomes such as
length of stay in hospital and adverse events including vomiting,
acute confusional state and respiratory and cardiac complications.
In the absence of any strong evidence favouring one method over
the other, the GDG decided that the choice of anaesthesia should
be based on the patient preference after being given sufficient
information about the options available and the expertise of the
anaesthetist.

Refer to the Association of Anaesthetists of Great Britain and Ireland (AAGBI) Guidelines on Anaesthesia for Hip Fractures (to be cited for final draft once published).

Recommendation	Consider intraoperative nerve blocks for all patients undergoing surgery.
Relative values of different outcomes	The GDG considered pain relief, post-operative mobility and reduction in opioid usage to be the main outcomes.
Trade off between clinical benefits and harms	As discussed in chapter 7 on using nerve blocks for hip fracture analgesia, local nerve blocks may serve as a means of reducing the need for, and side effects of, opioids and other analgesia. However, they are associated with a very rare incidence of nerve damage and must be admisitered by trained health care professionals.
Economic considerations	The GDG thought this likely to be cost-effective because the administration of nerve blocks avoids the complications and side effects of opioids, and therefore might result in a reduced length of hospital stay. Please see the analgesia chapter for evidence on the cost-effectiveness of nerve blocks in general.
Quality of evidence	Some studies have investigated the effectiveness of nerve blocks in conjunction with general anaesthesia to determine if this reduces the requirements for opioid analgesics and improve pain management. These studies show that nerve blocks reduce the degree of pain compared to other forms of analgesia alone and that they may have fewer side effects compared to systemic analgesia.(see analgesia chapter 7)
Other considerations	Nerve blocks are often administered before a spinal anaesthetic, in order to position the patient. They are usually administered before a general anaesthetic and many are now conducted using ultrasound guidance. This reduces the chance of complications, such as an intraneural injection and also enables the dose of local anaesthetic administered to be lower. The use of nerve blocks in surgery has increased in recent years and has almost become routine practice. Therefore, studies to show any benefit may now be difficult to conduct, as withholding analgesia from such patients may be unethical. Administration of nerve blocks should not delay surgery.

3 8.3 Research recommendation on anaesthesia

- 4 The GDG recommended the following research question:
- 5 What is the clinical and cost effectiveness of regional versus general anaesthesia on postoperative morbidity in patients with hip fracture?
- 7 Why this is important

1

1 No recent randomised controlled trials were identified that fully address this question. The 2 evidence is old and does not reflect current practice. In addition, in most of the studies the 3 patients are sedated before regional anaesthesia is administered and this is not taken into 4 account when analysing the results. The study design for the proposed research would be 5 best addressed by an randomised controlled trial. This would ideally be a multi-centred trial 6 including 3,000 participants in each arm. This is achievable if one considers that there are 7 70, 000 hip fractures a year in the UK³⁸. The study should have three arms which look at 8 spinal anaesthesia versus spinal anaesthesia plus sedation versus general anaesthesia, this 9 would separate those with regional anaesthesia from those with regional anaesthesia plus 10 sedation. The study would also need to control for surgery, especially type of fracture, 11 prosthesis and grade of surgeon.

- A qualitative research component would also be helpful to study patient preference fortype of anaesthesia.
- 14

1 9 Surgeon seniority

2 9.1 Introduction

- As a general observation of life one would conclude that to have a job completed
 thoroughly, effectively and efficiently it would be appropriate to give the task to somebody
 with adequate training and experience. Whether this can be extrapolated to the
 relationship of the management of hip fractures to the seniority of the surgeon involved is
 the purpose of this chapter.
- 8 The historical background of this question has to be considered in relation to the 9 environment in which hip fracture patients were treated. In the United Kingdom hip 10 fractures were commonly regarded as the surgical material for trainee surgeons to gain 11 their experience. In the past much of this work would have been unsupervised, and in the 12 main the trainees would have enjoyed the challenge and responsibility this gave them.
- 13The operations were often performed outside of scheduled list times as extra or emergency14cases. Under these circumstances it was more likely that the anaesthetist involved in the15procedure would be more junior and the nursing scrub team not specifically from a trauma16theatre.
- Any variations in outcome which may be simply labelled as related to surgeon seniority may
 in fact have multiple underlying causes. A more senior surgeon is more likely to be
 operating on a scheduled list, with more senior anaesthetists and a regular nursing scrub
 team.
- 21 9.2 Surgeon seniority

22 9.2.1 Review question

What is the clinical and cost effectiveness of surgeon seniority (consultant or equivalent) in
 reducing the incidence of mortality, the number of patients requiring reoperation, and poor
 outcome in terms of mobility, length of stay, wound infection and dislocation? (See
 evidence table 5.5, Appendix E and forest plots G50 and G51 in Appendix G).

27 9.2.2 Clinical evidence

28 No randomised evidence was identified. Four prospective cohorts that adjusted for some29 confounding factors were identified.

2 Table 9-30: Junior/less senior surgeon vs. senior surgeon – Clinical study characteristics

Table 3-30. Juliolyless senior surgeon vs. senior surgeon - ennear study characteristics						
Outcome	Numbe r of studies	Design	Limitations	Inconsistency	Indirectness	Other considerations/ imprecision
Reoperations (follow up 6 months) ²⁴⁸	1	Cohort	serious limitations (a,b)	no serious inconsistency	serious indirectness ^{(c,d,} ^{e)}	serious imprecision ^(h)
Dislocation in hemiarthroplasty (follow up 0 to 10 years) ⁸³	1	Cohort	serious limitations (b)	no serious inconsistency	serious indirectness (f,g)	serious imprecision ^(h)
Dislocation in total hip replacement (follow up 0 to 11 years) ⁸³	1	Cohort	serious limitations ^(c)	no serious inconsistency	serious indirectness (f,g)	serious imprecision ^(h)
(a) Conject supreme an excepted on significantly many particular with a paper and functions machility server and						

(a) Senior surgeons operated on significantly more patients with a poor pre-fracture mobility score and performed significantly more arthroplasties and significantly fewer osteosyntheses.

- (b) Only a limited number of confounders were included in the analysis. No adjustment or mention of the anaesthetists experience or grade.
- (c) Surgeon seniority measured by years experience rather than the grade of surgeon. Experienced surgeons with more than 3 years orthopaedic surgical experience either performing surgery or supervising junior registrars were compared unsupervised orthopaedic junior registrars with less than 3 years orthopaedic surgical experience.
- (d) Only the technically demanding fractures were included in the analysis, not all surgery for hip fractures.
- (e) Reoperation rate only measured at 6 months, not longer.
- *(f)* The focus of the study is on surgical approach therefore baseline data by surgeon seniority is not reported.
- (g) Dislocation is not a primary outcome.
- (h) The wide confidence intervals make the estimate of effect imprecise.

19 Table 9-31: Junior/less senior surgeon vs senior surgeon – Clinical summary of findings

Outcome	Intervention	Control	Relative risk	Absolute effect	Quality
Reoperations (follow up 6 months)	16/56 (28.6%)	47/309 (15.2%)	multivariate odds ratio 2.01 (1.01 to 4.02)	289 more per 1000 (from 3 more to 864 more)	Very low
Dislocation in hemiarthroplasty (median follow up 4.3 (0 to 10) years)	37/404 (9.2%)	8/135 (5.9%)	multivariate odds ratio 1.3 (0.6 to 3)	18 more per 1000 (from 24 fewer to 118 more)	Very low
Dislocation in total hip replacement (median follow up 2.3 (0 to 11) years)	37/636 (5.8%)	8/77 (10.4%)	multivariate odds ratio 0.9 (0.3 to 2.8)	10 fewer per 1000 (from 73 fewer to 187 more)	Very low

20

21 9.2.2.1 Economic evidence

22 No studies were identified.

2 9.2.2.2 Evidence statement (s)

Clinical There is a statistically significant, but not clinically significant increased reoperation rate at 6 months with unsupervised junior orthopaedic registrars with less than 3 years experience than with experienced surgeons with more than 3 years experience. (VERY LOW QUALITY).

There is no statistically significant difference between Swedish post registrars and registrars in dislocation rate at a median follow up of 2.3 years after hemiarthroplasty in patients with hip fracture. (VERY LOW QUALITY).

There is no statistically significant difference between Swedish post registrars and registrars in dislocation rate at a median follow up of 2.3 years after total hip replacement in patients with hip fracture. (VERY LOW QUALITY).

There was no evidence identified for mortality, mobility, length of stay or wound infection.

Economic No studies were identified.

3

4 9.3 Recommendations and link to evidence

Recommendation	Schedule surgery for hip fracture patients on a planned trauma list
Relative values of different outcomes	Mortality, reoperation rate, dislocations, length of stay in secondary care and wound infection were considered the main outcomes. Complications, pain and functional status were also considered.
Trade off between clinical benefits and harms	There is a significantly higher reoperation rate with unsupervised/junior orthopaedic surgeons with less than 3 years experience than senior more experienced surgeons. There was no statistically significant difference in dislocation rates. No other outcomes were reported.
Economic considerations	The GDG acknowledges that a planned trauma list (as opposed to a generic emergency list) for hip fracture patients will require, among others, the presence of consultant surgeons and anaesthetists. On the other hand, a generic emergency list would more likely see junior members of staff, especially during weekends and public holidays.
	The personnel cost per hour for a planned trauma list have been estimated at £337, and for a general emergency list at £197 (please see Appendix H section 8.2XX for further details).
	These costs would be at least partially off-set by savings due to lower re-operation rates and by a higher number of patients operated per hour.

Quality of evidence	There is no evidence for the majority of the outcomes and only very low quality evidence from non-randomised studies for two outcomes: reoperation rate and dislocations.
Other considerations	We have specified in the recommendation that surgery for hip fractures should occur on a planned trauma list. To establish a scheduled trauma list management and clinicians are required to provide adequate facilities and staff for it to run. For a planned list it is necessary to have a chain of responsibility to a consultant surgeon and consultant anaesthetist who have time in their programs to execute that responsibility. To run a planned trauma list requires ready access to an image intensifier and radiographer. The nursing team would need to be appropriate to the work planned for that theatre. The recommendation therefore recognises the need for adequate seniority of the surgeon but makes what we believe to be a reasonable assumption that this recognition should also apply to the rest of the operating theatre team caring for the hip fracture patient. The GDG consider this recommendation a key priority for implementation.
Recommendation	Unsupervised trainees should not undertake surgery or anaesthesia on patients with hip fracture.
Relative values of different outcomes	Mortality, reoperation rate, dislocations, length of stay in secondary care and wound infection were considered the main outcomes. Complications, pain and functional status were also considered.
Trade off between clinical benefits and harms	There is a significantly higher reoperation rate with unsupervised/junior orthopaedic surgeons with less than 3 years experience than senior more experienced surgeons. There was no statistically significant difference in dislocation rates. No other outcomes were reported.
Economic considerations	Higher grade surgeons or those with more experience are likely to be entitled to a higher wage than junior surgeons. However, as their rate of re-operations is statistically significantly lower, having hip fracture patients operated on by experienced surgeons will plausibly result in cost savings and improved health outcomes. In addition, the GDG believe experienced surgeons use theatre time more efficiently allowing greater throughput of cases.
Quality of evidence	There is no evidence for the majority of the outcomes and only very low quality evidence from non-randomised studies for two outcomes: reoperation rate and dislocations.
Other considerations	The level of supervision required for a trainee or junior staff member for a particular case depends on two main factors: the junior's ability and the complexity of the case. It is therefore implicit that the senior staff responsible for the trauma list must have knowledge of both of these factors before determining the

level of supervision required. Potential surgical, anaesthetic or nursing problems may be evident to an experienced surgeon, anaesthetist or nurse preoperatively. This gives the opportunity to both avoid the problem occurring and to enhance the training opportunity. An unsupervised list would therefore be one in which those responsible did not have adequate prior knowledge of the capabilities of the more junior members of the team and the specific problems they may encounter, or when they did not use this knowledge to provide adequate supervision.

1 **10 Surgical procedures**

2 10.1 Introduction

20

The options for hip fracture surgery depend on the type of fractures. They can be divided into two main groups according to their relationship to the capsular attachment of the hip joint. Those above the insertion of the capsule are termed intracapsular and those below are termed extracapsular. Extracapsular fractures can be further divided into three types: pertrochanteric (also called intertrochanteric), reverse oblique or subtrochanteric. 8

9 Broadly speaking there are two surgical options for treating hip fractures, replacement 10 arthroplasty or internal fixation. Replacement arthroplasty involves removing part or all of 11 the damaged bone and replacing it with a prosthesis which then functions in place of the 12 removed bone. It may describe a hemiarthroplasty or a total hip arthroplasty. Both involve 13 replacement of the femoral head with a metal implant, the stem of which is secured in the 14 femoral shaft. A total hip arthroplasty involves, in addition, replacement of the socket. Both 15 implants can be inserted with or without the use of cement. Internal fixation involves 16 returning the bone fragments to an acceptable position and then holding that position with 17 screws, plates or nails. This should allow healing of the facture fragments in an acceptable 18 position for long term function and maintenance of patient function whilst that healing 19 occurs.

21 10.2 Surgery with regard to early mobilisation

22 This section relates to the section on early mobilisation (chapter 11) as well as surgery. 23 When embarking on any surgical procedure there should be a clear objective. In 24 orthopaedic and trauma surgery it is easy to attach a rather bland aim of "safe restoration 25 of function". Prior to any surgery commencing the surgeon should already know what his 26 planned post operative care of that patient is to be. Given the poor reserve functional 27 capacity of many hip fracture patients any prescribed limits on mobility and weight-bearing 28 may significantly alter and restrict their post-operative care. In particular unnecessary 29 restriction of weight-bearing has the potential to compromise independence, discharge 30 destination, general health and final level of function. As a consequence of these 31 considerations, and as a result of the recommendation for early mobilisation (section 32 11.2.2) the GDG felt it appropriate to make a recommendation on post operative weight-33 bearing status.

Recommendation	Operate on patients with the aim to allow them to fully weight bear (without restriction) in the immediate post operative period.
Relative values of different outcomes	The aim of surgery and rehabilitation is for patients to regain their prefracture functional status. Early mobilisation with a physiotherapist appears safe and is effective in promoting early recovery. The most important outcomes considered by the GDG were functional status, mobility, pain and quality of life.
Trade off between clinical benefits and harms	The evidence from the early mobilisation question shows that the only outcome relating to harm or safety was mortality, which showed no statistically significant difference. If safety issues were a concern it is likely that they would be reflected in the overall functional outcomes, all of which improved or had no significant effect, therefore we don't believe that harm is caused harm from this evidence.
Economic considerations	See also early mobilisation section 8.2. One of the main aims of surgery is for patients to regain their pre-fracture functional status. As the GDG has agreed to consider early mobilisation strategy as a cost-effective intervention for our population, this recommendation is unlikely to result in extra costs.
Quality of evidence	There is no direct evidence relating to this recommendation, but the evidence from the early mobilisation review question is indirectly applicable, see Chapter 8.
Other considerations	Elderly patients may be physically frail, suffering from cognitive impairment or delirium and so cannot be expected to mobilise non-weight-bearing or partially weight-bearing. Post-operative instructions requesting non-or partial weight-bearing will frequently result in the patient not mobilising at all.

Recommendations and link to evidence 1 10.2.1

2 3

4 10.3 Displaced intracapsular fractures

5 In an intracapsular fracture the proximal fragment includes the femoral head alone or the 6 femoral head with a small portion of neck. The size and shape of this fragment combined 7 with the often soft nature cancellous bone of which it is constituted makes secure fixation 8 difficult. This can potentially compromise early function. In addition, the blood supply of 9 the femoral head may be disrupted, leading to poor healing or bone death.

10

11 The displacement of an intracapsular fracture is determined on the anteroposterior and 12 lateral radiographs of the area. An undisplaced fracture may as its name suggests 13 demonstrate no change in position from that it would have occupied prior to the injury. 14 However it is also customary to include in the undisplaced group valgus impacted fractures.

- 15 In this impacted group the harder bone of the femoral neck has been driven into the softer
- 16 bone of the femoral head. In both of these these undisplaced fracture types there is

generally already inherent stability and little likelihood of damage to the blood supply.
 Fixation in situ is generally accepted
 Fixation in situ is generally accepted

In practice a displaced fracture is one in which the preoperative radiographs demonstrate
the fragments have moved in relation to each other to an unacceptable position for fixation
in situ. The implication of this is that the fragments have moved in relation to each other to
a greater extent. The particular anatomy of the region mean that the blood supply to the
femoral head is at risk. There will also be less inherent stability either as a consequence of
fragmentation along the fracture line or difficulties in obtaining precise reduction.

11 In patients with these displaced intracapsular fractures a decision initially needs to be made 12 as to whether to reduce the fracture and internally fix it or to carry out some form of 13 replacement arthroplasty. Each has potential advantages and disadvantages. Internal 14 fixation retains the patient's own tissues and is often a smaller procedure. However, it may 15 require a more prescriptive post-operative regime to protect the healing bone. Should 16 replacement arthroplasty be appropriate it is necessary to determine the indications for a 17 hemiarthroplasty in which only the damaged bone of the proximal femur is replaced or a 18 total hip replacement when both the femoral head and the hip socket are replaced.

19 10.3.1 Internal fixation versus hemiarthroplasty

20 10.3.1.1 Review question

In patients having treatment for displaced intracapsular hip fracture what is the clinical and
 cost effectiveness of internal fixation compared to hemiarthroplasty on mortality, number
 of reoperations, functional status, length of stay in hospital, total time to resettlement in
 the community, quality of life, pain and place of residence after hip fracture.

25 See evidence table 7, Appendix E and forest plots G74 to G82 in Appendix G.

26 10.3.1.2 Clinical evidence

27 Table 10-32: Internal fixation vs hemiarthroplasty – Clinical study characteristics

(a) The studies with the most weight in the meta-analysis have inadequate or unclear allocation concealment.

(b) The relatively few events and few patients give wide confidence intervals around the estimate of effect. This makes it difficult to know the true effect size for this outcome.

- (c) There is significant statistical heterogeneity between the studies. This could be due to the different types of implant or arthroplasty and different follow up periods.
- (d) There is significant statistical heterogeneity between the studies. This could be due to the different types of implant or arthroplasty.
- (e) The wide confidence intervals around the estimate make the result imprecise. Consequently, it is difficult to determine the true effect size for this outcome.
- (f) There is significant statistical heterogeneity between the studies. This Cochrane review reports this is likely to be due to the variation in the definition for this outcome.

Table 10-33: Internal fixation vs hemiarthroplasty - Clinical summary of findings

2 10.3.1.3 Economic evidence

3	Two economic studies were identified ^{171,283} . Rogmark et al (2003) ²⁸³ is a cost-consequence
4	analysis based on a RCT but it was excluded because it does not distinguish patients on the
5	basis of whether they received hemiarthroplasty or total hip replacement. Keating et al
6	(2005) ¹⁷¹ compare internal fixation vs. hemiarthroplasty in a cost-consequence analysis
7	based on a RCT. Please see Economic Evidence Table 14 in Appendix Ffor further details

8

9 Table 10-34: Internal Fixation vs Hemiarthroplasty - Economic study characteristics

Study	Limitations	Applicability	Other Comments
Keating 2005 ¹⁷¹	Minor limitations ^(a)	Partially applicable ^(b)	Costs not discounted because mainly incurred within 1 year of injury

10 (a) Small number of patients.

- 11 (b) UK study, but does a CUA.
- 12

13 Table 10-35: Internal Fixation vs Hemiarthroplasty - Economic summary of findings

Study	Incremental cost per patient (£)	Incremental effects	ICER	Uncertainty
Keating 2005 ¹⁷¹	£2726(a)	Various (b)	N/A	Two-way sensitivity analysis showed that the direction of change in cost did not change when cost of prostheses and cost of readmission were varied over a range from -50% to +100% around the baseline values.

 14
 (a) The mean cost per patient for internal fixation was £12,623 (95% CI: 10,768 – 14,478) and for £9,897

 15
 (95% CI: 8,062 – 11,732) for hemiarthroplasty (2001 GBP)

(b) Several outcomes were reported. Internal fixation entailed lower mortality at 4 and 12 months from the operation than hemiarthroplasty (3% vs. 5%; 8% vs. 10%) and slightly higher EQ-5D scores at 24 months (0.55 vs 0.53); (all effects were not statistically significant). Hemiarthroplasty involved a significantly lower number of patients needing further surgery at 12 and 24 months (31% vs. 5% and 39% vs. 5%), and higher EQ-5D scores at 4 and 12 months (0.56 vs. 0.61 and 0.58 vs.0.64; difference not statistically significant).

23 10.3.1.4 Evidence statement (s)

Clinical There is a statistically and clinically significant decrease in patients who require reoperations with hemiarthroplasty than with internal fixation. The follow up varied between 1 and 5 years. (LOW QUALITY)

There is a statistically significant, but not clinically significant, increase in patients who have a Barthel Index Score of 95 or 100 at 1 year with

hemiarthroplasty compared to internal fixation but there is no statistically significant difference at 2 years (MODERATE QUALITY)

There is a statistically significant, but not clinically significant, increase in patients who have a higher Harris Hip Score at 1 year with hemiarthroplasty compared to internal fixation but there is no statistically significant difference at 2 years (MODERATE QUALITY)

There is a statistically significant, but not clinically significant, increase in patients who have a higher Eq-5d (Euroqol) score at 2 years with hemiarthroplasty compared to internal fixation but there is no statistically significant difference at 1 year (MODERATE QUALITY)

There is no statistically significant difference between internal fixation and hemiarthroplasty in mortality at 1 months (LOW QUALITY), 3 to 6 months (LOW QUALITY) or 1 to 2 years (MODERATE QUALITY), the number of patients reporting pain at 1 year (VERY LOW QUALITY), the number of patients failing to return to the same residence at 1 to 3 years (LOW QUALITY), failure to regain mobility at 1 to 5 years and length of hospital stay (MODERATE QUALITY).

No RCT evidince was identified reporting on total time to resettlement in the community.

Economic Hemiarthroplasty is cost saving with respect to internal fixation. This evidence has minor limitations and partial applicability.

1

2 10.3.2 Internal fixation versus total hip replacement

3 10.3.2.1 Review question

In patients having treatment for intracapsular hip fracture what is the clinical and cost
effectiveness of internal fixation compared to total hip replacement on mortality, number
of reoperations, functional status, length of stay in hospital, total time to resettlement in
the community, quality of life, pain and place of residence after hip fracture. (See evidence
table 7, Appendix E and forest plots G83 to 86 in Appendix G).

13 10.3.2.3 Economic evidence

14	Three economic studies were identified ^{161,171,28}	³ . Rogmark et al (2003) ²⁸³ is a cost-	

15 consequence analysis based on a RCT which was excluded because it does not distinguish

16 patients on the basis of whether they received hemiarthroplasty or total hip replacement.

- Keating et al (2005)¹⁷¹ compare Internal Fixation vs Total Hip Replacement in a costconsequences analysis included in a Health Technology Assessment based on a RCT.
- Johansson et al (2006)¹⁶¹ is a cost-consequence analysis based on a RCT. Please see
- 4 Economic Evidence Tables 14 in Appendix F for further details.

6 Table 10-38: Internal fixation vs total hip replacement - Economic study characteristics

Study	Limitations	Applicability	Other Comments
Keating 2005 ¹⁷¹	Minor limitations ^(a)	Partial applicability ^(b)	Costs not discounted because mainly incurred within 1 year of injury
Johansson 2006	Potentially serious limitations (c)	Partial applicability ^(d)	

(a) Small number of patients.

(b) Study set in the UK, but not a CUA.

(c) Costs were derived from just one hospital. No sensitivity analysis was conducted.

(d) Study set in Sweden.

12 Table 10-39: Internal fixation vs total hip replacement - Economic summary of findings

	Incremental cost	Incremental		
Study	per patient (£)	effects	ICER	Uncertainty
Keating 2005 ¹⁷¹	£3224 ^(a)	THR has higher EQ-5D scores at 4, 12 and 24 months by 0.08; 0.12 and 0.14 respectively ^(b)	THR dominant	Two-way sensitivity analysis showed that the direction of change in cost did not change when cost of prostheses and cost of readmission were varied over a range from -50% to +100% around the baseline values.
Johansson 2006 ¹⁶¹	£265	More patients with good/fair Harris hip score at 1 and 2 years in THR group ^(c)	THR dominant	NR

- (a) The mean cost per patient included cost of hospital admission (inpatient and day case), theatre costs, prosthesis and profile of hardware. The mean cost per patient for internal fixation was £12,623 (95% CI: 10,768 14,478) and £9,399 (95% CI: 8,265-10,532) for THR.
 (b) THR had better outcomes than internal fixation: lower number of deaths within 4, 12 and 24
 - (b) THR had better outcomes than internal fixation: lower number of deaths within 4, 12 and 24 months from operation: (3% vs. 4%; 8% vs. 6% and 15% vs. 9%; p value not significant). Lower number of patients requiring further surgery within 4, 12 and 24 months from operation: 22% vs. 7%; 31% vs. 9% and 39% vs. 9%; p value not reported). Higher mean EQ-5D scores at 4, 12 and 24 months from operation: 0.56 vs 0.68 (p value not significant); 0.58 vs 0.70 (p = 0.04); 0.55 vs 0.69 (p value not significant).
 - (c) Percentage of patients with a Harris hip score excellent or good/fair or poor at 1 year: 12.5% vs. 100% (p value: <0.0001); at 2 years: 14.29% vs.95.23% (p value: <0.001)

25 10.3.2.4 Evidence statement (s)

Clinical There is a statistically and clinically significant decrease in patients who require reoperations with total hip replacement than with internal fixation. The follow up varied between 1 and 13 years. (LOW QUALITY)

8 9 10

11

17

18

19

20

21

22

23

24

There is a statistically significant, but not clinically significant, increase in patients who reported pain at 1 year with internal fixation compared to total hip replacement (MODERATE QUALITY).

There is no statistically significant difference in mortality at 2 to 4 months, 12 to 18 months or 2 years (LOW QUALITY) and length of hospital stay (MODERATE QUALITY) between internal fixation and total hip replacement.

No RCT evidence was identified reporting functional status, quality of life, total time to resettlement in the community and place of residence after hip fracture.

Economic THR is the dominant strategy with respect to internal fixation (less costly and more effective). This evidence has minor limitations and partial applicability.

1

2

3 10.3.3 Hemiarthroplasty versus total hip replacement

4 10.3.3.1 Review question

In patients having treatment for intracapsular hip fracture what is the clinical and cost
effectiveness hemiarthroplasty versus total hip replacement on mortality, number of
reoperations, functional status, length of stay in hospital, total time to resettlement in the
community, quality of life, pain and place of residence after hip fracture. (See evidence
table 7, Appendix E and forest plots G87 to G95 in Appendix G).

10 10.3.3.2 Clinical evidence

Length of hospital stay ¹⁷²	4	RCT	no serious limitations	no serious inconsistency	no serious indirectness	serious imprecision ^(c)

(a) The studies with the most weight in the meta-analysis have inadequate or unclear allocation concealment.

(b) The relatively few events and few patients give wide confidence intervals around the estimate of effect. This makes it difficult to know the true effect size for this outcome.

(c) The wide confidence intervals around the measurement make the result imprecise. This makes it difficult to know the true effect size for this outcome.

(d) There is significant heterogeneity between the studies which maybe due to the types of arthroplasty used.

1

2 10.3.3.3 Economic evidence

Two studies were identified. Rogmark et al (2003)²⁸³ is a cost-consequence analysis based
 on a RCT which was excluded because it does not distinguish patients on the basis of

5 whether they received hemiarthroplasty or total hip replacement. A cost-consequence

analysis comparing internal fixation vs. total hip replacement by Keating et al (2005)¹⁷¹ was included. (Economic Evidence Table 14 in Appendix F)

4 Table 10-42: Hemiarthroplasty vs total hip replacement - Economic study characteristics

Study	Limitations	Applicability	Other Comments
Keating 2005 ¹⁷¹	Minor limitations ^(a)	Partially applicability ^(b)	Costs not discounted because mainly incurred within 1 year of injury

(a) Small number of patients.

(b) UK study but did not a CUA.

Table 10-43: Hemiarthroplasty vs total hip replacement - Economic summary of findings

Study	Incremental cost per patient (£)	Incremental effects	ICER	Uncertainty
Keating 2005 ¹⁷¹	£498 ^(b)	Hemiarthroplasty has lower EQ-5D scores at 4, 12 and 24 months ^(b)	NA	Two-way sensitivity analysis showed that the direction of change in cost did not change when cost of prostheses and cost of readmission were varied over a range from -50% to +100% around the baseline values.

- (a) The mean cost per patient for hemiarthroplasty was 9,897 (95% CI: 8,062 11,732) and £9,399 (95% CI: 8,265-10,532) for THR.
- (b) Hemiarthroplast had higher number of deaths within 4, 12 and 24 months from operation than THR: 5%
 vs.4%; 10% vs. 6% and 16% vs. 9%; (p values not significant), but lower reoperation rates at 4, 12 and 24
 months: 5% vs. 7%; 5% vs 9%; and 5% vs. 9% (p value NR). THR had higher mean EQ-5D scores at 4, 12
 and 24 months: 0.61 vs. 0.68 (not significant); 0.64 vs. 0.70 (not significant); 0.53 vs 0.69 (p=0.008).
- 16

17 10.3.3.4 Evidence statement (s)

Clinical There is a statistically significant, but not clinically significant, decrease in patients who reported pain and had a lower Harris Hip score for pain (indicating better function) at 1 year with total hip replacement compared to hemiarthroplasty (LOW QUALITY).

There is a statistically significant, but not clinically significant, increase in patients who have a lower Oxford Hip Score at 40 months (indicating better function) with total hip replacement compared to hemiarthroplasty (MODERATE QUALITY).

There is a statistically significant, but not clinically significant, increase in patients who have a higher Barthel Score (indicating better function) at 1 and 4 years (LOW QUALITY), a higher total Harris Hip Score at 1 and 4 years (LOW QUALITY), a higher Harris Hip Score for function at 1 year (LOW QUALITY) and a longer self reported walking distance at 40 months (MODERATE QUALITY) with total hip replacement compared to hemiarthroplasty.

There is a statistically significant, but not clinically significant, increase in patients who have a higher Eq-5d (Euroqol) score at 2 years with total hip

1

2

3

5 6

replacement compared to hemiarthroplasty (MODERATE QUALITY).

There is no statistically significant difference in mortality at 2 to 4 months (LOW QUALITY), 6 months (MODERATE QUALITY), 1 year (LOW QUALITY) or 2 to 4 years (LOW QUALITY), the number of reoperation at 8 to 48 months (LOW QUALITY), the number of patients who fail to regain mobility at 1 to 4 years (LOW QUALITY), the Hip Rating Questionnaire Score at 2 years (MODERATE QUALITY), the Short Form 36 (SF 36) score (MODERATE QUALITY) and length of hospital stay (MODERATE QUALITY) between hemiarthroplasty and total hip replacement.

No RCT evidence was identified reporting total time to resettlement or place of residence after hip fracture for studies comparing total hip replacement and hemiarthroplasty.

Economic THR is dominant compared to hemiarthroplasty. This evidence has minor limitations and partial applicability.

1

2 10.3.4 Recommendations and link to evidence

Recommendation	Offer replacement arthroplasty to patients with a displaced intracapsular fracture
Relative values of different outcomes	The number of reoperations, functional status, pain and quality of life were considered the important outcomes with the number of reoperations being the most important. The interventions were not anticipated to have a significant impact on mortality so this was considered to be less important. Place of residence after hip fracture was also considered to be less important as it is a surrogate measurement for functional status.
Trade off between clinical benefits and harms	Compared to internal fixation there was a significantly lower reoperation rate with both hemiarthroplasty and total hip replacement, less patient reported pain with total hip replacement and better functional or quality of life scores with hemiarthroplasty. There was no significant difference for mortality, length of stay, failure to return to the same place of residence and failure to regain mobility. None of the reported outcomes showed any advantage of internal fixation over arthroplasty.
Economic considerations	Evidence partially applicable to the UK with only minor limitations was available on the cost-effectiveness of internal fixation vs. hemiarthroplasty and internal fixation vs. total hip replacement. The evidence shows that hemiarthroplasty is cost saving compared to internal fixation. In particular, hemiarthroplasty involved a significantly lower number of patients needing further surgery at 12 and 24 months compared to internal fixation. Similarly, THR required a lower rate of re-operation than internal fixation, albeit not statistically significant.
Quality of evidence	The evidence was of low or moderate quality. Most outcomes were downgraded due to poor or uncertain allocation

	concealment. Several results were imprecise as the confidence intervals were near to one, making it difficult to determine the true effect size. Some studies were also heterogenous that could be due to the different types of arthroplasty.
	Overall, the GDG felt that despite some of the results being of low quality and data not being available for some outcomes where there is a difference it shows arthroplasty being better than internal fixation. Consequently arthroplasty is recommended.
Other considerations	There maybe rare circumstances where reduction and internal fixation is appropriate for displaced intracapsular fragility fractures.
	People with cognitive impairment were excluded from a lot of the studies. However, the GDG felt there is no reason for this group of patients should be excluded from equal treatment to others.
	All patients should be allowed to be mobilised full weight bearing after hip fracture surgery (see section 10.2). All modern implants are designed to be load sharing devices to facilitate this.
	The GDG consider this recommendation a key priority for implementation.
Recommendation	Offer total hip replacement to patients with a displaced
	intracapsular fracture who:
	were independently mobile before fracture and
	 are not cognitively impaired and
	 are medically fit for anaesthesia and the operation.
Relative values of different outcomes	The number of reoperations, functional status, pain and quality of life were considered the important outcomes with the number of reoperations being the most important. The interventions were not anticipated to have a significant impact on mortality so this was considered to be less important. Place of residence after hip fracture was also considered to be less important as it is a surrogate measurement for functional status.
Trade off between clinical benefits and harms	There was a significantly less patient reported pain and a better Oxford Hip Score, Barthel Score, Harris Hip Score, self reported walking distance and quality of life score (Eq-5d) with total hip

to the same place of residence and failure to regain mobility. None

The cost-effectiveness evidence shows that THR replacement was

of the reported outcomes showed any advantage of

patient group.

Economic considerations

hemiarthroplasty over total hip replacement in the selected

cost-saving compared to both hemiarthroplasty and internal fixation.

Quality of evidenceThe evidence was of low or moderate quality. Most outcomes
were downgraded due to poor or uncertain allocation
concealment. Several results were imprecise as the confidence
intervals were near to one making it difficult to determine the true
effect size. Some studies were also heterogenous that could be due
to the different types of arthroplasty.

Overall, the GDG felt that despite some of the results being of low quality and data not being available for some outcomes where there is a difference it all shows total hip replacement being better than hemiarthroplasty in the selected patient group. Consequently total hip replacement is recommended for that group.

Other considerationsAll but one of the studies excluded patients who were not
medically fit, were not independently mobile before the fracture
and were cognitively impaired. Consequently this recommendation
does not include these groups. All the studies included in this
review used a small head size for total hip replacement. Modern
total hip replacements use a larger head which can reduce the risk
of dislocation.

All patients should be allowed to be mobilised full weight bearing after hip fracture surgery (see section 10.2). All modern implants are designed to be load sharing devices to facilitate this.

monoblock as an example of a proven femoral stem design as £249

The GDG consider this recommendation a key priortiy for implementation.

Recommendation Consider using a proven femoral stem design rather than Austin Moore or Thompson stems for arthroplasties. Suitable designs include those with an Orthopaedic Data Evaluation Panel rating of 10A, 10B, 10C, 7A, 7B, 5A, 5B, 3A or 3B. **Relative values of different** The number of reoperations, functional status, pain and quality of outcomes life were considered the important outcomes. The interventions were not believed to have a significant impact on mortality so this was considered to be less important. Place of residence after hip fracture was also considered to be less important. Trade off between clinical Stem designs recommended here have a revision rate less than benefits and harms other stem designs. A higher failure rate would lead to a lower quality of life for patients. **Economic considerations** No economic evidence was found. Stems with a higher failure rate would require more reoperations and consequently, increased costs and a lower quality of life for patients. Data supplied by an expert advisor reported the cost of an Exeter Trauma stem (ETS)

at 2008 prices.

Quality of evidence	No randomised evidence comparing modern stems with older stems was found.
Other considerations	 There is a move towards modern style cemented stems. The Orthopaedic Data Evaluation Panel (OEDP) was set up in response to the NICE guidance on selection of prosthesis for primary total hip replacement²²⁴. The ratings used relate to the revision rate of stems and cups in arthroplasty. The results are available via the NHS Supply Chain website (http://www.supplychain.nhs.uk/portal/page/portal/Communities/Orthopaedics/ODEP%20database). A rating of 10A, 10B or 10C relates to devices with a failure rate of arthroplasty of 10% or less at 10 years. A rating of 7A and 7B relate to a failure rate of 7% or less at 5 years. A rating of 3A and 3B relate to a failure rate of 3% or less at 3 years.
	This recommendation was based on expert opinion. In the light of such good evidence being available for the adequacy of femoral stem design for patients with degenerative change it was thought that specific research in the fracture group would not be appropriate.
	All patients should be allowed to be mobilised full weight bearing after hip fracture surgery (see section 10.2). All modern implants are designed to be load sharing devices to facilitate this.
	Patients with hip fracture, particularly older patients have been treated by methods which have evolved very little over the last 50 years. This has led to a perception that they may be receiving second-class treatment. An example is the difference in the design of hip replacement implants used in patients with fractures compared with those used in patients with degenerative change. Many of those used in the fracture patients now appear archaic and their equivalents in the elective orthopaedic patients were superseded many years ago.
	Long-term follow-up studies to identify function and durability of a replacement component in a fracture patient are difficult to carry out as so many of the patients are frail and their life expectancy is limited. However such studies are easier in patients with degenerative change and there is a well recognised system of assessing the adequacy of the design of a femoral stem for these patients.
	mmendations on displaced intracapsular fractures
10.3.5.1 Large head total	hip replacement versus hemiarthroplasty

The GDG recommended the following research question:

What is the clinical and cost effectiveness of large head total hip replacement versus hemiarthroplasty on functional status, reoperations and quality of life in patients with displaced intracapsular hip fracture?

4 Why this is important

1

2

3

5 Large head total hip replacement is a development of traditional total hip replacement 6 where a larger head makes the joint more stable and hence reduces the risks of dislocation. 7 Three small trials have shown traditional small head total hip replacement have better 8 outcomes and function yet with an increased dislocation rate in selected groups of patients. 9 The drawback with the large head arthroplasty is the additional implant cost and theatre 10 time. This cost can account for up to 20% of current NHS tariff (up to £2000) and the study 11 aims to address whether this translates to improved patient outcome. The study design for 12 the proposed research would be best addressed by an randomised controlled trial. This 13 would have two arms to compare current standard care (using hemiarthroplasty) with using 14 large head total hip replacement for patients sustaining displaced intracapsular hip 15 fractures. Primary outcome would be patient mobility at 1 year and secondary outcomes 16 would include functional outcomes, quality of life and cost effectiveness of the 17 intervention.

18 It would be expected that a sample size of approximately 500 patients would be required to
 19 show a significant difference in the mobility, hip function and quality of life (assuming 80%
 20 power p<0.05). Recruiting centres through a trauma research network it is estimated that
 21 10 centres would be able to recruit 20 patients per month (from 45 eligible patients) giving
 22 a recruitment period of 25 months.

2 10.4 Use of cement in arthroplasty

3 The cement used in securing a hip replacement is not an adhesive but a grout, that is it is 4 used to fill the gaps between the metal prosthesis and the bone. Thus, a component fixed 5 with cement may be more secure resulting in less pain after surgery and decreased need 6 for surgical revision due to loosening of the prosthesis. However, it has been suggested that 7 cementing may induce side effects including cardiac arrhythmias and cardiorespiratory 8 collapse, both of which may be fatal. NPSA data reports 26 deaths and six cases of severe 9 harm when bone cement was used during hip surgery between October 2003 and October 10 2008. Data from the MHRA reports 20 deaths and four cases of severe harm with bone 11 cement between 2000 and 2008. The NPSA published advice on cementing techniques to 12 reduce such risk. However, patients undergoing surgery for proximal femoral fractures are 13 often elderly and frequently have multiple comorbidities, often severe. Therefore some 14 intraoperative deaths may occur and be unrelated to the use of cement.

15 10.4.1 Use of cement in older designs of arthroplasty

16 **10.4.1.1** *Review question*

In patients having replacement arthroplasty for hip fracture what is the clinical and cost
 effectiveness of a cemented stem versus an uncemented stem on mortality, number of
 reoperations, wound healing complications, functional status, length of stay in hospital and
 total time to resettlement in the community, quality of life, pain and place of residence
 after hip fracture?

22 See Evidence Table 7 and forest plots G52 to G66 in Appendix G.

23 10.4.1.2 Clinical evidence

2 10.4.1.3 Economic evidence

3	Two economic studies were identified. Santini (2005) ²⁹⁰ is a cost-consequence analysis
4	based on a RCT included in our clinical review (see 10.3.3.2). See evidence table 15 in
5	Appendix F for additional details. Marinelli (2008) ²⁰⁴ was excluded because of poor
6	methodology.

7 Table 10-46: Cemented vs. uncemented hemiarthroplasty - Economic study characteristics

Study	Limitations	Applicability	Other Comments
Santini 2005 ²⁹⁰	Potentially serious limitations ^(a)	Partially applicable ^(b)	Based on RCT included in our clinical review (see 10.3.3.2).

8 (a) Surgical time not included in cost calculation although it was significantly different (patients in the uncemented hemiarthroplasty group had shorter operating time). The only difference considered was the cost of prostheses.

11 (b) Not a cost-utility analysis. Study conducted in Italy.

13 Table 10-47: Cemented vs. uncemented hemiarthroplasty - Economic summary of findings

Study	Incremental cost per patient (£)	Incremental effects	ICER	Uncertainty
Santini 2005 ²⁹⁰	Cost saving (-£710)	(b)	N/R	N/R

14 (a) Cost of medical and nursing staff, drugs, diagnostic procedures, prostheses, blood transfusion and

15 hospital sta. Converted into GBP from 2001 euro using the Purchasing Power Parities.

16 *(b)* Different outcomes were reported but none of them were significantly different.

17 10.4.1.4 Evidence statement (s)

Clinical There is a statistically significant, but not clinically significant, increase in patients who have a lower reduction in mobility score (less loss of mobility) at 12 months (LOW QUALITY).

There is a statistically significant, but not clinically significant, decrease in patients who reported pain at 3 months (LOW QUALITY) and 1 to 2 years (MODERATE QUALITY). However, there was no significant difference in a pain score at 6 months (LOW QUALITY).

There is no statistically significant difference in perioperative mortality (LOW QUALITY), mortality at 3 months (LOW QUALITY) or 1 year (MODERATE QUALITY), failure to return home (MODERATE QUALITY), length of hospital stay (LOW QUALITY), number of patients requiring reoperations (LOW QUALITY), number of patients failing to regain mobility (LOW QUALITY), deep sepsis (MODERATE QUALITY), wound haematoma (MODERATE QUALITY) and all medical complications combined (VERY LOW QUALITY).

No RCT evidence was identified reporting quality of life, total length of stay to community resettlement or place of residence after hip fracture

No RCT evidence was identified to suggest there is a safety issue with using cement.

Economic Cemented hemiarthroplasty is cost saving compared to uncemented hemiarthroplasty. This evidence has potentially serious limitations and partial applicability.

1

2 **10.4.2** Use of cement in newer designs of arthroplasty

3 10.4.2.1 Review question

In patients having replacement arthroplasty for hip fracture what is the clinical and cost
 effectiveness of a cemented stem versus an uncemented stem on mortality, number of
 reoperations, wound healing complications, functional status, length of stay in hospital and
 total time to resettlement in the community, quality of life, pain and place of residence
 after hip fracture.

9 See Evidence Table 7 and forest plots G67 to G73 in Appendix G.

10 10.4.2.2 Clinical evidence

11 Table 10-48: Cemented vs. uncemented stem (newer designs of arthroplasty) – Clinical study

(a) Data only available for bipolar hemiarthroplasty

(b) The relatively few events and few patients give wide confidence intervals around the estimate of effect. This makes it difficult to know the true effect size for this outcome.

(c) The effect size is uncertain as the confidence intervals suggest the length of stay could be over 2 days shorter or over 1 day longer with cemented hemiarthroplasty.

2 **10.4.2.3** *Economic evidence*

No cost-effectiveness evidence was identified. The cost for the stems used in Figved et al (2009)⁹² corresponds to £347 for the cemented stem and £966 for the uncemented stem. Both were of a proven stem design. All these prices are based on the NHS supply catalogue 2010.

7 10.4.2.4 Evidence statement (s)

Clinical There is no statistically significant difference in mortality at 30 days, 90 days, 1 year or 2 years (LOW QUALITY).

There is no statistically significant difference at 1 year in the number of patients requiring reoperations, number of patients pain requiring medication, number of patients unable to walk without aids, Barthel Score of less than 19, Harris Hip Score, Eq-5d index score and visual analogue score, deep wound sepsis, any wound infection, length of hospital stay (LOW QUALITY).

No RCT evidence was identified reporting total time to resettlement in the community and place of residence after hip fracture

No RCT evidence was identified to suggest there is a safety issue with using cement.

- **Economic** No studies were identified on the cost-effectiveness of cemented vs newer designs uncemented stem of arthroplasty.
- 8

9

10 10.4.3 Recommendations and link to evidence

Recommendation	Offer cemented implants to patients undergoing surgery with arthroplasty
Relative values of different outcomes	The outcomes considered were mortality, functional status, quality of life, pain, requirement for reoperation, non-healing and requirement for surgical revision, total length of stay (i.e. the time in hospital plus any time spent in rehabilitation). Mortality was of particular importance because of reported deaths by the NPSA.
Trade off between clinical benefits and harms	There is no significant difference in mortality. There is evidence of less pain at 3 months and 1 to 2 years and better mobility score at 12 months with the older designs of cemented hemiarthroplasties.

SURGICAL PROCEDURES

	There was no significant difference for length of stay, failure to return to the same place of residence and failure to regain mobility. None of the reported outcomes showed any advantage of uncemented arthroplasty over cemented.
	There is no direct evidence comparing the use of cemented and uncemented total hip replacement.
	No RCT evidence was found to raise concerns about the safety of the use of cement.
Economic considerations	One study with potentially serious limitations and partial applicability found that the older cemented hemiarthroplasty are cost saving compared to uncemented hemiarthroplasty.
	As the clinical evidence did not show any advantage of uncemented over cemented arthroplasty in the newer design, and as the price of new designs of cemented implants are significantly lower than those of uncemented implants, the GDG agreed to consider cemented implants cost-effective for hip fracture patients.
Quality of evidence	The evidence was of low or moderate quality. All but one of the studies comparing older arthroplasty designs used a Thompson or Austin Moore hemiarthroplasty (these are the first generation of implants to be used). The other study used an unspecified bipolar hemiarthroplasty. The evidence for modern stem designs is low quality mainly due to the lack of certainty around the effect size and only evidence being identified in bipolar hemiarthroplasty.
	Overall, the GDG felt there was sufficient evidence to recommend the use of cemented arthroplasties over uncemented.
Other considerations	All studies comparing the effectiveness of internal fixation with THR and hemiarthroplasty with THR used cemented THR (see section 10.3.2)
	All patients should be allowed to be mobilised full weight bearing after hip fracture surgery (see section 10.2). All modern implants are designed to be load sharing devices to facilitate this.

1

2 **10.5 Surgical approach to hemiarthroplasty**

Hemiarthroplasties are usually inserted using one of two approaches, either an
anterolateral or a posterior approach. The choice of surgical approach for a surgeon is
often dictated by local custom and practice and personal experience. This review looks at
the evidence to see if one is better than the other. RCTs and cohorts adjusted for
confounders were included.

8 10.5.1.1 Review question

9 In patients having surgical treatment for intracapsular hip fracture with hemiarthroplasty 10 what is the clinical and cost effectiveness of anterolateral compared to posterior surgical

- 1 approach on mortality, number of reoperations, dislocation, functional status, length of 2 hospital stay, quality of life and pain.
- 3 See Evidence Table 9, Appendix E.

4 10.5.1.2 Clinical evidence

5 Table 10-50: Posterior vs. anterolateral approach to hemiarthroplasty – Clinical study

6 characteristics

	Numbe r of	Desig				Other considerations/
Outcome	studies	n	Limitations	Inconsistency	Indirectness	imprecision
Mortality ³⁰¹	1	RCT	serious limitations ^(a, b)	Unable to assess this ^(f)	serious indirectness ^(c)	serious imprecision ^(d)
Number of patients with impairment of mobility at 6 months compared to prefracture ³⁰¹	1	RCT	serious limitations ^(a, b)	no serious inconsistency	serious indirectness ^(c)	serious imprecision ^(d)
Dislocation at 0 to 2 years ³⁰¹	1	RCT	Very serious limitations ^(a, b)	no serious inconsistency	serious indirectness ^(c)	serious imprecision ^(d)
Dislocation at 0 to 10 years ⁸³	1	Cohor t	serious limitations ^(e)	no serious inconsistency	no serious indirectness	no serious imprecision
Pain at 1 month ³⁰¹	1	RCT	serious limitations ^(a)	no serious inconsistency	serious indirectness ^(c)	serious imprecision ^(d)

- (b) Patients allocated to the posterior approach were nursed flat in bed for two weeks after surgery as a precaution against dislocation.
- (c) Most operations performed by surgical trainees
- (d) The wide confidence intervals make the estimate of effect imprecise.
- (e) Only a limited number of confounders were included in the analysis. No adjustment or mention of the anaesthetists experience or grade.
- (f) Actual event rates were not provided for this, mortality was given as percentages in a graph. The percentages were estimated usingthis. Mortality was significantly higher at three months, six months, 12 months and two years in the posterior group _p<0.05. The rate was around double for all these time points.

19 Table 10-51: Posterior vs. anterolateral approach to hemiarthroplasty - Clinical summary of

20 findings

Outcome	Intervention	Control	Relative risk	Absolute effect	Quality
Mortality at 6 months, 12 months & 2 years	Not reported	Not reported	Significantly higher in posterior group (p<0.05)	Not estimable	Very low
Number of patients with impairment of mobility at 6 months compared to prefracture	5/34 (14.7%)	15/41 (36.6%)	RR 0.40 (0.16 to 0.99)	220 fewer per 1000 (from 4 fewer to 307 fewer)	Very Low
Dislocation at 0 to 2 years	1/57 (1.8%)	1/57 (1.8%)	RR 1.00 (0.06 to 15.60)	0 fewer per 1000 (from 16 fewer to 256 more)	Very Low

Dislocation at 0 to 10 years (posterior approach with posterior repair)	15/176 (8.5%)	13/431 (3%)	multivariate odds ratio 3.9 (1.6 to 9.8)	87 more per 1000 (from 18 more to 265 more)	Very Low
Dislocation at 0 to 10 years (posterior approach without posterior repair)	17/129 (13.2%)	13/431 (3%)	multivariate odds ratio 6.9 (2.6 to 19)	178 more per 1000 (from 48 more to 543 more)	Very Low
Pain at 1 month	2/55 (3.6%)	6/55 (10.9%)	RR 3.0 (0.63, 14.22)	218 more per 1000 (from 40 fewer to 1442 more)	Very low

2 10.5.1.3 Economic evidence

3 No cost-effectiveness evidence was identified.

4 10.5.1.4 Evidence statement (s)

5

Clinical	Two studies of different designs showed different effects for dislocation rates. One old RCT showed no statistically significant difference in dislocation rate between approaches. (VERY LOW QUALITY). One recent cohort which adjusted for confounders showed a statistically and clinically significant higher dislocation rate with the posterior approach compared to the anterolateral approach. (VERY LOW QUALITY)
	Significantly fewer patients had impaired mobility at 6 months with a posterior approach to hemiarthroplasty compared to an anterior approach when the procedure was performed by surgical trainees. (VERY LOW QUALITY)
	One study reported a significantly higher mortality with a posterior approach at 6 months, 12 months and two years but did not provide the event rates. (VERY LOW QUALITY]
Economic	No evidence was identified regarding the cost-effectiveness of posterior vs. anterolateral approach to hemiarthroplasty.

6

7 10.5.2 Recommendations and link to evidence

Recommendation	Consider an anterolateral approach in favour of a posterior approach when inserting a hemiarthroplasty.
Relative values of different outcomes	Functional status, reoperation rate, and quality of life were considered the main outcomes. Pain, wound infection, dislocations, length of stay in secondary care and mortality were also considered.

Trade off between clinical benefits and harms	The cohort study showed a significantly higher dislocation rate with a large effect size with the posterior approach compared to the anterolateral approach. This reduces the potential complications of re-operation or revision surgery. An old RCT data showed a significantly lower impaired mobility at 6 months with a posterior approach, a doubling of mortality and no difference in dislocations compared to an anterolateral approach. However, the operations had been carried out by trainees with varying degrees of experience. Also, the group operated on with an antrolateral approach were allowed to mobilise straight away and the group operated on with a posterior approach had two weeks post- operatively bed rest.
	None of the other outcomes were reported.
Economic considerations	An anterolateral approach is likely to result in cost savings because of their lower dislocation rates, and hence less revision surgery.
Quality of evidence	Both the studies available are of very low quality. The RCT is an old study where the operations were mostly carried out by surgical trainees. This RCT also treated patients differently, with those receiving a posterior approach being nursed flat in bed for two weeks after surgery as a precaution against dislocation and had a much higher mortality in the posterior group. The cohort study, which adjusted for important factors in their results, is a recent study and shows a large effect size in favour of an anterolateral approach.
Other considerations	The GDG considered this evidence along with the GDG opinions and decided the recent evidence is more relevant. They therefore recommend the anterolateral approach over the posterior. It is also recognized that the posterior approach may well be as safe in preventing dislocation in those surgeons with a large experience of using it. However, the GDG believe the majority of surgeons who perform the surgery do not regularly perform posterior approaches. It is also noted that all the RCTs comparing hemiarthroplasty and total hip replacement utilized the anterolateral approach in all of the studies.

2 **10.6 Extracapsular fracture fixation**

3 In the extracapsular fractures the femoral head blood supply is unaffected and the proximal 4 fragment large enough to allow secure fixation, therefore internal fixation is the norm. The 5 surgical decision in this group is which of the various available methods of fracture fixation 6 is most effective for each pattern. When treating the extracapsular fractures around the 7 trochanter it is necessary to stabilise the intact femoral head and neck onto the shaft of the 8 femur. The head portion is stabilised by one or more screws up the neck and into the head. 9 This screw is attached to either a plate on the outside of the bone (called extramedullary 10 fixation) or a metal rod which is inserted down the middle of the femoral shaft 11 (intramedullary fixation). The rod can either be short, spanning approximately a third of the 12 length of the femur, or long spanning the whole length of the femur. The generic term for

- the plate and screw used for the extramedullary fixation is a sliding hip screw and the term
 for the intramedullary fixation is the intramedullary nail.
 3
- Extracapsular fractures are split into pertochanteric (also called intertrochanteric), reverse
 oblique and subtrochanteric (see Introduction, Figure 1).
- 7 10.6.1 Intramedullary versus extramedullary implants for fixation of

trochanteric extracapsular fractures

9 There are numerous studies comparing intramedullary and extramedullary results. The 10 intramedullary nails can vary in size and shape, with most evolving from the initial nail 11 design which was changed due to an increase in per-and post operative fractures of the 12 femur. When reviewing the evidence, the trochanteric fractures were divided into stable 13 fractures, (those with an intact lesser trochanter – AO/ OTA A1), unstable fractures (those 14 with a fracture between the trochanters with displacement of the lesser trochanter -15 AO/OTA A2 fractures) and reverse obligue fractures (AO/OTA A3). Historically and presently 16 there have been numerous implants used to treat these and we have divided them into 17 intramedullary (those which have a rod down the shaft of the bone) and extramedullary 18 where the device sits on the outside of the bone. Commonly these are called 19 intramedullary nails and sliding hip screws respectively. The intramedullary nails can come 20 in various designs from different manufacturers. Their size and shape have evolved over the 21 last twenty years. The design of the sliding hip screw has not changed over the last thirty

22 years and sliding hip screws are generally very similar between the different manufacturers.

23 **10.6.1.1** Review question

In patients undergoing repair for trochanteric extracapsular hip fractures what is the clinical
 and cost effectiveness of extramedullary sliding hip screws compared to intramedullary
 nails on mortality, surgical revision, functional status, length of stay, quality of life, pain and
 place of residence after hip fracture?

28 See evidence table 5.8, Appendix E and forest plots G96 to G106 in Appendix G.

3

4 **10.6.1.3** Economic evidence

Three economic studies were indentified ^{108,112,177}. All these studies have been excluded. ¹¹²
 is a cost-consequence analysis based on a retrospective cohort study set in the US
 comparing trochanteric fixation nail with sliding hip screw. This study was excluded due to
 poor methodological design and to the limited applicability to the UK NHS. ¹⁷⁷ compared
 proximal femoral nail with long-stem cementless calcar-replacement prosthesis which was
 not an included intervention. Another study ¹⁰⁸ was excluded as no cost figures were
 reported.

The GDG was informed of the prices of implants produced by all major orthopaedic
 suppliers in the UK. At 2010 prices, the average cost for a sliding hip screw was estimated at
 £252.51, of a short intramedullary nail at £760.08, and of a long intramedullary nail at
 £1,175.40. Please see section 8.3 in Appendix H for further details.

5

6 10.6.1.4 Evidence statement (s)

Clinical There is a statistically significant and clinically significant increase in operative or postoperative fracture of the femur with intramedullary implants compared to extramedullary implants for fixation of trochanteric extracapsular fractures. (LOW QUALITY)

There is no statistically significant difference in mortality, reoperation, and mean mobility score with intramedullary implants compared to extramedullary implants for fixation of trochanteric extracapsular fractures. (HIGH QUALITY)

There is no statistically significant difference in cut-out, infection, non-union and length of hospital stay with intramedullary implants compared to extramedullary implants for fixation of trochanteric extracapsular fractures. (MODERATE QUALITY)

There is no statistically significant difference in pain, with intramedullary implants compared to extramedullary implants for fixation of trochanteric extracapsular fractures. (LOW QUALITY)

No studies were identified investigating reverse oblique trochanteric extracapsular fractures.

Economic -No applicable evidence was identified regarding the cost-effectiveness of Intramedullary vs. extramedullary implants.

7 10.6.1.5 Recommendations and link to evidence

Recommendation	Offer extramedullary implants such as a sliding hip screw in preference to an intramedullary nail to patients with trochanteric fractures above and including the lesser trochanter (AO classification types A1 and A2).
Relative values of different outcomes	The most important outcomes considered by the GDG include early and late mortality, re-operation, post-operative fracture, length of hospital stay and post fracture mobility.
Trade off between clinical benefits and harms	None of the studies reported have shown any advantage of intramedullary devices over extramedullary devices. Intramedullary devices had been shown to have a higher re- operation rate due to an increased incidence of periprosthetic fracture both in the perioperative period and the post operative period (risk ratio 5.61). This may be due to the inclusion of studies with original nail designs no longer implanted. All other outcomes have been reported as similar.

Economic considerations	The price of intramedullary fixation devices varies but on average is three times the price of sliding hip screws for short nails and five times the price for long nails. As no significant benefit has been proven of the advantages of intramedullary devices over extramedullary devices, the GDG agreed to consider extramedullary implants cost-effective for hip fracture patients.
Quality of evidence	The level of evidence is high with numerous studies producing very similar findings.
Other considerations	All patients should be allowed to be mobilised full weight bearing after hip fracture surgery (see section 10.2). All modern implants are designed to be load sharing devices to facilitate this. Full weight bearing allows early mobilisation and rehabilitation.
	The GDG highlighted this recommendation as a key priority for implementation.

3

2 10.6.2 Intramedullary versus extramedullary implants for fixation of reverse

oblique trochanteric extracapsular fractures

In the reverse oblique fractures, which lie anatomically between the trochanteric and the
 subtrochanteric fractures there is loss of this lateral stabilizing cortical buttress. Such
 fractures are difficult to adequately reduce and fix at the time of the surgery. It is then the
 more unpredictable as to whether that adequate reduction will be retained during the
 healing process whilst allowing early mobilisation of the patient

9 10.6.2.1 Review question

- 10 In patients undergoing repair for reverse oblique trochanteric extracapsular hip fractures
- what is the clinical and cost effectiveness of extramedullary sliding hip screws compared to
 intramedullary nails on mortality, surgical revision, functional status, length of stay, quality
- 13 of life, pain and place of residence after hip fracture?
- 14 **10.6.2.2** Clinical evidence
- 15 No RCT evidence was identified.

16 **10.6.2.3** Economic evidence

- 17 No cost-effectiveness evidence was identified.
- 18 **10.6.2.4** Research recommendations

19 Intramedullary versus extramedullary fixation

- 20 The GDG recommended the following research question:
- What is the clinical and cost effectiveness of intramedullary versus extramedullary fixation on mortality, functional status and quality of life in patients with reverse oblique trochanteric hip fracture?

1 Why this is important

2 Reverse oblique trochanteric fractures account for approximately 5 % of all trochanteric hip 3 fractures. This means it affects approximately over 1000 patients per year in the UK. 4 Presently there is little evidence as to which is the preferable implant (which can be either 5 extramedullary - outside the bone, or intramedullary - inside the bone). The potential 6 biomechanical advantage of intramedullary advantage may be offset by increased cost 7 (which can be over £1000 more expensive). A randomised trial comparing the two implants 8 using patient mobility, function and re-operation would allow a more informed choice of 9 treatment for this injury.

10

11 **10.6.3** Intramedullary versus extramedullary implants for fixation of

12 subtrochanteric extracapsular fractures

Subtrochanteric fractures involve the shaft of the femur somewhere between the base of the lesser trochanter and a point 5 cm distal to this. They may extend proximally or distally. They have been considered as a separate group for practical purposes. Many of the implants available for treating a standard trochanteric fracture are not long enough to reach the intact bone distal to a subtrochanteric fracture. Thus whilst the general principles of extra and intramedullary fixation described earlier still apply a different inventory of implants to deal with these fractures is required.

- 19 implants to deal with these fractures is required.
- It is noted that subtrochanteric fractures can often occur as a result of a metastatic
 pathological deposit affecting the strength of the bone. The presence of pathological
- 22 deposits may not be obvious on the initial radiographs.

23 10.6.3.1 Review question

- 24 In patients undergoing repair for subtrochanteric extracapsular hip fractures, what is the
- 25 clinical and cost effectiveness of extramedullary sliding hip screws compared to
- intramedullary nails on mortality, surgical revision, functional status, length of stay, quality
 of life, pain and place of residence after hip fracture?
- 28 See evidence table 5.8, Appendix E and forest plots G107 to G111 in Appendix G.
- 29

30 10.6.3.2 Clinical evidence

31 Table 10-54: Intramedullary vs. extramedullary implants for subtrochanteric extracapsular 32 fracture – Clinical study characteristics

Outcome	Numbe r of studies	Desig n	Limitations	Inconsistency	Indirectness	Other considerations/ imprecision
Mortality – 1 year ^{75,273}	2	RCT	no serious limitations	serious ^(c)	serious ^(b)	serious ^(a)
Reoperation — within follow up period of study ^{9,75,212,273}	4	RCT	no serious limitations	serious ^(c)	no serious indirectness	serious ^(a)

Outcome	Numbe r of studies	Desig n	Limitations	Inconsistency	Indirectness	Other considerations/ imprecision
Cut-out (at latest follow up) ⁷⁵	1	RCT	serious ^(d)	no serious inconsistency	no serious indirectness	serious ^(a)
Infection (deep infection or requires reoperation) ^{212,273}	2	RCT	no serious limitations	no serious inconsistency	serious ^(b)	serious ^(a)
Non-union (at latest follow up) ^{75,273}	2	RCT	no serious limitations	no serious inconsistency	serious ^(b)	no serious imprecision

(a) The relatively few events and few patients give wide confidence intervals around the estimate of effect. This makes it difficult to know the true effect size for this outcome.

(b) These studies are comparing intramedullary nailing to a Medoff sliding plate or fixed angle blade plate.

(c) There is significant statistical heterogeneity in the results.

(d) Only one study with a small sample size.

Table 10-55: Intramedullary vs. extramedullary implants for subtrochanteric extracapsular fracture - Clinical summary of findings

	,	0-			
	Intramedull	Extramedull			
Outcome	ary	ary	Relative risk	Absolute effect	Quality
Mortality – 1 year	7/48 (14.6%)	5/42 (15%)	RR 0.93 (0.08 to 11.52)	10 fewer per 1,000 (from 138 fewer to 1578 more)	Very low
Reoperation – within follow up period of study	4/78 (5.1%)	11/71 (12.5%)	RR 0.56 (0.06 to 5.47)	55 fewer per 1,000 (from 117 fewer to 559 more)	Low
Cut-out (at latest follow up)	1/19 (5.3%)	1/13 (7.7%)	RR 0.68 (0.05 to 9.98)	25 fewer per 1,000 (from 73 fewer to 691 more)	Low
Infection (deep infection or requires reoperation)	3/45 (6.7%)	2/41 (5.9%)	RR 1.27 (0.28 to 5.88)	16 more per 1,000 (from 42 fewer to 288 more)	Low
Non-union (at latest follow up)	1/48 (2.1%)	9/42 (17.6%)	RR 0.15 (0.03 to 0.82)	150 fewer per 1,000 (from 32 fewer to 171 fewer)	Moderate

10

11 10.6.3.3 Economic evidence

12 No economic evidence was identified.

13 10.6.3.4 Evidence statement (s)

Clinical There is a statistically significant and clinically significant decrease in nonunion with intramedullary implants compared to extramedullary implants for

fixation of subtrochanteric extracapsular fractures. (MODERATE QUALITY)

There is no statistically significant difference in reoperation, cut-out and infection with intramedullary implants compared to extramedullary implants for fixation of subtrochanteric extracapsular fractures. (LOW QUALITY)

There is no statistically significant difference in mortality, with intramedullary implants compared to extramedullary implants for fixation of subtrochanteric extracapsular fractures. (VERY LOW QUALITY)

Economic No economic evidence was identified.

1

2 10.6.3.5 Recommendations and link to evidence

Recommendation	Offer an intramedullary nail to patients with a subtrochanteric fracture.
Relative values of different outcomes	The GDG considered the most important outcomes to be functional status, pain, requirement for reoperations and wound healing complications.
Trade off between clinical benefits and harms	There was no evidence of a difference except for non-union of fracture. It is accepted by expert opinion that the treatment of choice is intramedullary fixation which allows splinting of the whole of the femoral shaft.
Economic considerations	Although intramedullary nails are more expensive than extramedullary implants, the latter lead to more patients with non- union of fracture, which would require more re-operation.
Quality of evidence	There were few studies investigating this type of fracture. Several studies were excluded as the population was from road traffic accidents, therefore high energy trauma fractures, which were excluded from the scope. The reported outcomes were predominantly of low quality.
Other considerations	Surgeons should use a technique where they are happy for the patient to mobilise fully weight bearing (see section 10.2). When patients suffer from subtrochanteric fractures it is advised to consider whether there is a pathological process which would increase the fracture risk (suck as a metastatic deposit).
	As noted in the introduction subtrochanteric fractures may occur as a result of a pathological process in the bone such as metastatic disease. This pre-existing pathology may not always be recognised on the initial radiographs. It is considered to be an additional advantage of using a long intramedullary device that it provides mechanical protection to a potentially diseased bone.

1 **11 Mobilisation strategies**

2 11.1 Introduction

Mobilisation is the process of re-establishing the ability to move between postures (for
example sit to stand), maintain an upright posture, and to ambulate with increasing levels
of complexity (speed, changes of direction, dual and multi-tasking).

Early restoration of mobility after surgery for hip fracture has been suggested as an
 essential part of high quality care since the early 1980s^{301,302}. The suggested benefits are
 minimisation of hospital stay, avoiding complications of prolonged bed confinement, and
 re-establishing people into their normal environments^{166,166}.

Early restoration of mobility is an aspiration of many clinical services, although guidance on
 the optimal time to re-mobilise patients and strategies that can be used to accelerate and
 optimise recovery of mobility are less clear. Good quality clinical care, in particular effective
 pain management should be considered essential components of early mobilisation and a
 rehabilitation programme, as discussed in Chapter 7.

15 Specific therapeutic procedures, such as those implemented by physiotherapists and 16 occupational therapists have the potential to accelerate the recovery of mobility. Timing of 17 the intervention examined evidence about early (within 48 hours of surgery) mobilisation 18 and physiotherapy assessment, as opposed to later mobilisation (> 48 hours). Within the 19 type of intervention the GDG considered regimes that tested protocols delivering more 20 than one short session of physiotherapy per day (the benchmark for usual care), or more 21 intensive protocols than would comprise usual care. These protocols included intensive 22 strength training regimes (characterised by prescription and progression using recognised 23 American College of Sports Medicine criteria), intensive weight bearing exercise regimes 24 (supplemented by treadmill training), and increased numbers of physiotherapy usual care 25 sessions. Usual care was taken to be prescription of walking aids, gait re-education, and bed exercises^{239,239}. 26

27 Mobility can be measured in a range of different ways. The most simple and basic mobility 28 indicators, are the ability to transfer independently. This is usually taken to be between a 29 bed and a chair, but not all investigators report the exact definition they have used. Chair 30 rise ability and time to complete chair rises, along with timed tests of walking and balance 31 have a long established history for measuring mobility. In addition, the GDG considered 32 muscle strength, length of stay, discharge destination, independence in activity of daily 33 living (such as washing, bathing) and more complex tasks (for example, meal preparation), 34 and mortality as outcomes. Measurement of falls, and time to first fall are considered good safety indicators for interventions like early mobilisation, but no studies reported these
 outcomes.

3 11.2 Early vs. delayed mobilisation

4 11.2.1 Review question

- In patients who have undergone surgery for hip fracture, what is the clinical and cost
 effectiveness of early mobilisation (<48 hours after surgery) compared to late mobilisation
 on functional status, mortality, place of residence/discharge, pain and quality of life?
- 8 See Evidence Table 5.10, Appendix E and forests G112 to 116).

9 **11.2.1.1** Clinical evidence

10 Only one, small randomised controlled trial was identified.

11 Table 11-56: Early vs. delayed mobilisation – Clinical study characteristics

Outcome	Numbe r of studies	Desig n	Limitations	Inconsistency	Indirectness	Other considerations/ imprecision
Independent to transfer at day 7 239	1	RCT	Serious limitations	no serious inconsistency	no serious indirectness	no serious imprecision
Independent to step at day 7 ²³⁹	1	RCT	Serious limitations ^(b)	no serious inconsistency	no serious indirectness	no serious imprecision

12 13

14

15

16

(a) The relatively few events and few patients give wide confidence intervals around the estimate of effect. This makes it difficult to know the true effect size for this outcome.

- (b) Unclear blinding and allocation concealment, also the small sample size makes it difficult to know the true effect size for this outcome.
- (c) The data is a mean with a range and therefore no relative risk was calculated. The wide range around the mean indicates that the result may be imprecise.
- 17 18 19

Table 11-57: Early vs. delayed mobilisation - Clinical summary of findings

Outcome	Intervention	Control	Relative risk	Absolute effect	Quality
Independent to transfer at day 7	16/29 (55.2%)	4/31 (12.9%)	RR 4.28 (1.62 to 11.3)	423 more per 1000 (from 80 more to 1329 more)	Moderate

Independent to step at day 7	10/29 (34.5%)	23/31 (74.2%)	RR 0.46 (0.27 to 0.8)	401 fewer per 1000 (from 148 fewer to 542 fewer)	Moderate
Discharged to home	5/29 (17.2%)	1/31 (3.2%)	RR 5.34 (0.66 to 43.06)	140 more per 1000 (from 11 fewer to 1357 more)	Low
Discharged to fast stream rehab	8/29 (27.6%)	14/31 (45.2%)	RR 0.61 (0.3 to 1.24)	176 fewer per 1000 (from 316 fewer to 108 more)	Low
Discharged to slow stream rehab	14/29 (48.3%)	16/31 (51.6%)	RR 0.94 (0.56 to 1.55)	31 fewer per 1000 (from 227 fewer to 284 more)	Low
Discharged to nursing home	1/29 (3.4%)	0/31 (0%)	RR 3.2 (0.14 to 75.55)	0 more per 1000 (from 0 fewer to 0 more)	Low
Mortality	1/29 (3.4%)	0/31 (0%)	RR 3.2 (0.14 to 75.55)	0 more per 1000 (from 0 fewer to 0 more)	Low
Mean walking distance, metres	82.55 (0.5- 400)	34.7 (5-103)	N/A	_(a)	Moderate

(a) An absolute effect could not be calculated as the study did not provide a mean, only a range.

2 **11.2.1.2** Economic evidence

3 No studies were identified.

1

4

5 6

7

8

The GDG was informed of the hourly cost of physiotherapy in a hospital setting for England and Wales, which corresponds to $\pm 23^{59}$. Physiotherapist sessions delivered during the weekends and during public holidays would be paid at an enhanced rate of pay of time and a third (BMA contract, 2008).

11.2.1.3 Evidence statement (s)

Clinical There is a statistically significant and clinically significant increase in independence to transfer and independence to step at day 7 for patients who had early mobilisation compared to delayed mobilisation. (MODERATE QUALITY)

There is a doubling in the distance walked at day 7 for patients who had early mobilisation compared to delayed mobilisation. (MODERATE QUALITY)

There is no statistically significant difference between early versus delayed mobilisation for discharge destination or mortality. (LOW QUALITY)

Economic No studies were identified on the cost-effectiveness of early vs. delayed mobilisation.

Recommendation	Offer patients physiotherapy assessment and, unless medically or surgically contraindicated, mobilisation on the day after surgery.
Relative values of different outcomes	Early mobilisation with a physiotherapist appears safe and is effective in promoting early recovery of ability to transfer and to be able to step without help of a person or walking aid. These outcomes are important markers of early recovery of mobility. See also, chapter 10 section 10.2 where the recommendation is made that surgeons should operate on patients with the aim to allow them to fully weight bear (without restriction) in the immediate post operative period.
Trade off between clinical benefits and harms	The only outcome relating to harm or safety was mortality, which showed no statistically significant difference. If safety issues were a concern it is likely that they would be reflected in the overall functional outcomes, all of which improved or had no significant effect, therefore the GDG do not believe that harm is caused in relation to this evidence. If any attempt at mobilisation is supervised by a physiotherapist it should in any case be sensitive to limitations imposed by individuals' pre-fracture abilities and post- operative pain and fatigue. Thus a policy of early mobilisation with a physiotherapist should be seen as beneficial, and delayed only when individuals' clinical circumstances indicate this as appropriate.
Economic considerations	Evidence on the cost effectiveness of early mobilisation treatments is lacking. The GDG acknowledged that early mobilisation strategies will generally involve higher personnel costs (linked to the provision of physiotherapy sessions over the entire week, thus also during weekends and public holidays). However, the GDG considered the cost-savings associated with an earlier recovery of ability to transfer and step without help of a person or walking aid, and agreed that early mobilisation strategy represent a cost- effective intervention for our population.
Quality of evidence	There is only one RCT of low to moderate quality with a relatively small sample size (n = 60) and therefore the findings were interpreted with caution by the GDG.
Other considerations	Early mobilisation protocols may require new service delivery models for weekend or 7 day physiotherapy services.
	The GDG highlighted this recommendation as a key priority for implementation

1 11.2.2 Recommendations and link to evidence

1 **11.3 Intensity of physiotherapy**

2 11.3.1 Review question

In patients who have undergone surgery for hip fracture, what is the clinical and cost
 effectiveness of intensive physiotherapy compared to non intensive physiotherapy on
 functional status, mortality, place of residence/discharge, pain and quality of life?

6 See evidence table 5.10, Appendix E and forest plots G116 to G128.

11.3.1.1 Clinical evidence

- 8 Three randomised studies were found, comparing three different types of intensive
- 9 physiotherapy/physical medicine programme. Hauer et al (2002)^{137,138} investigated
- 10 intensive, progressive strength training. Moseley et al (2009)^{214,214} tested an intensive
- 11 weight bearing exercise programme supplemented by treadmill gait re-training
- 12 programme, and Karumo (1977)^{169,169} investigated twice daily physiotherapy (of one hours
- 13 duration) in comparison to usual care (<=30 mins, once daily).

NCGC cost analysis	Minor limitations ^(a)	Partially applicable ^(b)	Cost analysis based on resources used in the studies included in the clinical review ^{138,169,214}			

- 7 (a) No sensitivity analysis. 8
 - (b) UK study but does not estimate QALYs. One study¹⁶⁹ quite outdated. All studies not UK based and therefore may not reflect current NHS practice.
- 9 10
- 11

12 Table 11-61: Intensive exercise or physiotherapy vs. usual care - Economic summary of findings

Study	Incremental cost (£)	Incremental effects	ICER	Uncertainty
NCGC cost analysis	 £12 (strength training programme vs. usual care ¹³⁸) ^(a) £180.18 (more intensive physiotherapy vs usual care ¹⁶⁹) ^(b) £827.62 (inpatient-based part of the weight bearing and treadmill exercise programme ²¹⁴) ^(c) 	N/A	N/A	N/R

- 13 (a) Intervention group slightly more costly than the control group because of the use of ad-hoc 14 exercise equipment. 15
 - (b) Intervention group more costly because of longer physiotherapy sessions
- 16 (c) It was not possible to estimate the outpatient costs of the rehabilitation programme as 17 insufficient information was given in the study.

18 Evidence statement (s)

Clinical Strength training

Additional, progressive strength training produces a statistically significant and clinically significant increase in leg extensor power, hip flexor strength and walking speed compared to placebo motor training (control) at 3 months

after surgery. (HIGH QUALITY)

There is no statistically significant difference in basic or extended activities of daily living or gait and balance as measure by the Performance Orientated Mobility Assessment with strength training compared to placebo motor training (control) at 3 months after surgery. (HIGH QUALITY)

There is no statistically significant difference in timed up and go test and chair rises with strength training compared to placebo motor training (control) at 3 months after surgery. (MODERATE QUALITY)

Weight bearing exercise and treadmill training

There is no statistically significant difference in functional performance tests, quality of life, walking speed or pain with weight bearing exercise and treadmill gait training compared to the control. (HIGH QUALITY)

There is no statistically significant difference in length of hospital stay with weight bearing exercise and treadmill gait training compared to the control. (MODERATE QUALITY)

Intensive (more frequent) physiotherapy

There is no statistically significant difference in knee extensor strength adductor muscle strength or length of stay in hospital with an increased number of physiotherapy sessions per day compared to the control. (LOW QUALITY)

Economic All intensive exercise and physiotherapy programmes are more expensive than usual care, albeit the strength programme is only slightly more costly compared to usual care.

This evidence has minor limitations and partial applicability.

1 11.3.2 Recommendations and link to evidence

Recommendation	Offer patients mobilisation at least once a day and ensure regular physiotherapy review.
Relative values of different outcomes	The outcomes considered most important were mobility, functional status, pain, quality of life and length of hospital stay.
	There is evidence of training effects in muscle strength and other variables which are known to be important determinants of ability to walk, and hence live independently. Further research is needed to confirm effects on outcomes including return to independent living, quality of life, health service resource, and time to discharge.
	The evidence shows that there was no difference in once a day or twice a day physiotherapy for length of hospital stay and adductor muscle strength ¹⁶⁹ , and thus the GDG are recommending at least once a day mobilisation.

Trade off between clinical benefits and harms	GDG consensus was that mobilisation at least once a day has potential benefits of improved mobility and balance, increased independence, and reduced need for institutional and social care. The included studies failed to show improvements for these outcomes, but are all small low quality studies. There is no evidence of harm from mobilisation once a day. There is potential to exacerbate pain and induce excessive fatigue, and training should be prescribed and overseen by a physiotherapist.
Economic considerations	The GDG acknowledged the lack of cost-effective evidence on this question, and agreed that intensive rehabilitation sessions are likely to be more expensive than usual care. The GDG also noted that intensive rehabilitation can bring some benefits in terms of strength and on other factors affecting the ability to walk and live independently.
	The GDG agreed that daily mobilisation sessions and regular physiotherapy review represent a cost-effective intervention for our patients.
Quality of evidence	Although 3 RCTs were included, the interventions were not comparable and could not be combined in a meta-analysis. The studies were all considered individually and the evidence base is limited. The quality of the evidence ranged from low to high, but due to few studies being identified the GDG considered the overall quality to be poor.
	The economic evidence is based on the resources described in the programmes in the three RCTs included in the clinical review. Only the costs of the interventions and of the usual care programme were considered. The analysis is also only partially applicable in that, even current NHS unit costs were used, the actual level of resources reported in the trials may not reflect the current practice in the UK NHS.
Other considerations	GDG expert opinion indicates that patients may benefit from more intensive protocols of rehabilitation therapy (including occupational and physiotherapy), but that more evidence is needed.
	The GDG highlighted this recommendation as a key priority for implementation

11.3.3 Research recommendations on mobilisation

11.3.3.1 Frequency of physiotherapy

4 The GDG recommended the following research question:

5	\succ	What is the clinical and cost effectiveness of additional intensive physiotherapy
6		and/or occupational therapy (for example progressive, resistance training) after hip
7		fracture?

1 Why this is important

The rapid restoration of physical and self care functions is critical to recovery from hip
fracture, particularly where the goal is to return the patient to preoperative levels of
function and residence. Approaches that are worthy of future development and
investigation include progressive resistance training, progressive balance and gait training,
supported treadmill gait re-training, dual task training, and Activities of Daily Living training.
The optimal time point at which these interventions should be started requires clarification.

8 The ideal study design is a randomised controlled trial. Initial studies may have to focus on 9 proof of concept and be mindful of costs. A phase III randomised controlled trial is required 10 to determine effectiveness and cost-effectiveness. The ideal sample size will be around, 400 11 - 500 patients, and the primary outcome should be physical function and health related 12 quality of life. Outcomes should also include falls. A formal sample size calculation will need 13 to be undertaken. Outcomes should be followed over a minimum of 1 year, and compare if 14 possible, either the recovery curve for restoration of function or time to attainment of 15 functional goals.

16

1 12 Multidisciplinary management

2 12.1 Introduction

Multidisciplinary care is central to the management of frail older people with multiple
 medical, psychological and social problems. Since these are the people who typically suffer
 hip fracture every Trauma Unit will provide some form of multidisciplinary care. Although
 the prevalence of comorbidity is generally lower in younger patients, the key principles of
 multidisciplinary intervention are applicable across the adult age spectrum and the same
 skills and organisational approaches derived within the development of a focus on the older
 population should be provided irrespective of chronological age.

- In this chapter the evidence for the different models of enhanced inpatient and community
 management were considered that have evolved to meet the specific needs of patients
 with hip fracture.
- 13 Secondary prevention of fracture by means of the assessment and management of both osteoporosis^{228,229} and risk of falling ²²⁵ are covered in separate NICE guidance. It is, 14 15 however, important in practice that the elements of multidisciplinary management covered 16 in this guidance relate in an organized manner closely and reliably with these secondary 17 prevention programmes to deliver all the elements of comprehensive care required by each 18 patient. The precise organizational approach to this differs amongst centres. In some there 19 is considerable overlap and/or cross-representation between the secondary prevention 20 programmes and the service models covered in this guideline.
- Units across the UK have adopted a variety of multidisciplinary service models, but most
 have at least some form of access to geriatrician input into the care of these patients. Local
 circumstances and expertise have determined the precise model developed in different
 centres, but in general these are variations on the following four approaches.
- 25 The traditional model of orthopaedic care 'usual care'.
- The patient with hip fracture is admitted to a trauma ward where the orthopaedic surgical team lead both their surgical care and subsequent rehabilitation.
 Geriatrician input to such wards may be limited, with referrals and medical queries being dealt with on a consultative basis by the on-call medical registrar or on occasional geriatrician visits, but without a proactive geriatrician lead to the multidisciplinary team.
- A more collaborative model of trauma ward working is formal 'orthogeriatric' care with
 trauma patients admitted to a specialised ward under the joint care of both geriatricians

1 2	and orthopaedic surgeons. Surgical and geriatrician ward rounds may happen independently, or be combined in multidisciplinary ward rounds.
3 4 5 6 7	 This collaborative model is particularly relevant to hip fracture patients. Such joint working can thus lead to the development of a formal 'Hip Fracture Programme' (HFP), with the geriatric medical team contributing to joint pre-operative patient assessment, and increasingly taking the lead for post-operative medical care, multidisciplinary rehabilitation (MDR) and discharge planning.
8 9 10	Both 'traditional' and 'orthogeriatric' models of the acute trauma ward may continue to care for patients throughout their recovery and rehabilitation following hip fracture, or each may be followed by a transfer of some patients to other models of rehabilitation.
11 12 13 14 15	 In some centres, surgical care and initial mobilisation is followed by early post- operative transfer to a 'Geriatric Orthopaedic Rehabilitation Unit' (GORU) - a separate geriatrician-led rehabilitation ward. The extent of surgical input to the GORU varies, depending on how early patients are moved from the acute trauma wards.
16 17 18	 In other centres, similar patients would be transferred to a generic 'Mixed Assessment and Rehabilitation Unit' (MARU), able to accept patients with a variety of medical, surgical and orthopaedic conditions.
19	A further service model is some form of community rehabilitation.
20 21 22 23 24	 One approach is 'Early Supported Discharge' (ESD) or 'Intermediate Care' at home. Patients are discharged home from the acute trauma ward, or in some cases a rehabilitation ward within the hospital, with a supported 4-6 week rehabilitation package. This may include patients living in care homes but in many parts of the country is limited to patients returning to live independently in their own homes.
25 26 27 28	 Alternatively, patients with more complex needs may be moved for rehabilitation to an Intermediate Care facility outside the hospital setting, such as a care home, or a community hospital. Again this will vary depending on the provision of services available locally.
29	
30	

8

9

2 **12.2** Hospital-based multidisciplinary rehabilitation versus usual care

- Multidisciplinary rehabilitation (MDR) after hip fracture has been taken by the GDG to
 incorporate medicine, nursing, physiotherapy, occupational therapy and social care as core
 components of assessment and management. Additional components may include
 dietetics, pharmacy and clinical psychology.
- 7 The GDG also assumes:
 - The required degree of relevant specialist expertise in each case.
 - Formal arrangements for co-ordination/teamwork, and
- Regular on-going multidisciplinary assessment.
- 'Usual care' will be taken to imply the traditional model, with *ad hoc* or selective referral to
 some or all of the separate MDR components listed above, but without formal
 arrangements for co-ordinated multidisciplinary teamwork.
- In contrast, the different models of 'orthogeriatric care' all assume the involvement of a
 geriatrician, in addition to the orthopaedic surgical team, in the development and
 supervision of a formal process of coordinated multidisciplinary care.
- 17 Such orthogeriatric models have been sub-divided into:
- Those focused predominantly or exclusively on the acute trauma ward; typified by the HFP model.
- Those provided in a subsequent inpatient rehabilitation setting (with GORU and
 MARU having been combined because no evidence has addressed a comparison of
 these models).
- Those with a community focus (the focus of Section 12.4).
- 24 12.2.1 Review questions
- In this section two review questions were combined as the evidence overlapped and could
 not be separated in a useful way. The questions were:
- In patients with hip fracture what is the clinical and cost effectiveness of hospital-based
 multidisciplinary rehabilitation on functional status, length of stay in secondary care,
 mortality, place of residence/discharge, hospital readmission and quality of life?
- 30All the published studies included in the analysis of hospital-based MDR are of models that31include geriatrician input. The results of a collective analysis of all such studies therefore
- 32 reflect both the effectiveness of hospital-based MDR, and the overall value of33 orthogeriatrician involvement in hip fracture care.
- In addition, the benefits of different models of hospital-based MDR can be considered by
 comparing 'usual care' with the two general sub-types of orthogeriatric care:

- Hip Fracture Programme (HFP)
- Geriatric Orthopaedic Rehabilitation Unit (GORU), or near equivalents such as a Mixed Assessment and Rehabilitation Unit (MARU).

In patients with hip fracture what is the clinical and cost effectiveness of orthogeriatrician
involvement in the whole pathway of assessment, peri-operative care and rehabilitation on
functional status, length of stay in secondary care, mortality, place of residence/discharge,
hospital readmission and quality of life?

- 8 The geriatrician is increasingly seen as having a key role in the integration of initial
 9 assessment and peri-operative care with the coordinated MDR (in whatever setting) which
 10 follows it.
- 11The usefulness of this early element of orthogeriatric input has been assessed; an element12that it is central to the first of the two models (HFP), but lacking from the second
- 13 (GORU/MARU). In the absence of trials directly comparing the two models the impact of
- 14 early geriatrician involvement can only be inferred from any differences that might be
- 15 apparent when each is compared to 'usual care'.
- 16 See Evidence Table 5.10, Appendix E and forest plots G129 to 138 in Appendix G.
- 17

(a) Intervention group in Huusko 2002^{155,156} had greater number of patients with dementia (32/120 vs. 20/123); fewer were functionally independent in ADL before hip fracture (41 vs. 66).

(b) Kennie 1988^{174,174}: difference in age mental state. Control group average age higher and with more moderate and severe impairment.

(c) In Galvard 1995^{105,105}, the intervention group were older than usual care (79.1 vs. 73.6), and there were a higher proportion of patients with subtrochanteric fractures, which often require longer rehab (12% vs. 4%).

(d) Kennie 1988^{174,174} is an all female population.

(e) In Shyu 2008²⁹⁷ the patient's insurance policy determined the number of physiotherapy sessions in the control group.
 (f) In Vidan 2005^{335,335} there is potential for contamination bias given both groups were on the same

(f) In Vidan 2005^{335,335} there is potential for contamination bias given both groups were on the same ward and had the same staff.

(g) In Stenvall 2007a^{311,312}, outpatient rehabilitation was not standardised.

(h) The relatively few events and few patients give wide confidence intervals around the estimate of effect. This makes it difficult to know the true effect size for this outcome.

(i) Galvard 2002^{105,105}, author's note that geriatric department had less experience with hip fracture patients than the orthopaedic ward, which may have contributed to increased length of stay in intervention group.

(j) The intervention in Naglie 2002^{220,220} was expected to increase the length of stay in hospital.

- (k) The wide confidence intervals around the estimate make it difficult to determine and effect size for this outcome.
 (l) There is significant statistical heterogeneity between the studies. This could be due to the variation in intervention and country of study.
 - (*m*) The intervention in Marcantonio 2001^{201,201} does not examine multidisciplinary rehabilitation in the form of an HFP, but focuses on the value of early comprehensive geriatric assessment and targeted intervention.
 - (n) There is significant statistical heterogeneity between the studies. However, this could be due to differences in access to hospital services and follow up procedures.
- 10

Table 12-63: Hospital based multidisciplinary rehabilitation vs. Usual care - Clinical summary of findings

Outcome	Intervention	Control	Relative risk	Absolute effect	Quality
	mervention	Control	Kelutive lisk		Quanty
Mortality at 6 months – GORU/MARU	31/238 (13%)	44/263 (16.8%)	RR 0.79 (0.52 to 1.21)	35 fewer per 1,000 (from 80 fewer to 35 more)	High
Mortality at 12 months – GORU/MARU	89/455 (19.6%)	96/466 (19.7%)	RR 0.95 (0.74 to 1.23)	10 fewer per 1000 (from 54 fewer to 47 more)	Moderate
Mortality at 12 months – HFP	72/400 (18%)	90/404 (21%)	RR 0.81 (0.61 to 1.06)	42 fewer per 1000 (from 87 fewer to 13 more)	Moderate
Mortality (at discharge) – GORU/MARU	46/693 (6.6%)	62/729 (8.4%)	RR 0.78 (0.54 to 1.13)	19 fewer per 1000 (from 39 fewer to 11 more)	Moderate
Mortality (at discharge) – HFP	3/193 (1.6%)	11/197 (5.8%)	RR 0.27 (0.07 to 0.96)	41 fewer per 1000 (from 2 fewer to 52 fewer)	Low
Non-recovery/decline in walking at 6 months – GORU/MARU	59/124 (47.6%)	56/117 (47.9%)	RR 0.99 (0.76 to 1.29)	5 fewer per 1000 (from 115 fewer to 139 more)	Moderate
Decline in transfers (bed to chair etc) at – GORU/MARU	45/124 (36.3%)	44/117 (37.6%)	RR 0.96 (0.69 to 1.34)	15 fewer per 1000 (from 117 fewer to 128 more)	Moderate
More dependent (based on Katz index) at 1 year – GORU/MARU	57/127 (44.9%)	77/111 (72.2%)	RR 0.64 (0.51 to 0.81)	250 fewer per 1000 (from 132 fewer to 340 fewer)	Low
Non-recovery in activities of daily living (ADL) at 1 year - GORU/MARU	51/84 (60.7%)	59/76 (77.6%)	RR 0.78 (0.63 to 0.96)	171 fewer per 1000 (from 31 fewer to 287 fewer)	Moderate

Length of hospital stay - HFP	245	240	N/A	MD -6.06 (-14.5 to 2.38)	Low
Pressure sores	8/155 (5.2%)	27/164 (16.5%)	RR 0.31 (0.15 to 0.67)	114 fewer per 1000 (from 54 fewer to 140 fewer)	High
Heart failure	12/155 (7.7%)	5/164 (3.1%)	RR 2.54 (0.92 to 7.04)	47 more per 1000 (from 2 fewer to 184 more)	Moderate
Pneumonia	6/155 (3.9%)	6/164 (3.7%)	RR 1.06 (0.35 to 3.21)	2 more per 1000 (from 24 fewer to 81 more)	Moderate
Confusion	53/155 (34.2%)	67/164 (40.9%)	RR 0.84 (0.63 to 1.11)	65 fewer per 1000 (from 151 fewer to 45 more)	High
Chest infection, cardiac problem, bedsore	6/38 (15.8%)	13/33 (39.4%)	RR 0.4 (0.17 to 0.94)	236 fewer per 1000 (from 24 fewer to 327 fewer)	Moderate
stroke, emboli	4/38 (10.5%)	1/33 (3%)	RR 3.47 (0.41 to 29.56)	75 more per 1000 (from 18 fewer to 865 more)	Moderate
Delirium	20/62 (32.3%)	32/64 (50%)	RR 0.65 (0.42 to 1)	175 fewer per 1000 (from 290 fewer to 0 more)	Low
Severe delirium	7/62 (11.3%)	18/64 (28.1%)	RR 0.4 (0.18 to 0.89)	169 fewer per 1000 (from 31 fewer to 231 fewer)	Low
Readmitted to hospital during follow-up - GORU/MARU	74/256 (28.9%)	87/262 (33.2%)	RR 0.86 (0.67 to 1.12)	46 fewer per 1000 (from 110 fewer to 40 more)	Low
Readmitted to hospital during follow-up – HFP	86/373 (23.1%)	78/378 (17%)	RR 1.14 (0.87 to 1.48)	29 more per 1000 (from 27 fewer to 99 more)	Moderate

1 12.2.1.2 Economic evidence

The included studies for hospital-based MDR consisted of Cameron (1994)^{41,43}, Galvard (1995)^{105,105}, Farnworth (1994)^{89,89} and Huusko (2002)^{155,156}. Further details on the studies are available in Evidence Table 16 of Appendix F. An HTA by Cameron (2000)⁴⁰ was excluded because the studies were grouped in a different way to that considered for our clinical review, and therefore its cost analysis was not applicable for our review question.

- An original decision analysis has been conducted comparing the cost-effectiveness of the
 HFP vs. GORU/MARU vs. usual care. A Markov model was developed, adopting a life-time
 horizon.
- An indirect comparison between the HFP and GORU/MARU models of care was made as no
 evidence was available which compares directly the two rehabilitation programmes. The
 usual care arms in the trials of HFP vs. usual care and of GORU/MARU vs. usual care were
 combined for this purpose.
- 8 Treatment effects were based on the findings of the clinical review and applied only up to 1
- 9 year from follow-up. Resource use was determined from the NHS and PSS perspective.
- 10 Effectiveness was measured in QALYs. Costs and QALYs were discounted at a rate of 3.5%.
- 11 Please see section 8.6 of Appendix H for further details.

Study	Limitations	Applicability	Other Comments
Cameron 1994 ⁴³ – HFP	Potentially serious limitations ^(a)	Partial applicability ^(b)	Accelerated rehab was compared to usual care. The follow up time was 4 months.
Farnworth 1994 ⁸⁹ – HFP	Potentially serious limitations (c)	Partial applicability ^(b)	Fractured Hip Managemen Program (FHMP) was compared to usual care. The follow up time was 6 months.
Galvard 1995 ¹⁰⁵ - GORU	Potentially serious limitations ^(d)	Partial applicability ^(e)	Rehabilitation in a geriatri department was compare to usual care. The follow u time was 1 year.
Huusko (2002) ¹⁵⁶ - MARU	Potentially serious limitations ^(f)	Partial applicability ^(g)	Intensive multidisciplinary geriatric team rehabilitati versus usual care. Follow was 1 year.
NCGC economic model	Minor limitations ^(h)	Direct applicability	Cost-effectiveness analysi of HFP vs. GORU/MARU vs usual care based on the meta-analysis of the trails included in the clinical review of this guideline

Table 12-64: Hospital based multidisciplinary rehabilitation vs. usual care - Economic study characteristics

(a) Patients in the intervention and control group treated in the same ward, so that results could be biased due to an underestimation of the cost effectiveness of accelerated rehab.

- (b) Study conducted in Australia. Not a CUA.
- (c) The year in which cost date were collected is not clear. The duration of follow up is not clear. HRQoL not calculated. The statistical significance of the outcome and cost measures between the two groups was not reported. Outcome at 1 year was not known for 12% of the intervention and 14% of the control group.
- (d) No sensitivity analysis was performed to test robustness of findings. HRQoL not calculated. The source used to estimate the unit cost of resources was unclear.
- (e) Study conducted in Sweden. Not a CUA.
- (f) Not a cost-effectiveness analysis. No sensitivity analysis was performed. 38 patients were lost during follow up. The year(s) at which cost data refer to is not clear. Imbalance of baseline characteristics. Intervention group had a more patients with dementia (32/120 vs. 20/123, and fewer who were functionally independent in ADL before hip fracture (41 vs. 66).
- 7 (g) Study conducted in Finland. Not a CUA.
- 18 (h) Treatment effects from meta-analysis of clinical trials available up to 1 year from follow-up.

	Incremental cost	Incremental		
Study	per patient (£)	effects	ICER	Uncertainty
Cameron 1994 – HFP	-£956 ^(a)	Several outcomes were reported ^(b)	Accelerated rehabilitation is the dominant strategy (less costly and more effective)	Threshold sensitivity analysis: results not sensitive to changes in % of patients recovering nor to the definition of recovery. Accelerated rehab becomes more costly than usual care when difference in LOS less than 1.5-2 days and when cost of treatment more than 40% per bed day.
Farnworth 1994 – HFP	£784 ^(c)	Several outcomes were reported ^(d)	N/A	Deterministic sensitivity analysis showed that results were robust to changes in the time spent to get patients to surgery more quickly; to the proportion of nursing home patients and to the average cost of the final days of a patient's stay
Galvard 1995 - GORU	-£665 ^(e)	Several outcomes were reported ^(f)	N/A	N/R
Huusko 2002 - MARU	£1310 ^(g)	Several outcomes were reported ^(h)	N/A	N/R
NCGC economic model – HFP vs. GORU/MARU vs. usual care (Appendix H)	-£ 2,000 (HFP vs. GORU/MARU) -£25,000 (HFP vs. usual care) ⁽ⁱ⁾	-0.13 QALYs (HFP vs. GORU/MARU) -1.01 QALYs (HFP vs. usual care) ^(j)	HFP is the dominant strategy compared to both GORU/MARU and usual care	Deterministic sensitivity analysis showed that results were sensitive to changes in the proportion of patients discharged to their own home following rehabilitation. A probabilistic sensitivity analysis showed that there is no uncertainty that hospital MDR is better than usual care. However, there is some uncertainty over the cost- effectiveness of HFP vs. GORU/MARU. ^(k) 95% CI (HFP vs usual care and GORU/MARU vs usual care): usual care dominated. 95% CI (HFP vs. GORU/MARU): HFP dominant – GORU dominant.

(a) Accelerated rehab is cost saving. A\$ converted using the PPP of 1990. p=0.186. The cost components estimated were: inpatients hospital costs, readmissions, community support services, institutional care.

MULTIDISCIPLINARY MANAGEMENT

1	(b)	No. of patients recovered at 4 months from surgery (mean Barthel index score): 63 (49.6%) vs. 52
	(D)	(41.6%); 95% Cl (-3% to 21%). Median length of stay (days, interquartile range): 13 (7-25) vs. 15 (8-
2 3		(41.0%), 55% CI (-5% to 21%). Weatan rength of stay (days, interquartile range). 15 (7-25) vs. 15 (8- 44).
4	(c)	Fractured Hip Management Program (FHMP) is cost saving.
5	(C) (d)	FHMP entails lower mortality and readmission at 1 year, and lower length of stay.
6	(u) (e)	Swedish Krona (SEK) converted using the PPP of 1989; Rehabilitation in geriatric department more
7	(8)	expensive than usual care (£665 per patient)
8	(f)	The intervention had a lower level of readmissions to hospital than usual care (36 vs. 57; p value
8 9	07	NR) but it had a higher mortality at 1 year (45 vs. 40, p value NR) and a higher mean length of stay
10		in hospital (53.3 vs. 28 days, p value NR).
11	(q)	The study expressed costs in Euros (values of 1999). The intervention is more costly than usual care
12	(0)	(p value NR).
13	(h)	Intervention did not statistically differ from usual care in terms of mortality at 12 months (15% vs.
14		16%); mortality at discharge (5 vs. 5) and length of stay in hospital during 1 year (80 vs. 80 days),
15		and number of patients reporting complications (51% vs. 46%, p=0.4). Patients in the intervention
16		group regained their independency in the IADL functions faster (p=0.005) than usual care at 3
17		months (but after 1 year there was no significant difference between the two groups).
18	(i)	The mean costs associated with HFP were estimated to be £34,000, for GORU/MARU £36,000 and
19		for usual care £59,000.
20	(j)	The mean effectiveness corresponded to 3.74 QALYs for HFP, 3.61 QALYs for GORU/MARU and 2.73
21		QALYs for usual care.
22	(k)	Usual care was never the most cost-effective strategy. At a willingness to pay of £20k per
23		incremental QALY, HFP was found to be the most cost-effective option in 70% of the 10,000
24		simulations run in the PSA, while GORU/MARU was the most cost-effective option in 30% of the
25		simulations. At a willingness to pay of £30K per incremental QALY, HFP was found to be the most
26		cost-effective option in 80% of the 10,000 simulations run in the PSA, while GORU/MARU was the
27		most cost-effective option in 20% of simulations.

30 12.2.2 Evidence statement (s)

Clinical

Hospital-based MDR (GORU/MARU)

There is a statistically significant and clinically significant reduction in pressure sores with hospital-based MDR (GORU/MARU) compared to usual care. (HIGH QUALITY)

There is a statistically significant, but not clinically significant improvement in recovery of activities of daily living at 1 year with hospital-based MDR (GORU/MARU) compared to usual care. (MODERATE QUALITY)

There is a statistically significant, but not clinically significant improvement in transfers (bed to chair) and being more dependent (Katz index) at 1 year with hospital-based MDR (GORU/MARU) compared to usual care. (LOW QUALITY)

There is a statistically significant, but not and clinically significant reduction in severe delirium with hospital-based MDR (GORU/MARU) compared to usual care. (LOW QUALITY)

There is no statistically significant difference in mortality at 6 months and functional outcomes at 6 months between hospital-based MDR (GORU/MARU) and usual care. (MODERATE QUALITY)

There is no statistically significant difference in mortality at 12 months and mortality at discharge between hospital-based MDR (GORU/MARU) and usual

care. (MODERATE QUALITY)

There is no statistically significant difference in length of hospital stay and readmission to hospital between hospital-based MDR (GORU/MARU) and usual care. (LOW QUALITY)

Hip fracture programme (HFP)

There is a statistically significant and clinically significant improvement in functional outcomes at 1 year with HFP compared to usual care. (MODERATE QUALITY)

There is a statistically significant and clinically significant reduction in mortality at discharge between HFP and usual care. (LOW QUALITY)

There is no statistically significant difference in mortality at 12 months and readmission to hospital, between HFP and usual care. (MODERATE QUALITY)

There is no statistically significant difference in length of hospital stay, between HFP and usual care. (LOW QUALITY)

EconomicHFP is the dominant strategy (less costly and more effective) than both
GORU/MARU and usual care as a hospital based multidisciplinary
rehabilitation of hip fracture patients. This evidence has minor limitations and
direct applicability.

1 12.2.3 Recommendations and link to evidence

Recommendation	 From admission, offer all hip fracture patients a formal, acute orthogeriatric or orthopaedic ward-based Hip Fracture Programme that includes all of the following: orthogeriatric assessment rapid optimisation of fitness for surgery early identification of individual goals for multidisciplinary rehabilitation to recover mobility and independence, and to facilitate return to prefracture residence and long-term wellbeing. continued coordinated orthogeriatric and multidisciplinary review communication with the primary care team.
Relative values of different outcomes	Patients, clinical staff and health services share the objective of safely returning patients to their original functional state and residence as quickly as possible. However, these objectives are often in conflict – for instance earlier discharge may be at the expense of functional improvement, while length of stay may increases if mortality is prevented among frailer individuals. Therefore the most important outcomes considered by the GDG were functional status, length of stay, discharge destination and mortality. All these outcomes were incorporated into an original

economic decision analysis.

Trade off between clinical
benefits and harmsStudies of MDR show no significant evidence of harm and a trend
towards improved outcomes across all outcomes. There is no
suggestion of harm resulting from orthogeriatric collaboration in
the HFP literature.

Evidence to support the effectiveness of coordinated hospitalbased orthogeriatric MDR is derived from studies of both HFP and GORU/MARU models.

Taken together these studies suggest:

- improvement in functional outcome at 1 year, though this has not been shown to lead to greater success in achieving patients' objective of returning to their original residence.
- trend toward reduced mortality at discharge, 1, 6 and 12 months, which must reflect an effect in reducing medical and/or surgical complications (problems with diagnosis, definition and ascertainment leave this issue unclear).
- reduced hospital length of stay, though some studies only examined orthopaedic ward length of stay, so the preferred measure of 'super-spell' (the total time until return home) was inconsistently characterised.

Additional evidence supporting the effectiveness of a hospitalbased model incorporating continuous orthogeriatrician supervision is derived from studies of Hip Fracture Programmes which suggest:

- reduced patient mortality at discharge and follow-up
- improved functional outcomes
- reduced hospital LOS
- reduced risk of delirium²⁰¹.

Both HFP and GORU/MARU proved markedly more cost-effective than usual care, although HFP emerged as the dominant strategy. The GDG took the view that HFP approach is also preferable because of its provision of a more extensive programme of multidisciplinary care that:

- supports admission assessment and peri-operative care, in addition to rehabilitation, discharge planning and follow-up
- addresses the needs of all patients, including those who might be viewed as inappropriate for a GORU/MARU (because of ongoing orthopaedic, medical or psychiatric problems)
- provides a coordinated multidisciplinary structure that will support other recommendations in this guideline (eg. early operation).

Economic considerations There were no published economic studies on hospital-based MDR for hip fracture patients, so an original decision analysis was developed to determine the cost-effectiveness of HFP vs.

GORU/MARU vs. usual inpatient rehabilitation (usual care).

The cost-effectiveness model was based on an indirect comparison of randomised trials, but clearly showed that usual care was not the optimal approach.

The increased costs of hospital MDR were more than offset by:

- reduction in the acute hospital stay costs, including those associated with complications such as delirium and pressure sores.
- a reduction in the level of domiciliary social care costs as a result of increased probability of regaining pre-fracture independence in activities of daily living.
- reduction in costs for patients who avoid the need for longterm care in a residential or a nursing home.

HFP was the strategy with the highest incremental net benefit averaged across all the probabilistic simulations, and appeared to be the optimal strategy in the cost-effectiveness analysis both in comparison to usual care, and in comparison to GORU/MARU.

However, there remains some uncertainty about the relative costeffectiveness of HFP and GORU/MARU. In particular, the results were sensitive to the proportion of patients returning home after completing the rehabilitation programme. Sensitivity analysis suggested that if the probability of returning home in the GORU/MARU programme was increased to 83% (instead of 79% as in the base case) then GORU/MARU would become the optimal strategy.

Quality of evidenceThe GDG noted that the precision of the cost-effectiveness analysis
was partially limited by the lack of clinical trials directly comparing
HFP vs. GORU/MARU, and by the heterogeneous patient
population in the meta-analysis of clinical trials on which the cost-
effectiveness analysis is based.

However, the GDG agreed that the outcomes used in the economic analysis were overall of moderate quality and that the decision model is likely to provide a relatively unbiased estimate of cost effectiveness.

There are consistent trends towards benefit across all outcomes, but the small size of individual trials with a highly heterogeneous patient population means that statistical significance is difficult to achieve.

Inconsistency in definition of outcome (variable length of followup, differing functional outcome measures, and poor definition of 'super-spell') result in several similar outcomes reported separately which could not be combined in a meta-analysis.

There are no studies in which orthogeriatrician input is confined to initial assessment and peri-operative medical care, (without then leading into orthogeriatric MDR). Therefore, the value of such <u>early</u> orthogeriatrician involvement can only be inferred from the

outcome of HFP studies.

The quality of the studies ranges from low to high, with the majority of outcomes obtaining a moderate score.

Other considerationsAssumptions – all papers included an orthogeriatrician, but the
outcomes are most plausibly those of coordinated hospital-based
multidisciplinary team working, with orthogeriatricians playing a
medical and supervisory role within the team.

An important function of the HFP is to ensure the required liaison with, or cross-coverage of, the programmes in place for the secondary prevention of fracture by means of the assessment and treatment of osteoporosis and risk of falling (see NICE Clinical Guideline 21 & Technology Appraisal 161 ^{225,228,229}). In some centres HFP staff (including the orthogeriatrician) have common or parallel commitments within these programmes, with the resulting potential to achieve additional economies over and above those identified in the model.

The GDG highlighted this recommendation as a key priority for implementation.

Recommendation	If a hip fracture complicates or precipitates a terminal illness, the multidisciplinary team should still consider the role of surgery, as part of a palliative care approach that: minimises pain and other symptoms and establishes patients' own priorities for rehabilitation and considers patients' wishes about their end-of-life care.
Relative values of different outcomes	Patients with advanced, life-threatening cardiorespiratory, neurological, and malignant disease make up a substantial proportion of those presenting with hip fracture.
	In addition the trauma of suffering a hip fracture, and orthopaedic and medical complications of the injury, immobility and surgery can themselves precipitate a deterioration in the health of individuals.
	In these circumstances such individuals and their families may view relief of pain, restoration of function and return home as a higher priority than survival. Taking this into consideration the GDG prioritised pain, functional status and discharge destination as the most important outcomes.
	Sometimes this may make it necessary to move from an active surgical and rehabilitative approach to a palliative focus that ensures that the patient can die with dignity, with appropriate attention pain and other symptoms, and all the support necessary to minimise their and their family's distress.

Trade off between clinical benefits and harms	Pain, immobility, continence, pressure ulcer risk and dignity are all improved if the hip fracture can be addressed surgically, and perioperative risk should not preclude consideration of surgical management as an integral component of palliative care.
	The prognosis for an individual patient's recovery, mobility and return home can change markedly and multidisciplinary assessment is necessary if patients, their families and carers are given information with which to make informed decisions about their priorities for care (see chapter 13 Patient and carer views and information).
	High quality palliative and terminal care requires a multi- disciplinary approach, which should be provided as a key part of the support that the Hip Fracture Programme offers. Early orthogeriatric assessment and ongoing multidisciplinary working will help in:
	 avoidance of complications such as pressure sores ³³⁵ and delirium ²⁰¹
	expediting discharge.
Economic considerations	No cost-effectiveness evidence was identified on this sub-group of patients. Additional time spent in counseling and supporting patients and their families will clearly carry a cost. While improvements in a patient's symptoms and quality of life may be of only short duration, sensitively handled palliative care can substantially improve their relatives' distress both before and for many years after bereavement.
Quality of evidence	There is no evidence directly relating to this very frail sub-group. Terminally ill patients were often excluded from these papers and if included were not reported in specific sub group analysis. This recommendation was based on GDG consensus opinion.
Other considerations	For patients whose hip fracture occurs in the context of advanced or terminal cancer-related illness, please see NICE Clinical Guideline "Improving supportive and palliative care for adults with cancer" ²²⁵ .
Recommendation	Actively look for cognitive impairment in patients presenting with hip fracture and offer individualised care in line with 'Delirium' (NICE clinical guideline 103) to minimise the risk of delirium and maximise independence.
Relative values of different outcomes	Patients with memory problems make up a substantial proportion of admissions, and face increased risk of delirium, medical complications, mortality, prolonged length of stay, and failure to return to pre-fracture independence.
	The GDG considered medical complications, mortality, length of stay and discharge destination as the most important outcomes.

Trade off between clinical benefits and harms	Patients with memory problems are known to benefit from acute comprehensive geriatric assessment and targeted intervention as a means of reducing their risk of delirium and severe delirium, which are significant contributors to increased length of stay and increased risk of morality at 6 months ^{148,148} , as well as being a source of profound distress for patients, their families and carers ^{201,201} .
	In addition, intensive rehabilitation has been shown to be effective in improving outcome in terms of independent living among patients with mild to moderate cognitive impairment ^{155,155} .
	No evidence of harm was found and the GDG would not expect harm. Although no evidence met our inclusion criteria for this area, GDG consensus is that the potential benefits include avoidance of the distress that delirium causes to patients, their family, carers, and other inpatients, along with avoidance of the persistent reduction in cognitive function that can follow an episode of delirium, and of the increased length of stay and mortality associated with delirium.
	The avoidance and management of delirium in patients with hip fracture is specifically addressed in the NICE Guideline on Delirium ²²² .
Economic considerations	The decision model from the NICE guideline on Delirium (CG103) found that the tailored multi-component intervention package was cost-effective for hip fracture patients (£8,000 per QALY gained), as this care would lead to a reduced risk of long-term institutional care placement, lower incidence of other medical complications and lower length of hospital stay for these patients.
Quality of evidence	Patients with cognitive impairment are usually a group excluded from studies. Over 60% of the papers reviewed either excluded patients with cognitive impairment and/ or dementia, or made no specific comments relating to this subgroup. The studies that specifically analysed this subgroup ^{155,201} are of moderate quality.

Other considerationsFor patients whose hip fracture occurs in the context of dementia,
please see the NICE guidance on dementia²²².Identification of cognitive impairment is a key part of assessment,
and a number of tools have been used in patients with hip fracture.
The Abbreviated Mental Test (AMT) score is often used, and forms
part of the National Hip Fracture Database's dataset, but the GDG
did not examine the choice of tool or approach to assessment.
Assessment of mental state can be complex in patients who are in

pain, or who have received strong analgesia at the time of presentation. Approaches to the prevention and management of delirium require much more than screening for cognitive impairment at admission, and must include a sensitivity to changes in mental state and an awareness that delirium may arise at any stage of a patient's stay.

Delirium is not confined to patients with pre-existing cognitive problems, and its incidence will be reduced most effectively by the provision of continuous orthogeriatric support to all patients²⁰¹. Evidence on the effectiveness of models to prevent and manage delirium following hip fracture were key to the recommendations made in the NICE Guideline on Delirium²²², and that Guideline should be read alongside our own when developing services for patients with hip fracture.

1 **12.3 Research recommendations on hospital multidisciplinary**

2 rehabilitation

3 12.3.1 Hip fracture unit

- The GDG recommended the following research question:
 - What is the clinical and cost effectiveness of a designated hip fracture unit within the trauma ward compared to units integrated into acute trusts on mortality, quality of life and functional status in patients with hip fracture?

8 Why this is important

9 The increasingly structured approach to hip fracture care has led to a number of UK units
10 considering or establishing a specific 'hip fracture ward' as a specialist part of their acute
11 orthopaedic service.

12

4

5

6

- 13 Designated hip fracture wards may prove an effective means of delivering the whole programme
- 14 of coordinated perioperative care and multidisciplinary rehabilitation which this NICE Guidance
- has proposed, but at present there is no high quality evidence of their clinical effectiveness whencompared to such care within general orthopaedic or trauma beds.
- 17 It may not be practical to run an RCT within a trauma unit, but there is certainly potential for
- 18 cohort studies to explore the effect of such units on individual patients' mobility, discharge
- 19 residence, mortality and length of stay. Units considering the establishment of hip fracture wards
- 20 should be encouraged to consider performing such trials.

1 12.4 Community-based multidisciplinary rehabilitation versus usual care

- In addition or as an alternative to hospital based multidisciplinary rehabilitation (MDR), a
 number of studies have evaluated the role of community based MDR.
- 4 Community-based MDR includes approaches that are:
- 5 > based in the patient's own home Early Supported Discharge (ESD)
- 6 > based within a residential care unit or community hospital
 - based within a Social Care Unit (SC) or their near equivalents.
- 8 The many versions of these services across the country are named differently (for example
 9 'intermediate care at home', 'intermediate care residential rehabilitation'), but each
 10 consists of a rehabilitation component delivered in one of the above settings.

11 12.4.1 Review question

7

- In patients with hip fracture what is the clinical and cost effectiveness of community-based
 multidisciplinary rehabilitation on functional status, length of stay in secondary care,
 mortality, place of residence/discharge, hospital readmission and quality of life?
- 15 See evidence table 11, Appendix E and forest plots G139 to G145 Appendix G.

2 12.4.2 Economic evidence

Our search identified five studies on community MDR versus usual care. Of these, one ^{53,53}
 was excluded as it included a mixed population with only 31% hip fracture patients. Van
 Balen et al., 2002^{331,331} was excluded as patients in the early supported discharge scheme
 were only discharged to a nursing home with rehabilitation facilities and not to their own
 home.

The following studies were included as economic evidence on the cost-effectiveness of home-based multidisciplinary early supported discharge vs. usual care: Hollingworth (1993)^{146,146} O'Cathain (1994)²³⁷ and Parker (1991)^{262,262}. Hollingworth (1993)^{146,146} is a cost analysis based on a case series. O'Cathain (1994)²³⁷ is a cost-consequences analysis based on a non-randomised trail with concurrent controls. Parker (1991)^{262,262} is a cost-consequences analysis based on a prospective observational study. For further details on

- 14 these studies please refer to the Evidence Table 16 in Appendix F.
- An original decision analysis has been conducted comparing the cost-effectiveness of the
 community MDR vs. usual care. A decision tree model with Markov states was developed,
 adopting a life-time horizon.
- Treatment effects and EQ-5Ds scores were based on the findings of Crotty (2002) ⁵⁸ and
 applied only up to 4 months from follow-up. Resource use was determined from the NHS
 and PSS perspective. Effectiveness was measured in QALYs. Costs and QALYs were
- and PSS perspective. Effectiveness was measured in QALYs. Costs and QALYs were
 discounted at a rate of 3.5%. Please see section 8.7 in Appendix H for further detail.

22

Study	Limitations	Applicability	Other Comments
Hollingworth 1993 ¹⁴⁶	Potentially serious limitations ^(a)	Partial applicability	A community-based MD at home scheme was compared to usual care. The MDR at home programme consisted of: care from trained nurses, nursing auxiliaries, physiotherapists, and occupational therapists in the patient's home for up to 24 hrs a day under the medical supervision of the general practitioner
O'Cathain 1994 ²³⁷	Potentially serious limitations	Partial applicability	MDR at home compared to usual care. MDR team consisted of district nurses, physiotherapists, occupational therapists and generic workers, all working under the clinica responsibility of a GP for a maximum of 12 days.
Parker 1991 ²⁶²	Potentially serious limitations	Partial applicability	MDR at home scheme compared to usual care. MDR team consisted of trained nurses, nursing auxiliaries, physiotherapists, and occupational therapists.
NCGC economic model	Minor limitations ^(d)	Direct applicability	Cost-effectiveness analysis of community MDR – ESD versus usual care based on the RCT by Crotty et al (2002) ⁵⁸ included in the clinical review.

1 Table 12-68: Home-based multidisciplinary early supported discharge vs. usual care -

- (a) Unclear follow up time. HRQoL not calculated. Information on costs obtained from hospital records, not national statistics. Not an RCT.
- (b) The length of time during which costs are calculated is unclear. No sensitivity analysis was conducted. Not based on a RCT. Not a CUA.
- (c) Not based on a RCT. No sensitivity analysis. Cost data from hospital source, not national statistics. Only patients admitted from their own home were then discharged under the HAH scheme.
- (d) The analysis consists of a decision tree with Markov states which spans a life-time horizon.
 Treatment effects based on the findings of the paper by Crotty in the clinical review and applied only up to 4 months from follow-up. Resource use determined from the NHS and PSS perspective, Effectiveness measured in QALYs. QALYs discounted at a rate of 3.5%.

Parker 1991	-£799.80 ⁽ⁿ⁾	Several outcomes reported ^(o)	N/A	N/R
NCGC economic model	£434.6 ^(p)	0.0456 QALYs ^(q)	£9533/QALYs	95% CI: Community MDR dominant –usual care dominant ^(r)

(I) LOS for MDR at home vs. usual care: 32.5 vs. 41.7 days (p<0.001); readmission rates at 1 year: 6.8% (53 patients) vs. 2.7% (8 patients), p=0.008

- (m) Several outcomes were reported: HRQoL measured with the Nottingham Health Profile questionnaire (14 vs. 24, p<0.05); Mortality (5.3% vs. 5.9%; p = NR); readmission rates at 3 months: (15.8% vs. 8.8%, p=0.187); LOS (median no of days): 10 vs. 17, p<0.001
- (n) Costs based on the following resource use: hospital length of stay; sessions with hospital occupational therapist; readmission days; MDR ESD staff time; other NHS or social services (GP visits, day care, meals on wheels, community services)
- (o) LOS (mean, days): 29 vs. 38 (p value: 0.035). Mortality (at 90 days): 40 (14%) vs. 14 (11%)
- (p) The mean costs associated with community MDR were estimated to be £6901.20 and for usual care £6466.60
- (q) The mean effectiveness corresponded to 3.1283 QALYs and 3.0827 QALYs for usual care.
- (r) Deterministic sensitivity analysis showed that findings were sensitive to the length of stay spent in hospital and during rehabilitation at home. Community MDR was found to be the most costeffective option in 50% of the 10,000 simulations run in the PSA at a willingness to pay of £20k, and in 60% of the simulations at a willingness to pay of 30k per QALY.

21 12.4.3 Evidence statement (s)

There is a statistically significant and clinically significant reduction in hospital Clinical length of stay, but an increase in total length of rehabilitation (hospital + home) with home-based multidisciplinary early supported discharge (ESD) compared with usual care. (MODERATE QUALITY)

> There is a statistically significant and clinically significant increase in functional independence measures with home-based multidisciplinary ESD compared with usual care. (HIGH QUALITY)

There is no statistically significant difference in mortality at 12 months and readmission to hospital at 4 months with home-based multidisciplinary ESD compared with usual care. (LOW QUALITY)

Economic Home-based MDR - ESD is cost-effective in the rehabilitation of patients with hip fracture. This evidence has minor limitations and direct applicability.

Recommendation	Consider offering early supported discharge (ESD) as part of the Hip Fracture Programme (HFP) provided the HFP multidisciplinary team (MDT) remain involved and the patient meets <u>all</u> of the following criteria: medically stable no cognitive impairment able to transfer and mobilise short distances rehabilitation potential not yet achieved.
Relative values of different outcomes	Length of hospital stay, functional outcomes and re-admission rates were considered the primary outcomes of interest. All these outcomes were used in the decision analytical model.
Trade off between clinical benefits and harms	Multidisciplinary ESD at home in selected patients reduces hospital length of stay but may result in overall prolonged rehabilitation (hospital + home) compared to hospital MDR. Selected patients were defined from the studies as medically stable, cognitively intact, able to transfer independently, and mobilise short distances.
	Despite only a few low quality studies being identified the GDG consensus was that multidisciplinary ESD at home is beneficial to a specific patient group, as defined above.
	Our decision analysis found QALYs were 0.0456 higher in the community MDR arm of the study compared to usual care.
Economic considerations	No cost-effectiveness studies were identified for this clinical question. An original decision analytical model was developed, which was based on the findings of an RCT included in our clinical review ^{56,58} . The analysis showed that there is uncertainty as to whether MDR ESD at home is cost-effective compared to usual care. In particular, findings were sensitive to the length of hospital stay and length of the home-based rehabilitation programme.
	However, the GDG noted that the ICER of £9533/QALYs is well below the £20,000 threshold.
	It is also important to note that our model did not find community MDR to be cost saving compared to usual care. This was because patients in the community MDR branch of the model underwent rehabilitation in their own home for a relatively longer period of time than those of the other studies included in the economic evidence profile in section 8.7 in Appendix H.
Quality of evidence	There were few studies identified, which ranged from low to high quality with often only one study per outcome. Therefore our confidence in the results is low.

1 12.4.4 Recommendations and link to evidence

	Studies were undertaken in medically stable and cognitively intact patients and there were no studies that evaluated multidisciplinary ESD at home in cognitively impaired patients or patients living in care/nursing homes. This recommendation was therefore partly based on evidence and partly GDG consensus opinion.	
Other considerations	Patient selection, as defined above is very important for multidisciplinary ESD at home and may represent a very small number of eligible patients.	
	The benefits of MDR ESD in patient with mild to moderate cognitive impairment living at home alone or with a relative /carer are unknown. MDR ESD in this context may be beneficial and should be considered.	
	The benefits of MDR ESD in patients living in care /nursing homes are unknown. MDR ESD in these patients, undertaken alongside the care/nursing homes may be beneficial.	
	The GDG highlighted this recommendation as a key priority for implementation.	
Recommendation	Only consider intermediate care (continued rehabilitation in a community hospital or residential care unit) if all the following criteria are met:	
	• intermediate care is included in the Hip Fracture Programme	
	• the Hip Fracture Programme leads clinically; on patient selection, and in agreeing length of stay and objectives for intermediate care	
	• the Hip Fracture Programme leads managerially; ensuring that intermediate care is not resourced at the expense of the acute hospital's multidisciplinary team.	
	•	
Relative values of different outcomes	The GDG considered the most important outcomes to be length of stay in hospital (in particular superspell) and return to pre fracture residence.	
Trade off between clinical benefits and harms	There are risks that transfer to intermediate care may prematurely move a co-morbid patient group from a diagnostically supported environment, impair continuity, and prolong the superspell.	
	In certain settings and specific circumstances, proximity to home with access for relatives/carers visiting and a more relaxed and "homely" atmosphere for continued rehabilitation than the acute hospital might be considered advantageous.	
Economic considerations	The average weekly cost of the social care received in an intermediate care setting based in residential homes varies from a minimum of £412 to a maximum of £840 for schemes run by local authorities. The average weekly cost of social and health care	

	services in the same setting but for schemes run by the local authority in conjunction with primary care trusts amounts to £574 (source: PSSRU 2009 ⁵⁹). Subject to the criteria in the recommendation above, intermediate care may be feasible for our population, but there is currently no evidence on its cost- effectiveness.
Quality of evidence	There is no evidence on the effectiveness or cost-effectiveness of rehabilitation within a community hospital or residential care unit in hip fracture rehabilitation. This recommendation was based on GDG consensus opinion.
Other considerations	Intermediate care rehabilitation for hip fracture remains ill-defined and highly variable in the UK in terms of its admission criteria, multidisciplinary composition, intervention components and mechanisms for shared outcome and resource accountability within a comprehensive hip fracture programme.
Recommendation	Patients admitted from care or nursing homes should not be denied the benefits of a rehabilitation programme in the community, hospital or as part of an early supported discharge programme.
Relative values of different outcomes	The GDG considered the most important outcomes to be functional status, readmission to hospital and return to pre-fracture residence.
	Early assessment and MDR offered as part of a hip fracture programme with continued rehabilitation for patients admitted from care/nursing homes is likely to improve/maintain the patient's functional ability with regard to mobility, transfers from bed to chair and activities of daily living. This is in the interests of both patients and care/nursing home staff. In addition patient status as a care home resident as opposed to a nursing home resident may be maintained and equality for patients in care/nursing homes is maintained with regard to access to rehabilitation.
Trade off between clinical benefits and harms	There is no evidence of harm accruing to care/nursing home residents from the provision of appropriately individualised rehabilitation programmes.
	For some patients admitted from care/nursing homes there may be advantages (and no particular risks) in completing their rehabilitation after hospital MDR within that home (subject to the recommended criteria above), recognising that their rehabilitation goals may be more complex and must be shared by the HFP team on a continuing basis with the care/nursing home staff.
	The potential benefits of ESD for patients admitted from care/nursing homes include the possibility of functional recovery within the patient's familiar environment, shared communication,

	goal setting and collaboration between care/nursing home staff and HFP team resulting in improved functional outcome, and the possibility of reduced hospital stay and inappropriate hospital readmission.
	This subgroup is considered at particular risk of premature discharge because of ease of access to the care/nursing home environment and the corresponding perception that functional recovery matters less. Failure to undertake adequate rehabilitation carries the subsequent risk of inappropriate functional decline and/or levels of dependency, reduced quality of life, unnecessary hospital readmission, and premature mortality.
Economic considerations	There was no cost-effectiveness evidence. The GDG believe that any increase in the cost of hospital bed days from the avoidance of premature discharge should be at least partially offset by the avoidance of inappropriate readmissions and reduction in subsequent care costs resulting from optimised functional status.
Quality of evidence	No RCTs were identified regarding patients admitted from care or nursing homes undergoing community ESD, as this patient subgroup has typically been excluded from clinical trials. The recommendation is based on GDG opinion and consensus that this group of patients would benefit from ESD.
Other considerations	There is a high prevalence of cognitive impairment in this population, therefore realistic rehabilitation goals need to be defined, but not at the expense of excluding rehabilitation.

12.5 Research recommendations on community multidisciplinary

2 rehabilitation

3	12.5.1	Early supported discharge
4	The	GDG recommended the following research question:
5 6 7	2	What is the clinical and cost effectiveness of early supported discharge on mortality, quality of life and functional status in patients with hip fracture who are admitted from a care home?
8	Why	this is important
9 10 11 12 13 14 15 16 17 18	hosp hom prev third read reha repro	and nursing homes residents account for 30% of all hip fracture patients admitted to ital. Two thirds of these come from care homes and the remainder from nursing es. These patients are frailer, more functionally dependent and have a higher alence of cognitive impairment than patients admitted from their own homes. One of those admitted from a care home are discharged to a nursing home and 1/5th are mitted to hospital within 3 months. There are no clinical trials to define the optimal bilitation pathway following hip fracture for these patients and they therefore esent a discrete cohort where the existing meta-analyses do not apply. As a equence, many are denied structured rehabilitation and are returned back to their /nursing home with very little or no rehabilitation input.
19 20 21 22 23 24 25	clinic they appr wou prov	In the patient frailty and comorbidities, rehabilitation may have a limited effect on cal outcomes for this group. However, the fact that they already live in a home where are supported by trained care staff, clearly provides an opportunity for a systematic oach to rehabilitation. Early care/nursing home based multidisciplinary rehabilitation Id take advantage of the day-to-day care arrangements already in place in homes and ide additional NHS support to deliver naturalistic rehabilitation, where problems are ed in the setting in which the patient lives.
26 27 28	retu	r supported multidisciplinary rehabilitation could reduce hospital stay, improve early rn to function, and affect both readmission rates and the level of NHS-funded nursing required.
29 30 31 32 33 34 35 36 37	selec cons colla profe inter latte hom	research would follow a two-stage design: (1) An initial feasibility study to refine the ction criteria and process for reliable identification and characterisation of those idered most likely to benefit, together with the intervention package and measures for boration between the HFP team, care-home staff and other community-based essionals, and (2) A cluster randomized controlled comparison (with, say, two or more vention units and matched control units) set against agreed outcome criteria. The r should include those specified above, together with measures of the impact on care- e staff activity and cost, as well as qualitative data from patients on relevant quality-of- rariables.

38 12.5.2 Care/nursing home residents

The GDG recommended the following research question:

Do patients admitted to hospital with a fractured hip who live permanently in a care/nursing home have equal access to multidisciplinary rehabilitation as patients admitted from their own homes?

Why this is important

5 The existing literature on the effectiveness of multidisciplinary rehabilitation typically 6 excludes patients who live in care/nursing homes. From an equality perspective it 7 hypothesised that this group of people do not have access to the same multidisciplinary 8 rehabilitation as patients who are returning home as it is assumed patients returning to 9 care/nursing homes will have their care needs met by the home. The research design would 10 be a prospective observational cohort study to determine the extent and quality of 11 rehabilitation services available to this group in comparison to patients returning to their 12 own homes.

3

4

13 Patient and carer views and information

2 13.1 Introduction

3	Patient views about their hip fracture and its management, and the way patients are
4	provided with information are important elements of the natural recovery and treatment of
5	hip fracture. Care givers also have need for information, and can influence the recovery
6	process. Timely and clear information could reduce stress and uncertainty for patients and
7	potentially improve their outcome. This section examines the literature on patient views

8 and the provision of information to patients.

9 13.2 Patient and carer views

- A systematic literature review was conducted into the views of patients and carers about
 their experience of hip fracture management from hospital admission until discharge from
 rehabilitation. Studies examining areas not covered by the guideline scope were not
 included. For example, hip protectors for falls management, nutrition support or patient
 views relating to the time after discharge from rehabilitation programmes.
- 15 The aim of this review was to provide:
- Supplementary evidence to clinical questions addressed in the guideline
 - A general overview of patients views' on hip fracture and hip fracture management
 - Evidence relating to the provision of information to patients and carers

Eleven qualitative studies are included here, only two of which are UK based studies. More
 details about the studies are presented in the evidence table (Evidence table 12 in
 Appendix E). Studies were assessed using the NICE methodology checklist for qualitative
 studies²²⁷.

Archibald et al (2003)⁸ conducted a qualitative study of 5 hip fracture patients in a community hospital in the UK. Their aim was to explore experiences of individuals who had suffered a hip fracture. Interviews with open ended questions were conducted during their stay in hospital.

Four main themes were identified: injury experience, pain experience, recovery experience, disability experience. Only the pain and recovery experience relate to their time in hospital and rehabilitation. Most patients described the pain they experienced, one mentioned being in a lot of pain in the orthopaedic unit despite pain killers. Another mentioned they thought the pain went with rest after a while, but not completely. Only 1 person was still having pain at time of interview. The recovery experience was split into 3 sequential categories: the operation, beginning the struggle and regaining independence. Only 1

person described the operation, they had a "horrendous" recollection of a noisy operating
theatre, like being in an engineering shop or something". Three patients remembered
'beginning the struggle': they reported not being able to do anything; struggling to get to
the toilet and into a chair; and hating using a bed pan. The comments relating to regaining
independence were all positive. Motivation, be it getting to the toilet, the dining room or
smoke room was found to be a key factor in the recovery of the patients.

Borkan et al (1991 & 1992)^{28,29} conducted a qualitative study of 80 hip fracture patients in 4 hospitals in the USA. Their aim was to investigate the meanings of hip fracture to older patients, and to identify potentially important prognostic indicators or risk factors for rehabilitation outcomes. Patients were interviewed during the first week after hip fracture with a combination of open-ended and multiple choice questions.

- 12 The study reports how patients perceive their fracture, their perception of their disability 13 and whether they were hopeful for the future (see evidence table). Also reported were 14 patient expectations of recovery (43 expected full recovery, 14 partial recovery and the rest 15 did not know or did not give an answer) and patient expectations about their living 16 situation (61% predicted going home, 15% into a nursing home though none came from 17 one, 9% predicted being discharged to their children's houses and 15% did not know or did 18 not respond). The actual figures showed that 43% were discharged to long term care 19 institutions, of these 38% remained in the institution at 1 year, 53% returned home and 9% 20 died.
- 21 **Bowman (1997)**³³ conducted a quantitative study of 43 patients undergoing surgery on the 22 hip in a hospital in Canada, 17 of these had a hip fracture. The main aim was to describe 23 sleep satisfaction, pain perceptions and psychological concerns of patients undergoing hip 24 operations. Also two open ended questions were asked at the time of admission to 25 elucidate the patient's biggest concerns about their injury and forthcoming surgery, and 26 whether they had concerns about their ability to recover fully and quickly. The mean age of 27 hip fracture patients was 80 years old and, unlike most the other studies, it also included 28 patients with delirium (8 out of 17). Six out of 17 patients feared being unable to walk 29 again, an additional 3 out of 17 were concerned about their recovery and managing on 30 their own.
- Fustenberg (1986)¹⁰³ conducted a qualitative study of 11 patients of hospitalised patients
 with hip fracture in a hospital in the USA. The aim of the study was to "construct a natural
 history of the hip fracture", from the events surrounding the hip fracture through the
 hospitalisation period. Ethnographic interviews were carried out at one or more points
 during their hospital stay.
- The findings were split into two main sets: immediate patient expectations about their recovery and "contextual factors" to the evolving expectations about their recovery. The immediate expectations mostly included expressions of despair and discouragement: hip fracture was going to result in extended period of slow recovery of function, with attendant dependency, postponement or relinquishment of plans and changed living situation with the threat of permanent loss of independent living. Participants also suffered uncertainty about timing and completeness of return to full recovery
- As time progressed participants commented that although progress was slow they could
 see improvements. They also took encouragement from other people's recovery. The study
 notes that while patients could focus on positive and negative points, the participants only
 focused on encouraging examples.

The study also reports that healthcare professionals' cues, encouragement and feedback guided the participants' perceptions about their own progress. However, some participants "referred to the elusiveness of the doctors and their own unanswered questions."

Olsson et al (2007)²⁴¹ conducted a qualitative study of 13 hospitalised patients in Sweden.
 The aim of the study was to describe patient's own perceptions of their situation and views
 of their responsibility in the rehabilitation process. Interviews were conducted with semi structured questions as soon after the operation as the patients felt strong enough.

8 The study categorised the findings into different conceptions: 'autonomous' – responses 9 from people who appeared confident and accustomed to managing on their own; 'modest' 10 responses from people who gave the impression of being vulnerable and dependent on 11 others, this group worried about their future more than the others; 'heedless' - responses 12 from people who appeared to have a sense of detachment. The heedless did not doubt 13 they would recover and that people around them would care for them. This group was 14 characterised predominantly by a reluctance to reflect on their own situation, by a refusal 15 to accept responsibility and by their need for information.

- 16 The study also identified some common traits: a lack of awareness - most patients lacked 17 awareness about their condition, what to do and how to act, and needed more 18 information; a shocking event - although several suspected they had a fracture all were 19 distressed by the diagnosis. The period before surgery was mostly blurred and filled with 20 fear and pain. The participants worried about how they would function postoperatively; 21 zest for life - all expressed a strong desire to recuperate although, while confined to bed 22 they worried about the pain, their inability to move their leg, their forthcoming operation 23 and the fear of being unable to walk again.
- Pownall 2004²⁶⁶ conducted a critical appraisal of a 60 year old women's experience with hip
 fracture in a UK hospital. The study was undertaken in an effort to understand further the
 nature of personal experience. Narrative was acquired as part of a routine nursing
 evaluation and helped to illuminate nursing care issues through the eyes of the patient. The
 participant was interviewed prior to discharge with four open-ended questions.
- The study identified three areas for improvement within the hospital: better communication skills; time management for staff so time spent with the patient is used effectively; and better pain management. The participant's comments included not understanding why they had to wait so long in the Emergency department after the x-ray as they had already been told their hip was fractured; staff were so busy, no one had time to sit and explain things to her; concern that the operation was explained to her son but not her; shock at being mobilised the day after surgery.
- Slauenwhite and Simpson (1998)³⁰⁶ conducted a qualitative study of 23 "caregivers" for 23
 patients who had experienced hip fracture in Canada. The purpose of the study was to
 investigate the impact of enhanced early discharge on families experiencing a repaired hip
 fracture in an older adult. "Caregivers" were interviewed 4 to 6 weeks after discharge.
- 40 The length of stay was considered too long by the patient with the fracture and too short by 41 the carer for families. 15 out of the 23 families found length of stay not an issue. 20 of the 42 families stated pain management was not a problem in hospital or at home. Several 43 families thought the transition from hospital to home was a problem as it took several 44 hours to days for all the information to be relayed to home care system. This went hand in 45 hand for those with comorbidities. Many caregivers had stories of dissatisfaction which was 46 suggested to be related to health care system and mismatched care. Mismatched care was 47 not well defined.

1

2

- Williams et al (1994)³⁴⁵ conducted a study into patient recovery and views for 120 patients
 after hospital discharge in the USA. Participants were asked what advice they would offer
 to other patients who had just fractured their hip. Patients were interviewed at 14 weeks
 after discharge.
- 5 The advice offered was grouped into categories: 94 patients emphasised the importance of 6 mental attitude with comments such as patients should "maintain hope" and "look to the 7 future"; 76 patients suggested that following experts' advice; 34 advised mobility was key 8 with comments such as keep mobile, rest before getting up to walk, use walker to help get 9 up; 15 advised maintain healthy lifestyle; 7 said use caution and be careful not to fall; 3 10 suggested limiting stay in institution and get help to be at home if possible; and 6 gave no 11 specific advice as they commented that everyone is different.
- Wykes et al (2009)³⁴⁶ conducted a qualitative pilot study to explore the impact of hip
 fracture on the lives of previously independent women and to identify their concerns when
 participating in inpatient rehabilitation. Five patients were interviewed during their stay in a
 rehabilitation hospital in Australia.
- 16 The impact of the fracture was an issue for all five women as others had to assume 17 responsibility for things they had done previously. The study categorised the women's 18 concerns into four categories: the behaviour of others; what was happening to them; the 19 impact of their injury on others; and other health issues. A few comments were raised 20 about the behaviour of others including things others said and did, friends and family doing 21 things without asking first, the family not being told when one woman had moved hospital, 22 concern that staff expect one woman's daughter to look after her until rehabilitation 23 started. Concerns about what was happening to them included a possible loss of 24 independence, possible accommodation changes after discharge and money issues. The 25 women were also concerned about inconveniencing or upsetting others by telling them 26 what they were feeling or asking too many questions. Two women had pre-existing health 27 issues which, combined with their hip fracture, had adverse effects on their outcome. These 28 overshadowed specific concerns about their hip fracture.
- Young and Resnick (2009)³⁴⁹ conducted a qualitative study to explore the perceptions of 62
 older adults regarding their functional recovery 1 year after hip fracture and after
 participating in rehabilitation programme in the USA. Participants were asked whether they
 were satisfied with their functional recovery, what helped or hindered recovery, what
 would improve recovery and what one piece of advice they would offer other hip fracture
 patients. The themes identified are listed below.
- 35 53 participants were satisfied with their functional recovery. The main factors they listed as 36 facilitators of recovery were seeing health care professionals and their positive attitude (40 37 respondents); social support, particularly from family and friends (13 respondents); and 38 their own determination (12 respondents). Other factors mentioned included lifestyle 39 factors or an environment that encourage healthy living, individualised care & verbal 40 encouragement; spirituality and identifying goals. The nine people who were dissatisfied 41 with their recovery listed medical complications or comorbidities, unpleasant sensations 42 and age as factors that hindered their recovery.
- The respondents also identified areas that would facilitate recovery: more direct physical &
 occupational therapy and more education about the recovery process and ways to optimise
 physical function (26 respondents); better follow up and care in the home setting after
 discharge from rehabilitation (9 respondents); spirituality (3 respondents), social support (2
 respondents); additional information (8 respondents); elimination of unpleasant sensations
 (4 respondents) and policy (1 respondent).

1 The patients also offered the following advice on how to facilitate recovery to anyone with 2 a hip fracture: listen to healthcare instructions (19 respondents) and participate as much as 3 possible in rehabilitation activities (48 respondents); participants strongly recommended 4 that older adults who sustain hip fractures maintain a positive attitude (20 respondents) 5 and remain determined throughout the recovery experience (13 respondents); be careful 6 to avoid subsequent trauma and prevent anything that would impede recovery (8 7 respondents); push through the pain and use all medication offered (6 respondents); and 8 don't worry (4 respondents).

2 Ziden et al (2008 & 2010)^{353,354} conducted a qualitative study to explore and describe the
 consequences of an acute hip fracture among home dwelling elderly people shortly after
 discharge from hospital in Sweden. Patients, who had participated in a randomised
 controlled trial investigating rehabilitation³⁵¹ included in the rehabilitation chapter (Section
 12.2), attended semi-structured interviews at 1 month and 1 year after hip fracture.

14 The study identified different responses or perceptions over time. At 1 month patients: 15 found they were limited in movement and have lost confidence in their body (18 people); 16 had become humble and grateful (7 people); respected themselves and their own needs (2 17 people); had become more dependent on others (12 people); gain more human contact 18 and are treated in a friendly way by others (2 people); were secluded and trapped at home 19 (4 people); were old, closer to death and have lost your zest for life (4 people); were taking 20 one day at a time and were uncertain about the future (7 people). At 1 year after discharge 21 patients felt: more insecure and afraid (11 patients); they had more limited ability to move 22 (12 patients); disappointed and sad that identity and life have changed (8 patients); 23 satisfied with the situation or felt even better than before their fracture (5 patients).

The study also identified some patient views about determinants of hip fracture recovery:
 10 patients stated their own mind and actions influenced recovery; 4 patients stated that
 treatment and the actions from others influenced recovery; whereas 6 patients stated you
 cannot influence recovery.

28

37

39

41

29 **13.2.2** Common themes

30 The following themes have been identified from the studies:

31 Initial outlook in hospital

Five studies with 126 participants reported views from this period ^{8,28,29,33,103,241}. One of the studies reported the responses varied "from stubborn optimism to despair"^{28,29}. Another
 study also reported all 13 participants expressed a strong desire to recuperate ²⁴¹. However,
 most of the expressions were negative with no positive comments reported in the papers.
 The concerns covered:

- pain and the inability to move their leg while confined to bed
- the fear of being unable to walk
 - not being able to do anything
- 40 hating using a bed pan
 - struggling to get out of the chair or bed
- 42 concern about recovery and managing on their own
- return to independent living
- limitations on their functioning and consequent implications
- being burden on their "caretakers" [families and carers]

- 1 further falls ٠ 2 uncertainty about timing and completeness of return to full recovery 3 Attitude as patients began to regain independence 4 Two studies reported comments relating to this period. 5 Archibald (2003)⁸ with 5 participants reported motivation to be key factor in recovery. 6 All comments in the study were positive about regaining independence during their 7 rehabilitation. In Furstenberg (1986)¹⁰³ (11 participants) participants commented that although 8 • 9 progress was slow they could see improvement. Participants also took encouragement 10 from others' progress. 11 Management by health care professionals 12 Positive and negative comments were reported about healtcare professionals: Encouragement and positive attitude - Furstenberg (1986)¹⁰³ (11 participants) reported 13 14 that healthcare professionals' cues, encouragement and feedback guided the 15 informants' perceptions about their own progress. 40 out of the 62 participants in Young (2009)³⁴⁹ identified that communication and a positive attitude by professionals 16 17 were seen as a facilitator of recovery. 18 Provision of information to patients - Two studies also noted some negative points, • 19 some patients "referred to the elusiveness of the doctors and their own unanswered 20 questions." in Furstenberg (1986)¹⁰³. The woman with a hip fracture in the individual 21 patient narrative ²⁶⁶ was unhappy that things were not explained to her. One of her 22 comments highlighted this where she reported that the "staff were so busy no one has 23 time to sit and explain things to you". 24 Explaining directly to patients - The patient from the individual narrative ²⁶⁶ was also • 25 unhappy that she could hear the nurse explaining the operation to her son, but 26 nothing was explained to her. 27 28 13.2.3 Recommendations and link to evidence
- Overall, little evidence was identified that provided direct comments relating to our review
 questions. Where applicable data were identified, reference to the evidence has been
 made in the link to evidence of the relevant recommendations. These related to:
- Several comments were identified that fed into our recommendation relating to the
 provision of information to patients (see next section 13.3).
- Some supplementary evidence was identified relating to pain that fed into our analgesia recommendations (see section 7.2.2).
- 36

1 13.3 Information for patients

This section covers structured health education approaches, advice, information and
 reassurance. In addition to qualitative literature the search conducted for patient views
 included terms relating to patient education interventions. This also aimed to identify
 randomised controlled trials investigating the effectiveness of different ways of providing
 information to patients with hip fracture in improving outcomes.

7 13.3.1 Evidence

- 8 No randomised evidence was identified. However, good quality advice, reassurance,
 9 information and education were highlighted by patients as important to the recovery
 10 process in the qualitative review presented above.
- 11 The evidence above suggests that
- The positive attitude of and encouragement by health professionals is important
- Patients value time spent with them, and the advice and explanation given. This seems
 important in the recovery process
- Patients should be treated with dignity, and provided with an explanation about their
 condition and information about recovery.
- Two studies asked participants to suggest what advice they would offer other hip fracture
 patients based on their experiences. The main advice by participants in the studies to other
 patients with hip fracture was:
- Maintain a positive attittude
- Follow experts advice and participate as much as possible in the rehabilitation process
- Keep mobile

23 13.3.2 Recommendations and link to evidence

24

Recommendation	Offer patients and their families and carers verbal and written information about treatment and care including:		
	diagnosis		
	choice of anaesthesia		
	choice of analgesia and other medications		
	surgical procedures		
	possible complications		
	post-operative care		
	rehabilitation programme		
	likely long-term outcome		
	healthcare professionals involved.		
	•		
Relative values of different outcomes	Patient views on their satisfaction with the management of their condition were the main outcomes.		
Trade off between clinical benefits and harms	The data highlighted examples where information was not provided to individual patients. Patients were unhappy when things were not explained to them. Patients were also unhappy when issues about their fracture were discussed with their family members instead of directly to them.		
	The themes that came out of the evidence suggest that: a positive attitude of healthcare professionals is important; patients value time spent with them, and the advice and explanation given; and patients should be treated with dignity, and provided with an explanation about their condition and information about recovery.		
	The GDG were unanimous in their view that discussion with patients (and where necessary their carers) about all aspects of the management of their hip fracture in is an important contributory factor in the recovery process.		
Economic considerations	Although staff time is a scarce resource, information can be passed on to patients in the course of usual care and therefore needn't increased costs. Furthermore there may be benefits from greater adherence to treatment plans.		
Quality of evidence	The qualitative evidence identified was of mixed quality. Data were not identified covering all the points mentioned above.		
Other considerations	No comments were identified in the studies mentioning that adequate or good information was provided. However, the studies did not specifically ask about the quality of the information provided.		

1 13.4 Carer involvment

In patients who have been discharged after hip fracture repair, what is the effectiveness of having a non paid carer (e.g. spouse, relative or friends) on mortality, length of stay, place of residence/discharge, functional status, hospital readmission and quality of life?

No published evidence was identified. The GDG recognised the often crucial and sometimes
major contribution made by involved relatives and other non-professional carers to
successful rehabilitation. Early discussion with carers of prognosis and discharge planning
avoids misunderstanding of rehabilitation objectives, enables those involved to prepare in
an informed and timely manner for a patient's return home, consequently averts
inappropriate delay in discharge, and may reduce both length of stay and the likelihood of
inappropriate readmission to hospital.

13

22

26

27

2

3

4

There is the potential for the delay of some decisions with this approach and it remains
 incumbent on clinicians with the agreement of patients (and/or any nominated proxy) to
 ensure that their best interests are correctly identified and not compromised, particularly
 (but not exclusively) in any urgent decision-making situation.

18 13.4.1 Clinical evidence

19 No relevant studies were identified.

20 13.4.2 Economic evidence

- 21 No relevant studies were identified.
- 23 13.5 Research recommendations

24 **13.5.1** Quality of life

- 25 The GDG recommended the following research question:
 - What quality of life value do individual patients and their carers place on different mobility, independence and residence states following rehabilitation?

28 Why this is important

It is important in evaluating future priorities for intervention to determine whether the
 perceived clinical and health economic benefits of rehabilitation outcomes in the research
 literature are matched over the same time-frame by the quality of life judgements,
 aspirations and expectations of patients themselves and their carers. There is currently no
 evidence.

34 13.5.2 Patient experience

- 35 The GDG recommended the following research question:
- What is the patient's experience of being admitted to hospital with a hip fracture in
 relation to surgery, pain management, timeliness of information given, and
 rehabilitation?

1

2

Why this is important

No studies from NHS populations were identified where patients commented specifically on their surgery, their pain management and rehabilitation programme. There were comments in the patient views studies about not being kept informed about the management of their condition, however, there was no information identified about the appropriate time to be told. It may be that different patients want the information at different times. The studies suggest that patients suffer from fear, pain and delirium until after surgery and it is important to learn what (if anything) can be done to alleviate this which for many will be considered the worst stage in their treatment.

1 Glossary

Abstract	Summary of a study, which may be published alone or as an introduction to a full scientific paper.
Algorithm (in guidelines)	A flow chart of the clinical decision pathway described in the guideline, where decision points are represented with boxes, linked with arrows.
Allocation concealment	The process used to prevent advance knowledge of group assignment in a RCT. The allocation process should be impervious to any influence by the individual making the allocation, by being administered by someone who is not responsible for recruiting participants.
AO classification	Classification system used to describe stable trochanteric fractures (type A1), unstable trochanteric (type A2), and transtrochanteric which includes those fracture lines at the level of the lesser trochanter and reversed fracture lines (type A3) ²¹⁷ .
Applicability	The degree to which the results of an observation, study or review are likely to hold true in a particular clinical practice setting.
Arm (of a clinical study)	Sub-section of individuals within a study who receive one particular intervention, for example placebo arm.
Association	Statistical relationship between two or more events, characteristics or other variables. The relationship may or may not be causal.
Baseline	The initial set of measurements at the beginning of a study (after run-in period where applicable), with which subsequent results are compared.
Before-and-after study	A study that investigates the effects of an intervention by measuring particular characteristics of a population both before and after taking the intervention, and assessing any change that occurs.
Bias	Systematic (as opposed to random) deviation of the results of a study from the 'true' results that is caused by the way the study is designed or conducted.
Blinding	Keeping the study participants, caregivers, researchers and outcome assessors unaware about the interventions to which the participants have been allocated in a study.

Carer (caregiver)	Someone other than a health professional who is involved in caring for a person with a medical condition.
Case-control study	Comparative observational study in which the investigator selects individuals who have experienced an event (For example, developed a disease) and others who have not (controls), and then collects data to determine previous exposure to a possible cause.
Case-series	Report of a number of cases of a given disease, usually covering the course of the disease and the response to treatment. There is no comparison (control) group of patients.
Clinical efficacy	The extent to which an intervention is active when studied under controlled research conditions.
Clinical effectiveness	The extent to which an intervention produces an overall health benefit in routine clinical practice.
Clinician	A healthcare professional providing direct patient care, for example doctor, nurse or physiotherapist.
Cochrane Review	The Cochrane Library consists of a regularly updated collection of evidence-based medicine databases including the Cochrane Database of Systematic Reviews (reviews of randomised controlled trials prepared by the Cochrane Collaboration).
Cohort study	A retrospective or prospective follow-up study. Groups of individuals to be followed up are defined on the basis of presence or absence of exposure to a suspected risk factor or intervention. A cohort study can be comparative, in which case two or more groups are selected on the basis of differences in their exposure to the agent of interest.
Comorbidity	Co-existence of more than one disease or an additional disease (other than that being studied or treated) in an individual.
Community hospital	A local hospital, unit or centre providing an appropriate range and format of accessible health care facilities and resources. These are typically small, and provide non-emergency services.
Comparability	Similarity of the groups in characteristics likely to affect the study results (such as health status or age).
Concordance	This is a recent term whose meaning has changed. It was initially applied to the consultation process in which doctor and patient agree therapeutic decisions that incorporate their respective views, but now includes patient support in medicine taking as well as prescribing communication. Concordance reflects social values but does not address medicine-taking and may not lead to improved adherence.
Confidence interval (CI)	A range of values for an unknown population parameter with a stated 'confidence' (conventionally 95%) that it contains the true value. The interval is calculated from sample data, and generally straddles the sample estimate. The 'confidence' value means that if the method used

	to calculate the interval is repeated many times, then that proportion of intervals will actually contain the true value.
Confounding	In a study, confounding occurs when the effect of an intervention on an outcome is distorted as a result of an association between the population or intervention or outcome and another factor (the 'confounding variable') that can influence the outcome independently of the intervention under study.
Consensus methods	Techniques that aim to reach an agreement on a particular issue. Consensus methods may used when there is a lack of strong evidence on a particular topic.
Control group	A group of patients recruited into a study that receives no treatment, a treatment of known effect, or a placebo (dummy treatment) - in order to provide a comparison for a group receiving an experimental treatment, such as a new drug.
Cost benefit analysis	A type of economic evaluation where both costs and benefits of healthcare treatment are measured in the same monetary units. If benefits exceed costs, the evaluation would recommend providing the treatment.
Cost-consequences analysis (CCA)	A type of economic evaluation where various health outcomes are reported in addition to cost for each intervention, but there is no overall measure of health gain.
Cost-effectiveness analysis (CEA)	An economic study design in which consequences of different interventions are measured using a single outcome, usually in 'natural' units (For example, life-years gained, deaths avoided, heart attacks avoided, cases detected). Alternative interventions are then compared in terms of cost per unit of effectiveness.
Cost-effectiveness model	An explicit mathematical framework, which is used to represent clinical decision problems and incorporate evidence from a variety of sources in order to estimate the costs and health outcomes.
Cost-utility analysis (CUA)	A form of cost-effectiveness analysis in which the units of effectiveness are quality-adjusted life-years (QALYs).
Credible Interval	The Bayesian equivalent of a confidence interval.
Lag screw cut-out	A complication in which the implant may protrude into the surrounding tissue or penetrate into the acetabulum. Symptoms include increasing pain and impaired mobility; and treatment depends on the severity of the symptoms as well as the fitness of the patient to undergo what may be major revision surgery. It may take the form of re-fixation of the fracture, replacement arthroplasty, or simple removal of the implant.

Decision analysis	An explicit quantitative approach to decision making under uncertainty, based on evidence from research. This evidence is translated into probabilities, and then into diagrams or decision trees which direct the clinician through a succession of possible scenarios, actions and outcomes.
Discounting	Costs and perhaps benefits incurred today have a higher value than costs and benefits occurring in the future. Discounting health benefits reflects individual preference for benefits to be experienced in the present rather than the future. Discounting costs reflects individual preference for costs to be experienced in the future rather than the present.
Dominance	An intervention is said to be dominated if there is an alternative intervention that is both less costly and more effective.
Drop-out	A participant who withdraws from a trial before the end.
Early Supported Discharge (ESD)	Patients are discharged home from the acute trauma ward, or in some cases a subsequent rehabilitation ward within the hospital, with a supported 4-6 week rehabilitation package.
Economic evaluation	Comparative analysis of alternative health strategies (interventions or programmes) in terms of both their costs and consequences.
Effect (as in effect measure, treatment effect, estimate of effect, effect size)	The observed association between interventions and outcomes or a statistic to summarise the strength of the observed association.
Effectiveness	See 'Clinical effectiveness'.
Efficacy	See 'Clinical efficacy'.
Epidemiological study	The study of a disease within a population, defining its incidence and prevalence and examining the roles of external influences (For example, infection, diet) and interventions.
EQ-5D (EuroQol-5D)	A standardise instrument used to measure a health outcome. It provides a single index value for health status.
Evidence	Information on which a decision or guidance is based. Evidence is obtained from a range of sources including randomised controlled trials, observational studies, expert opinion (of clinical professionals and/or patients).
Exclusion criteria (literature review)	Explicit standards used to decide which studies should be excluded from consideration as potential sources of evidence.
Exclusion criteria (clinical study)	Criteria that define who is not eligible to participate in a clinical study.

Extended dominance	If Option A is both more clinically effective than Option B and has a lower cost per unit of effect, when both are compared with a do- nothing alternative then Option A is said to have extended dominance over Option B. Option A is therefore more efficient and should be preferred, other things remaining equal.
Extramedullary implant	Implants used to fix extracapsular fractures. Examples of extramedullary implants include the sliding hip screw and the Medoff plate.
Extrapolation	In data analysis, predicting the value of a parameter outside the range of observed values.
Follow-up	Observation over a period of time of an individual, group or initially defined population whose appropriate characteristics have been assessed in order to observe changes in health status or health-related variables.
Generalisability	The extent to which the results of a study based on measurement in a particular patient population and/or a specific context hold true for another population and/or in a different context. In this instance, this is the degree to which the guideline recommendation is applicable across both geographical and contextual settings. For instance, guidelines that suggest substituting one form of labour for another should acknowledge that these costs might vary across the country.
Gold standard	See 'Reference standard'.
Geriatric Orthopaedic Rehabilitation Unit (GORU)	A separate geriatrician-led trauma ward. The extent of surgical input to the GORU varies, depending on how early patients are moved from the acute trauma wards.
GRADE / GRADE profile	A system developed by the GRADE Working Group to address the shortcomings of present grading systems in healthcare. The GRADE system uses a common, sensible and transparent approach to grading the quality of evidence. The results of applying the GRADE system to clinical trial data are displayed in a table known as a GRADE profile.
GRADE / GRADE profile Harms	shortcomings of present grading systems in healthcare. The GRADE system uses a common, sensible and transparent approach to grading the quality of evidence. The results of applying the GRADE system to
	shortcomings of present grading systems in healthcare. The GRADE system uses a common, sensible and transparent approach to grading the quality of evidence. The results of applying the GRADE system to clinical trial data are displayed in a table known as a GRADE profile.
Harms	shortcomings of present grading systems in healthcare. The GRADE system uses a common, sensible and transparent approach to grading the quality of evidence. The results of applying the GRADE system to clinical trial data are displayed in a table known as a GRADE profile. Adverse effects of an intervention. The study of the allocation of scarce resources among alternative healthcare treatments. Health economists are concerned with both increasing the average level of health in the population and improving

	treatment from separate studies seem to be very different – in terms of the size of treatment effects or even to the extent that some indicate beneficial and others suggest adverse treatment effects. Such results may occur as a result of differences between studies in terms of the patient populations, outcome measures, definition of variables or duration of follow-up.
Hip fracture programme (HFP)	Formal 'orthogeriatric' care - with the geriatric medical team contributing to joint pre-operative patient assessment, and increasingly taking the lead in post-operative medical care, MDR and discharge planning.
Imprecision	Results are imprecise when studies include relatively few patients and few events and thus have wide confidence intervals around the estimate of effect.
Inclusion criteria (literature review)	Explicit criteria used to decide which studies should be considered as potential sources of evidence.
Incremental analysis	The analysis of additional costs and additional clinical outcomes with different interventions.
Incremental cost	The mean cost per patient associated with an intervention minus the mean cost per patient associated with a comparator intervention.
Incremental cost effectiveness ratio (ICER)	The difference in the mean costs in the population of interest divided by the differences in the mean outcomes in the population of interest for one treatment compared with another.
	$ICER = \frac{\operatorname{Cost}_{A} - \operatorname{Cost}_{B}}{\operatorname{Effectiven}_{B} - \operatorname{Effectiven}_{B} - \operatorname{Effectiven}_{B}}$
Incremental net benefit (INB)	The value (usually in monetary terms) of an intervention net of its cost compared with a comparator intervention. The INB can be calculated for a given cost-effectiveness (willingness to pay) threshold. If the threshold is £20,000 per QALY gained then the INB is calculated as: (£20,000 x QALYs gained) – Incremental cost.
Indirectness	The available evidence is different to the review question being addressed, in terms of PICO (population, intervention, comparison and outcome).
Intention to treat analysis (ITT)	A strategy for analysing data from a randomised controlled trial. All participants are included in the arm to which they were allocated, whether or not they received (or completed) the intervention given to that arm. Intention-to-treat analysis prevents bias caused by the loss of participants, which may disrupt the baseline equivalence established by randomisation and which may reflect non-adherence to the protocol.
Intermediate care	Care provided in community hospitals or residential care units as an intermediate step between hospital care and care in a person's own home

Intervention	Healthcare action intended to benefit the patient, for example, drug treatment, surgical procedure, psychological therapy.		
Intraoperative	The period of time during a surgical procedure.		
Intramedullary implant	Implants used to fix extracapsular fractures. Examples of intramedullary implants are the Gamma nail, the intramedullary hip screw and the proximal femoral nail.		
Kappa statistic	A statistical measure of inter-rater agreement that takes into account the agreement occurring by chance.		
Length of stay	The total number of days a participant stays in hospital.		
Licence	See 'Product licence'.		
Life-years gained	Mean average years of life gained per person as a result of the intervention compared with an alternative intervention.		
Likelihood ratio	The likelihood ratio combines information about the sensitivity and specificity. It tells you how much a positive or negative result changes the likelihood that a patient would have the disease. The likelihood ratio of a positive test result (LR+) is sensitivity divided by 1- specificity.		
Long-term care	Care in a home that may include skilled nursing care and help with everyday activities. This includes nursing homes and care homes.		
Loss to follow-up	Also known as attrition. The loss of participants during the course of a study. Participants that are lost during the study are often call dropouts.		
Markov model	A method for estimating long-term costs and effects for recurrent or chronic conditions, based on health states and the probability of transition between them within a given time period (cycle).		
Meta-analysis	A statistical technique for combining (pooling) the results of a number of studies that address the same question and report on the same outcomes to produce a summary result. The aim is to derive more precise and clear information from a large data pool. It is generally more reliably likely to confirm or refute a hypothesis than the individual trials.		
Mixed Assessment and Rehabilitation Unit (MARU)	A rehabilitation unit able to accept patients with a variety of medical, surgical and orthopaedic conditions.		
Mobilisation	Mobilisation is the process of re-establishing the ability to move between postures (for example sit to stand), maintain an upright posture, and to ambulate with increasing levels of complexity (speed, changes of direction, dual and multi-tasking).		

Multidisciplinary rehabilitation (MDR)	Rehabilitation after hip fracture incorporating the following core components of assessment and management: medicine; nursing; physiotherapy; occupational therapy; social care. Additional components may include: dietetics, pharmacy, clinical psychology.
Multivariate model	A statistical model for analysis of the relationship between two or more predictor (independent) variables and the outcome (dependent) variable.
Negative predictive value (NPV)	[In screening/diagnostic tests:] A measure of the usefulness of a screening/diagnostic test. It is the proportion of those with a negative test result who do not have the disease, and can be interpreted as the probability that a negative test result is correct. It is calculated as follows: $NPV = \frac{(\text{specificity})(1 - \text{prevalence})}{(\text{specificity})(1 - \text{prevalence}) + (1 - \text{sensitivity})(\text{prevalence})}$
Non-union	The terms non-union, pseudarthrosis or delayed union are used for those fractures that fail to heal after a few months.
Number needed to treat (NNT)	The number of patients that who on average must be treated to prevent a single occurrence of the outcome of interest.
Observational study	Retrospective or prospective study in which the investigator observes the natural course of events with or without control groups; for example, cohort studies and case–control studies.
Odds ratio	A measure of treatment effectiveness. The odds of an event happening in the treatment group, expressed as a proportion of the odds of it happening in the control group. The 'odds' is the ratio of events to non- events.
Opportunity cost	The loss of other health care programmes displaced by investment in or introduction of another intervention. This may be best measured by the health benefits that could have been achieved had the money been spent on the next best alternative healthcare intervention.
Orthogeriatrician	A care of the elderly physician with an interest in fracture care.
Outcome	Measure of the possible results that may stem from exposure to a preventive or therapeutic intervention. Outcome measures may be intermediate endpoints or they can be final endpoints. See 'Intermediate outcome'.

P-value	The probability that an observed difference could have occurred by chance, assuming that there is in fact no underlying difference between the means of the observations. If the probability is less than 1 in 20, the P value is less than 0.05; a result with a P value of less than 0.05 is conventionally considered to be 'statistically significant'.
Perioperative	The period from admission through surgery until discharge, encompassing the pre-operative and post-operative periods.
Placebo	An inactive and physically identical medication or procedure used as a comparator in controlled clinical trials.
Polypharmacy	The use or prescription of multiple medications.
Positive predictive value (PPV)	In screening/diagnostic tests: A measure of the usefulness of a screening/diagnostic test. It is the proportion of those with a positive test result who have the disease, and can be interpreted as the probability that a positive test result is correct. It is calculated as follows: $PPV = \frac{(\text{sensitivity})(\text{prevalence})}{(\text{sensitivity})(\text{prevalence}) + (1 - \text{specificity})(1 - \text{prevalence})}$
Postoperative	Pertaining to the period after patients leave the operating theatre, following surgery.
Post-test probability	For diagnostic tests. The proportion of patients with that particular test result who have the target disorder (post test odds/[1 + post-test odds]).
Power (statistical)	The ability to demonstrate an association when one exists. Power is related to sample size; the larger the sample size, the greater the power and the lower the risk that a possible association could be missed.
Preoperative	The period before surgery commences.
Pre-test probability	For diagnostic tests. The proportion of people with the target disorder in the population at risk at a specific time point or time interval. Prevalence may depend on how a disorder is diagnosed.
Primary care	Healthcare delivered to patients outside hospitals. Primary care covers a range of services provided by general practitioners, nurses, dentists, pharmacists, opticians and other healthcare professionals.
Primary outcome	The outcome of greatest importance, usually the one in a study that the power calculation is based on.
Product licence	An authorisation from the MHRA to market a medicinal product.
Prognosis	A probable course or outcome of a disease. Prognostic factors are patient or disease characteristics that influence the course. Good prognosis is associated with low rate of undesirable outcomes; poor

prognosis is associated with a high rate of undesirable outcomes.

- Prospective studyA study in which people are entered into the research and then
followed up over a period of time with future events recorded as they
happen. This contrasts with studies that are *retrospective*.
- Publication biasAlso known as reporting bias. A bias caused by only a subset of all the
relevant data being available. The publication of research can depend
on the nature and direction of the study results. Studies in which an
intervention is not found to be effective are sometimes not published.
Because of this, systematic reviews that fail to include unpublished
studies may overestimate the true effect of an intervention. In
addition, a published report might present a biased set of results (e.g.
only outcomes or sub-groups where a statistically significant difference
was found.
- Quality of life See 'Health-related quality of life'.
- Quality-adjusted life year (QALY) An index of survival that is adjusted to account for the patient's quality of life during this time. QALYs have the advantage of incorporating changes in both quantity (longevity/mortality) and quality (morbidity, psychological, functional, social and other factors) of life. Used to measure benefits in cost-utility analysis. The QALYs gained are the mean QALYs associated with one treatment minus the mean QALYs associated with an alternative treatment.
- Quick Reference GuideAn abridged version of NICE guidance, which presents the key priorities
for implementation and summarises the recommendations for the core
clinical audience.
- RandomisationAllocation of participants in a research study to two or more alternative
groups using a chance procedure, such as computer-generated random
numbers. This approach is used in an attempt to ensure there is an
even distribution of participants with different characteristics between
groups and thus reduce sources of bias.
- Randomised controlled trial
(RCT)A comparative study in which participants are randomly allocated to
intervention and control groups and followed up to examine
differences in outcomes between the groups.
- Residential care unitA unit or centre where care is given outside of the patient's home. Care
can be 24 hour care or partial care depending on the person's needs.
- RCT See 'Randomised controlled trial'.
- Receiver operated
characteristic (ROC) curveA graphical method of assessing the accuracy of a diagnostic test.
Sensitivity Is plotted against 1-specificity. A perfect test will have a
positive, vertical linear slope starting at the origin. A good test will be
somewhere close to this ideal.
- **Reference standard** The test that is considered to be the best available method to establish the presence or absence of the outcome this may not be the one that

	is routinely used in practice.
Relative risk (RR)	The number of times more likely or less likely an event is to happen in one group compared with another (calculated as the risk of the event in group A/the risk of the event in group B).
Reporting bias	See publication bias.
Resource implication	The likely impact in terms of finance, workforce or other NHS resources.
Retrospective study	A retrospective study deals with the present/ past and does not involve studying future events. This contrasts with studies that are <i>prospective</i> .
Review question	In guideline development, this term refers to the questions about treatment and care that are formulated to guide the development of evidence-based recommendations.
Secondary outcome	An outcome used to evaluate additional effects of the intervention deemed a priori as being less important than the primary outcomes.
Selection bias	A systematic bias in selecting participants for study groups, so that the groups have differences in prognosis and/or therapeutic sensitivities at baseline. Randomisation (with concealed allocation) of patients protects against this bias.
Sensitivity	Sensitivity or recall rate is the proportion of true positives which are correctly identified as such. For example in diagnostic testing it is the proportion of true cases that the test detects.
	See the related term 'Specificity'
Sensitivity analysis	A means of representing uncertainty in the results of economic evaluations. Uncertainty may arise from missing data, imprecise estimates or methodological controversy. Sensitivity analysis also allows for exploring the generalisability of results to other settings. The analysis is repeated using different assumptions to examine the effect on the results.
	One-way simple sensitivity analysis (univariate analysis): each parameter is varied individually in order to isolate the consequences of each parameter on the results of the study.
	Multi-way simple sensitivity analysis (scenario analysis): two or more parameters are varied at the same time and the overall effect on the results is evaluated.
	Threshold sensitivity analysis: the critical value of parameters above or below which the conclusions of the study will change are identified.
	Probabilistic sensitivity analysis: probability distributions are assigned to the uncertain parameters and are incorporated into evaluation models based on decision analytical techniques (For example, Monte Carlo simulation).

Significance (statistical)	A result is deemed statistically significant if the probability of the result occurring by chance is less than 1 in 20 (p <0.05).
Specificity	The proportion of true negatives that a correctly identified as such. For example in diagnostic testing the specificity is the proportion of non-cases incorrectly diagnosed as cases.
	See related term 'Sensitivity'.
	In terms of literature searching a highly specific search is generally narrow and aimed at picking up the key papers in a field and avoiding a wide range of papers.
Stakeholder	Those with an interest in the use of the guideline. Stakeholders include manufacturers, sponsors, healthcare professionals, and patient and carer groups.
Subtrochanteric extracapsular fracture	Subtrochanteric fractures are those in which the fracture is predominantly in the 5cms of bone immediately distal to the lesser trochanter.
Superspell	Total time in NHS care.
Systematic review	Research that summarises the evidence on a clearly formulated question according to a pre-defined protocol using systematic and explicit methods to identify, select and appraise relevant studies, and to extract, collate and report their findings. It may or may not use statistical meta-analysis.
Time horizon	The time span over which costs and health outcomes are considered in a decision analysis or economic evaluation.
Treatment allocation	Assigning a participant to a particular arm of the trial.
Trochanteric extracapsular fracture	Extracapsular fractures occur outside or distal to the hip joint capsule and include basal, trochanteric and subtrochanteric fractures. Trochanteric fractures may be further subdivided into two part fractures, which are also termed stable fractures, and those that are comminuted or multi-fragmentary, which may be termed unstable fractures.
Univariate	Analysis which separately explores each variable in a data set.

11	APPENDIX J: EXCLUDED STUDIES	609

2 Appendix A: Scope

3 13.6 Guideline title

4 Hip fracture: the management of hip fracture in adults

5 **13.6.1** Short title

6 Hip fracture

7 13.7 The remit

- 8 The Department of Health has asked NICE: "to prepare a clinical guideline on the
- 9 management of fractured neck of femur".

10 13.8 Clinical need for the guideline

11 13.8.1 Epidemiology

12	a)	About 70–75,000 hip fractures (proximal femoral fractures) occur annually in

- 13 the UK. Hip fracture is the commonest reason for admission to an orthopaedic
- 14 ward, and is usually a 'fragility' fracture ² caused by a fall affecting an older
- 15 person with osteoporosis or osteopaenia (a lesser degree of bone reduction
- 16 and weakness due to the same process as in osteoporosis). The average age of
- a person with hip fracture is 77 years. The annual cost of medical and social

² The strict definition of a fragility fracture is one caused by a fall from standing height or less. For the purposes of this guidance, the definition will be slightly more flexible to encompass all hip fractures judged to have an osteoporotic or osteopaenic basis

APPENDIX A

care for all the hip fracture cases in the UK amounts to about £2 billion. Demographic projections indicate that the UK annual incidence will rise to 91,500 by 2015 and 101,000 in 2020, with an associated increase in annual expenditure that could reach £2.2 billion by 2020. The majority of this expenditure will be accounted for by hospital bed days and a further

substantial contribution will come from health and social aftercare. About a
quarter of patients with hip fracture are admitted from institutional care.
About 10–20% of those admitted from home ultimately move to institutional
care.

b) Mortality is high – about 10% of people with a hip fracture die within
1 month, and about one third within 12 months. However, fewer than half of
deaths are attributable to the fracture. This reflects the high prevalence of
comorbidity in people with hip fractures; often the combination of fall and
fracture brings to light underlying ill health. This presents major challenges for
anaesthetic, surgical, postoperative and rehabilitative care.

16 13.8.2 Current practice

1

2

3

4

5

17 a) The primary and secondary prevention of fragility fractures by treating
18 osteoporosis and reducing the risk of falls are of key importance to the
19 current and future epidemiology of hip fracture. These are, or will be, covered
20 by related NICE guidance (see section 5).

b) The diagnosis and management of hip fracture itself and of any comorbidity
before, during and after surgery, have a profound effect on outcome, both for
individuals and for services.

c) Patients with hip fracture need immediate referral to hospital (other than in
 exceptional circumstances). Their assessment and management on admission
 commonly involve a range of specialties and disciplines, but it is not always
 clear how and when this involvement should take place. Prompt surgery is
 important but is sometimes delayed for administrative or clinical reasons. It is

		204	Appendix A
1 2			ential that mobilisation and rehabilitation after surgery are undertaken ording to individual need, but this does not always happen.
3 4 5	d)	res	pite of a significant body of evidence, hip fracture management and the ulting length of hospital stay vary markedly among centres across England I Wales.
6	e)	Exis	sting UK guidance from other sources includes:
7 8 9 10 11 12 13		• •	Scottish Intercollegiate Guidelines Network (2002) Prevention and management of hip fracture in older people. Available from www.sign.ac.uk/guidelines/fulltext/56/index.html British Orthopaedic Association (2007) The care of patients with fragility fracture. Available from www.nhfd.co.uk Department of Health (2001) National service framework for older people ³ . Available from www.dh.gov.uk
14 15 16 17	f)	ope reh	s clinical guideline will provide guidance on the emergency, preoperative, erative and postoperative management of hip fracture, including abilitation, in adults. It will not cover those aspects of hip fracture fressed by related NICE guidance, but will refer to them as appropriate.
18 19 20 21 22	g)	the the car	all stages of hip fracture management, and especially during rehabilitation, importance of optimal communication with, and support for, patients mselves and those who provide or will provide care – including unpaid e family members or others – will be a fundamental tenet of guidance velopment.

³ Elaborates on relevant (but not specific) standards of contextual importance (intermediate care, general hospital care and falls).

1	13.9 The guideline			
2	The guideline development process is described in detail on the NICE website (see section			
3	6, 'Further information').			
4	This scope	defines what the guideline will (and will not) examine, and what the guideline		
5	developer	s will consider. The scope is based on the referral from the Department of		
6	Health.			
7	The areas	that will be addressed by the guideline are described in the following sections.		
8	13.9.1	Population		
9	13.9.1.1 Groups that will be covered			
10	a)	Adults aged 18 years and older presenting to the health service with a clinical		
11		diagnosis (firm or provisional) of fragility fracture of the hip.		
12	b)	People with the following types of hip fracture: ⁴		
13		 intracapsular (undisplaced and displaced) 		
14		 extracapsular (trochanteric and subtrochanteric). 		
15	c)	Those with comorbidity strongly predictive of outcome, and those without		
16		such comorbidity. The influence (if any) of advanced age or gender on clinical		
17		decision-making, management and outcome will be specifically evaluated.		
18	13.9.1.2 G	roups that will not be covered		
19	People younger than 18 years.			
20	People wit	th fractures caused by specific pathologies other than osteoporosis or		
21		osteopaenia (because these would require more condition-specific guidance).		

 $^{^{\}rm 4}$ These terms explain where the bone has fractured, which can be either near or within the hip joint.

	206	APPENDIX A
1	13.9.2	Healthcare setting
2	a)	Secondary care settings where preoperative, operative, and postoperative
3		acute and subacute care are undertaken.
4	b)	Primary, secondary and social care settings, as well as an individual's own
5	6)	home, where rehabilitation is undertaken.
J		nome, where renabilitation is undertaken.
6	13.9.3	Clinical management
7	13.9.3.1 K	ey clinical issues that will be covered
8	a)	Using alternative radiological imaging to confirm or exclude a suspected hip
9		fracture in patients with a normal X-ray.
10	b)	Involving a physician or orthogeriatrician in the care of patients presenting
11	6)	with hip fracture.
12	c)	Early surgery (within 48 hours).
13	d)	Optimal preoperative and postoperative analgesia (pain relief), including the
14		use of nerve blockade.
15	e)	Regional (spinal – also known as 'epidural') versus general anaesthesia in
16	-,	patients undergoing surgery for hip fracture.
17	f)	Does surgeon experience reduce the incidence of mortality, the need for
18		repeat surgery, and poor outcome in terms of mobility?
19	g)	For displaced intracapsular fracture:
20		 internal fixation versus arthroplasty (hip replacement surgery)
21		• total hip replacement versus hemiarthroplasty (replacing the head of the
22		femur only) .
23	h)	Choice of surgical implants - Sliding hip screw versus intramedullary nail for
24		trochanteric extracapsular fracture.

- i) Choice of surgical implants Sliding hip screw versus intramedullary nail for
 subtrochanteric extracapsular fracture.
- 3 j) Cemented versus non-cemented arthroplasty implants.
- 4 k) Hospital-based multidisciplinary rehabilitation for patients who have
- 5 undergone hip fracture surgery.
- 6 l) Early transfer to community-based multidisciplinary rehabilitation for patients
 7 who have undergone hip fracture surgery.

8 13.9.3.2 Clinical issues that will not be covered

- 9 The following will not be directly covered in this guideline, but related NICE guidance will
- 10 be referred to if appropriate:
- 11 a) Primary and secondary prevention of fragility fracture.
- 12 b) Prevention and management of pressure sores.
- 13 c) Prophylaxis for venous thromboembolism.
- 14 d) Prevention and management of infection at the surgical site.
- 15 e) Nutritional support.
- 16 f) Selection of prostheses for hip replacement.
- 17 g) Complementary and alternative therapies.
- 18 13.9.4 Main outcomes
- 19 a) Requirement for surgical revision.
- 20 b) Short-term and long-term mortality.
- 21 c) Length of stay in secondary care.
- 22 d) Length of time before community resettlement/discharge.
- 23 e) Place of residence (compared with baseline) 12 months after fracture.

208

1	f)	Short-, medium- and long-term functional status	s.
---	----	---	----

2 g) Short-, medium- and long-term quality of life.

3 13.9.5 Economic aspects

4 Developers will take into account both clinical and cost effectiveness when making

- 5 recommendations involving a choice between alternative interventions. A review of the
- 6 economic evidence will be conducted and analyses will be carried out as appropriate. The
- 7 preferred unit of effectiveness is the quality-adjusted life year (QALY), and the costs
- 8 considered will usually be only from an NHS and personal social services (PSS)
- 9 perspective. Further detail on the methods can be found in 'The guidelines manual' (see
- 10 'Further information').
- 11 13.9.6 Status
- 12 13.9.6.1 Scope
- 13 This is the final scope.

14 13.9.6.2 Timing

15 The development of the guideline recommendations will begin in June 2010.

1 14 Appendix B: Declarations of Interest

2 14.1 Introduction

- 3 All members of the GDG and all members of the NCGC staff were required to make
- 4 formal declarations of interest at the outset of each meeting, and these were
- 5 updated at every subsequent meeting throughout the development process. No
- 6 interests were declared that required actions.

1 14.2 Declarations of interests of the GDG members

2 14.2.1 Professor Cameron Swift

GDG meeting	Declaration of Interests
First GDG meeting (1 st July 2009)	No interests to declare
Second GDG Meeting (17th July 2009)	No interests to declare
Third GDG Meeting (15th September 2009)	No interests to declare
Fourth GDG Meeting (8th December 2009)	No interests to declare
Fifth GDG Meeting (14 th December 2009)	No interests to declare
Sixth GDG Meeting (Subgroup meeting) (18th January 2010)	No interests to declare
Seventh GDG Meeting (9th March 2010)	No interests to declare
Eighth GDG Meeting (26th April 2010)	No interests to declare
Tenth GDG Meeting (11th June 2010)	No interests to declare
Eleventh GDG Meeting (30th June 2010)	Declared a non personal non pecuniary interest: has been invited to join the Department of Health Board on Fragility Fractures Programme
Twelfth GDG Meeting (29th July 2010)	No change
Thirteenth GDG Meeting (8th September 2010)	No change
Fourteenth GDG Meeting (18 th January 2011)	
Fifteenth GDC Meeting (24 th March 2011)	
Actions	None required

3

14.2.2 Professor Opinder Sahota

GDG meeting	Declaration of Interests
First GDG meeting (1 st July 2009)	No interests to declare
Second GDG Meeting (17th July 2009)	Did not attend
Third GDG Meeting (15th September 2009)	No interests to declare
Fourth GDG Meeting (8th December 2009)	No interests to declare
Fifth GDG Meeting (14 th December 2009)	No interests to declare
Sixth GDG Meeting (Subgroup workshop) (18th January 2010)	No interests to declare
Seventh GDG Meeting (9th March 2010)	Declared a non personal, non pecuniary interest regarding involvement in the Map of Medicine project with the Department of Health.
Eighth GDG Meeting (26th April 2010)	No change
Tenth GDG Meeting 11th June 2010)	Did not attend
Eleventh GDG Meeting (30th June 2010)	Declared a non personal non pecuniary interest: has been invited to join the Department of Health Board on Fragility Fractures Programme
Twelfth GDG Meeting (29th July 2010)	No change
Thirteenth GDG Meeting (8th September 2010)	No change
Fourteenth GDG Meeting (18 th January 2011)	
Fifteenth GDC Meeting (24 th March 2011)	
Actions	None required

14.2.3 Dr Antony Johansen

GDG meeting	Declaration of Interests
First GDG meeting (1 st July 2009)	No interests to declare
Second GDG Meeting (17th July 2009)	No interests to declare
Third GDG Meeting (15th September 2009)	No interests to declare
Fourth GDG Meeting (8th December 2009)	No interests to declare
Fifth GDG Meeting (14 th December 2009)	No interests to declare
Sixth GDG Meeting (Subgroup Workshop) (18th January 2010)	No interests to declare
Seventh GDG Meeting (9th March 2010)	No interests to declare
Eighth GDG Meeting (26th April 2010)	No interests to declare
Tenth GDG Meeting (11th June 2010)	Did not attend
Eleventh GDG Meeting (30th June 2010)	No interests to declare
Twelfth GDG Meeting (29th July 2010)	No interests to declare
Thirteenth GDG Meeting (8th September 2010)	No interests to declare
Fourteenth GDG Meeting (18 th January 2011)	
Fifteenth GDC Meeting (24 th March 2011)	
Actions	None required

1 14.2.4 Mr Tim Chesser

GDG meeting	Declaration of Interests
First GDG meeting (1 st July 2009)	Performed consultancy work with orthopaedic manufacturer for unrelated orthopaedic implants (locking plates for particular fractures)- compliance and worded guidelines. His Department receives research support from orthopaedic manufacturers including DePuy, Smith and Nephew, Biomet and Stryker. Department have research fellows funded by orthopaedic manufacturer. Publishing RCT on surgical treatment for peri-articular fractures which was not funded by industry.
Second GDG Meeting (17th July 2009)	Did not attend
Third GDG Meeting (15th September 2009)	Performed consultancy work with orthopaedic manufacturer for unrelated orthopaedic implants (locking plates for particular fractures)- compliance and worded guidelines. His Department receives research support from orthopaedic manufacturers including DePuy, Smith and Nephew, Biomet and Stryker. Department have research fellows funded by orthopaedic manufacturer. Publishing RCT on surgical treatment for peri-articular fractures which was not funded by industry.
Fourth GDG Meeting (8th December 2009)	Travel and accommodation funded by the Orthopaedic Trauma Association in the US to present a poster on outcomes in Pelvic Fractures at an Experts in Pelvic Trauma meeting (sponsored by Stryker Trauma).
Fifth GDG Meeting (14 th December 2009)	No change
Sixth GDG Meeting (Subgroup workshop) (18th January 2010)	Did not attend
Seventh GDG Meeting (9th March 2010)	Did not attend
Eighth GDG Meeting (26th April 2010)	No change
Tenth GDG Meeting (11th June 2010)	No change
Eleventh GDG Meeting (30th June 2010)	Did not attend meeting
Twelfth GDG Meeting (29th July 2010)	Declared a personal non pecuniary interest- invited to teach on a hip fracture surgical techniques course organised by Stryker who paid his travel expenses. No other payment was received.
Thirteenth GDG Meeting (8th September 2010)	No change
Fourteenth GDG Meeting (18 th January 2011)	
Actions	None required

2

GDG meeting	Declaration of Interests
First GDG meeting (1 st July 2009)	Non personal pecuniary interest: responsibility for – Synthes Fellows in the Trauma Department at the John Radcliffe hospital- 2 week fellowships usually 3-4 per year.
Second GDG Meeting (17th July 2009)	No change
Third GDG Meeting (15th September 2009)	No change
Fourth GDG Meeting (8th December 2009)	No change
Fifth GDG Meeting (14 th December 2009)	No change
Sixth GDG Meeting (Subgroup workshop) (18th January 2010)	Did not attend
Seventh GDG Meeting (9th March 2010)	No change
Eighth GDG Meeting (26th April 2010)	No change
Tenth GDG Meeting (11th June 2010)	No change
Eleventh GDG Meeting (30th June 2010)	Did not attend meeting
Twelfth GDG Meeting (29th July 2010)	No change
Thirteenth GDG Meeting (8th September 2010)	No change
Fourteenth GDG Meeting (18 th January 2011)	
Actions	None required
· · · · · · · · · · · · · · · · · · ·	

14.2.5 Mr Bob Handley

14.2.6 Ms Karen Hertz

GDG meeting	Declaration of Interests
First GDG meeting (1 st July 2009)	No interests to declare
Second GDG Meeting (17th July 2009)	No interests to declare
Third GDG Meeting (15th September 2009)	No interests to declare
Fourth GDG Meeting (8th December 2009)	Miss Karen Hertz- funding for flights and accommodation by a Chinese university to attend a conference in Hong Kong.
Fifth GDG Meeting (14 th December 2009)	No change
Sixth GDG Meeting (Subgroup workshop) (18th January 2010)	No change
Seventh GDG Meeting (9th March 2010)	KH declared a non personal, non pecuniary interest regarding involvement in the Map of Medicine project with the Department of Health.
Eighth GDG Meeting (26th April 2010)	No interests to declare
Tenth GDG Meeting (11th June 2010)	Did not attend
Eleventh GDG Meeting (30th June 2010)	No change
Twelfth GDG Meeting (29th July 2010)	Declared a non personal non pecuniary interest: has been invited to join the Department of Health Board on Fragility Fractures Programme
Thirteenth GDG Meeting (8th September 2010)	No change
Fourteenth GDG Meeting (18 th January 2011)	
Fifteenth GDC Meeting (24th March 2011)	
Actions	None required

14.2.7 Dr Richard Griffiths

GDG meeting	Declaration of Interests
First GDG meeting (1 st July 2009)	No interests to declare
Second GDG Meeting (17th July 2009)	Did not attend
Third GDG Meeting (15th September 2009)	Did not attend
Fourth GDG Meeting (8th December 2009)	Did not attend
Fifth GDG Meeting (14 th December 2009)	No interests to declare
Sixth GDG Meeting (Subgroup workshop) (18th January 2010)	Did not attend
Seventh GDG Meeting (9th March 2010)	Did not attend
Eighth GDG Meeting (26th April 2010)	No interests to declare
Tenth GDG Meeting (11th June 2010)	No interests to declare
Eleventh GDG Meeting (30th June 2010)	No interests to declare
Twelfth GDG Meeting (29th July 2010)	Did not attend
Thirteenth GDG Meeting (8th September 2010)	Did not attend
Fourteenth GDG Meeting (18 th January 2011)	
Fifteenth GDC Meeting (24 th March 2011)	
Actions	None required

GDG meeting	Declaration of Interests
-	-
First GDG meeting (1 st July 2009)	Did not attend
Second GDG Meeting (17th July 2009)	Declared a non personal pecuniary interest: NIHR funded research grant. One trial is in the final stages of finding approval in primary care- using peripheral fracture (including hip fracture). The second- potential trial- ideas unclear as to whether they will be submitted. Vitamin D in Hip fracture; anaemia in hip fracture.
Third GDG Meeting (15th September 2009)	No change
Fourth GDG Meeting (8th December 2009)	No change
Fifth GDG Meeting (14 th December 2009)	No change
Sixth GDG Meeting (Subgroup workshop) (28th January 2010)	Did not attend
Seventh GDG Meeting (9th March 2010)	Did not attend

14.2.13 Mr Martin Wise

GDG meeting	Declaration of Interests
First GDG meeting (1 st July 2009)	No interests to declare
Second GDG Meeting (17th July 2009)	No interests to declare
Third GDG Meeting (15th September 2009)	No interests to declare
Fourth GDG Meeting (8th December 2009)	No interests to declare
Fifth GDG Meeting (14 th December 2009)	No interests to declare
Sixth GDG Meeting (Subgroup workshop) (18th January 2010)	Did not attend
Seventh GDG Meeting (9th March 2010)	No interests to declare
Eighth GDG Meeting (26th April 2010)	Did not attend
Tenth GDG Meeting (11th June 2010)	No interests to declare
Eleventh GDG Meeting (30th June 2010)	No interests to declare
Twelfth GDG Meeting (29th July 2010)	No interests to declare
Thirteenth GDG Meeting (8th September 2010)	No interests to declare
Fourteenth GDG Meeting (18 th January 2011)	
Fifteenth GDC Meeting (24 th March 2011)	
Actions	None required

1 14.3 Declarations of interests of the NCGC members

GDG meeting	Declaration of Interests of the NCGC members
First GDG meeting (1 st July 2009)	No interests to declare
Second GDG Meeting (17th July 2009)	No interests to declare
Third GDG Meeting (15th September 2009)	No interests to declare
Fourth GDG Meeting (8th December 2009)	No interests to declare
Fifth GDG Meeting (14 th December 2009)	Antonia Morga declared her husband works for Novartis
Sixth GDG Meeting (Subgroup workshop) (18th January 2010)	No change
Seventh GDG Meeting (9th March 2010)	No change
Eighth GDG Meeting (26th April 2010)	No change
Tenth GDG Meeting (11th June 2010)	No change
Eleventh GDG Meeting (30th June 2010)	No change
Twelfth GDG Meeting (29th July 2010)	No change
Thirteenth GDG Meeting (8th September 2010)	No change
Fourteenth GDG Meeting (18 th January 2011)	
Fifteenth GDC Meeting (24 th March 2011)	
Actions	None required

2

1 14.4 Declarations of interests of the Expert Advisors

2 14.4.1 Mr Martin Parker

Mr Martin Parker only attended the first and second GDG meetings. He declared
 that he had received and may in the future receive money for advising implant
 manufacturing companies about their products and advising on implant design. He
 has produced research papers with different conclusions and publically presented
 the results. No actions were required as the first two meetings were introductory
 and did not involve any discussions about the evidence or formulating
 recommendations.

10 14.4.2 Mrs Pamela Holmes

Mrs Pamela Holmes had no interests to declare and did not attend any GDGmeetings

13 14.4.3 Professor Judith Adams

- Professor Judith Adams only attended the twelfth GDG meeting on July 29th 2010
 and did not have any interests to declare.

- 17

15 Appendix C: Review protocols

15.1 Review protocol – Imaging in occult hip fracture

Component	Description
Review question	In patients with a continuing clinical suspicion of hip fracture, despite negative radiographic findings, what is the clinical and cost- effectiveness of additional imaging (radiography after at least 48 hours), Radionuclide scanning (RNS), ultrasound (US) and cpmputed tomography (CT), compared to magnetic resonance imaging (MRI), in confirming, or excluding, a hip fracture?
Objectives	To identify an alternative method of diagnosis of occult hip fractures when MRI is not available.
Population	Patients >18 years old with a hip fracture undergoing different types of surgery for hip fracture repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	 Computed tomography Radionuclide scanning (also known as isotope scanning or scintigraphy).
Comparison	 Magnetic resonance imaging
Outcomes	 Sensitivity Specificity Positive and negative predictive values Positive and negative likelihood ratios

Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered. If no RCTs are found for certain outcomes such as adverse events, well conducted cohort studies and observational studies may also be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin
The review strategy	Meta-analysis will not be conducted for diagnostic studies. Ranges of results will be reported.
	 If there is heterogeneity the following subgroups will be analysed separately: Comorbidities strongly predictive of outcome (as mentioned in the scope but will need the GDG to list them) Concurrent medication Age Gender Cognitive impairment Palliative care patients

15.2 Review protocol – Timing of surgery

Component	Description
Review question	In patients with hip fractures what is the clinical and cost effectiveness of early surgery (within 24, 36 or 48 hours) on the incidence of complications such as mortality, pneumonia, pressure sores, cognitive dysfunction and increased length of hospital stay?
Objectives	To investigate whether early surgery improves patient outcomes.
Population	Patients >18 years old with a hip fracture undergoing different types of surgery for hip fracture repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Early surgery (within the cut off of 24, 36 and 48 hours of admission to hospital)
Comparison	Late surgery (after the cut off of 24, 36 and 48 hours of admission)
Outcomes	Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Length of time before community resettlement/discharge. Place of residence (compared with baseline) 12 months after fracture. Functional status (30 days, 3 months, 1 year) Quality of life (30 days, 3 months, 1 year) Complications (including pressure ulcers)
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered. If no RCTs are found well conducted cohort studies and observational studies may also be considered. In particular, cohort studies using logistic regression to adjust for confounders such as comorbidity and age, which is a particular bias in this area.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin
The review strategy	Meta-analyses will be conducted where possible.
	 If there is heterogeneity the following subgroups will be analysed separately: Reason for delay to surgery (administrative or medical reasons) Comorbidities strongly predictive of outcome (as mentioned in the scope but will need the GDG to list them) Concurrent medication Age

- Gender
- Cognitive impairment

15.3 Review protocol – Analgesia- systemic medications

Component	Description
Review question	In patients who have or are suspected of having a hip fracture, what is the comparative effectiveness and cost effectiveness of systemic analgesics in providing adequate pain relief and reducing side effects and mortality?
Objectives	To identify the most effective systemic analgesia medication for pain relief in hip fracture patients
Population	Patients >18 years old with a hip fracture undergoing different types of surgery for hip fracture repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Systemic:
Comparison	Systemic:

Non Opioid e.g.

	 Paracetamol, iv, PR, oral Non steroidal anti inflammatory (NSAIDs)
Outcomes	 Pain (generally measured by visual analogue scale or verbal rating) Need for 'breakthrough' analgesia Mortality Adverse effects Paracetamol Virtually none but may decrease blood pressure with iv Opioids Itching/histamine release, PONV, respiratory depression, decrease in blood pressure, delerium
Search strategy	 The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED. Randomised controlled trials (RCTs) will be considered. If no RCTs are found for certain outcomes such as adverse events, well conducted cohort studies and observational studies may also be considered. Studies will be restricted to English language only No date restriction will be applied. Databases will be searched from their date of origin
The review strategy	Meta-analyses will be conducted where possible. If there is heterogeneity the following subgroups will be analysed separately: Comorbidities strongly predictive of outcome Concurrent medication Age Gender Cognitive impairment Type of fracture Type of surgery

- THR vs. hemiarthroplasty
- o THR vs. internal fixation

15.4 Review protocol – Analgesia- Nerve blocks comapared to systemic analgesics

Component	Description
Review question	In patients who have or are suspected of having a hip fracture, what is the clinical and cost effectiveness of nerve blocks compared to other forms of analgesia in providing adequate pain relief and reducing side effects and mortality?
Objectives	To identify an optimal analgesia protocol including the use of nerve blocks which may help reduce usage of other forms of analgesics with strong side effects in this patient group.
Population	Patients over 18 years old with a hip fracture undergoing different types of surgery for hip fracture repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Nerve blocks (any type: lateral cutaneous, femoral, triple, psoas, 3-in-1 [includes femoral, obturator, lateral femoral cutaneous nerves], fascia iliaca, with ultrasound guidance for localisation)
Comparison	Pharmacological (systemic):
Outcomes	 Pain (generally measured by visual analogue scale or verbal rating) Need for 'breakthrough' analgesia Mortality Adverse effects

• Nerve Block:

	 Nerve damage Pressure necrosis following motor block Post operative nausea and vomiting (PONV) Paracetamol Virtually none but may decrease blood pressure with iv Opioids Itching/histamine release, PONV, respiratory depression, decrease in blood pressure, delirium NSAIDs upper gastrointestinal bleeding renal, hepatic and cardiovascular side effects
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered. If no RCTs are found for certain outcomes such as adverse events, well conducted cohort studies and observational studies may also be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin
The review strategy	Meta-analyses will be conducted where possible.
	If there is heterogeneity the following subgroups will be analysed separately: Comorbidities strongly predictive of outcome Concurrent medication Age Gender Cognitive impairment Type of fracture Type of surgery

- Type of surgery
 - THR vs. hemiarthroplasty
 - THR vs. internal fixation

15.5 Review protocol - Anaesthesia

Component	Description
Review question	In patients undergoing surgical repair for hip fractures, what is the clinical and cost effectiveness of regional (spinal/epidural) anaesthesia compared to general anaesthesia in reducing complications such as mortality, cognitive dysfunction thromboembolic events, post operative respiratory morbidity, renal failure and length of stay in hospital?
Objectives	To identify whether regional anaesthesia confers any benefit compared to general anaesthesia with regards to reducing complications and improving patient outcomes after surgery.
Population	Patients over 18 years old with a hip fracture undergoing different types of surgery for hip fracture repair People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	General anaesthesia for different types of surgery
Comparison	 Regional anaesthesia for the same type of surgery Spinal/epidural without nerve block Spinal/epidural with nerve block
Outcomes	 Patient preference Mortality at 30 days Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Adverse effects General: post-operative lung complications Pulmonary emboli Pneumonia Myocardial infarction Renal failure Post operative nausea and vomiting (PONV) Regional Neural damage Spinal haematoma

Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered. If no RCTs are found for certain outcomes such as adverse events, well conducted cohort studies and observational studies may also be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin
The review strategy	Meta-analyses will be conducted where possible.
	 If there is heterogeneity the following subgroups will be analysed separately (where possible): Comorbidities strongly predictive of outcome Concurrent medication

- Age
- Gender
- Cognitive impairment
- Type of surgery
 - THR vs. hemiarthroplasty
 - THR vs. internal fixation
- Duration of anaesthesia

15.6 Review protocol – surgeon seniority

Component	Description
Review question Objectives	Does surgeon seniority (consultant or equivalent) reduce the incidence of mortality, operative revision and poor functional outcome? To investigate whether senior surgeons lead to better outcomes for hip fracture patients
Population	Patients >18 years old with a hip fracture undergoing different types of surgery for hip fracture repair People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	 Consultant grade or equivalent
Comparison	Below consultant grade or equivalentTrainee
Outcomes	 Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Reoperation rate Dislocations Wound infection
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library and CINAHL. Randomised controlled trials (RCTs) will be considered. If no RCTs are found well conducted cohort studies and observational studies may
	also be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin
The review strategy	Meta-analyses will be conducted where possible.
	If there is heterogeneity the following subgroups will be analysed separately: Age

15.7 Review protocol – Cement

Component Review question	Description In hip fracture patients undergoing total hip replacement what is the clinical and cost effectiveness of cemented total hip replacement versus uncemented total hip replacement on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?
Objectives	To examine the effectiveness of cement when inserting arthroplasty for surgical repair
Population	Patients >18 years old with a hip fracture undergoing surgical repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Cemented arthroplasty
Comparison	Uncemented arthroplasty
Outcomes	 Perioperative mortality Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell) Place of residence 12 months after fracture Wound healing complications
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered.
	No date restriction will be applied. Databases will be searched from their date of origin
	All questions relating to surgical repair for hip fractures will be searched together.
The review strategy	Meta-analyses will be conducted where possible.
	Studies will be restricted to English language articles
	If there is heterogeneity the following subgroups will be analysed

separately:

- Comorbidities
- Age
- Ideally "younger and fitter" patients compared to the "older and frailer" patients. Could be a combination of age and comorbidities

15.8 Review protocol – Intracapsular fractures

Component	Description
Review question	In patients undergoing repair for intracapsular hip fractures what is the clinical and cost effectiveness of internal fixation compared to hemiarthroplasty compared to total hip replacement on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?
Objectives	To examine the effectiveness of the 3 different techniques for fixing displaced intracapsular fractures
Population	Patients >18 years old with a hip fracture undergoing surgical repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	 Internal fixation Hemiarthroplasty Total hip replacement
Comparison	All of the above are compared to each other.
Outcomes	 Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell) Place of residence 12 months after fracture
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered.
	No date restriction will be applied. Databases will be searched from their date of origin
	All questions relating to surgical repair for hip fractures will be searched together.

The review strategy

Meta-analyses will be conducted where possible.

Studies will be restricted to English language articles

If there is heterogeneity the following subgroups will be analysed separately:

 Ideally "younger and fitter" patients compared to the "older and frailer" patients. Could be a combination of age and comorbidities

15.9 Review protocol – surgical approach

Component	Description
Review question Objectives	In patients having surgical treatment for intracapsular hip fracture with hemiarthroplasty what is the clinical and cost effectiveness of anterolateral compared to posterior surgical approach on mortality, number of reoperations, dislocation, functional status, length of hospital stay, quality of life and pain? To investigate whether one surgical approach is better than the other when inserting a hemiarthroplasty.
Population	Patients >18 years old with a hip fracture undergoing replacement arthroplasty with a hemiarthroplasty
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	 Anterolateral approach
Comparison	 Posterior approach
Outcomes	 Mortality (30 days, 3 months, 1 year) Length of hospital stay Reoperation rate Dislocations Functional status Quality of life Pain
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library and CINAHL.
	Randomised controlled trials (RCTs) and well conducted cohort studies and observational studies that adjust for confounders will be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin

The review strategy

Meta-analyses will be conducted where possible.

If there is heterogeneity the following subgroups will be analysed separately:

• Type of procedure

15.10 Review protocol – Hemiarthroplasty stem design

Component	Description
Review question	In patients undergoing surgery for hip fracture what is the clinical and cost effectiveness of 'OEDP 10A rating' designs of stems in preference to Austin Moore or Thompson stems when inserting a hemiarthroplasty on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?
Objectives	To examine the effectiveness of modern design stems ('OEDP 10A rating') compared to Austin Moore or Thompson stems.
Population	Patients >18 years old with a hip fracture undergoing hemiarthroplasty
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Hemiarthroplasty with a modern design stem ('OEDP 10A rating')
Comparison	Hemiarthroplasty with an Austin Moore or Thompson
Outcomes	 Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell) Place of residence 12 months after fracture
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered.
	No date restriction will be applied. Databases will be searched from their date of origin
	All questions relating to surgical repair for hip fractures will be searched together.

The review strategy

Meta-analyses will be conducted where possible.

Studies will be restricted to English language articles

If there is heterogeneity the following subgroups will be analysed separately:

 Ideally "younger and fitter" patients compared to the "older and frailer" patients. Could be a combination of age and comorbidities

15.11 Review protocol – extracapsular fractures

Component	Description
Review question	In patients undergoing repair for trochanteric extracapsular hip fractures what is the clinical and cost effectiveness of extramedullary sliding hip screws compared to intramedullary nails on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?
	In patients undergoing repair for subtrochanteric extracapsular hip fractures, what is the effectiveness of extramedullary sliding hip screws compared to intramedullary nails on mortality, surgical revision, functional status, length of stay, quality of life, pain and place of residence after hip fracture?
Objectives	To examine the effectiveness of extramedullary implants, including sliding hip screws, compared to intramedullary implants, including nails, in fixing trochanteric and subtrochanteric fractures.
Population	Patients >18 years old with a extracapsular hip fracture undergoing surgical repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Extramedullary sliding hip screws
Comparison	Intramedullary nails
Outcomes	
	 Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation (operative or postoperative fracture of the femur, cut-out and non-union) Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell) Wound healing complications
Search strategy	 Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation (operative or postoperative fracture of the femur, cut-out and non-union) Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell)
Search strategy	 Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Requirement for reoperation (operative or postoperative fracture of the femur, cut-out and non-union) Length of stay in hospital/acute care Length of stay in to community or resettlement (i.e. superspell) Wound healing complications

All questions relating to surgical repair for hip fractures will be searched together.

The review strategy

Meta-analyses will be conducted where possible.

Studies will be restricted to English language articles

If there is heterogeneity the following subgroups will be analysed separately:

- Stability of fracture
- Comorbidities
- Age
- Previous fracture or surgery to femur

15.12 Review protocol – Mobilisation strategies

Component	Description
Review question	In patients who have undergone surgery for hip fracture, what is the clinical and cost effectiveness of early mobilisation (<48 hours after surgery) compared to late mobilisation on functional status, mortality, place of residence/discharge, pain and quality of life?
Objectives	To examine the effectiveness of early mobilisation on functional outcomes compared to delayed mobilisation
Population	Patients >18 years old that have had surgery for a hip fracture.
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Mobilisation (physiotherapy) within 48 hours of surgery.
Comparison	Mobilisation (physiotherapy) after 48 hours of surgery.
Outcomes	 Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Discharge destination
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered.
	No date restriction will be applied. Databases will be searched from their date of origin
	All questions relating to surgical repair for hip fractures will be searched together.
The review strategy	Meta-analyses will be conducted where possible.
	Studies will be restricted to English language articles
	 If there is heterogeneity the following subgroups will be analysed separately: Comorbidities Age Previous fracture or surgery to femur

Component	Description
Review question	In patients who have undergone surgery for hip fracture, what is the clinical and cost effectiveness of intensive physiotherapy compared to non intensive physiotherapy on functional status, mortality, place of residence/discharge, pain and quality of life?
Objectives	To examine the effectiveness of intensity of mobilisation on functional outcomes.
Population	Patients >18 years old that have had surgery for a hip fracture.
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Intensive physiotherapy, defined by an increased number of sessions or an increase in intensity (strength) of exercise.
Comparison	Fewer sessions of physiotherapy or usual care ad defined by the paper.
Outcomes	 Mortality at 30 days, 3 months & 1 year or longer Functional status up to 1 year Pain (generally measured by visual analogue scale or verbal rating) Quality of life Discharge destination Mobility
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered.
	No date restriction will be applied. Databases will be searched from their date of origin
	All questions relating to surgical repair for hip fractures will be searched together.
The review strategy	Meta-analyses will be conducted where possible.
	Studies will be restricted to English language articles
	If there is heterogeneity the following subgroups will be analysed separately:
	 Type or component of exercise programme Comorbidities Age Previous fracture or surgery to femur

15.13 Review protocol – Multidisciplinary rehabilitation

Component	Description
Review question	In patients with hip fracture what is the clinical and cost effectiveness of 'orthogeriatrician' involvement in the whole pathway of assessment, peri-operative care and rehabilitation on functional status, length of stay in secondary care, mortality, place of residence/discharge, hospital readmission and quality of life?
Objectives	To identify the benefit of an orthogeriatrician involved early in the care pathway to patient outcomes.
Population	Patients >18 years old with a hip fracture undergoing different types of surgery for hip fracture repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Involvement of an orthogeriatrician/physician throughout patient care, starting from admission
Comparison	No involvement of an orthogeriatrician/physician throughout the care pathway (e.g. only present in rehabilitation).
Outcomes	 Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Length of time before community resettlement/discharge. Place of residence (compared with baseline) 12 months after fracture. Functional status (30 days, 3 months, 1 year) Hospital readmission Quality of life (30 days, 3 months, 1 year)
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered. If no RCTs are found for certain outcomes such as adverse events, well conducted cohort studies and observational studies may also be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin

The review strategy

Meta-analyses will be conducted where possible.

If there is heterogeneity the following subgroups will be analysed separately:

- Comorbidities strongly predictive of outcome (as mentioned in the scope but will need the GDG to list them)
- Concurrent medication
- Age
- Gender
- Cognitive impairment
- Palliative care patients
- Patients from nursing homes

Component	Description
Review question	In patients with hip fracture what is the clinical and cost effectiveness of hospital-based multidisciplinary rehabilitation on functional status, length of stay in secondary care, mortality, place of residence/discharge, hospital readmission and quality of life?
Objectives	To identify the effectiveness of hospital-based multidisciplinary rehabilitation compared to usual care.
Population	Patients >18 years old with a hip fracture undergoing different types of surgery for hip fracture repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Multidisciplinary hospital-based rehabilitation. Multidisciplinary rehabilitation after hip fracture will be assumed if the following core components are present: medicine; nursing; physiotherapy; occupational therapy; social care. Additional components may include: nutrition, pharmacy, clinical psychology. Additional criteria include formal arrangements for co-ordination/teamwork and regular on-going multidisciplinary assessment. Types of multidisciplinary hospital-based rehabilitation include Geriatric orthopaedic rehabilitation unit (GORU); mixed assessment and
	rehabilitation unit (MARU); geriatric hip fracture programme (GHFP).
Comparison	Usual hospital-based care (not multidisciplinary)
Outcomes	 Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Length of time before community resettlement/discharge. Place of residence (compared with baseline) 12 months after fracture. Functional status (30 days, 3 months, 1 year) Hospital readmission Quality of life (30 days, 3 months, 1 year)
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered. If no RCTs are found for certain outcomes such as adverse events, well conducted cohort studies and observational studies may also be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin

The review strategy

Meta-analyses will be conducted where possible.

If there is heterogeneity the following subgroups will be analysed separately:

- Type of hospital-based MDR
- Comorbidities strongly predictive of outcome (as mentioned in the scope but will need the GDG to list them)
- Concurrent medication
- Age
- Gender
- Cognitive impairment
- Palliative care patients
- Patients from nursing homes

Component	Description
Review question	In patients with hip fracture what is the clinical and cost effectiveness of community-based multidisciplinary rehabilitation on functional status, length of stay in secondary care, mortality, place of residence/discharge, hospital readmission and quality of life?
Objectives	To compare community-based programmes with each other and usual care.
Population	Patients >18 years old with a hip fracture undergoing different types of surgery for hip fracture repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Community-based multidisciplinary rehabilitation, including intermediate care unit-based, home-based (early supported discharge) and social care unit-based. Any programme starting more than 1 week post-operatively will be excluded.
Comparison	Usual hospital-based care (not multidisciplinary)
Outcomes	 Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Length of time before community resettlement/discharge. Place of residence (compared with baseline) 12 months after fracture. Functional status (30 days, 3 months, 1 year) Hospital readmission Quality of life (30 days, 3 months, 1 year)
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered. If no RCTs are found for certain outcomes such as adverse events, well conducted cohort studies and observational studies may also be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin

The review strategy

Meta-analyses will be conducted where possible.

If there is heterogeneity the following subgroups will be analysed separately:

- Type of community rehabilitation programme
- Comorbidities strongly predictive of outcome (as mentioned in the scope but will need the GDG to list them)
- Concurrent medication
- Age
- Gender
- Cognitive impairment
- Palliative care patients
- Patients from nursing homes

15.14 Review protocol – Carer involvement

Component	Description
Review question	In patients who have been discharged after hip fracture repair, what is the clinical and cost effectiveness of having a non paid carer (e.g. spouse, relative, friends) on mortality, length of stay, place of residence/discharge, functional status, hospital readmission and quality of life?
Objectives	To compare the effectiveness of hospital-based multidisciplinary rehabilitation with involvement of a carer versus without a carer.
Population	Patients >18 years old with a hip fracture undergoing different types of surgery for hip fracture repair
	People with fractures caused by specific pathologies other than osteoporosis or osteopaenia, and patients under 18 years old are excluded from the scope.
Intervention	Hospital-based multidisciplinary rehabilitation with involvement of a non paid carer (e.g. spouse, relative, friends).
Comparison	Hospital-based multidisciplinary rehabilitation without involvement of a non paid carer (e.g. spouse, relative, friends).
Outcomes	 Mortality (30 days, 3 months, 1 year) Length of stay in secondary care Length of time before community resettlement/discharge. Place of residence (compared with baseline) 12 months after fracture. Functional status (30 days, 3 months, 1 year) Hospital readmission Quality of life (30 days, 3 months, 1 year)
Search strategy	The databases to be searched are Medline, Embase, The Cochrane Library, CINAHL and AMED.
	Randomised controlled trials (RCTs) will be considered. If no RCTs are found for certain outcomes such as adverse events, well conducted cohort studies and observational studies may also be considered.
	Studies will be restricted to English language only
	No date restriction will be applied. Databases will be searched from their date of origin
The review strategy	Meta-analyses will be conducted where possible.
	 If there is heterogeneity the following subgroups will be analysed separately: Comorbidities strongly predictive of outcome (as mentioned in the scope but will need the GDG to list them)

- Concurrent medication
- Age
- Gender
- Cognitive impairment
- Palliative care patients
- Patients from nursing homes

15.15 Review protocol – Health Economics

Objectives	The aim is to identify economic studies relevant to the review questions set out above.
Criteria	Populations, interventions and comparators as specified in the review protocols above. Must be a relevant economic study design (cost-utility analysis, cost-benefit analysis, cost-effectiveness analysis, cost- consequence analysis, comparative cost analysis).
Search strategy	See Appendix D, section 4.2
The review strategy	Each study is assessed using the NICE economic evaluation checklist – NICE (2009) Guidelines Manual, Appendix H.
	Inclusion/exclusion criteria
	• If a study is rated as both 'Directly applicable' and 'Minor limitations' (using the NICE economic evaluation checklist) then it should be <i>included</i> in the guideline. An evidence table should be completed and it should be included in the economic profile.
	• If a study is rated as either 'Not applicable' or 'Very serious limitations' then it should be <i>excluded</i> from the guideline. It should not be included in the economic profile and there is no need to include an evidence table.
	• If a study is rated as 'Partially applicable' and/or 'Potentially serious limitations' then there is <i>discretion</i> over whether it should be included. The health economist should make a decision based on the relative applicability and quality of the available evidence for that question, in discussion with the GDG if required. The ultimate aim being to include studies that are helpful for decision making in the context of the guideline. Where exclusions occur on this basis, this should be noted in the relevant section of the guideline with references.
	Also exclude:
	 unpublished reports unless submitted as part of the call for evidence
	abstract-only studies
	letters

- editorials
- reviews of economic evaluations⁵
- foreign language articles

Where there is discretion

The health economist should be guided by the following hierarchies.

Setting:

- 1. UK NHS
- 2. OECD countries with predominantly public health insurance systems (e.g. France, Germany, Sweden)
- 3. OECD countries with predominantly private health insurance systems (e.g. USA, Switzerland)
- 4. Non-OECD settings (always 'Not applicable')

Economic study type:

- 1. Cost-utility analysis
- 2. Other type of full economic evaluation (cost-benefit analysis, cost-effectiveness analysis, Cost-consequence analysis)
- 3. Comparative cost analysis
- 4. Non-comparative cost analyses including cost of illness studies (always 'Not applicable')

Year of analysis:

• The more recent the study, the more applicable it is

Quality of effectiveness data used in the economic analysis:

• The more closely the effectiveness data used in the economic analysis matches with the studies included for the clinical review the more useful the analysis will be to decision making for the guideline.

⁵ Recent reviews will be ordered although not reviewed. The bibliographies will be checked for relevant studies, which will then be ordered.

16 Appendix D: Literature search strategies

16.1 Search Strategies

Searches were constructed by using the following groups of terms. These groups are expanded in full in Section 1.2 below.

All searches were run in Medline, Embase and the Cochrane Library. Additionally CINAHL and PsychINFO were searched where this was deemed appropriate. Economic searches were conducted in Medline, Embase, NHS EED and the HTA (Health Technology Reports) database from the Cochrane Library.

Anaesthesia search

Hip fracture terms AND Anaesthesia terms AND RCT filter or systematic review filter NOT Animal/publication filter

Analgesia search

Hip fracture terms AND Analgesia terms AND RCT filter or systematic review filter NOT Animal/publication filter

Carer involvement search

Hip fracture terms AND Carer involvement terms NOT Animal/publication filter Early surgery search

Hip fracture terms AND Early surgery terms NOT Animal/publication filter

Economic searches (Medline and Embase)

Hip fracture terms AND Economic filter NOT Animal/publication filter

Economic searches (NHS EED and HTA)

Hip fracture terms

Orthogeriatrician search

Hip fracture terms AND Orthogeriatrician terms NOT Animal/publication filter

Patient education search

Hip fracture terms AND Patient education terms NOT Animal/publication filter

Patient views search

Hip fracture terms AND Patient view terms NOT Animal/publication filter

Radiological imaging search

Hip fracture terms AND Radiological imaging terms AND RCT filter or systematic review filter or diagnostic filter NOT Animal/publication filter

Rehabilitation search

Hip fracture terms AND Rehabilitation terms NOT Animal/publication filter

Surgeon seniority search

Hip fracture terms AND Surgeon seniority terms NOT Animal/publication filter

Surgical interventions search

Hip fracture terms AND Surgical intervention terms AND RCT filter or systematic review filter NOT Animal/publication filter

Bridle et al., 1991 ^{37,37} Country of study: UK, London Study design: Randomised prospective comparison List who was masked to interventions: Not reported. Duration of follow-up: At least 6 months	 Patient group: Patients with intertrochanteric fractured femur. Inclusion criteria: Patients diagnosed with intertrochanteric fractured femur Exclusion criteria: Not reported All patients N: 100 No. lost to follow up: 6 Group 1: Gamma nail No. randomised: 49 Age: 81.0 M/F: 9/40 Other factors: ASA score: = 2 = 2 = 23 = 20 V = 4 	Group 1 The Gamma nail was inserted using a 'closed' technique under image intensifier control. The patient is positioned on the traction table, and the fracture is reduced with the leg adducted. A 6 cm incision is made just proximal to the greater trochanter, which is entered using a curved awl. The entry point is just lateral to the tip of the trochanter. A guide wire is introduced into the femoral shaft, and flexible reamers are used to the appropriate size. A nail, 1 to 1.5 mm smaller than the final reamer, is selected. No attempt is made to ream the shaft to accept a large nail. The angle of the nail ranges from 125 to 140 degrees. Study	Archibald 2003 ⁸ . Country: UK. Setting: community hospital in Bradford		
Aim	To explore experiences of individuals who had suffered a hip fracture. Not to produce generalisable findings but to generate "rich description" of the		
	experience of incurring and recovering from hip fracture to inform nursing practice.		
Population	5 patients with hip fracture		
	Age >65; 4 women and 1 man; all were cognitively intact		
Method of	In depth audio-recorded interviews with open ended questions, ranging between 25 and 50 minutes duration were conducted during stay in the		
gaining views	hospital.		
Data analysis	"Colaizzi's analysis framework. 6 step methodological interpretation		
	 Interviews transcribed verbatim and read to get a feel for responses 		
	Significant statements and phrases extracted		
	Meanings formulated from significant statements		
	Organised into clusters of themes		
	Themes used to provide full description of experience		
	Researcher returns description to participants for confirmation of validity		
Findings	4 main themes: injury experience, pain experience, recovery experience, disability experience.		
	Injury – relates to falling and breaking their hip		
	Pain - Most participants described the pain they had. One mentioned being in a lot of pain in orthopaedic unit despite pain killers. Another mentioned		
	they thought the pain went with rest after a while, but not completely. Only 1 person was still having pain at time of interview. One said "I have not suffered, not what I call real pain, at all",		
	Recovery - operation : varied comments - some did not remember anything or much, one had a "horrendous" recollection of operating theatre: "The		
	operation was pretty horrendous. I had the injection in the spinal cord, [an] epidural There was no pain, but the noises [laughs] – it was like being in		
	an engineering shop or something. The noise was terrible. I thought 'What are they doing me?' Anyway, it came to an en (it took quite a long		
	time)and before I knew it I was back on the ward."		
	Recovery - beginning struggle: 3 patients discussed this, 1: not being able to do anything, 2: struggling to get to toilet & into the chair, 3: hated using		
	bed pan.		
	Recovery - regaining independence: Motivation found to be key factor in recovery, all comments in study positive comments about regaining		
	independence during their rehabilitation.		
	Disability: comments about reduced functional status, dependence on others, being house bound.		
Comments	Not stated how patients were selected for the study. No baseline data provided about patients. The role of the researcher is not described.		

1 Evidence tables – patient views

Study	Borkan 1991 & 1992 ^{28,29} . Country: USA. Setting: 4 hospitals (no more detail)
Aim	Two research questions addressed:
	• What are the meanings present in the narratives of elderly hip fracture patients?
	What is the importance of narrative elements as prognostic indicators or 'risk factors' for predicting rehabilitation outcomes?
Population	80 patients with hip fracture (from a pool of 174) "functionally hardy elderly, intact mental status, independent or lightly-supervised residence outside
	long-term care facilities, full pre-fracture ambulation; >65 years; 65 women and 15 men; diagnosed within 48 hours of fracture; treated surgically
	within 1 week.
	Excluded open pathological or multiple fractures.
Method of	Interviewed during first week after hip fracture, generally 1 or 2 days after surgery, in participant's hospital room. In depth initial interviews included
gaining views	demographics, open ended questions and standardised scales. Combination of open-ended and multiple choice questions. Interview content validated
	through pretesting with 10 subjects, and reviewed by a panel of experts. Inconsistencies and ambiguities revised or deleted from study. Follow up
	interviews at 3 and 6 months post-fracture generally conducted in participants' current residence, except where movement to distant states or
	particular patient preferences precluded face to face contact. These attempted to match some of the patient's perceptions to what actually happened.
	In addition, observations carried out on main orthopaedic floors over the course of 2 years in order to familiarise research team with the treatment
	and rehabilitation as well as to confirm information drawn from interviews and uncover unexpected associations.
Data analysis	Quantitative analysis & qualitative narrative. Names coded and interview transcripts sent to independent expert panel to identify emergent or
	recurrent themes. 13 dimensions identified and grouped into 3 composite. Subjects' narrative accounts rated on a 7 point bipolar scale.
Findings	Gives themes around the patient perception of hip fracture, how it happened, how they perceive their injury, what the future holds, their subsequent
	level of ability and their future. Categories derived from narratives are rated on a bipolar scale and presented in 3 groups. The remaining percentage
	not given for each category relates to patients either not giving a view or indicating an equal rating for both polar elements.
	1. Explanation of fracture: described as disease (1%) or fracture (49%); fall as secondary (4%) or primary (82%); etiology, internal degeneration –
	primary (6%) or secondary (11%); broke and fell (10%) or fell and broke (64%); course of rehabilitation described as chronic (19%) or acute
	(49%); functional severity – total impairment (14%) or complete recovery (70%); range of severity – whole body (11%) or affected leg or hip (15%).
	2. Perception of disability: vulnerable (41%) or not vulnerable (34%); dependency increased (21%) or not increased (30%); sense of alienation
	from the world – alienated (20%) or integrated (29%); objectification of body part – alienation (4%) or wholeness (7%).
	3. Futurity: hopefulness (54%) or hopelessness (19%).
	Expectations of recovery during initial hospitalisation: 43 (53.7%) expected full recovery; 14 (17.5%) partial recovery; the rest did not know or did not
	give an answer. Narrative responses varied "from stubborn optimism to despair".
	Expectations of living situation: 61% predicted going home, 15% predicted going into a nursing home (none came from nursing home), 9% going to
	children's house, 15% did not know or did not respond. Actual figures: 34 (43%) discharged to long-term care institutions, 13 (38%) of these remained
	in institution at 1 year, 18 (53%) returned home, 3 (9%) died.
Comments	The role of the researcher is not well described.

1 Evidence tables – patient views

Study	Bowman 1997 ³³ . Country: Canada. Setting: hospital
Aim	To describe sleep satisfaction, pain perceptions & psychological concerns of patients undergoing planned & emergency hip operations. Two additional
	questions on perceptions of how they would manage.
Population	43 out of 50 consecutively admitted patients: 17 with hip fracture & 26 undergoing elective hip replacement. Gender for overall study 29 women and
	14 men. Characteristics of hip fracture patients: mean age 80 (+7.5); 8/17 had delirium; 11/17 patients claimed to be active or very active prior to
	fracture
Method of	Pain assessment was conducted using a visual analogue scale. Sleep satisfaction was conducted using a 'Likert' scale.
gaining views	
	Not much detail on methods for qualitative part of study. Interviewed on day of admission. Two structured questions but no details on how or by
	whom they were delivered. 1. What are your biggest concerns at this time as a result of this injury and your upcoming surgery? 2. Do you have any
	concerns about your ability to recover fully and quickly?
Data analysis	Numerical analysis of responses to two questions.
Findings	6/17 feared being unable to walk again; additional 3/17 concerned about recovery and managing on their own; 5/17 put their trust in God.
Comments	Little detail about methods used for the qualitative part of this review. Little baseline data provided about patients. The role of the researcher is not
	described.

1 Evidence tables – patient views

Study	Furstenberg 1986 ¹⁰³ . Country: USA. Setting: Large urban teaching hospital
Aim	2 parts to study: 1. community residents without hip fracture, 2. hospitalised patients with hip fracture. "The purpose of hospital study was to
	construct a natural history of the hip fracture, from the events surrounding the fracture through the hospitalisation period.
Population	11 patients hospitalised for hip fracture. Patient characteristics: age 59 to 85 years; 4 men & 7 women; cognitively intact, fracture that had not
	resulted from malignancy or its treatment.
Method of	Interviewed at one or more points during their hospital stay. "Ethnographic interviews" recorded and transcribed in full. Interviews took place in
gaining views	physical therapy hospital rooms or in rehabilitation centre for 3 who were transferred. During interview informants requested to talk about the
	fracture, their reactions to it, their pre-fracture functioning, their experiences during hospitalisation and the process for planning for discharge.
Data analysis	"Analysis consisted of identifying salient and recurrent issues and themes and grouping the portions of the interviews dealing with each theme. The
	variations on each theme were described, and correlates of these variations were identified".
Findings	Split into two main sets: (1) immediate expectations about recovery explicitly or implicitly expressed by patients; (2) contextual factors to the evolving
	expectations about recovery.
	1. Immediate or early expectations of recovery - most expressions of despair and discouragement. Only 1 patient feared "it was over". First
	reactions "varied from shock to a focus on immediate problems, and for some, immediate concern about the consequences of their way of
	life. As the situation progressed, patients' concerns focused more exclusively on limitations on their functioning and the implications these
	would have". Most expressed worry about the degree to which they would recover, and when. Several talked repeatedly about the slowness
	of the process of recovery of physical function. Some worried about being burdens on their caretakers, some worried about further falls.
	Those who went temporarily to a home of an adult child worried about being able to return to independent living. Summary - hip fracture was
	going to result in extended period of slow recovery of function, with attendant dependency, postponement or relinquishment of cherished
	plans and changed living situation with the threat of permanent loss of independent living. Also suffered uncertainty about timing & completeness of return to full recovery.
	2. Contextual factors - as time progressed. Only positive points, not negative ones, came out in this section. Patients observing their own
	progress sometime after surgery commented that although progress slow they could see improvement. Participants also took encouragement
	from others progress. The study notes that while patients could focus on positive and negative points, the informants only focused on
	encouraging examples.
	3. Contextual factors - health professionals influence on patients' perceptions. Healthcare professionals' cues, encouragement and feedback
	guided the informants' perceptions about their own progress. Quotes of the healthcare professionals were scattered throughout participants'
	responses. Some patients "referred to the elusiveness of the doctors and their own unanswered questions."
	4. Contextual factors - other health issues. Also reports a few comments by patients on other health issues.
Comments	Little baseline data provided about patients. The role of the researcher is not described.

1 Evidence tables – patient views

Study	Olsson 2007 ²⁴¹ . Country: Sweden. Setting: geriatric/orthopaedic ward
Aim	To describe patients' own perceptions of their situation and views of their responsibility in the rehabilitation process.
Population	13 hip fracture patients from a geriatric/orthopaedic ward, non-institutional residence pre-fracture, median age 81 (range 71 to 93) years, 2 men & 11 women. Excluded patients with severe illness, cognitive impairment, dementia or pathological fracture.
Method of gaining views	30-45 minute interviews conducted in informant's room or in a secluded area of the ward as soon after the operation as the informants felt strong enough. Semi-structured questions were used "such that the main questions, related to the informant's perception of the transitional properties, were included in all interviews." Deliberate efforts were made to encourage informants to reveal and comment freely on their personal experiences of and reflections on their situation, without imposing the interviewer's own values on what was being said. The interviewees all talked freely and appeared to be grateful for the attention and for having someone to listen to their reflections. All interviews were recorded and transcribed.
Data analysis	Transcripts read several times. 5 transitional properties & 542 meaning units identified & pooled. A "saturation" was observed when 9 interviews had been conducted "meaning units describing qualitatively similar conceptions were grouped together and the nature of this similarity was articulated." Categories were labelled and exemplified with representative quotations from interviews. To test the reliability of the categories the second author evaluated the categories in relation to the interviews.
Findings	 Participant's responses were categorised into different conceptions: autonomous – appeared confident and accustomed to managing for themselves and being in control of their lives. Willing to listen to staff, but made their own decisions. Even if they appeared strong they felt just as vulnerable as the other groups. However, they were aware of the importance of information, personal support and their own responsibility. One informant commented that more information given preoperatively could have made a great difference:

APPENDIX E

	 1 patient knew someone who had undergone rehabilitation for hip fracture. shocking event - although several suspected they had a fracture all were distressed by the diagnosis. Period before surgery was mostly blurred and filled with fear and pain. They worried about how they would function postoperatively; zest for life - all expressed a strong desire to recuperate. While confined to bed they were worried remembering the pain and inability to move their leg. The suffering experienced in anticipation and preparation for the operation led them to believe they might not be able to walk. 	
Comments	Comments Not stated how patients were 'strategically selected' for the study. Little baseline data provided about patients. The role of the researcher is not described.	

1 Evidence tables – patient views

Study	Pownall 2004 ²⁶⁶ . Country: UK. Setting: trauma and orthopaedic ward
Aim	Critical appraisal of an individual patient narrative of their experience with hip fracture. Undertaken in an effort to understand further the nature of
	personal experience. Narrative was acquired as part of a routine nursing evaluation and helped to illuminate nursing care issues through they eyes of
	the patient.
Population	A 60 year old woman with an intracapsular fracture in Nottingham hospital. She stated she was fully independent prior to fracture.
Method of	Interviewed prior to discharge from acute trauma and orthopaedic ward, exact time point unclear. A list of structured questions were devised but not
gaining views	rigidly adhered to:
	What did you feel about requiring hospitalisation?
	What were the good aspects of your hospitalisation?
	What were the bad aspects of your hospitalisation?
	What do you feel could be improved?
Data analysis	Narrative assessment of patient's views
Findings	A few areas for potential improvement for the hospital/department were identified:
	communication skills
	 time management for staff so time spent with patient is used effectively
	pain management
	Ann's comments that were included in the study:
	• I could not understand why I had to wait so long in A & E, they had done the X-ray, it was broken the X-ray person told me that. So why did I have to wait?
	• The pain was unbearable; I didn't care what happened or what was said I just wanted to get rid of the pain.
	• The staff were so kind, they could not do enough for me.
	 Initially, I could not understand why they (the staff) wanted to keep checking my bottom, I was comfortable why keep moving me? It was terrible to be kept nil by mouth the first day, I didn't feel like eating but I really wanted a drink.
	 It was such a disappointment to be told my operation was cancelled; I just wanted to be fixed.
	• When I came back from theatre I really needed a drink, but I could not reach my glass. I didn't want to bother the staff they looked so busy.
	 It was a relief to come back from theatre and be able to press a button and get pain relief, but it was taken away the next day when the physiotherapist came. So I had to keep asking for pain killers.
	• The staff are so busy no one has time to sit and explain things to you.
	 I could hear the nurse explaining the operation to my son, but what about me I needed to know.
	• It was frightening to wake up from the operation and see that I was having a blood transfusion, no-one said that I might need a blood
	transfusion. It makes you feel something has gone terribly wrong.
	• I couldn't believe it when they wanted to mobilise me the day after the operation, even my son was shocked to see me out of bed.

Appendix E

Comments	Almost no methodology described so results could be unreliable. It is unclear how this patient was chosen. The role of the researcher is not described.

1 Evidence tables – patient views

Study	Slauenwhite 1998 ³⁰⁶ . Country: Canada. Setting: interviewed at home after discharge from hospital		
Aim	Purpose of this study was to investigate the impact of enhanced early discharge on families experiencing repaired hip fracture in an older adult.		
Population	Convenience sample of 23 caregivers for 23 patients who had experienced hip fracture . Patient characteristics: age 75.9 (range 56-97) years; 19 women 4 men. Care giver characteristics: 16 women, 7 men.		
Method of gaining views			
Data analysis	2 investigators separately analysed the transcripts and developed themes that emerged from the data. Themes were then compared, contrasted and collapsed until only main themes remained.		
Findings	 Length of stay not a major issue for 15/23 families, care-recipient thought too long while patient-carer thought too short for 3 families, 4 families said people heal better in own homes. 20/23 families stated pain management not a problem in hospital or at home several families thought transition from house to home a problem as took several hours to days for all info to be relayed to home care system. This went hand in hand for those with comorbidities. "Instrumental functioning" not a concern when patients were allowed to manipulate their own resources in their own home. Older people and men more capable of role flexibility while younger people and women talked more about role strain. Many caregivers had stories of dissatisfaction which was suggested to be related to health care system and mismatched care. Mismatched care not well defined. 		
Comments	No description of 'early supported discharge'. No baseline description of patients and no indication of how patients were selected.		

1 Evidence tables – patient views

418

Study	Williams 1994 ³⁴⁵ . Country: USA. Setting: At home after discharge from 4 hospitals	
Aim	Aim to gain information on: (1) the recovery pattern in functional status & mood in first 14 weeks after hospital discharge; (2) factors most associated with the extent of assistance required in specific mobility activities & patient assessment of their problems; (3) problems patients identified as most	
	important; (4) advice those patients would give to others.	
Population 120 consecutive patients meeting inclusion criteria with hip fracture. Older patients who were relatively healthy & home dwelling be Mean 79.9 (+9.7) range 60 to 100). Included intracapsular (68), extracapsular (52), internal fixation (76), femoral head replacement (4- included only white women as a result of low number in region of study.		
Method of gaining views	Interviewed before hospital discharge and followed up at 2, 8 and 14 weeks. At 14 weeks participants asked what advice they would give to other persons who fractured their hip. Also assessed functional status, perceived return to normal mobility, mood states, and other factors including urinary problems according to scales.	
Data analysis	Coding of responses to advice to give to other hip fracture patients done by the two "co-principal investigators" with recategorisation occurring until 100% agreement was reached.	
Findings	 Advice to patients with newly fractured hips from women with a personal experience of hip fracture Number of comments by category: 94 importance of mental attitude - maintain hope & look to the future 76 follow experts advice 34 mobility – keep mobile, rest before getting up to walk, use walker to help get up 15 maintain healthy lifestyle 7 use caution & be careful not to fall 3 limit stay in institution and get help to be at home if possible; 6 gave no specific advice as they commented that everyone is different. 	
Comments	nments	

1 Evidence tables – patient views

Study	Wykes 2009 ³⁴⁶ . Country: Australia. Setting: rehabilitation hospital		
Aim	Pilot study to explore "the impact of fractured neck of femur on the lives of previously independent women and identifies their concerns when participating in inpatient rehabilitation".		
Population	5 patients undergoing inpatient rehabilitation for hip fracture at 2 rehabilitation hospitals, aged 60-85 years, living alone and independently before fracture, cognitively intact and able to converse fluently in English		
Method of	Interviewed in a private room during stay in rehabilitation hospital. Interviews were shared by two researchers previously unknown to the patients.		
gaining views			
Data analysis	Thematic analysis using stages set out by Burnard 1991. Two researchers independently made notes of themes apparent in the data as a whole. Transcript lines were coded. Similar codes combined into higher order categories. Same two researchers carried out the analysis. Researchers engaged in "reflexive self-awareness". This included a conscious awareness of previous experiences of and with patients who had fractured a neck of the femur.		
Findings	 Two major findings: Impact of fracture for previously independent women was an issue for all. Primarily, others had to assume responsibility for things they had done previously. Concerns following fracture listed in 4 sections: a. behaviour of others (22 instances identified) - these included: what others do - things staff said or did (1 women upset when she overheard staff talking about the possibility of limb shortening if they stayed in a wheelchair too long, 1 women upset about being put on a ward with people "completely of the planet" as a result of dementia; 1 patient commented that staff don't understand because they encouraged her to walk when she felt she could not because of Parkinson's Disease interfering with her mobility), friends & family doing things without consulting her what others do not do -; family not told by staff when patient moved hospital; not enough information about complications what others expect – 1 women concerned by staff expecting her daughter to look after her before rehabilitation started; family and friends expectations upset participants. b. what was happening to them - possible accommodation changes after discharge; possible loss of independence; money issues c. impact of their injury on others - inconveniencing and upsetting others d. other health issues – 2 women had pre-existing conditions that overshadowed their concerns about hip fracture and had adverse effects on their rehabilitation outcomes. – 1 severely disabled with Parkinson's Disease; 1 had recent cardiac surgery and a long-standing vertebral disc prolapse. 		
Comments	Study notes: only 5 patients included so it only reveals some of the concerns of older women with hip fractures; not enough data to explore the differences between hospitals; analysis only at 1 point in time.		

1 Evidence tables – patient views

Study	Young 2009 ³⁴⁹ , Country: USA. Setting: rehabilitation programme	
Aim To explore the perceptions of older adults regarding their functional recovery 1 year after hip fracture.		
Population	62 hip fracture patients ('convenience sample' from a longitudinal study of rehabilitation and functional recovery after hip fracture involving 280 patients). Age 65 or older (average: 78, range 65-91), 47 women, 15 men, cognitively intact, community dwelling, admitted to one of the five predetermined rehabilitation sites with a primary diagnosis of acute hip fracture, receiving a surgical procedure, non pathological fracture, no evidence of metastatic cancer.	
Method of	Participants invited and completed an exit interview immediately after the 12-month post hip fracture follow up data collection. The exit interview	
gaining views	was a thematic survey with open-ended questions that explored areas of functional recovery and participants' willingness to engage in rehabilitation activities. Questions:	
	1. Have you been satisfied with your functional recovery since your hip fracture surgery? – YES, NO	
	a. If "YES" what do you think has helped the most with regards to your recovery process?	
	b. If "NO" what do you think has hindered your recovery process most?	
	c. If "NO" what things would you have liked to see differently regarding you recovery process?	
	2. What do you think needs to be done to help improve the functional recovery process for future hip fracture patients?	
	3. What one piece of advice would you give a hip fracture patient to help them with their recovery?	
	Responses were transcribed verbatim by a physical therapist and a physician assistant, both of whom were familiar with hip fracture care and received three sessions of interview training at the Center on Aging and Health at John Hopkins University in Baltimore.	
Data analysis	Data analysis conducted using basic content analysis. "Although the interview guide used in this study contained specific themes and directed	
	participants to address things that facilitated their recovery process, response analysis was conducted using participants' own words to capture their	
	particular responses and ideas about thematic areas." A list including a definition of each code was developed and continually revised as new codes were added. "	
	"Confirmability" Data were initially coded by first reviewer, a geriatric nurse practitioner, and researcher familiar with the hip fracture trajectory. The coded data were then given to a second researcher, an epidemiologist and gerontologist who had studied patients post-hip fracture across the entire	
	recovery period. The second interviewer independently coded the transcripts, compared her coding to the coding of the first reviewer, and then discussed the findings with the first reviewer. As the discrepancies were identified, the reviewers went back to the data to clarify their interpretations. This process repeated until consensus was reached. Codes were then grouped based on similarities and differences.	
	Data credibility was addressed by presenting the findings to an interdisciplinary group of clinicians and researchers (one physician, four	
	epidemiologists, three exercise trainers, one physical therapist, and one occupational therapist) familiar with the hip fracture trajectory to establish if	
	the findings made sense and were consistent with the current understanding of the recovery process post hip-fracture. The findings were presented in	
	a small group and one on one in the clinical setting. Participants were asked to verbally confirm or refute the findings.	
Findings	53 participants were satisfied with their functional recovery, 9 were not satisfied. 25 codes were identified and collapsed into four main themes.	
	1. Facilitators of recovery (identified by 53 participants satisfied with their recovery):	
	 professionals (40) – comments covered being buoyed by seeing physician frequently, having good doctors or surgeons, getting 	
	"correct" or "professional" care. "They evaluated professionals as a team and did not single out one provider over another in terms	

of help and support received". Communication and a positive attitude by professionals also important;
• social support (13) – from family and friends essential to their recovery. Specifically mentioned verbal encouragement helped them
maintain a positive attitude
• determination (12) – own determination to exercise and be involved
• lifestyle factors (4) & environment (1) – eating healthy food, taking appropriate medications and vitamins, and engaging in physical
activity. "an environment that encouraged healthy behaviors (i.e. facilitated physical activity) was important to promote exercise"
 individualised care – verbal encouragement (4);
• spirituality (4) – spirituality and belief in a supreme being helped them maintain their optimism throughout the process
• identifying goals (3) – returning home, regaining independence and being able to walk like they could prefracture
2. Factors that hinder recovery (identified by 9 participants dissatisfied with their recovery):
 medical complications/comorbidities (4)
 unpleasant sensations (3) – pain reported as a limiting factor
• age (1)
3. System recommendations to facilitate recovery:
• more care (26) – more direct physical & occupational therapy and more education about the recovery process and ways to optimise
physical function
 better care (9) – follow up and care in the home setting after discharge from rehabilitation
• spirituality (3), social support (2) – some participants said they would have like exposure to spiritual support options throughout the
course of their rehabilitation programme. Some participants also felt that additional social and spiritual supports were needed from
family and friends.
additional information (8)
 elimination of unpleasant sensations (4)
 policy (1)
4. Peer advice to facilitate recovery:
 participate (48) & listen to providers (19) – listen to healthcare instructions and participate as much as possible in rehabilitation activities. Comments included "listen to the advice from medical staff such as doctors, therapists, and nurses" and "Do a lot of
physical and occupational therapy even if it's painful
 positive attitude (20) & determination (13) – participants strongly recommended that older adults who sustain hip fractures
maintain a positive attitude, avoid worry and remain determined throughout the recovery experience
 be careful (8) – avoid subsequent trauma, prevent anything that would impede recovery, prevent falls
 push through pain (6), relieve pain – "do your physical therapy even though it may hurt" & "use all offered medications that could
alleviate pain and relax muscles"
 don't worry (4).
Numbers in brackets relate to the number of times noted

Comments Paper reports the study used to as the basis to recruit participants for this paper had stringent eligibility criteria because it was designed to evaluate	
	rehabilitation. Therefore, the findings of this study may only be applicable to a similar patient group. Although the findings were found to be credible
	with rehabilitation clinicians and researchers they were not verified with patients who had sustained hip fracture. Themes were determined by the
	interview guide.

1 Evidence tables – patient views

Study	Ziden 2008 & Ziden 2010 ^{353,354} . Country: Sweden. Setting: hospital		
Aim	Aim to explore & describe the experienced consequences of an acute hip fracture among home dwelling elderly people shortly after discharge. " ambition was to let the subjects concretize their experiences, for instance by describing in as great details as possible their ordinary daily activitie before and after the fracture."		
Population	Patients selected from a larger sample of 102 participants (ZIDEN2008 RCT) with acute hip fracture, >65 years old, living in own home, no cognitive impairment, and able to understand Swedish. Participants asked if they were willing to participate a few days after surgery. At 1 month: 18 participants, 16 women and 2 men At 1 year: 15 participants, 13 women and 2 men		
Method of	Semi-structured interviews using the phenomenographic method. Interviews held in patients own homes 1 month & 1 year after hospital discharge.		
gaining views	Interviews conducted in a conversational manner that allowed interviewees to speak freely and to express their own experiences of the consequences of the hip fracture. As an introduction, the subject was asked to narrate what had happened when he or she broke their hip. Follow up questions and prompts were used, such as "Tell me more about it", What does this mean to you?" and "Can you clarify?" Interviews were taped and were transcribed verbatim.		
Data analysis	Phenomenographic method described by Dahlgren & Fallsberg: interviews read through repeatedly to obtain a total concurrent overview ; statements extracted that dealt with consequences of hip fracture to achieve a concentrated and representative version of entire dialogues; quotes from previous step were compared in order to uncover sources of variation or agreement; similar quotes were grouped together, an attempt was made to "describe the essence of similarity within each group" (stage called articulating); these groups were then labelled/categorised and compared to ensure categories did not overlap. The grouping and describing stages were revised several times before the analysis was judged to be satisfactory. Sequence of steps in the analysis made separately by authors before joint discussions leading finally to consensus.		
Findings	At 1 month 8 categories in 3 focused areas were identified: In relation to your body and yourself: • You are limited to move and have lost confidence in your body (18 people) • You become humble and grateful (7 people) • You respect yourself and your own needs (2 people) In relation to others: • You become more dependent on others (12 people) • You gain more human contact and are treated in a friendly way by others (2 people) In relation to the life situation: • You are secluded and trapped at home (4 people) • You are old, closer to death and have lost your zest for life (4 people) • You take one day at a time and are uncertain about the future (7 people) At 1 year 6 categories in 2 focused areas were identified:		

APPENDIX E

	 Isolated life with more restricted activity and fewer social contacts 					
	a. more insecure and afraid (11 patients)					
	b. more limited ability to move (12 patients)					
	 Disappointed and sad that identity and life have changed (8 patients) 					
	 Satisfied with the situation or feeling even better than before fracture (5 patients) 					
	Conceptions of what influences hip fracture recovery					
	Own mind and actions influence recovery (10 patients)					
	 Treatment and actions from others influences recovery (4 patients) 					
	You cannot influence recovery (6 patients)

2 20 Appendix H: Health economic analysis

3 20.1 Cost analysis of nerve blocks, non-opioid analgesics and opioid

4 analgesics

- 5 20.1.1 Nerve block cost analysis
- 6 7

8

9

1

No studies were identified on the cost-effectiveness of nerve blocks compared to other forms of analgesia in providing adequate pain relief and reducing side effects and mortality.

10 As a consequence, we conducted a cost analysis where the different types and level of resources

11 used to administer a nerve block to a patient with a suspected hip fracture are based on the

12 GDG's opinion, summarised in Table 71 below.

13

14 Table 71: Cost analysis for nerve block

Resources	Unit price	Source of unit price
Spinal pack (gown and drape) *	£4.50	NHS hospital***

1 The **personnel costs** can vary depending on the time required to administer a nerve block, 2 which in turn depends on the technique used (nerve stimulator, ultrasound-guided, 3 landmark only) and the block used (3-in-1, femoral nerve only or fascia iliaca block). If a 4 fascia iliaca block is administered using a landmark technique only, then the following 5 sequence would be observed: 6 Obtaining equipment (needle, disinfectant, gloves, local anaesthetic etc) 7 Estimating patient's weight 8 Obtaining patient's consent 9 Identifying landmark -10 **Disinfecting skin** 11 Anaesthetising skin 12 Passing needle 13 Injecting local anaesthetic 14 Maintaining manual pressure distal to injecting site for a minute after injection -15 16 The GDG estimates that the whole process would require about 15 - 20min, and that the time 17 required would not change substantially if the block is administered by a consultant anaesthetist 18 or a SAS (staff and associate specialist). 19 20 At present, in most emergency departments that do advocate nerve blocks for hip fracture 21 patients, the block would be performed by 'middle grade doctors', i.e. specialist registrars (SpR), 22 senior specialist trainees (ST3-6) or senior clinical fellows. In some departments, junior doctors 23 can also administer the procedure. In operating departments and if asked to do elsewhere 24 anaesthetists will always have a trained assistant with them, usually an ODP, which would 25 increase the total cost for a nerve block to £63.33 (assuming an ODP wage of £27 per hour as that 26 of a senior nurse) 27 28 The GDG recognises that there is likely to be a wide variation in practice as far as the 29 administration of nerve blocks is concerned. 30 31 1) The nerve block may be administered with a ultrasound-guided technique, which would 32 require the use of ultrasound anaesthetic machines. An average cost of these machines 33 has been estimated at around £34,000 from hospital records supplied by the 34 Peterborough and Stamford Hospital NHS Foundation Trust. The equivalent annual cost 35 would be £5,313, assuming a life expectancy of 7 years and discount rate of 3.5%. 36 37 If we assume that the ultrasound machine would be used solely for nerve blocks in the 38 anaesthetic department and that it would be used 7 hours per day every day, including 39 weekends with 4 scans per hour, then the machine costs 52p per scan. 40 41 2) Bupivacaine can be used as local anaesthetic instead of Levobupivacaine, but the 42 difference in price would be minimal. 43 44 3) A nerve locator could be used when performing the nerve block, but its cost would be 45 minimal (GDG expert's opinion) 46

1 20.1.2 Non-opioid analgesics

- 2 We assume that patients will take a simple analgesic, such as paracetamol, continuously
- throughout their inpatient stay. The GDG noted that aspirin would not generally be used as an
 analgesic for our population, unless it is used as a low dose to prevent strokes. The average cost
- 5 of these drugs is less than £0.1p per dose (BNF 58).

6 20.1.3 Opioid analgesics

7

8 Table 72: Opioids controlled drugs

Category	Dose cost (source: BNF 58)
Diamorphine hydrochloride	£2.69
Morphine salts	£0.36
Oxycodone hydrochloride	£1.60
Buprenorphine	£0.72
Average cost	£1.34

⁹

10 The opioids reported in Table 723 are non-controlled drugs and can be administered within

existing nurse drug rounds, and therefore there is little extra cost associated with their

12 administration.

13

14 Table

- 15 2 summarises the opioids controlled drugs that could be administered to hip fracture
- 16 patients. This category of analgesics requires an additional round of two trained nurses to
- administer. The GDG estimates that this would involve approximately 15 minutes per
- 18 dose, with an extra cost of £10.50 (considering that the cost per hour of a staff nurse is
- 19 £21 (PSSRU 2009)). Hence, the cost of administering these controlled drugs is £11.84
- 20 (nurse time plus drug cost).
- 21

22 Table 72: Opioids controlled drugs

Category	Dose cost (source: BNF 58)
Diamorphine hydrochloride	£2.69
Morphine salts	£0.36
Oxycodone hydrochloride	£1.60
Buprenorphine	£0.72
Average cost	£1.34

1

2

- The opioids reported in Table 723 are non-controlled drugs and can be administered within
- existing nurse drug rounds, and therefore there is little extra cost associated with their
- 4 administration.
- 5

6 Table 3: Opioids non-controlled drugs

Category	Dose cost
	(source: BNF 58)
Codeine phospate	£1.83
Dihydrocodeine Tartrate	£2.58
Tramadol Hydrochoride	£1.47
Average cost	£1.96

7 The remaining opioid drugs (dipipanone hydrochloride, hydromorphone hydrochloride,

8 meptazinol, methadone hydrochloride, paperetum, pentazocine, pethidine hydrochloride) are

9 very rarely used in our population, as they are highly specialist analgesics for palliative care.

10 Fentanyl is rarely used in acute care, and is therefore not included in the dose cost.

- 11
- 12
- 13

14 **20.2** Hourly wage costs for a planned trauma list

- 15 The table below estimates the cost of one hour of personnel input for a planned trauma list.
- 16

17 Table 4: Personnel input cost

Categories of personnel	Cost of hourly wage (source:
	PSSRU 2009)
Consultant surgeon	£108
Consultant anaesthetist	£108
Scrub nurse (senior staff	£27
nurse)	
Unscrub nurse (runner –	£21
staff nurse)	
Radiographer	£25
Anaesthesia assistant [ODP]	£27
(as senior staff nurse)	
Recovery nurse (staff nurse)	£21

Tota	personnel costs	
------	-----------------	--

1

2 A general emergency list relies on registrars (both surgeons and anaesthetists) rather

£337

- than consultants. The hourly cost for registrars is £38 (per 48 hour week; source: PSSRU
- -3 4 2009⁵⁹). The total personnel costs per hour of a general emergency list would then be
- 5 £197.
- 6

1 20.3 Prices for sliding hip screws and short and long intramedullary nails

2 3

- 2 Healthcare UK Limited
- 3 (b): We have estimated the hospital stay using the unit cost per excess day associated with complex elderly patients (that is, the unit cost per day for days
- 4 exceeding the trim point). Using all the HRG unit costs reported for all Complex Elderly patients (Hospital Episode Statistics for England, Inpatient Statistics,
- 5 2007-08) we found a weighted mean of £152.

1 **20.5** Cost-effectiveness analysis of hospital investment versus no hospital

2 investment for early surgery

3 20.5.1 Introduction

4 The GDG assigned a high priority in the economic plan for an original economic analysis to the5 question:

6 "In patients with hip fractures what is the clinical and cost effectiveness of early surgery (within

7 24, 36 or 48 hours) on the incidence of complications such as mortality, pneumonia, pressure

8 sores, cognitive dysfunction and increased length of hospital stay?"

A review of the literature was conducted. The literature search and review methods can be found
 in Chapter 3. No cost-effectiveness analysis was found which addressed our clinical question. As a

11 consequence, the GDG felt that an original decision model was essential in order to inform their

- 12 recommendations.
- 13 The following general principles were adhered to:
- The GDG was consulted during the construction and interpretation of the model.
- When published data was not available, we used hospital records and experts' opinion to populate the model.
- Model assumptions were reported fully and transparently.
- The results were subject to sensitivity analysis and limitations were discussed.
- We followed the methods of the NICE reference case. Therefore costs were calculated
 from the NHS and PSS perspective. Health gain was measured in terms of quality adjusted life-years (QALYs) gained. Both future costs and QALYs were discounted at 3.5%.
- The model employed a cost-effectiveness threshold of £20,000 per QALY gained.
- The model was peer-reviewed by another health economist at the NCGC.
- 24

25 **20.5.2** Background

There are fundamentally two reasons why a patient with a diagnosed hip fracture is delayed in receiving surgery. First, the patient may be considered to be *unfit* for surgery for medical reasons, and therefore made to wait until the medical team optimises her status. Alternatively, a patient may be deemed to be fit for surgery at the time of admission, but will still incur delays linked with *administrative reasons*, such as lack of space on theatre lists and/or problems with theatre, surgical and anaesthetic staff cover.

32 In our economic analysis, we focus exclusively on the *administrative reasons* for surgical delay.

33 This is because, albeit all studies in the clinical review were initially considered for inclusion in the

34 economic model, the GDG concluded that only the subgroup of papers with a population that

35 excluded patients unfit for surgery was appropriate for basing the economic model upon.

36 In particular, the GDG considered that by removing patients unfit for surgery (defined as those for

37 whom: 'any medical reason when orthopaedic or anaesthetic staff felt that operation should be

38 *delayed in order to improve the patient's fitness for surgery*³⁰⁰) from our model, we would be

39 excluding confounding factors from the decision model, thus allowing more confidence in the

40 cost-effectiveness findings.

- 1 Those studies that had not excluded patients unfit for surgery from their population would
- 2 potentially have an imbalance in baseline characteristics which could result in skewing the data in
- 3 favour of the early surgery group. Even though these studies had used logistic regression to adjust
- 4 for confounding factors (such as ASA score, sex, age and comorbidities like cardiac problems), the
- 5 GDG still felt that the subgroup of papers that excluded patients unfit for surgery were more
- 6 robust.
- 7 Overall, three studies which excluded patients unfit for surgery from their population were
- 8 included in our clinical review: Moran (2005), Siegmeth (2005) and Orosz (2004)^{213,242,300}. Of these,
- 9 only Siegmeth³⁰⁰ reports data regarding whether patients returned to their original place of
- 10 residence or whether they changed residence (at 1 year follow up) and this was considered
- 11 essential information for modelling the different health states in our analysis.
- 12 Siegmeth (2005)³⁰⁰ excluded patients who were delayed for any medical reason when orthopaedic
- 13 or anaesthetic staff felt that operation should have been delayed in order to improve the patient's
- 14 fitness for surgery. Reasons for delays included anaemia requiring transfusion, correction of
- 15 electrolyte imbalance, uncontrolled diabetes and untreated heart failure. The GDG agreed that
- 16 the study adopted a set of diagnostically objective criteria in deciding which patients were
- 17 considered fit for surgery, and that no selection bias had been introduced in this process.
- 18 Furthermore, Siegmeth³⁰⁰ is a study set in the UK, and as such was considered to be more
- applicable to our question than studies set in different countries. As the paper interprets "early
- surgery" as surgery that took place within 48 hours from admission, we adopt this specific cut-off
- 21 point in our model.

22 20.5.3 Population and time horizon

- 23 The population for the cost-effectiveness analysis consists of hip fracture patients (male and
- female) hospitalised for surgery and considered to be fit for surgery. The model spans over a lifetime horizon.

26 **20.5.4** Software

27 The cost-effectiveness analyses were conducted using TreeAge Pro 2008.

28 20.5.5 Methods

- 29 We built a decision tree with Markov states where the expected costs and effectives of two
- alternatives are evaluated and compared: "investment for early surgery" vs. "no investment for
 early surgery". As discussed in section 20.5.8, this investment consists of the addition of extra
- 32 operating lists to the existing weekly number of theatre lists.
- 33 The health states of the model reflect the outcomes of Siegmeth (2005)³⁰⁰: at one year after
- surgery, patients can be "living in their own home", "living in a residential home", "living in anursing home", or "dead".
- 36 Since patients were followed at 1 year from surgery in Siegmeth (2005)³⁰⁰, the *cycle length* of the
- 37 Markov model is supposed to last one year. At the end of each cycle, patients can either stay in
- 38 the same health state or can transit to the "dead" state (the "absorbing" health state in the
- model). This is because no data were available from Siegmeth (2005)³⁰⁰ over the possible
- 40 transitions of patients between the other health state ("living in own home", "living in residential home" or "living in purging home"). Use of the state o
- home" or "living in nursing home"). Hence, we assume that patients' place of residence at 1 year
 stays the same for the rest of their lifetime. Although this is obviously a simplification, it is unlikely

that the impact of the intervention ("investment for early surgery") will have an effect after 1 year
from surgery.

3 The model starts with a simple decision node, which represent the decision to invest or not in

4 providing extra operating theatre lists. Following the investment, surgery takes place. However,

5 whether surgery will indeed take place "early" (within 48 hours from admission) or "late" is an

6 *uncertain* event. As a consequence, in our decision model we are able to address the question of 7 whether it is cost-effective to invest in extra operating lists (and therefore in extra personnel and

whether it is cost-effective to invest in extra operating lists (and therefore in extra personnel and
all the required resources) in order to increase the *probability* that those patients deemed "fit for

9 surgery" at admission are indeed operated within a certain time target. The probabilities of a

10 patient being in one of the four possible health states in the first cycle depend on whether they

11 have been operated within 48 hours or after 48 hours.

12 20.5.6 Treatment effects

13 The proportion of patients in each health state depends on the effectiveness of the treatment

14 (that is, of investment for early surgery), and on the proportion of patients still alive, which falls as

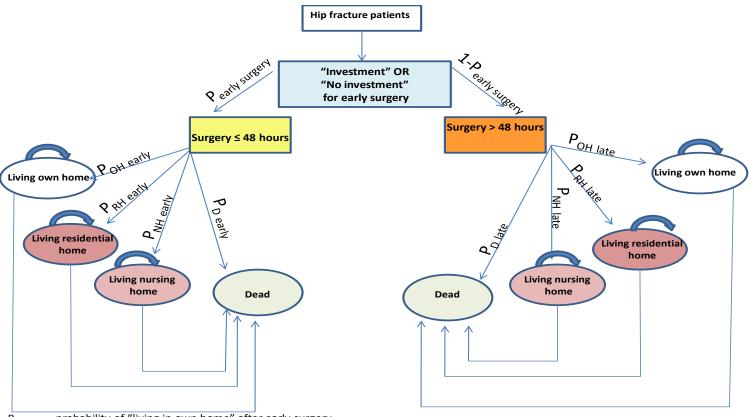

15 the number of cycles and therefore age increases.

16 Primary data were obtained from a GDG expert advisor regarding the proportion of patients in

17 each health state at 1 year follow up. These data (reported in Table 73 below) have been

18 extracted from the same database used in the Siegmeth³⁰⁰ study included in our clinical review,

and therefore refer to patients who were delayed for surgery not for medical reason but only foradministrative reasons.

 $P_{OH early} =$ probability of "living in own home" after early surgery $P_{RH early} =$ probability of "living in residential home" after early surgery $P_{NH early} =$ probability of "living in nursing home" after early surgery $P_{D early} =$ probability of being "dead" after early surgery

$$\begin{split} & P_{OH \ late} = \text{probability of "living in own home" after late surgery} \\ & P_{RH \ late} = \text{probability of "living in residential home" after late surgery} \\ & P_{NH \ late} = \text{probability of "living in nursing home" after late surgery} \\ & P_{\ D \ late} = \text{probability of being "dead" after late surgery} \end{split}$$

Figure 147: Decision tree with Markov states - investment for early surgery vs. no hospital investment for early surgery

	Patients who had	Patients who had	RR (surgery ≤ 48 hours
	surgery ≤ 48 hours	surgery > 48 hours	vs. surgery > 48 hours)
Total number of admissions	3445 (0.952%)	175 (0.048%)	
No. patients living in own	1734 (0.503%)	76 (0.434%)	1.16
home at 1 year			
No. patients living in	489 (0.142%)	22 (0.126%)	1.13
residential home at 1 year			
No. patients living in nursing	307 (0.089%)	16 (0.091%)	0.97
home at 1 year			
No. patients dead at 1 year	915 (0.266%)	61 (0.349%)	0.76

1 Table 73: Place of residence and mortality at 1 year

2

3 It is important to point out that, for the first cycle in our model, the mortality data are based on4 the information obtained from the database reported in Table 73.

5 For the long-term mortality, we considered a mean age of 81 for our cohort of patient, as this was

6 the mean age of patients in Siegmeth³⁰⁰. Following Parker(1992)²⁶⁰, the life expectancy after the

7 first cycle was assumed to be the same as that of the general population, and was obtained from

8 the Life Tables for the general population of England and Wales in the year 2005-2007 from the

- 9 Government Actuary Department:
- 10 (http://www.gad.gov.uk/Documents/Demography/EOL/ILT%202005-07/wltewm0507.xls).
- 11

12 This value was then adjusted for the ratio male/female corresponding to the patients

- 13 characteristics in the study as follows:
- 14 Total LE = LE_{female} * %female + LE_{male} * %male

15 **20.5.7** Quality of life

- 16 The EQ-5D utility weights for patients living in their own home, in a residential or nursing home
- 17 used in our model are based on the findings of the paper by Tidermark (2002)³²⁰ and are
- 18 summarised in Table 74 below.

19 Table 74: EQ-5D scores for health states

Health state	Utility score
Living in own home (at 1 year from the fracture)	0.64
Living in own home (after 1 year from the fracture)	0.56
Living in an institution	0.35

(a) Source: Tidermark (2002)

We have assumed that patients living in their own home correspond to those "living
 independently" in Tidermark (2002)³²⁰.

4 For each strategy, the expected QALYs in each cycle are calculated as follows:

Expected QALYs = Σ (U_i x P_i)

6 Where:

1

5

- 7 U_i = the utility score for health state i
- 8 P_i = the proportion of patients in health state i
- 9 and where health state i could be any of the health states reported in table 1.
- 10 The overall *lifetime expected QALYs* are given by the sum of QALYs calculated for each cycle. The
- incremental QALYs gained associated with a treatment strategy ("investment for early surgery" in our case) are calculated as the difference between the expected QALYs with that strategy and the
- 13 expected QALYs with the comparator (that is, "no investment for early surgery").
- 14 20.5.8 Cost analysis

15 20.5.8.1Early surgery implementation costs

16 The "investments for early surgery" in our model consists of adding extra operating lists aimed at 17 increasing the theatre capacity as a way of reducing the time hip fracture patients have to wait 18 before they receive surgery. The evidence for this strategy refers to hospital records supplied by a 19 GDG member. In 2008, the John Radcliffe hospital in Oxford implemented a policy aimed at 20 increasing the number of patients operated with 48 hours from admissions. This was achieved by 21 adding an extra five half-day operating lists to the weekly number of lists. All the extra lists were 22 added during a normal working week, not during the weekend. Each extra theatre list consisted of 23 four hours of operating time. Table 75 below describes the extra personnel that had to be 24 employed to run these extra lists and the associated costs incurred by the hospital.

25 Table 75: Personnel costs for extra operating lists

Categories of personnel	Hours per additional list	Cost of hourly wage (source: PSSRU 2009)	Additional personnel costs for the 5 extra
			lists
Consultant surgeon	4	£108	£2,160
Consultant anaesthetist	4	£108	£2,160
Orthogeriatrician	1	£108	£540
Scrub nurse (as senior staff nurse)	4	£27	£540
Unscrub nurse (runner)	4	£21	£420
Radiographer	4	£25	£500
Anaesthesia assistant [ODP] (as	4	£27	£540
senior staff nurse)			

Recovery nurse (as staff nurse)	4	£21	£420
Total pe	£7,280		
Total person	£378,560		

1

2 In addition to the extra personnel costs, we have to consider the *overhead costs* involved with

3 running the operating theatre for the extra five half-day lists. These costs have been estimated on

- 4 the basis of hospital records obtained from the Peterborough and Stamford District Hospital, and
- 5 are summarised in the Table 76 below.

6

7 Table 76: Overhead costs for the additional operating lists

Resource	Cost per minute (£)
Energy	0.18
Premises maintenance	0.09
Staff uniforms and clothing	0.01
Medical and surgical equipment (including instruments)	0.82
Dressings	0.06
Total overhead costs per minute	£1.16
Total overhead costs for 5 additional weekly lists	£1,392
Total overhead costs for 5 additional over 1 year	£72,384

8

9 It follows that the overall total implementation cost for early surgery amounts to £450,944.

10 Probability of early surgery after hospital investment

The following table summarises the number of patients operated within 48 hours from admissions before the extra operating lists were added (i.e. at baseline, year 2007-08) and for the years following the investment in extra operating lists. These data are also based on hospital

14 records supplied by the John Radcliffe Hospital in Oxford.

15 Table 77: Patients operated within and after 48 hours from admission - before and after

16 investments in extra operating lists

	2007-8	2008-9	2009-10	2010-2011*
	(baseline)	(intervention)		
Total cases operated during the	431	434	441	123
year				
Number of patients fit for	363	347	374	114
surgery within 48 hours during				
the year				

Number of patients delayed over	68	87	67	9
48hrs because unfit for surgery				
Number of patients <u>fit for</u>	192	233	316	109
surgery and operated within 48	(52.89%)	(67.15%)	(84.49%)	(95.61%)
hrs (%)				
Number of patients <u>fit for</u>	171 (47.11%)	114 (32.85%)	58 (15.51%)	5 (4.39%)
surgery but delayed >48hrs				

1 *data collected up to July 2010.

2 As Table 77 shows, the addition of the extra operating lists affected the *probability* that patients

3 fit for surgery are operated "early" (in our case, within 48 hours from admission). However, even

4 following this investment, early surgery is still a *random* event which is affected by many other

5 factors beyond the number of operating sessions available. Still, the data in Table 77 shows that

6 there is a clear trend in the increase in the number of patients fit for surgery that are operated

7 within 48 hours. There are several possible reasons for this trend, but they can mostly be seen as

8 the result of a learning process (by all the health care professionals involved in the care of the

9 patients) that produced positive spillover effects and efficiency gains in the years following the

10 implementation of the extra operating lists.

11 We use the data for 2008-09 as our intervention in the base case analysis. Data referring to other

12 years (2009-10 and 2010-11) are used in a sensitivity analysis.

13 Incremental cost per patient of implementation costs for extra theatre lists

14 The extra cost per patient of implementing an early surgery strategy for the first year following

the investment (that is, for 2008-09) correspond to $\pm 450,944/434 = \pm 1039.04$ (where 434 is the

total number of patients operated for hip fracture – whether within or after 48 hours from

17 admission – in the intervention year).

18 20.5.8.2Costing hospital length of stay

19 In addition to the costs linked with the extra operating lists, we have consider the costs for the

20 length of hospital stay. We assume that the daily cost of a hospital bed in an orthopaedic ward

corresponds to £241.69 (which is obtained from a weighted average of the costs of the excess bed

days for hip all hip fracture procedures (major, intermediate and minor) with all types of

complications). This cost is then multiplied by the length of stay for each group of patients,

summarised in Table 78 below and based on the findings of ³⁰⁰

25 Table 78: Mean length of hospital stay

days (95% Cl)			p<0.0001

26

27 **20.5.8.3**Health state costs

Health and social care costs for patients in the "living at own home" health state

1 We acknowledge that even if a patient is discharged to his own home and returns to an 2 independent living status, he will still incur in a higher level of use of health and domiciliary social 3 care compared to his pre-fracture status, as it is unlikely that he will completely regain his pre-4 fracture level of independence. The PSSRU (2009)⁵⁹ describes five possible "community care 5 packages" for individuals who live in their own home and consume a level of health and 6 domiciliary social care resources that varies according to their specific level of independence in 7 functional status. For our model, we assume that the health and domiciliary social care costs for 8 the patients in the "living in their own home" health state is an average of the cost of the "very 9 low", "low" and "medium" community care packages stated in the report. It follows that the 10 weekly average health care costs for patients living in their own home after the fracture amounts 11 to £9.9, and the weekly domiciliary social care costs to £98.1. While the health care costs are fully 12 funded by the NHS, the domiciliary social care costs will only be partially met by the local 13 authority. We found no published evidence regarding a national average of the percentage of domiciliary social care funded by local authorities⁶⁹, ³³⁹, ⁷⁰, ¹⁴². In our base case analysis, we 14 15 assume that 60% of these costs would be funded by the local authorities, and then test this 16 assumption in a sensitivity analysis.

Health and social care costs for patients in the "living in residential home" and "living in nursing home" health states

19 For patients living in a residential or in a nursing home, we need to consider the cost of long term

20 care. This is estimated from the unit cost of stay in private nursing homes and in private

- 21 residential care reported in the PSSRU 2009. The health care costs and fees per permanent
- 22 <u>residential week</u> are described in Table 79.

23 Table 79: Weekly health and social care costs for patients living in residential or nursing homes

Place of residence	Weekly health care costs	Weekly fees
Private nursing home	 £30.80, of which: £30 (GP weekly home visit) £0.80 (community nursing) 	£ 678
Private residential care	 £26.3, of which: £19.30 (GP weekly home visit) £7.00 (community nursing) 	£467

24

Once again, while the NHS fully funds the health care costs, it does not pay towards long-term
care for all patients. Moreover, only a proportion of the weekly fees will be met by the local
authorities. We found no published evidence regarding a national average of the percentage of
long-term care costs funded by local authorities, and as a consequence we assumed that the
proportion of the costs of long-term care borne by the NHS and PSS is equal to 60% in the base
case analysis, and changed it afterwards in a sensitivity analysis.

31 **20.5.9** Cost-effectiveness analysis

Table 80 below summarised the findings of the cost-effectiveness analysis for the determinist case. We found that, for the first year following the investment in extra operating lists, the

1 strategy "investment for early surgery" is not cost-effective at a willingness to pay of £20k per

2 QALYs gained.

3 Table 80: Cost-effectiveness results - deterministic analysis – first year following investment in

4 extra lists

Strategy	Cost	Incremental Cost	Effectiveness	Incremental Effectiveness	Incremental cost- effectiveness
No hospital investment for early surgery	£46.4K		2.32		(ICER)
Hospital investment for early surgery (with probability of early surgery =67.15%)	£47.4K	£1.0K	2.3622	0.0421	£/QALY 22776

5

- 6 Table 81: Costs breakdown for "investment" and "no investment" in early surgery reports a
- 7 breakdown of all the cost categories included in the model for the first year in which the extra8 operating lists were introduced.

9 Table 81: Costs breakdown for "investment" and "no investment" in early surgery

Resource item	Investment in extra	No investment in
	operating lists	extra operating lists
Rehab cost	NA	NA
Hospital-related costs (for length of stay and investment in extra operating lists)	7442	6917
Readmission	NA	NA
Community health care (own home)	1664	1630
Community social care (own home)	9892	9690
Community health care (residential and nursing home)	2224	2206
Community social care (residential and nursing home)	26200	26000
Total cost	£47422	£46443

10

In order to ascertain how robust the findings of Table 80 are, we ran a series of sensitivity analyses. Deterministic sensitivity analysis showed that the findings of our model are not sensitive to the hospital bed day cost. However, threshold sensitivity analyses found that "investing for early surgery" is the strategy with the highest net benefit in correspondence to a range of values

15 for different variables of the model, as summarised in Table 82 below.

16 **Table 82: Threshold sensitivity analyses**

Variable	Threshold values	Strategy with highest net benefit					
Probability of being operated	>0.68	Investment for early surgery					
within 48 hours when investing							
for early surgery							
Probability of living at home at 1	>0.53	Investment for early surgery					
year for early surgery							
Probability of living in nursing	<0.10	Investment for early surgery					

home at 1 year – early surgery		
	<0.15	Investment for early surgery
Probability of living in residential	<0.15	Investment for early surgery
home at 1 year – early surgery		
Mean length of hospital stay for	<18.47 days	Investment for early surgery
early surgery patients		
Number of extra operating lists	>4.38	No investment for early surgery
(of 4 hours each)		
Proportion of social care costs	>0.43	No investment for early surgery
paid by the NHS and local		
authorities		
Cost per day in hospital	>£292.50	Investment in early surgery

2 20.5.9.1 Probabilistic sensitivity analysis

3 A probabilistic sensitivity analysis was performed to assess the robustness of the model results to

4 plausible variations in the model parameters. Probability distributions were assigned to each

5 model parameter, where there was some measure of parameter variability. We then re-calculated

6 the main results 10000 times, and each time all the model parameters were set simultaneously,

7 selecting from the respective parameter distribution at random. Table 83 summarises the type

8 and properties of distributions used in the probabilistic sensitivity analysis.

9

10 Table 83: Description of the type and properties of distributions used in the probabilistic

11 sensitivity analysis

sensitivity analy		
Parameter	Type of distribution	Properties of distribution
Baseline risk	Beta	Bounded on 0 – 1 interval. Derived from sample size, number of patients experiencing events
Cost	Gamma	Bounded at 0, positively skewed. Derived from mean and standard error
Utility	Beta	Bounded on 0 – 1 interval. Derived from mean and sample size
Risk ratio	Lognormal	Bounded at 0. Derived from log (RR) and standard error of log (RR)

12

13 Table 84 reports the distribution, parameters and expected values for each variable of the model.

lambda = 0.063579259

1

- 2 The conventional way to interpret a cost-effectiveness analysis is to look at the option that is
- 3 optimal based on mean results from the probabilistic sensitivity analysis. These findings are
- 4 summarised in Table 85 below:

5 Table 85: Cost-effectiveness findings from probabilistic sensitivity analysis – first year following

6 investment in extra lists

Strategy	Cost	Incremental Cost	Effectiveness	Incremental ffectiveness	Incremental C/E ratio (ICER)	95% CI
No hospital investment for early surgery	£46.4K		2.3212			
Hospital investment for early surgery (<48 hours)	£47.4K	£1.0K	2.3637	0.0425	£/QALY 22542	Cost saving - dominanted

7

8 The PSA shows that there is a high uncertainty as to whether "investment for early surgery" is

9 cost-effective compared to "no investment for early surgery". This uncertainty can be graphically

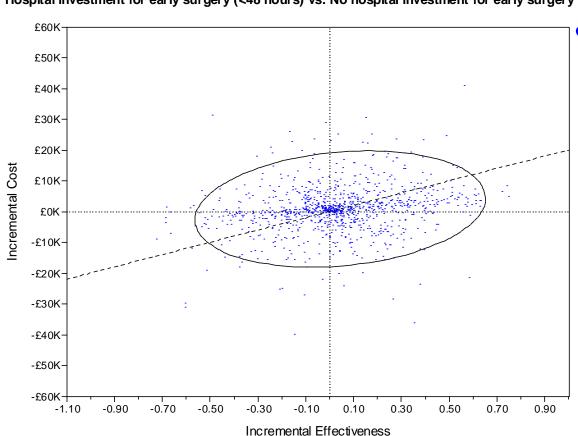

10 represented by plotting the results of the incremental analysis for all the 10,000 simulations into a

11 cost-effectiveness plane. Each point on the scatter plot represents the ICER of investment for

12 early surgery versus no investment for early surgery for each simulation. The dotted line

13 represents the £20,000/QALY threshold while the ellipse delimits the 95% confidence interval.

14

We found that the strategy of "investment in extra operating lists" was cost-effective in 50% of
the simulations, both at a willingness to pay of £20,000 per QALY and of 30,000 per QALY.

4 20.5.9.2Scenario analysis: second year following implementation

5 We now compare the non-investment strategy versus the investment strategy, where for the

6 latter we use data referring to the second year following the introduction of the additional

7 operating lists. The findings of the deterministic and of the probabilistic cost-effectiveness

8 analysis are summarised in Table 86 and Table 87 below.

9 Table 86: Cost-effectiveness results - deterministic analysis – second year following investment

10 in extra lists

Strategy	Cost	Incremental Cost	Effectiveness	Incremental effectiveness	Incremental Cost- effectiveness ratio (ICER)
No hospital investment for early surgery	£46.4K		2.32		
Hospital investment for early surgery (<48 hours) (with probability of early surgery from second year of investment=84.49% and with total number of patients operated in that year = 441)	£47.3К	£0.8K	2.413	0.093	£/QALY 9070

2 Table 87: Cost-effectiveness findings from probabilistic sensitivity analysis – first year following

3 investment in extra lists

Strategy	Cost	Incremental Cost	Effectiveness	Incremental effectiveness	Incremental Cost- effectiveness ratio (ICER)
No hospital investment for early surgery	£46.4K		2.321		
Hospital investment for early surgery (<48 hours) (with probability of early surgery from second year of investment=84.49% and with total number of patients operated in that year = 441)	£47.3K	£0.8K	2.415	0.094	£/QALY 8933

4

5 The strategy of introducing extra theatre list is therefore cost-effective from the second year of6 implementing the change aimed at reducing the waiting time to surgery for hip fracture patients.

7

8 20.5.10 Discussion

9 Our analysis showed that adding extra operating lists as a way of undertaking surgery within 48

10 hours from admission is slightly above the threshold of 20K/QALYs in the first year of

11 implementation, but becomes clearly cost-effective from the second year onwards.

- 12 However, our cost-effectiveness estimates are likely to be conservative in that we did not look at
- 13 the impact of early surgery on the presence of complications. This was because no information on
- 14 complications was available from Siegmeth (2005)³⁰⁰, and the other studies from the clinical

15 review that did report data on complications could not be used since they did not exclude

16 patients unfit for surgery from their population.

17 As resources and treatment effects data are based on information received from two specific

18 hospital settings (John Radcliffe hospital in Oxford and the Peterborough and Stamford Hospital

19 Foundation Trust), our findings may not be generalised to the whole NHS. For example, for some

- 20 hospitals the addition of extra operating lists may not be feasible if no spare theatre capacity is
- 21 available for this purpose.

22 A possible extension of the model could look at the possibility of introducing extra operating lists 23 during the weekend, which would be more expensive than weekdays, as personnel would have to 24 be paid up to a time and a third more in salary (BMA contract 2003). Patients admitted at 25 weekends or public holidays tend to do worse (Foss 2006)⁹⁵). However, most large hospitals have 26 trauma lists at the weekend, with planned trauma lists built into job plans. The reason why extra 27 lists were introduced during weekdays in the model that we have developed is because it was 28 acknowledged that there are more competing patients for planned trauma lists in those days, for 29 example patients requiring specialist reconstructions such as pelvic fractures or complex joint 30 injuries.

31

2 **20.6 Cost-effectiveness analysis of Hospital MDR vs Usual care**

3 20.6.1 Introduction

- The GDG identified as a high priority area for economic analysis the multidisciplinary managementin hospital for hip fracture patients.
- 6 In the economic plan, the clinical question (number 13) linked to this high priority area is the7 following:
- 8 "What is the clinical effectiveness and cost-effectiveness of the following hospital-based
 9 multidisciplinary rehabilitation programmes:
- 10 Hip Fracture Programme (HFP),
- 11 Geriatric Orthopaedic Rehabilitation Unit (GORU), and
- Mixed Assessment and Rehabilitation Unit (MARU)
- 13 versus each other and versus usual inpatient rehabilitation for hip fracture patients?"
- 14 The GDG felt that there were sufficient similarities between the GORU and MARU rehabilitation
- 15 programmes, and therefore decided to group the evidence for these interventions under the
- 16 same category of "GORU/MARU". A detailed discussion of the main characteristics of each

17 rehabilitation programme is presented in Chapter 12 of this Guideline.

A review of the literature was conducted. The literature search and review methods can be found
 in section 3. No cost-effectiveness analysis was found which addressed our clinical question. As a
 consequence, the GDG felt that an original economic model of the listed interventions was

- 21 essential in order to inform their recommendations.
- 22 The following general principles were adhered to:
- The GDG was consulted during the construction and interpretation of the model.
- When published data was not available we used expert opinion to populate the model.
- Model assumptions were reported fully and transparently.
- The results were subject to sensitivity analysis and limitations were discussed.
- We followed the methods of the NICE reference case. Therefore costs were
 calculated from a NHS and personal social services perspective. Health gain was
 measured in terms of quality-adjusted life-years (QALYs) gained. Both future costs
 and QALYs were discounted at 3.5%.
- The model employed a cost-effectiveness threshold of £20,000 per QALY gained.
- The model was peer-reviewed by another health economist at the NCGC.

2 20.6.2 Population and time horizon

The population for the cost-effectiveness analysis consists of hip fracture patients (male and
female) hospitalised for surgery. The model spans over a life-time horizon.

5 **20.6.3** Software

6 The cost-effectiveness analyses were conducted using TreeAge Pro 2008.

7 20.6.4 Structure of the model

8

20.6.4.1 Model cycles at time 0

9 We develop a Markov model with a cycle length of 3 months. Thus, all events are calculated on a

10 3 month basis at the end of which patients are in one of the possible health states. As the time

- 11 horizon in our model is lifetime, these cycles will keep repeating for the duration of the life
- 12 expectancy of the population in the studies.
- 13 The specific health states of our Markov model have been determined on the basis of the findings
- 14 of the clinical review. During cycle 0 the health states are determined by the *types of*
- 15 <u>complications</u> experienced while in hospital (and while undergoing their rehabilitation
- 16 programme). Using evidence from the clinical review, we assume that during cycle 0, patients can
- 17 occupy one of the following health states: "not recovered and with no complications", "not
- 18 recovered and with pressure sores", "not recovered and with moderate delirium", "not recovered
- 19 and with severe delirium", and "dead".
- 20 This is a graphic representation of cycle 0 of the Markov model:

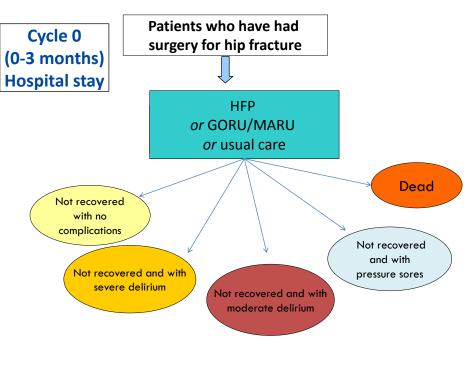

Figure 148: Cycle 0 Markov model

- 1 The above diagram illustrates that throughout their hospital stay (and hence, while still
- 2 undergoing their rehabilitation programme) patients will be considered as "not recovered". Some
- 3 of these "not recovered" patients will not develop any complications, but others will experience
- 4 delirium (moderate or severe), or pressure sores.

5 Evidence and treatment effects on complications – Cycle 0 of the Markov model

- 6 The clinical review found evidence of complications only from RCTs of HFP vs usual care. The
- 7 following complications were identified:
- 8

Table 88: Types of complications identified in the clinical review

Type of complication as reported in the clinical review	Source
Pressure sores	Vidan (2005) ³³⁵
Heart failure	Vidan (2005) ³³⁵
Pneumonia	Vidan (2005) ³³⁵
Confusion	Vidan (2005) ³³⁵
Chest infection, cardiac problem, bedsore	Swanson (1998) ³¹⁷
Stroke, emboli	Swanson (1998) ³¹⁷
Delirium	Marcantonio (2001) ²⁰¹
Severe delirium	Marcantonio (2001) ²⁰¹

9

10 The GDG decided to include the evidence on pressure sores from Vidan (2005)³³⁵ and on delirium

11 from Marcantonio (2001)²⁰¹. This was because of the good quality of the evidence; the reliable

12 ascertainment of these complications, and their well recognised impact on costs of hospital stay.

13 The findings of Vidan (2005)³³⁵ on "confusion" were not considered in the economic model since

14 they were not statistically significant and because they did not distinguish between "moderate"

and "severe" confusion, so it was not possible to use these findings alongside those of

16 Marcantonio (2001)²⁰¹ on delirium.

17 The evidence on complications from Swanson (1998)³¹⁷ was not included in the economic model

18 since the paper only provided a composite figure for chest infections, cardiac problems and

19 bedsores and did not distinguish among the different types of complications. As a consequence, it

was not possible to determine the loss in health-related Quality of Life (QoL) due to each

21 complication and the associated costs.

- 22 The evidence on pneumonia (Vidan 2005)³³⁵ was also not included in the economic model,
- 23 because it showed no difference between the intervention and control group.

- 1 The GDG decided to exclude the remaining complications (heart failure, and stroke) due to the
- 2 weaker evidence of effectiveness in prevention and the unreliable ascertainment of the
- 3 conditions. In particular, it was pointed out that 'heart failure' is very difficult to define and
- 4 diagnose clinically, and that 'stroke' is a whole series of different conditions with hugely differing
- 5 origins and outcomes.
- 6 As a consequence, the model only looked at the following complications: pressure sores (from
- 7 Vidan 2005)³³⁵, moderate delirium and severe delirium (Marcantonio 2001)²⁰¹.
- 8 The clinical review did not find evidence of complications for GORU/MARU vs usual care. The GDG
- 9 decided to consider the sample complications from the HFP (pressure sores, moderate and severe
- 10 delirium) and assume that there was no difference between the intervention and usual care (and
- 11 hence to consider a RR equal to 1). This assumption was subject to a sensitivity analysis. Table 19
- 12 below reports the transition probabilities for cycle 0 of the Markov model.

13 Table 89: Transition probabilities - cycle 0 of the Markov model

Transition Probability	Usual care	HFP	GORU
Probability moderate delirium*	22.0%	20.9% (RR 0.95)	22% (RR 1.00)
Probability severe delirium*	28.12%	11.25% (RR 0.4)	28.12% (RR 1.00)
Probability pressure sores**	16.46%	5.10 % (RR 0.31)	16.46% (RR 1.00)

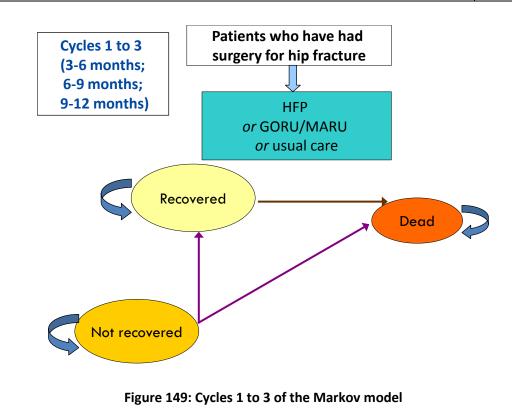

- 14 *= source: Marcantonio $(2001)^{201}$.
- 15 **= source: Vidan (2005)³³⁵
- 16
- 17

20.6.4.2Cycles 1 - onwards

18 As for the health states for cycle 1 – onwards, we again used the findings of the clinical review and

assume that, after their hospital discharge (and therefore, after their hospital-based MDR or their

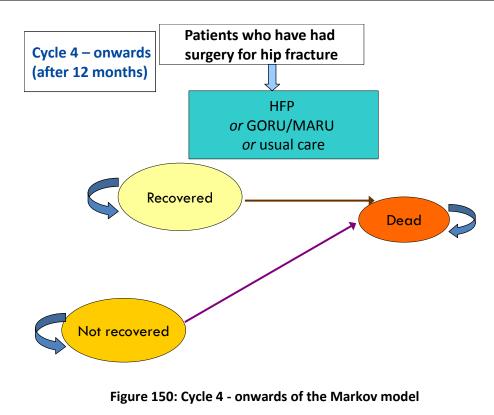

- usual care has been completed), patients can transit between the following health states:
 "recovered", "not recovered", and "dead".
- Vidan $(2005)^{335}$, Stenvall $(2007)^{312}$ and Shyu $(2008)^{297}$ report findings regarding the effectiveness
- 23 of hospital MDR programmes versus usual care to help patients recover their pre-fracture
- 24 Activities of Daily Living (ADL) levels. The "recovered" health state in our model refers therefore
- 25 to the case in which patients have gone back to their pre-fracture ADL levels.
- 26 This is a graphic representation of cycles 1 to 3 of Markov model, following hospital discharge:

- 4 The above diagram illustrates that, up until 12 months, patients who are in the "recovered"
- 5 health state can stay in the same state in the following cycles, or can transit to the "dead" health 6 state.
- 7 However, patients in the "not recovered" health state can stay in the same state at the end of
- 8 each cycle, or transit to the "recovered" or "dead" states. This is because, from the clinical review, 9
- we only have data regarding the transition of patients from the "not recovered" to the
- 10 "recovered" health state, and these data are only available up until 12 months follow up period.
- 11 No clinical data are available regarding the possible transition of the "recovered" patients to the 12 "not recovered health state".
- 13 From 12 months onwards, we assume that patients will no longer transit from the "not
- 14 recovered" to the "recovered" health state, and that patients can only remain in the state they
- 15 are in or transit to the "dead" state. This is because no clinical data are available from the clinical
- 16 review after that point. Hence, the relevant transitions between health states after 12 months will
- 17 be:

3

That is, from cycle 4 onwards, patients who are in the "recovered" health state will stay in that
state or transit to the "dead" state. Similarly, patients in the "not recovered" health state will

6 remain in that state or transit to the "dead" state.

7 Whether they are "recovered" or "not recovered", the place of residence at hospital discharge for

patients will also be affected by whether they received usual care, HFP or GORU/MARU as a form
 of rehabilitation programme. This circumstance is represented in Figure 150 below:

10

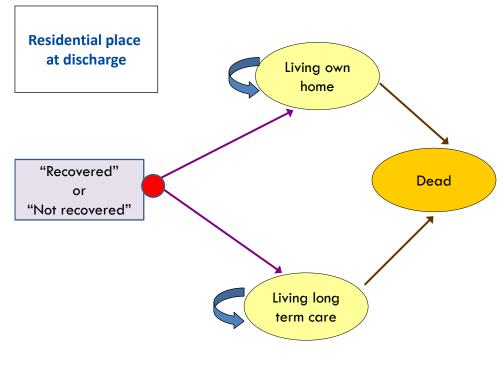

Figure 151: Place of residence at discharge

- 4 No evidence is available from the clinical review regarding whether patients discharged to their
- 5 own home would then transit to the "living in long term care" setting in subsequent cycles of the
- 6 model, and vice versa. Hence, we make the assumption that patients will keep living in the same
- 7 place of residence they had when they were discharged from hospital, and that they can only
- 8 transit to the "dead" state in the following cycles.

9 Evidence and treatment effects on recovery of ADL levels and on place of residence at discharge

- 10 Table 90 reports the levels of the transition probabilities used in the model
- 11

12 Table 90: Transition probability of Not Recovery of ADL pre-fracture levels

Transition probability of Not Recovery of ADL pre-fracture levels	Usual care	HFP	GORU/MARU
At 3 months ⁽¹⁾	0.73	0.5767 (RR=0.79)	0.5694 (RR=0.78)
At 6 months ⁽¹⁾	0.67	0.5293 (RR=0.79)	0.5226 (RR=0.78)
At 9 months ⁽²⁾	0.63	0.4977 (RR=0.79)	0.4914 (RR=0.78)
At 12 months ⁽³⁾	0.59	0.4661 (RR=0.79)	0.4602 (RR=0.78)

⁽¹⁾Data at 3 and 6 months from Vidan³³⁵ 13

- ⁽³⁾Data at 12 months pooled from Vidan, Shyu and Stenvall^{297,312,335} 16
- 17

¹⁴ ⁽²⁾Data at 9 months obtained with a linear extrapolation from the transition probabilities in Vidan³³⁵ 15

- 1 As for the place of residence following hospital discharge, we use the following treatment effects
- 2 in our model:

	Usual care	HFP	GORU/MARU	
Probability of returning to own home*	0.71	0.8094 (RR=1.14)	0.7881 (RR=1.11)	
*source: NCGC meta-analysis of clinical trials				

5 20.6.5 Evidence and treatment effects on mortality

6 In our model we distinguished two types of mortality: short-term mortality (within 12 months
7 from the start of the rehab programme) and long-term mortality (after 12 months).

8 <u>SHORT-TERM MORTALITY</u>

- 9 In order to take into account the difference in mortality due to the intervention, we used the data
- 10 from the RCTs included in our meta-analysis to estimate mortality. The data available from the
- 11 RCTs can be found in Table 21.

12 Table 91: Proportion of patients dead at different time points

	6 months	12 months
Usual care ¹	16.73%	21.38%
HFP ²	NA	17.32% (RR 0.81)
GORU/MARU ²	13.22% (RR 0.79)	20.31% (RR 0.95)

- 13 1 Data pooled from the usual care arms of RCTs in the clinical review
- 14 2 RR calculated compared to usual care
- 15

16 Data were available for usual care and GORU at 6 and 12 months from randomisation. Only 12

- 17 month data were available for the HFP intervention.
- 18 When more than one time points was available (i.e. for the usual care and GORU/MARU arms),
- 19 the probability of dying was calculated from the data reported in Table 4 as follows:
- 20

Prob_die_y to x = (% dead time x - % dead time y)/(1 - % dead time y)

- 21 Where:
- 22 Prob_die_y to x is the probability of dying from time y to the following time x
- 23• "% dead time x" is the proportion of patients dead at time x
- 24• "% dead time y" is the proportion of patients dead at time y
- To convert probabilities into a 3-month transition probability, which is the cycle length of themodel, we used the formula:

27 **1** - exp((ln(1- Prob_die_y to x))/((x-y)/3)

28

1 Where x and y are the initial and final time points of the interval considered, exp(a)=exponential

- 2 of a; and ln(a)=natural log of a.
- 3 <u>LONG-TERM MORTALITY</u>
- 4 The mean age of the patients when entering the model was 81 as this was the mean age of 5 patients in the RCTs.
- 6 Life expectancy in people who were alive one year after a hip fracture was assumed to be the
- 7 same as the general population in England and Wales, as reported in a study (Parker1992, citing
- 8 Elmerson1988)²⁶⁰. The remaining life expectancy for the participants of the RCTs was obtained
- 9 from the Life Tables for the general population of England and Wales in the year 2005-2007 from
- 10 the Government Actuary Department
- 11 (<u>http://www.gad.gov.uk/Documents/Demography/EOL/ILT%202005-07/witewm0507.xls</u>).
- The value was adjusted for the ratio male/female corresponding to the patients characteristics inthe RCTs as follows:
- 14 Total LE = LE_{female} * %female + LE_{male} * %male
- 15
- 16 20.6.6 Utilities data
- 17

20.6.6.1Utilities for cycle 0 (0-3 months)

- 18 Utilities indicate the preference for health states on a scale from 0 (death) to 1 (perfect health).
- 19 Quality of life values are attached to all health states.
- 20 Stage 0 of the model refers to the first three months of the Markov model. They capture the time
- 21 that the patients spend in hospital, during which they undergo a surgical treatment of the
- 22 fracture, following which the rehabilitation process starts.
- 23 The utility weights for the health states in cycle 0 are summarised in table 5.

24 Table 92: Utility weights for cycle 0

Table 5: Utility weights for cycle 0 Health state	Base case value	Source
"Not recovered, no complications"	0.314	ADL levels from Kennie (1988) ¹⁷⁴ ; EQ-5D scores from Tidermark (2002) ³²⁰
"Not recovered and with pressure sores"	0.19	Essex (2009) ⁸⁴
"Not recovered and with moderate delirium"	0.314	ADL levels from Kennie (1988) ¹⁷⁴ ; EQ-5D scores from Tidermark (2002) ³²⁰
"Not recovered and with severe delirium"	0.25	NICE clinical guideline on Delirium ²²²

- 1 We assume that the utility for the "not recovered, no complication" health state in the first three
- 2 months is the same as that of the "Not recovered" health state after the hospital discharge (i.e.
- 3 after the first cycle). The following paragraph explains how the utility for the "not recovered, no
- 4 complication" health state is obtained.
- 5 The NICE guideline on Delirium²²² reports utility weights for patients with moderate and severe
- 6 delirium using the finding of Ekman (2007)⁷⁴ on patients with dementia. Ekman (2007)⁷⁴ estimates
- 7 that the mean utility score for mild, moderate and severe dementia correspond to 0.62, 0.40 and
- 8 0.25 respectively. As for pressure sores, Essex (2009)⁸⁴ reports an EQ-5D score of 0.19 for patients
- 9 experiencing this complication. EQ-5D scores were obtained from a survey of a sample of 6
- 10 patients with pressure ulcers.
- 11 We proceeded by selecting the *lowest* EQ-5D score between the "not recovered with no
- 12 complication" health state and the EQ-5D linked with that particular complication (moderate
- 13 delirium, severe delirium or pressure sores). Thus, being the utility for "moderate delirium" 0.4,
- and being this utility higher than the one of the "not recovered with no complication" health state
- 15 (0.4 vs 0.314), we selected the latter also for the "not recovered and with moderate delirium"
- 16 health state.
- 17 However, the utility score for patients with severe delirium identified in the literature was lower
- 18 than then the score for the "not recovered, no complications" health state (0.25 vs 0.314).
- 19 Similarly, the utility score for pressure sores identified in the literature was lower than the one of
- 20 the "not recovered, no complications" health state (0.19 vs 0.314). Hence, we used the EQ-5D
- 21 score for those specific complications (severe delirium, pressure sores) in our model.
- 22

20.6.6.2Utilities for cycles 1 - onwards (3 months - onwards)

- 23 In order to assign an utility level to each of the health states for the model in cycles 1-onwards
- 24 (that is, "recovered" and "not recovered"), we proceeded by using the RCT included in our clinical $\frac{25}{1000}$
- review by Kennie et al (1988)¹⁷⁴ which reports the number of patients (in the treatment and
 control group) classified according to their level of independence in activities of daily living *before*
- admission (i.e. before the hip fracture) and *at entry into study* (i.e. before the rehabilitation
- 28 program has started). This information is summarised in tables 23 and 24 below.
- 29

Table 93: ADL levels before admission for treatment and control group (source: Kennie et al 1988)¹⁷⁴

Independence in activities of daily living before admission (Katz index)	Treatment group (n=54)	Control group (n=54)

Α	0	0
В	1	0
С	1	0
D	2	3
Е	18	19
F	23	16
G	7	15
Not classified	2	1

4 Source: Kennie et al (1988)¹⁷⁴

6 We use the data for the "independence in ADL before admission" to calculate the proportion of

7 independent and dependent patients that are in the "recovered" health state. Similarly, we use

8 the information on ADL for patients at entry into study to calculate the proportion of independent

9 and dependent patients that are in the "not recovered" health state.

10 As a consequence, we have:

- 12 (21+14) (from the treatment group) + (28+11) (from the control group)/100 = 74%
- 13 % of patients with A-B score in the "not recovered" state:
- 14 1/100 = 1%

Hence, in the "recovered" health state, 74% of patients have an ADL score of A-B, and 26% of

patients in the same state have an ADL score of C-G. On the other hand, in the "not recovered"
health state, only 1% of patients have ADL score of A-B, the rest having an ADL score of C-F.

18 For each of these two states we calculated the *composite utility*, that is the utility for the

19 "independent" and for the "dependent" patients. Tidermark (2002)³²⁰ reports EQ-5D scores

20 associated with ADL scores of A-B and C-F for hip fracture patients at 4 months after the fracture.

21 These weights correspond to: 0.68 for ADLs of A-B, and to 0.31 for ADLs of C-G.

Using the proportion of patients who were reported as independent and as dependent beforeadmission for the "recovered" health state we have:

- 24 74% * 0.68 = 0.053
- 25 26% * 0.31= 0.081
- 26 Thus, the utility weight for "recovered" health state corresponds to 0.584
- 27 As for the "Not recovered" health state we have:

⁵

- 1
- 2 1% *0.68 = 0.0068
- 3 99%*0.31 = 0.307

4 Thus, the utility weight for "not recovered" health state is: 0.314. We summarise these findings in

- 5 table 8:
- 6

7 Table 95: Utility weights for health states in cycles 1 -onwards

Health state	EQ-5D	Source
"Recovered"	0.584	ADL levels from Kennie (1988) ¹⁷⁴ ; EQ-5D scores from Tidermark (2002) ³²⁰
"Not recovered"	0.314	ADL levels from Kennie (1988) ¹⁷⁴ ; EQ-5D scores from Tidermark (2002) ³²⁰

8

9 20.6.7 Calculating QALYs gained

- 10 For each strategy (HFP, GORU/MARU and usual inpatient rehabilitation), the expected QALYs in
- 11 each cycle are calculated as follows:
- 12

24

Expected QALYs = Σ (U_i x P_i)

- 13 where
- 14 U_i = the utility score for health state i
- 15 P_i = the proportion of patients in health state i
- 16 and where health state i could be any of the health states reported in the Figures 147 and 148.
- 17 The proportion of patients in each health state depends on the effectiveness of the treatment,
- and on the proportion of patients still alive, which falls as the number of cycles and therefore ageincreases.
- The overall *lifetime expected QALYs* are given by the sum of QALYs calculated for each cycle. The *incremental QALYs gained* associated with a treatment strategy are calculated as the difference
- between the expected QALYs with that strategy and the expected QALYs with the comparator.
- 23 20.6.8 Cost data

20.6.8.1Cost data: cycle 0 (hospital stay)

During hospital stay, the costs will depend on the rehabilitation programme, the length of hospital
stay and health state related costs. We analyse each category in turn.

1 *Cost of the rehabilitation programme*

- 2 The NICE "Guide to the methods of technology appraisal" points out that national data based on
- 3 healthcare resource groups (HRGs), such as the Payment by Results tariff, are a valuable source of
- 4 information for resource use and costs and should be considered for use whey they are
- 5 appropriate and available ("Guide to the methods of technology appraisal", 2008, page 40).
- 6 However, data based on HRGs may not be appropriate in all circumstances, especially when the
- 7 definition of the HRG is broad or the mean cost probably does not reflect resource use in relation
- 8 to the interventions we are evaluating.
- 9 In our case, we would be using the HRG4 as the source to cost our rehab programmes. In the

10 document: "Casemix Service HRG4 - Guide to unbundling" it is pointed out that the HRG4 refers

- 11 to cases of **Discrete Rehab** services:
- "[..] only discrete rehabilitation activity and costs should be reported using the rehabilitation HRG4
 categories, for the reference costs collection."
- 14 And the 2007 document on Collection Guidance on Reference Costs for 2006-07 specifies that:
- 15 *"Rehabilitation HRGs are only generated where care is identified as taking place under a specialist*
- 16 rehabilitation consultation or within a discrete rehabilitation ward or unit. [..] Where a patient is
- 17 not admitted specifically to a rehabilitation unit or where rehabilitation treatment is undertaken
- 18 without transfer to a specialist consultant, or without transfer to a rehabilitation unit, this should
- 19 not be reported as discrete rehabilitation".
- 20 It would therefore seem that whilst this definition could apply to the GORU/MARU model (where
- 21 a patient is discharged from the orthopaedic unit and admitted to a separate geriatric
- 22 orthopaedic unit to receive the rehabilitation), it could not reflect the case of a HFP, where a
- patient is not usually discharged to the care of a specialist rehabilitation consultant.
- Thus, whilst we could use the HRG4 to cost a GORU and a MARU programme, we would not beable to use it to cost a HFP.
- 26 As a consequence, the GDG decided to evaluate the cost of the different rehabilitation
- 27 programmes using the level of resources specified in the different RCTs included in the clinical
- 28 review. When necessary, such levels have been adjusted by expert opinion to reflect a pattern of
- 29 care closer to the UK health care setting (see below).
- 30 The resources used in the different RCTs have been reported as *incremental* resources used with
- 31 respect to the usual care arm of the study. Using information on unit costs for NHS personnel
- 32 provided by the PSSRU 2009, we were then able to estimate the *incremental cost* of both HFP and
- 33 GORU/MARU with respect to usual care.
- 34 Moreover, it is important to note that the level of resources used in the two hospital-based MDR
- 35 programmes are calculated in such a way to reflect the length of hospital stay of the patients in
- 36 our model. Thus, we use the length of stay for the HFP to calculate the incremental resources and
- 37 costs for that programme, as follows. Similarly, we use the length of stay for GORU/MARU to
- 38 calculate the incremental resources and costs for that rehab programme.
- 39 Tables 9 11 summarise the incremental resources used in the HFP and the GORU/MARU
- 40 programme, compared to usual care.

Table 96: Incremental resource use for GORU/MARU programme versus usual care

Staff resources	Incremental resources	Source	Unit cost (source:	Incremental
	used, based on a LOS of		PSSRU 2008/09),	cost
	32.88 days		£ per hour	
Orthogeriatrician	Two consultant ward rounds (0.25/hour per patient each) and one weekly conference (0.25/hour = 0.75 hour per week per patient 0.75*4.6 weeks = 3.45 hours per patients	Kennie et al (1988) ¹⁷⁴	£108	£372.6
Physiotherapist	8.5 hours per patient	Naglie 2002 ²²⁰	£23	£195.5
Occupational therapist	5 hr/patient	GDG adjustment from the 7.5 hr/pt reported in Naglie ²²⁰	£23	£115
Nurse	Initial assessment within 72 hours (0.5 hour per patient) and twice weekly assessment afterwards (0.25*2)/hour per patient 0.5+0.5*4.6 weeks= 2.8 hours per patient	Naglie 2002 ²²⁰	Nurse team leader: £27 Nurse day ward: £21	£75.6 £58.8
Social worker	-0.4 hour per patient	Naglie 2002 ²²⁰	£29 (from community data)	-£11.6
Dietician	-0.4 hour per patient	Naglie 2002 ²²⁰	£23/	-£9.2
Total incremental	cost for GORU/MARU over	usual care:		£721 (with generic nurse, Band 5); £738 (with team leader nurse, Band 6)

Staff resources	Incremental resources	Source	Incremental cost
	used based on a LOS of		(using PSSRU
	25.5 days		2008/09 unit costs)
Orthogeriatrician	Initial assessment 0.5	Cameron (1993) ⁴² ;	£108*6.625=£715.50
	hour per patient, and	Shyu (2008) ²⁹⁷ ;	
	subsequently 0.25 hour	Marcantonio ²⁰¹	
	per day:		
	0.50 + 0.25*24.5 =6.625		
	hour per patient		
Physiotherapist	0.5 hour per patient per	Cameron (1993) ⁴²	£23*12.75=£293.25
or nurse	day:		
	0.50*25.5=12.75 hours		
Total incremental cost of HFP over usual care: £1009			

.... . . 1

2

3 Hence, the incremental cost for HFP over usual care is £1009, while for the GORU/MARU

4 programme it is £721 (with generic nurse) or £738 (with team leader nurse).

5 Health state related costs in cycle 0

6 To calculate the health state costs during the hospital stay, we used the NHS reference cost for

7 excess bed days reported in table 28 below. The excess bed day cost is the cost per day for days

8 exceeding the trimpoint, a cut-off that determines patients with exceptionally long stay, and as

9 such usually estimates the cost of care without the cost of procedures (i.e. without the cost of the

10 surgery. These costs reflect the presence of complications experienced by hip fracture patients

11 during their entire hospital stay. Moreover, they distinguish between "major" and "intermediate"

12 complications, thus allowing users to take into account the different degrees of resource use.

13 Table 98: National Schedule of Reference Costs Year : '2008-09' - NHS Trusts and PCTs combined 14 Non-Elective Inpatient (Long Stay) Excess Bed Day HRG Data for hip procedures

Currency Code	Currency Description	Activity	National Average Unit Cost
HA11A	Major Hip Procedures Category 2 for Trauma with Major CC	360	£243
HA11B	Major Hip Procedures Category 2 for Trauma with Intermediate CC	620	£242
HA11C	Major Hip Procedures Category 2 for Trauma without CC	162	£220
HA12B	Major Hip Procedures Category 1 for Trauma with CC	9,760	£237
HA12C	Major Hip Procedures Category 1 for Trauma without CC	1,230	£226
HA13A	Intermediate Hip Procedures for Trauma with	14,891	£240

	Major CC		
HA13B	Intermediate Hip Procedures for Trauma with Intermediate CC	12,856	£249
HA13C	Intermediate Hip Procedures for Trauma without CC	2,972	£223
HA14A	Minor Hip Procedures for Trauma with Major CC	5,195	£234
HA14B	Minor Hip Procedures for Trauma with Intermediate CC	5,808	£245

2 The GDG decided to calculate a weighted average cost of the different categories of hip fractures3 taking into account the level of activity associated with each procedure.

4 To cost the health state "not recovered with pressure sores" we use evidence from Bennett

5 (2004)¹⁷ regarding the cost of pressure ulcer treatment in the UK. The paper calculates the daily

6 cost of treating pressure ulcers looking at resources such as nurse time (dressing changes, patient

7 repositioning and risk assessment) dressings, antibiotics, diagnostic tests, and support surfaces.

8 These costs do not include inpatient costs, but assume that the patients are cared for in an

9 institutional setting (hospital or long-term care).

10 Pressure ulcers can have a different "grade", ranging from 1 to 4 as their complexity increases.

11 However, the GDG emphasised that the published evidence on the incidence of the different

12 types of pressure sores in hip fracture patients reports many contradictory findings from which it

13 is difficult to draw definitive conclusions when it comes to costs. We followed the evidence in

- 14 Rademakers (2007)²⁷⁰ and assumed that 97% of the pressure ulcers were of grade 2, and 3% of
- 15 grade 3 or 4.

16 Bennett (2004)¹⁷ reports a daily cost for grade 2 pressure sores of £42, and of £50 for grade 3 and

17 4. These daily costs refer to patients who do not develop any further complications linked to the

18 pressure sores (such as critical colonisation, cellulites, or osteomyelitis), as no evidence on such

19 conditions was available from the RCTs included in our clinical review. Table 99 reports the total

20 daily cost for the "not recovered with pressure sores" health state.

21 Table 99: Total daily hospital cost for patients with pressure sores

Category of cost	Level of cost
Daily inpatient hospital cost without	£220.07
complications	
Daily cost of grade 2 pressure sore	0.97*£45
Daily cost for grade 3 and 4 pressure sore	0.03*£50
Total daily cost for patients with pressure	£265.22
sores	

22

23 For the cost of the health state "not recovered with moderate delirium" we used the mean

24 weighted average cost for minor complications (£237), and for the cost of the health state "not

recovered with severe delirium", we used the mean weighted average cost for major and

intermediate complications (£242.89). One limit with this approach is that all patients with

27 moderate delirium are assumed to have undergone a Major Hip Procedures Category 1 for

1 Trauma. Even if the difference between the two cost figures is quite low (£5.89) we test the

- 2 impact of this assumption on the base case findings in a sensitivity analysis.
- 3 It has to be emphasised that this approach to calculate the health state costs in cycle 0 is
- 4 necessary in that only figures regarding the *total* length of hospital stay are available from the
- 5 evidence included in our clinical review. Ideally, we would have needed information regarding the
- 6 *additional* length of hospital stay for the patients experiencing a particular complication, both for
- the control and for the intervention groups, but this information was not available from the
 clinical review. Moreover, even if Marcantonio (2001)²⁰¹ reports the hospital days of delirium per
- 9 episode, it does not distinguish between the two types of delirium (moderate and severe) that
- 10 correspond to our health states in cycle 0 of the Markov model, and only gives an overall figure
- 11 for all types of delirium.

12

Health state	Average daily cost	Source
Not recovered and with	£220.07	Mean weighted average of excess bed days costs –
no complications		NHS reference costs 2008-08 Major, Intermediate
		and Minor Hip procedures with no complications
Not recovered and with	£265.22	See Table 29
pressure sores		
Not recovered and with	£237	Mean weighted average of excess bed days costs –
moderate delirium		NHS reference costs 2008-08. Major, Intermediate
		and Minor Hip procedures with minor complications
Not recovered and with	£242.89	Mean weighted average of excess bed days costs –
severe delirium		NHS reference costs 2008-08. Major, Intermediate
		and minor hip procedures with intermediate and
		major complications

13 Table 100: Daily inpatient average cost for health states in cycle 0

14

15 Evidence and treatment effects on length of hospital stay

16 The studies included in the clinical review comparing the GORU/MARU programme vs usual care

17 only reported the *total* length of hospital stay for patients in the intervention arm of the study.

18 Hence, no information was available to evaluate the number of days patients spent in the

- 19 orthopaedic ward and the number of days they spent in the orthogeriatric rehabilitation hospital
- 20 ward.
- 21 To calculate the length of stay at baseline (i.e. the usual care arm of the model), we pooled the
- 22 data for the usual care arm from all RCTs included in the clinical review. Table 101 reports the
- 23 relevant values for hospital length of stay used in the model:

24 Table 101: Mean length of hospital stay

Mean length of stay - usual care (days)	31.56

Mean difference length of stay - HFP (days)	-6.06
Mean difference length of stay - GORU/MARU (days)	1.32

2

20.6.8.2Cost data: cycle 1 - onwards

From cycle 1 – onwards, the costs for our model will depend on the place of discharge (whether
own home or residential or nursing home), which in turn will affect the level of health care
services and social care used, and on the probability of hospital readmissions.

6 Hospital readmissions

7

8 The RCTs on HFP versus usual care included in the clinical review did not report any information9 over the reasons for hospital readmissions nor the associated length of stay.

10 Two RCTs on GORU/MARU versus usual care (Galvard 1995 and Stenvall 2007)^{105,312} reported data

11 on length of stay following readmission available from two RCTs on GORU/MARU. However, the

12 reasons for readmissions (whether orthopaedic-related or any other medical reason) were only

13 given in Galvard (1995)¹⁰⁵.

14 Given the lack of data from the clinical review, the GDG decided to assume that readmissions

15 were composed by an equal proportion of patients are readmitted for surgery, medicine and

16 rehabilitation reasons. This assumption was also supported by unpublished data on readmissions

- following hip fracture obtained from a GDG member and based on hospital records from
- 18 Peterborough and Stamford NHS Foundation Trust.
- As for the length of stay following a hospital readmission, we followed the most recent clinical paper (Stenvall 2007)³¹² and assumed a LOS for readmission for usual care is 11 days and in the
- 21 intervention (whether GORU/MARU or HFP) is 7 days.

22 The cost data for the hospital readmissions were obtained from Czoski-Murray (2007)⁶¹, which

reports the unit costs for inpatient stay (at 2002 prices) for surgery (£381), medicine (£282) and

rehabilitation (£188). These costs are based on Netten et al (2002)²³³. The mean unit cost for inpatient stay for readmissions (at 2009 prices) was estimated at £367.00. This price has been

inpatient stay for readmissions (at 2009 prices) was estimated at £367.00. This price has been
 obtained using the annual percentage increases for prices of hospital and community health

27 services (HCHS) for 2002/03 - 2008/09 reported in the PSSRU 2009 report⁵⁹.

Community care costs for the "recovered" and "not recovered" health states when discharged to own home

To analyse the costs associated with the "recovered" and the "not recovered" health states we
 need to take in to consideration whether patients are discharged to a long-term care setting or to
 their own home.

33 The GDG decided that in determining the level of community (that is, health care and social care)

34 resources used after the hip fracture and after the rehabilitation programme it was important to

35 reflect the level of "dependency" and "independency" in activities of daily living of patients in each

36 of the health state.

37 The PSSRU 2009 identifies five different "packages" of community care provided in the home

38 setting of the patient (also known as "domiciliary care"), according to the different level of

- 1 dependency in the activities of daily living of the recipients. These packages of care are
- 2 summarised in Table 102 below.

Table 102: Weekly costs of community care packages – excluding accommodation and living expenses. Source PSSRU 2009.

Community care package	Description of the level of functional ability of the recipient of care	Weekly cost (excluding accommodation, living expenses and independently provided home care)	Average weekly cost of social care services	Average weekly cost of health care services
"Very low cost"	Mrs A. had problems with three activities of daily living: stairs, getting around outside, and bathing. Her problems stemmed from a previous stroke.	£49	£41.3 (£18.10 of home care (one hour of weekly local authority- organised home care)) and £23.20 of meals on wheals)	£7.70 for a 11.7 minutes of GP surgery visit (one every four weeks)
"Low cost"	Mrs B. had problems with three activities of daily living: stairs, getting around outside and bathing. Her problems stemmed from arthritic conditions and cardiovascular disease.	£87(1)	£72 of home care (4 hours of local authority- organised home care)	£14.3 (of which £6.60 of community nurse (one visit per month) and £7.70 of one GP visit (one every four weeks))
"Median cost"	Mrs C. had problems with four activities of daily living: stairs, getting around outside, dressing and bathing.	£188	£181 of home care (10 hours of weekly local authority- organised home care)	£7.70 for a 11.7 minutes of GP surgery visit (one every four weeks)
"High cost"	Mr D. had problems with seven activities of daily living: stairs, getting around outside and inside the house, using the toilet, transferring between	£273	£216 (of which £181 of home care (10 hours of weekly local authority- organised home care) and £35 for a	£58 £26 of community nurse (once a week); £24 for two monthly OT visits; £7.70 for a 11.7 minutes of GP

	chair and bed, dressing and bathing. His problems stemmed from arthritic conditions and a previous stroke.		day centre attended once a week)	surgery visit (one every four weeks)
"Very high cost"	Mrs E suffered from dementia and needed help with nine activities of daily living: stairs, getting around outside and inside the house, using the toilet, transferring between chair and bed, dressing, bathing, washing and feeding.	£576	£542 of home care (30 hours of weekly local authority- organised home care)	£34 £26 of community nurse (once a week); £7.70 for a 11.7 minutes of GP surgery visit (one every four weeks)

(1) Please note that the cost figure reported in the PSSRU 2009 for "low cost" is not correct
 (£129) as the cost for the independently provided health care has not been subtracted (£42).
 The correct figure should be £87.

We used the data from Kennie (1988)¹⁷⁴ to determine the proportion of patients with level of
independence from A to G to attribute the community care costs to the "recovered" and "not
recovered" health state.

For both health states ("recovered" and "not recovered"), we assume that patients with ADL
score A or B do not incur in any domicilary care cost. However, we assume that the same type of
patients will each visit the GP once weekly.

10 The weekly health and social care costs are calculated by multiplying the weekly unit cost of the

11 different type of care (as obtained from the PSSRU 2009) times the proportion of patients with

12 the corresponding ADL score in the specific health state and times the level of resources used

13 (which depend on the level of dependency). The health and social care costs for the "recovered"

14 and "not recovered" health states are described in Table 103 and in Table 104 below.

Table 103: Health and social care costs for patients in the "recovered" health state discharged at their own home

ADL	% ADL in recovered state	Unit health care costs	Health cost for recovered state	Unit social care costs	Social care costs for recovered state
A	0.454	7.7	3.4958	N/A	N/A

			20.9548		151.658
		Annual health care cost	1089.65	Annual social care cost	7886.19

4

5 Hence, the annual health and social care costs for the "recovered" and the "not recovered" health

6 state are:

7 Table 105: Annual health and social care costs for the "recovered" and the "not recovered"

8 health state

Annual health care costs	£557	£2989
Annual social care costs	£1090	£7886
Total community care costs	£1647	£10875

9

10 While the health care costs will be fully funded by the NHS, the social care costs will only be

11 generally partially funded by the local councils⁶⁹, ³³⁹, ⁷⁰, ¹⁴². It was not possible to identify a

12 national average for the social care costs funded by local authorities in the published literature,

13 and as a consequence an assumption had to be made regarding the proportion of this care that

14 was publicly funded. In the base case analysis, we assume that 60% of social care costs are funded

15 by the local authorities, and are therefore includable in the model, and we then test this

16 assumption in a sensitivity analysis.

1Community care costs for the "recovered" and "not recovered" health states when discharged to2long term care

- 3 The cost of long term care used in the model was estimated from the unit cost of stay in private
- 4 nursing homes, private residential care, voluntary residential care and local authority residential
- 5 care facility for older people. The care package costs per permanent residential week are
- 6 described in Table 106.

7 Table 106: Weekly long term care costs for patients not discharged to their own home.

8 (Source: PSSRU 2009).

Type of long term care	Weekly health care costs	Weekly fees (minus living expences)
Private nursing home	£30.80 £30.00 (GP weekly home visit) £0.80 (community nursing)	£678
Private residential care	£26.3 £19.30 (GP weekly home visit) £7.00 (community nursing)	£467
Voluntary residential care	£28.7 £19.30 (GP weekly home visit) £9.40 (community nursing)	£470
Local authority residential care	£20.9 £10.60 (GP weekly surgery visit) £10.30 (community nursing)	£902

9

10 These unit costs include the cost of external services such as community nursing, GP services as

well as personal living expenses. They also include capital costs for the local authority residential

12 care, and fees for the private and voluntary residential care. We subtracted £9.20, the cost of

personal living expenses per week, from each unit cost and estimated <u>£717.05</u>, the weighted
 average of £708.80, £493.80, £489.80 and £913.80, to be the weekly unit cost of long term care.

By also subtracting the health care costs, we get: <u>£557.64 as the weekly fees</u> for long term care

16 (£28997 per year). The (weighted) <u>health cost per week is £27</u> (£1404 per year).

17 The weighting is based on the distribution of residents, 65 years and older, in care homes in 1996.

18 It was reported that in nursing homes, local authority, private and voluntary residential homes the

19 number of residents were 5746, 5476, 2791 and 3664 respectively (Netten et al 1998)²³². A

similar approach is also followed in the cost-effectiveness analysis conducted in the NICE Delirium
 Guideline²²².

22 It is important to note that, contrary to the community care packages for domiciliary care, we

23 could not distinguish the level of long-term residential care according to the level of

24 "dependency" in ADL of the patients in the different health state. Hence, the same figure for

- community costs had to be used both for the "recovered" and "not recovered" health states if notdischarged at their own home.
- 27 As with the domiciliary care, the health care costs in table 18 will be fully funded by the NHS, but

the residential fees for long term care will only be generally partially funded by the local councils.

29 Moreover, only a very small proportion of patients (about 2%) qualifies for fully funded NHS care

- 1 (the so called "continuing care")⁶⁹, ³³⁹, ⁷⁰, ¹⁴². It was not possible to identify a national average for
- 2 this figure in the published literature, and as a consequence an assumption had to be made
- 3 regarding the proportion of residential costs in long term care paid by local authorities. In the
- 4 base case analysis, we assume that 60% of residential fees costs are funded by the local
- 5 authorities, and then change this assumption in a sensitivity analysis.

6 20.6.9 Cost-effectiveness findings for base-case analysis

7 In the base case analysis, HFP is the dominant strategy (more effective, less costly) than both8 GORU/MARU and usual care.

8 GORU/MARU and usual of

9

10 Table 107: Cost-effectiveness findings from the deterministic base case analysis

Strategy	Cost (£000)	Incremental Cost* (£000)	Effectiveness (QALYs)	Incremental Effectiveness* (QALYs)	Incremental cost- effectiveness
HFP	£34		3.75		
GORU/MARU	£36	£2	3.62	-0.13	(Dominated by HFP)
Usual care	£59	£26	2.73	-1.02	(Dominated by HFP)

11

*Compared with HFP

12

- 13 Table 38 below shows the breakdown of the different cost categories for the three strategies of
- 14 the deterministic base case
- 15

16 Table 108: Cost breakdown for usual care, HFP and GORU/MARU

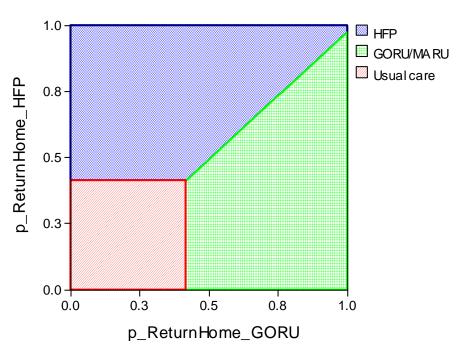

Resource item	Usual Care	HFP	GORU	
Rehab cost (initial costs)*	-	1009	729	
Complications*	-	-548	217	
Readmission	969.5	762.2	535.3	
Health care costs – living in own home	9178	4032	3738	
Social care costs – living in own home	14,000	5,000	5,000	
Health care costs – residential and nursing home	2,615	1,801	1930	
Social care costs (fees) - residential and nursing home	32,000	22,000	24,000	
Total cost	58762.50	33595.2	35203.3	

- 17 * calculated incrementally vs usual care
- 18
- 19 *20.6.9.1*Sensitivity analyses

The results were not sensitive to changes in several parameters (length of hospitals stay, cost
 of long-term care, proportion of long-term care borne by the NHS and PSS).

However, the results were sensitive to changes in the probability of returning home for both
HFP and GORU/MARU. In the base case analysis, the probability of returning home for the
HFP is 0.81 (RR of HFP vs usual care: 1.14), and for GORU/MARU it is 0.79 (RR of GORU/MARU
vs usual care: 1.11). The findings of a two-way sensitivity analysis on such probabilities are
reported in the graph below.

- 10
- 11

Net Monetary Benefit (wtp=20000.) Sensitivity Analysis p_ReturnHome_GORU and p_ReturnHome_HFP

- 12 13
- 14
- 15 A threshold sensitivity analysis shows that:
- a) If the probability of returning home for HFP <0.77 (it is 0.81 in the base case scenario),
 then GORU/MARU is the most cost-effective option at a willingness to pay threshold of
 £20,000 per QALY.
- b) If probability of returning home for GORU/MARU <0.83 (it is 0.79 in the base case
 scenario), then HFP is the most cost-effective option at a willingness to pay threshold of
 £20,000 per QALY.

- 4 is always the most cost-effective option.
 - 20.6.9.2 Probabilistic sensitivity analysis
- 6 A probabilistic sensitivity analysis was performed to assess the robustness of the model 7 results to plausible variations in the model parameters.
- 8 Probability distributions were assigned to each model parameter, where there was some
- 9 measure of parameter variability. We then re-calculated the main results 10,000 times, and
- 10 each time all the model parameters were set simultaneously, selecting from the respective
- parameter distribution at random. Table 109 describes the type and properties of the
- 12 distributions used in the probabilistic sensitivity analysis.
- 13

Table 109: Description of the type and properties of distributions used in the probabilistic sensitivity analysis

Parameter	Type of distribution	Properties of distribution
Baseline risk	Beta	Bounded on 0 – 1 interval. Derived from sample size, number of patients experiencing events
Cost	Gamma	Bounded at 0, positively skewed. Derived from mean and standard error
Utility	Beta	Bounded on 0 – 1 interval. Derived from mean and sample size
Risk ratio, length of stay	Lognormal	Bounded at 0. Derived from log and standard error of log
Mean differences (e.g. in length of stay, time of therapies, etc.)	Normal	Derived from mean and standard deviation

16

- Table 110 summarises the distribution, parameters and expected values for each variable ofthe model.

- 2 The conventional way to identify the most cost-effective strategy is to look at the option that is
- 3 optimal based on the mean costs and mean QALYs averaged across all of the probabilistic
- 4 simulations. These findings are summarised in Table 111.

5

6 Table 111: Cost-effectiveness analysis from probabilistic analysis

Strategy	Cost	Incremental Cost	Effectiveness	Incremental effectiveness	Incremental C/E (ICER)
HFP	£34K		3.74		
GORU/MARU	£36K	£2K	3.61	-0.13	(Dominated)
Usual care	£59K	£25K	2.73	-1.01	(Dominated)

7

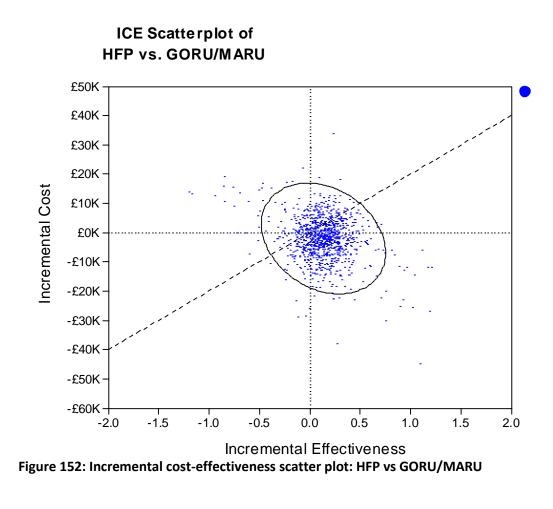

8 The probabilistic results are very similar to the deterministic ones indicating that HFP is dominant
 9 (has lower cost and more QALYs) compared with the two alternatives.

10 These findings are described in Figures 151, 152 and 153. Each point on the second scatter plot

11 represents the incremental cost and QALYs gained for HFP vs GORU for one simulation. The

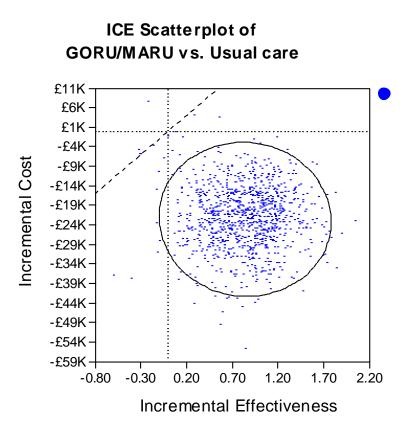

12 dotted line represents the £20,000/QALY threshold and the ellipse delimits the 95% confidence

13 space.

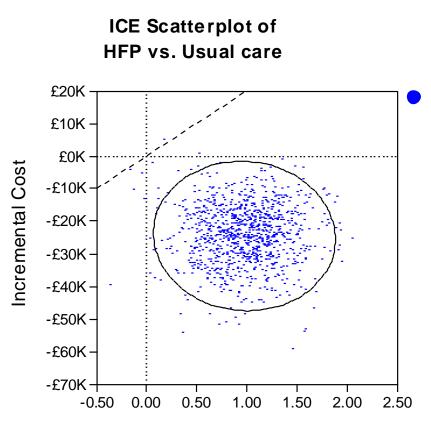

4 The scatter plot of HFP vs usual care shows the high certainty of HFP being cost-effective as all the

dots in the 95% confidence ellipse are below the £20,000/QALY threshold and more than 95% are
cost saving.

3 Figure 153: Incremental cost-effectiveness scatter plot: GORU/MARU vs. usual care

1Incremental Effectiveness2Figure 154: Incremental cost-effectiveness scatter plot - HFP vs usual care3

4 However, when we compared HFP with GORU the 95% CI showed a greater uncertainty as HFP

5 was dominant in the lower bound and GORU was dominant in the upper bound. The uncertainty

6 can be graphically represented by plotting the results of the incremental analysis for all the

7 10,000 simulations into a cost-effectiveness plane.

8 We also found that, at a willingness to pay equal to £20,000 per QALY, HFP was the optimal

9 strategy in 70% of the simulations; GORU/MARU was the most cost-effective intervention in 30%

10 of simulations, and usual care was never the optimal strategy. These findings are summarised in

11 table 42 below:

12 Table 42: Probability most cost-effective intervention at a willingness to pay of £20,000 and 13 £30,000 per QALY

Strategy	Probability most cost-effective intervention at a WTP of £20,000 per QALY	Probability most cost-effective intervention at a WTP of £30,000 per QALY
HFP	0.70	0.80
GORU/MARU	0.30	0.20
Usual care	0	0

- 14
- 15

16

1 20.6.10 Discussion

2 The optimal strategy in a cost-effectiveness analysis is the one with the highest incremental net 3 benefit averaged across all the probabilistic simulations. This was HFP.

4 The model showed that usual care was clearly not the optimal strategy.

5 However, there was some uncertainty about which strategy was the most cost-effective between 6 HFP and GORU/MARU. In particular the results were sensitive to the proportion of patients 7 returning home after their rehabilitation: if the probability of returning home after undergoing a

8 GORU/MARU programme was 83% (instead of 79% in the base case) then GORU is the optimal

- 9 strategy.
- 10
- 11 Our analysis had to rely on several assumptions.

12 Firstly, no evidence was available which compared directly HFP vs GORU/MARU. As a

13 consequence, only an indirect comparison between the two hospital MDR programmes was

14 possible. This meant that findings had to be pooled in the usual care arm of the different RCTs

15 included in our clinical review, thus assuming that "usual care arms" in all such studies were

16 sufficiently similar. However, the GDG agreed that the population included in the RCTs on HFP

17 and the population included in the RCTs on GORU were sufficiently similar and that therefore our

18 findings were not affected by counfounding factors.

19 Secondly, no data were available regarding the presence and incidence of complications in the

20 GORU/MARU programme versus usual care. The assumption that in this case the relative risk for

21 that rehab programme was equal to 1 implies that we may have underestimated the efficacy of

22 GORU/MARU in reducing the presence of post-operative complications, and as a consequence,

23 that we may have overestimated its costs and decrement in quality of life compared to HFP.

24 However, when we changed the probabilities of complications for GORU/MARU in a one-way sensitivity analysis, the findings of the cost-effectiveness analysis did not change, and HFP was still

- 25
- 26 the dominant strategy.

27 Finally, the finding of the meta-analysis of clinical trials regarding the length of stay showed a

28 longer length of stay for the GORU/MARU programme versus usual care (mean difference (days):

- 1.32). However, the inclusion of the study by Galvard (1995)¹⁰⁵ in the meta-analysis may have 29
- 30 biased this finding. This is because Galvard (1995)¹⁰⁵ reports a mean length of stay of 53.3 days for

31 the intervention (GORU) group and of 28 days for usual care. This finding, according to the

32 authors, was due to the fact that GORU was a new rehabilitation programme that had just been

33 implemented in their hospital, and the hospital staff was not yet experienced in the management

34 of the programme, which could have resulted in a longer length of stay for patients in the

35 intervention group. As a consequence, we may have overestimated the costs of hospital stay for

36 GORU/MARU. However, when we changed the length of hospital stay for the GORU/MARU 37 programme in a one-way sensitivity analysis, the findings of the cost-effectiveness analysis did not

- 38 change, and HFP was still the dominant strategy.
- 39

2 **20.7** Cost-effectiveness analysis of Community MDR vs Usual care

3 20.7.1 Introduction

- 4 The GDG identified the multidisciplinary management in the community for hip fracture patients5 as a high priority area for economic analysis.
- 6 The clinical question linked to this high priority area is the following:
- 7 What is the comparative effectiveness of community -based multidisciplinary rehabilitation8 models versus usual care?
- 9 A review of the literature was conducted followed by economic modelling of the cost-
- 10 effectiveness of the listed interventions in England and Wales. The literature search and review
- 11 methods can be Chapter 3. No cost-effectiveness analysis was found which addressed our clinical
- 12 question. As a consequence, the GDG felt that an original economic model was essential in order
- 13 to support their recommendations.
- 14 The following general principles were adhered to:
- The GDG was consulted during the construction and interpretation of the model.
- When published data was not available we used expert opinion to populate the model.
- Model assumptions were reported fully and transparently.
- The results were subject to sensitivity analysis and limitations were discussed.
- We followed the methods of the NICE reference case. Therefore costs were
 calculated from a health services perspective. Health gain was measured in terms
 of quality-adjusted life-years (QALYs) gained. Both future costs and QALYs were
 discounted at 3.5%.
- The model employed a cost-effectiveness threshold of £20,000 per QALY gained.
- The model was peer-reviewed by another health economist at the NCGC.

26 20.7.2 Population and time horizon

The population for the cost-effectiveness analysis consists of hip fracture patients (male andfemale) hospitalised for surgery. The model spans over a life-time horizon.

29 **20.7.3** Software

30 The cost-effectiveness analyses were conducted using TreeAge Pro 2008.

1 20.7.4 Economic evaluation type

- 2 We conduct a cost-utility analysis, where health outcomes are measured as Quality-
- Adjusted Life-Years (QALYs). The cost effectiveness outcome of the model is measured as
 cost per QALY gained.

5 20.7.5 Time horizon, Perspective, Discount rates used

- 6 The model spans over a life-time horizon. The perspective used is that of the UK NHS and
- 7 PSS. All costs considered in the model were calculated at on the basis of a four-months
- 8 follow-up time and hence were not discounted. However, we used a discount rate of 3.5%
- 9 for the health gains, as these were calculated throughout the remaining life of the cohort
- 10 of patients.

11 **20.7.6** Structure of the model

- 12 The structure of our model reflects the findings of the RCT by Crotty et al (2002)⁵⁸. The paper
- reports SF-36 scores for surviving patients, both in the community MDR and in the usual care arm
 of the study, at a 4 months follow up.
- 15 We develop a decision tree with Markov states, where a hip fracture patients can either receive a
- 16 community based MDR programme or usual inpatient rehabilitation. Following this decision
- 17 node, a chance node determines whether patients survive or die following their specific
- 18 rehabilitation programme. The probability associated to this chance node is derived from Crotty
- 19 et al (2002)⁵⁸ at a 4 months follow up. Subsequently, patients who are alive after the 4-months
- follow up period transit in a Markov state, "alive after follow up". Patients will then either stay in
- 21 that state or transit to the "dead" state in the following cycles.

22 The structure of the model is the following:

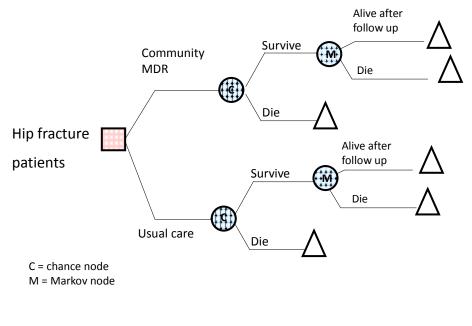

Figure 155: Model structure - community MDR vs usual care

1 20.7.7 Utility data

- 2 Utility weights are calculated using SF-36 scores obtained from Crotty et al (2002)⁵⁸. The
- 3 paper only reports total scores for the physical and mental components. Following
- 4 personal communications with the authors, we were able to access individual SF-36
- 5 scores, reported in Table 112 below:

6 Table 1123: SF-36 scores based on Crotty et al (2002)⁵⁸.

SF-36 domain, Mean (SD)	Conventional Care, n=29	Early Discharge, n=30
Physical functioning	28.8 (25.2)	41.2 (26.6)
Social functioning	62.1 (40.0)	72.5 (32.4)
Role-physical	61.2 (41.0)	53.3 (40.9)
Role-emotional	83.9 (31.6)	77.8 (38.5)
Mental health	77.9 (14.2)	80.1 (19.8)
Vitality	45.0 (21.9)	54.2 (24.3)
Bodily pain	61.4 (30.9)	65.1 (24.4)
General health	61.8 (30.1)	69.3 (24.1)

7 Source: primary data supplied by the authors of Crotty et al (2002)⁵⁸

8 Using the Ara-Brazier method⁷, we mapped the individual SF-36 scores in EQ-5D utility weights.

9 We found that the EQ-5D weight for patients undergoing community MDR is 0.732, and for

10 patients undergoing usual inpatient rehabilitation is 0.643. As the effectiveness data refer to

findings at 4 months ⁵⁸, we used these utility weights for cycle 0 only. For cycle 1-onwards we

12 assume that there is no difference in the utility score of the two groups of patients, and use the

13 EQ-5D score of the control group also for patients in the community MDR arm of the model.

14 **20.7.8** Mortality

15 The mortality rates for the community MDR and usual care patients have been adjusted to take 16 into account the baseline characteristics of the two groups, which were very different in the two 17 arms of Crotty et al (2002)⁵⁸, since 62% of patients were female in the COMMUNITY MDR versus 18 75% in the usual care group, and the median age for COMMUNITY MDR patients was 81.6 versus 19 83.5 years in the usual care arm.

20 First, we have calculated the age and gender-adjusted mortality rate (AMR) for the general UK

21 population as per characteristics in usual care arm and the same for community MDR arm. Then,

we have calculated the Standardised Mortality Rate (SMR) as = MR/AMR, both the usual care and

the community MDR arm. We have then assumed that the average age for the overall population

in the model was 80 years of age, and we have determined the probability of death using the

25 formula: SMR*pDeath[80].

26 We have found that that probability of death at 4 months for the patients in the usual care arm

27 corresponds to 0.07239, and for patients in the community MDR group is equal to 0.067. The

relative risk of the mortality rate for community MDR compared to usual care is 0.925.

1 20.7.9 Calculating QALYs gained

- For each strategy (community MDR and usual inpatient rehabilitation), the expected QALYs in the
 "survived" health state at each cycle are calculated as follows:
- 4

Expected QALYs = Σ (U_{survived} x P_{survived})

- 5 where: $U_{survived}$ = the utility score for the patients who are still alive and $P_{survived}$ = the proportion of 6 alive patients
- 7 The proportion of patients in the "alive" health state depends on the effectiveness of the
- 8 treatment, and on the proportion of patients still alive, which falls as the number of cycles and
- 9 therefore age increases.

10 The overall *lifetime expected QALYs* are given by the sum of QALYs calculated for each cycle. The

11 *incremental QALYs gained* associated with a treatment strategy are calculated as the difference

12 between the expected QALYs with that strategy and the expected QALYs with the comparator.

13 20.7.10 Cost analysis

14 **20.7.10.1**Cost for the community MDR and inpatient rehabilitation programmes.

15 While in hospital, we assume that there is no difference in the level and type of resources used by

patients in the two groups, as no evidence of the contrary was found in the literature. Moreover,

17 as patients receive their inpatients rehabilitation services without being discharged to a different

18 ward, they will still be under the same HRG recorded at admission. Thus, the rehabilitation that

patients receive while in hospital is not a type of discrete rehabilitation service, that is, a service that can be cost using its own HRG, since: *"rehabilitation HRGs are only generated where care is*

that can be cost using its own HRG, since: *"rehabilitation HRGs are only generated where care is identified as taking place under a specialist rehabilitation consultation or within a discrete*

22 rehabilitation ward or unit. [..] Where a patient is not admitted specifically to a rehabilitation unit

23 or where rehabilitation treatment is undertaken without transfer to a specialist consultant, or

24 without transfer to a rehabilitation unit, this should not be reported as discrete rehabilitation"

25 (Collection Guidance on Reference Costs for 2006-07⁶⁸).

- As a consequence, we use the reference cost for excess bed days reported in the National
- Schedule of Reference Costs Year : '2008-09' NHS Trusts and PCTs combined Non-Elective
 Inpatient (Long Stay)
- 29 Crotty et al (2002)⁵⁸ report evidence on the presence of complications experienced by hip fracture
- 30 patients in the two groups while in acute care. None of these complications were statistically

31 significant different between usual care and community MDR (the complications were:

32 pneumonia, pressure sores, confusion, wound infection and urinary tract infection). Moreover, no

33 additional information was provided in the paper as to whether those complications resulted in a

34 prolonged length of hospital stay for patients in the community MDR scheme. Thus, we used the

35 weighted average NHS reference cost for excess bed days for major, intermediate and minor hip

36 procedures with all types of complications, amounting to £241.68 per day.

37 As for the daily cost of the community MDR scheme, we use the NHS reference cost (2008-09)

reported for "Hospital at Home/ Early Discharge Schemes - Fractured Neck of Femur", which
 corresponds to £94 per day.

40 We conduct a sensitivity analysis on these values in section 32.1 of this chapter.

1 *20.7.10.2Length of stay*

- 2 Crotty et al (2002)⁵⁸ reports the following findings for the length of stay for the community MDR
- 3 and the usual inpatient rehabilitation:

4 Table 113: Length of stay in hospital and in own home

Length of stay community MDR (at home stay)	20.3 (mean, days)
Length of stay community MDR (at home stay) (in	7.8 (mean, days)
hospital stay)	
Length of stay usual care (in hospital stay)	14.3 (mean, days)

5

6 20.7.10.3 Hospital readmissions and related length of stay

Crotty et al (2002)⁵⁸ gives information about the levels of readmissions during the four months
follow up of the study. The paper distinguishes between related readmissions and unrelated
readmissions, and gives the length of stay for both cases. However what these related and
unrelated admissions were was not clear in the paper. We consider surgery and the rehabilitation
admissions to be the "related" readmissions, and we consider the cost of a bed day in medicine
for the cost of not-related admissions.

13 These unit bed day costs are based on Czoski-Murray (2007)⁶¹, which reports the cost per day for

14 hospital stay in an orthopaedic, rehabilitation or general medicine ward at 2002 prices. We

15 assume that the "related readmissions" take place either for orthopaedic or for rehabilitation

16 reasons, and that the "unrelated readmission" are those in the generic medicine ward.

17 Taking into account of the inflation index, the cost per day of hospital stay for a related

18 readmission corresponds to £367.85 (assuming that half of these readmissions took place for

19 surgery and half for rehabilitation reasons) and to £364.61 for unrelated readmission.

20

21 Table 114: Evidence on readmissions (Crotty et al, 2002)⁵⁸

Number of not related readmission for usual care	0.43
Mean difference for unrelated readmissions	0.38
Number of related readmission for usual care	0.27
Mean difference for related readmissions	-0.05
Length of hospital stay for not related readmissions (usual care)	4.9
Mean difference for length of hospital stay for unrelated readmissions	-0.3
Length of hospital stay for related readmissions (usual care)	3.6

Mean difference for length of hospital stay for related readmissions	0.1
--	-----

2 20.7.10.4 Social services costs

3 For community services, Crotty et al (2002)⁵⁸ intended any of the following: outpatient 4 rehabilitation; private therapy, district nursing, day care, respite care, employment rehabilitation 5 training, carer time off work and Meals on Wheels. As we do not have data regarding the exact 6 amount of resources for each of the above categories that were actually used by patients in the 7 two arms of the study, we assume that the weekly cost of social care is given by a weighted 8 average of the five categories of packages of care reported in the PSSRU 2009⁵⁹ and discussed in 9 section 18.2.2 of the hospital MDR model. We assume that an equal proportion of patients used 10 each type of social care package. However, in a sensitivity analysis we look at the case in which all 11 patients used a "very low cost" type of social care package and when all of them used a "very high 12 cost" package of care.

- 13 Only a proportion of the social care costs will generally be funded by local authorities⁶⁹, ³³⁹, ⁷⁰, ¹⁴².
- 14 It was not possible to identify a national average for the social care costs funded by local

15 authorities in the published literature, and as a consequence an assumption had to be made

16 regarding the proportion of this care that was publicly funded. In the base case analysis, we

17 assume that 60% of social care costs are borne by local authorities, and are therefore includable

18 in the model, and we then test this assumption in a sensitivity analysis.

19 As no further data were given regarding the use of social care services after the 4 months follow

20 up, we adopted a conservative approach and assumed that after that period there was no

21 difference in the use of social services that could be due to the different rehabilitation scheme

22 used.

23 20.7.10.5 Primary care costs

24 Crotty et al (2002)⁵⁸ point out that: "[..] patients [in the community MDR scheme] tended to call 25 the GPs if problems arose and this invariably meant a visit to the home for the GP" (Crotty et al 26 2002, page 11⁵⁸). On the other hand, no details were provided regarding whether *all* GP visits to 27 patients in the community MDR scheme took in fact place in the patients' own home. Similarly, 28 no information was given regarding where GP visit took place for patients in the usual care arm. 29 As a consequence, we have assumed that the unit cost for a GP visit for patients in the usual care 30 scheme is the average between the cost of a GP visit at the patient's own home (£117) and a GP 31 surgery visit (£76) as reported in the PSSRU 2009⁵⁹, and corresponds to £96.5.

As no further data were given regarding the use of primary care services after the 4 months follow
 up, we adopted a conservative approach and assumed that after that period there was no
 difference in the use of GP services that could be ascribed to the different rehabilitation scheme
 used.

36

37 Table 115: Evidence on GP visits (Crotty et al, 2002)

Number of GP visits (usual care)	4.5
Number of GP visits (community MDR)	3.3
	(mean difference: -1.2)

2 20.7.11 Cost effectiveness findings

- 3 The cost-effectiveness findings for the deterministic base case analysis is presented in Table 116:
- 4 Cost-effectiveness analysis deterministic base case below:

5 Table 116: Cost-effectiveness analysis - deterministic base case

Strategy	Cost	Incremental Cost	Effectiveness	Incremental Effectiveness	Incremental cost- effectiveness ratio
Usual care	£6469.1		3.0827 QALYs		
Community MDR	£6903.2	£434.1	3.1283 QALYs	0.0456 QALYs	9521 £/QALYs

6

- 7 Hence, the community MDR scheme is a cost-effective treatment for the rehabilitation of hip
- 8 fracture patients in the deterministic case scenario. **Table 117** reports a breakdown of costs for
- 9 the relevant resources used in the community MDR and in the usual care group.

10 Table 117: Cost breakdown for community MDR and usual care

	,	
Resource item	Usual Care	Community MDR
Rehab cost	3456	3793
Readmission	1124	1657
Domiciliary social care	1453	1133
GP visits	434	318
Total cost	£6467	£6901

11

12 20.7.11.1Sensitivity analysis

We now proceed by investigating how robust the findings of the deterministic analysisare by conducting a series of sensitivity analysis.

To begin with we note that the model is not sensitive to changes in the level of social
services paid by the NHS (from 0 to 100%), as community MDR is still cost-effective.

17 Moreover, when the cost per week of social services is varied between the minimum (£41

18 per week) and the maximum (£542) the option with the highest net benefit is still

19 community MDR.

20 However, our findings are sensitive to the length of hospital stay (both for community

21 MDR and for usual care patients) and on the length of rehabilitation programme at home,

- as well as on the daily cost of hospital stay following surgery and on the daily cost of the
- 23 community MDR programme. These findings are summarized in Table 118 below.

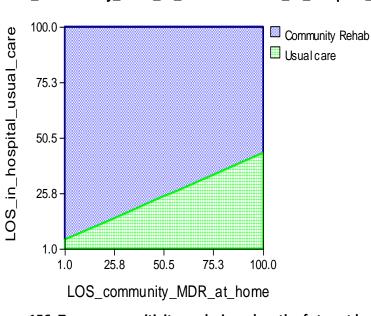

1 Table 118: Threshold sensitivity analysis

Variable	Values	Strategy with the highest net benefit
Length of stay in hospital for	≥ 9.78 (days)	Usual care
community MDR patients	< 9.78 (days)	Community MDR
Length of stay at home for	≥ 25.38 (days)	Usual care
community MDR patients	< 25.38 (days)	Community MDR
Length of stay in hospital for usual	≥ 12.32 (days)	Community MDR
care patients	< 12.32 (days)	Usual care
Daily cost for hospital stay	>f168.18	Community MDR
Daily cost for community MDR	< £ 117.53	Community MDR
rehab programme		

2

10

- 3 Our cost-effectiveness findings are not sensitive to changes in the cost per day in hospital
- 4 of the related readmissions and to changes in the proportion of social care costs borne by 5 local authorities.
- 6 The following figure summarise the findings of a two-ways sensitivity analysis on the
- 7 length of stay in hospital and at home (the vertical axe reports the length of stay at home
- 8 for community MDR patients and the horizontal axe the length of stay in hospital for
- 9 usual care).

Net Monetary Benefit (wtp=20000.) Sensitivity Analysis on LOS_community_MDR_at_home and LOS_in_hospital_usual_c

Figure 156: Two-way sensitivity analysis on length of stay at home and in hospital

- 1 A probabilistic sensitivity analysis was performed to assess the robustness of the model results to
- 2 plausible variations in the model parameters.
- 3 Probability distributions were assigned to each model parameter, where there was some measure
- 4 of parameter variability. We then re-calculated the main results 10000 times, and each time all
- 5 the model parameters were set simultaneously, selecting from the respective parameter
- 6 distribution at random.
- 7 Table 119: Description of the type and properties of distributions used in the probabilistic
- 8 sensitivity analysis

Parameter	Type of distribution	Properties of distribution
Baseline risk	Beta	Bounded on 0 – 1 interval. Derived from sample size, number of patients experiencing events
Cost	Gamma	Bounded at 0, positively skewed. Derived from mean and standard error
Utility	Beta	Bounded on 0 – 1 interval. Derived from mean and sample size
Risk ratio, length of stay	Lognormal	Bounded at 0. Derived from log and standard error of log
Mean differences (e.g. in length of stay, time of therapies, etc.)	Normal	Derived from mean and standard deviation

10 Table 120 summarises the expected values of the variables in our model from the

11 different distributions used in the PSA.

12 Table 120: Distribution and parameters - probabilistic sensitivity analysis

2 The cost-effectiveness findings of the PSA are summarized in Table 121 below:

1 Table 121: cost-effectiveness finding from probabilistic sensitivity analysis

Strategy	Cost	Incr Cost	Eff	Incr Eff	Incremental cost- effectiveness ratio	95% CI on ICERs
Usual care	£6466.6		3.0827 QALYs			
Community Rehab	£6901.2	£434.6	3.1283 QALYs	0.0456 QALYs	9533 £/QALYs	Cost saving - dominated

2

- 3 The PSA shows that there is a high uncertainty as to whether community MDR is cost-
- 4 effective compared to usual care. This uncertainty can be graphically represented by
- 5 plotting the results of the incremental analysis for all the 10,000 simulations into a cost-
- 6 effectiveness plane. Each point on the scatter plot represents the ICER of community
- 7 MDR versus usual care for each simulation. The dotted line represents the £20,000/QALY
- 8 threshold while the ellipse delimits the 95% confidence interval.

ICE Scatterplot of

2 3

1

4 From the simulations conducted for the PSA, we found that at a willingness to pay equal to

5 £20,000 per QALY, community MDR was the optimal strategy in 50% of the simulations. At a

6 willingness to pay of £30,000 per QALY, community MDR was the optimal strategy in 60% of the 7 simulations.

8

9 Table 122: Probability most cost-effective intervention at a willingness to pay of £20,000 and

10 30,000 per QALY

	effective intervention at a	intervention at a WTP of £30,000
	WTP of £20,000 per QALY	per QALY
Community	0.50	0.60

MDR		
Usual care	0.50	0.40

2 20.7.12 Discussion

- 3 The model shows that community MDR is cost-effective in the rehabilitation of patients
- 4 after a hip fracture. However, this finding is rather sensitive to variations in the length of
- 5 stay, both in hospital and at home. Moreover, a PSA has shown that there is high
- 6 uncertainty over the cost-effectiveness of community MDR compared to usual care.
- 7 The model has several limitations, such as the fact that it is based on the clinical evidence
- 8 derived from only one RCT)⁵⁸ based in Australia. Moreover, the evidence on treatment
- 9 effects⁵⁸ was available only up to 4 months follow up. No information was available
- 10 regarding the impact of community MDR after that time point.

21 Appendix I: High Priority Research 1

Recommendations 2

3 21.1 Imaging options in occult hip fracture

4 Research question: In patients with a continuing suspicion of a hip fracture but 5 whose radiographs are normal, what is the effectiveness of computed tomography 6 compared to magnetic resonance imaging, in confirming or excluding the fracture?

7 Why this is important:

8 The GDG's consensus decision to recommend CT over a radionuclide bone scan as

9 an alternative to MRI to detect occult hip fractures reflects current NHS practice but

10 assumes that advances in technology have made the reliability of CT comparable to

- 11 that of MRI. If modern CT indeed can be shown to have similar reliability and
- 12 accuracy to MRI, then this has considerable implications because of its widespread 13 availability out of hours and lower cost. It is a high priority, therefore, to confirm or
- 14
- refute this assumption by direct randomised comparison. The study design would 15 need to retain MRI as the 'gold standard' for cases of uncertainty and would clearly
- 16 need to standardise the criteria, expertise and procedures for radiological
- 17 assessment. Numbers required would depend on the degree of
- 18 sensitivity/specificity (the key outcome criteria) set as target requirement for
- 19 comparability, but need not necessarily be very large.
- 20 Criteria for selecting high-priority research recommendations:

PICO question	In patients with a continuing suspicion of a hip

evidence base, including details of trials and	
systematic reviews. The date on which the	
final literature search was undertaken should	
be specified.	
be specifica.	
<u>Equality</u>	No specific equality issues.
Does the research recommendation address	
equality issues? For example, does it focus on	
I THE ADDRESS OF A DESCRIPTION OF A DESC	
groups that need special consideration, or focus on an intervention that is not available	

for use by people with certain disabilities?	
Study design It should also specify the most appropriate study design to address the proposed question(s). Primary research or secondary research (for example, systematic reviews) can be recommended.	The research design of choice would be a two- stage design comprising (1) an initial small- scale prospective randomised trial to test an agreed minimum percentage variability between methods followed (subject to outcome) by (2) a prospective cohort study using CT alone.
<u>Feasibility</u> Can the proposed research be carried out in a realistic timescale and at an acceptable cost? As part of cost-effectiveness analysis, formal value-of-information methods may also sometimes be used to estimate the value for money of additional research. Are there any ethical or technical issues?	It should be possible to undertake both elements in a realistic timescale and at reasonable cost. This would not be the case if a full-scale Phase 3 trial (as distinct from a prospective cohort) were considered essential. It would be ethically necessary to retain the availability of MRI as opt-out gold standard throughout both studies.
Other comments Any other important issues should be mentioned, such as potential funders or outcomes of previous attempts to address this issue or methodological problems. However, this is not a research protocol.	The ideal study would compare both CT and MRI in the same patients. This is, however, impractical. The proposed research design has some limitations, but does have the potential to provide useful evidence. The alternative of awaiting an "evolutionary" approach to progress in this area is less acceptable.
Importance How important is the question to the overall guideline? The research recommendation should be categorised into one of the following categories of importance: • High: the research is essential to inform future updates of key recommendations in the guideline • Medium: the research is relevant to the recommendations in the guideline, but the research recommendations are not key to future updates • Low: the research is of interest and will fill existing evidence gaps.	The research is of high priority, since its findings have the potential to alter future guidance on the diagnosis of occult hip fracture.

1 21.2 Anaesthesia

Research question: What is the clinical and cost effectiveness of regional versus
 general anaesthesia on postoperative morbidity in patients with hip fracture?

4 Why this is important

- 5 No recent randomised controlled trials were identified that fully address this 6 question. The evidence is old and does not reflect current practice. In addition, in 7 most of the studies the patients are sedated before regional anaesthesia is 8 administered and this is not taken into account when analysing the results. The 9 study design for the proposed research would be best addressed by an randomised 10 controlled trial. This would ideally be a multi-centred trial including 3,000 11 participants in each arm which. This is achievable if one considers that there are 70, 12 000 hip fractures a year in the UK. The study should have three arms which look at 13 spinal anaesthesia versus spinal anaesthesia plus sedation versus general 14 anaesthesia, this would separate those with regional anaesthesia from those with 15 regional anaesthesia plus sedation. The study would also need to control for 16 surgery, especially type of fracture, prosthesis and grade of surgeon.
- A qualitative research component would also be helpful to study on patientpreference for type of anaesthesia.
- 19 This needs to be multicentre and could be conducted in one year in the U.K.Sample 20 size, may need to have 3,000 in each limb which is achievable if one considers that 21 there are 80,000 his fractures a year in the UK
- 21 there are 80, 000 hip fractures a year in the UK.
- 22 Criteria for selecting high-priority research recommendations:

PICO questionWhat is the clinical and cost effectiveness ofEach research recommendation should be formulated as an answerable question or a set of closely related questions. knowledge and/or evidence)? techniques in this group of patients. The	knowledge and/or evidence)?	techniques in this group of patients. The

	current evidence is old and unreliable. The hip fracture population is now older and has more comorbidities than the population in which the historical studies were conducted. The studies are also important to help patients and their carers make informed decisions about the form of anaesthesia most appropriate for them. Importance : High
<u>Relevance to the NHS</u> What would be the impact on the NHS and (where relevant) the public sector of any new or altered guidance (for example, financial advantage, effect on staff, impact on strategic planning or service delivery)?	There may be a reduction in length of stay in patients receiving spinal anaesthesia, without sedation. Postoperative recovery should be quicker.
<u>National priorities</u> Is the question relevant to a national priority area (such as a national service framework or white paper)? The relevant document should be specified.	SIGN recommend spinal but without any evidence base. The evidence for benefit is weak and was conducted over 30 years ago.
Current evidence base What is the current evidence base? What are the problems with the current evidence base? (that is, why is further research required?) Reference should be made to the section of the full guideline that describes the current evidence base, including details of trials and systematic reviews. The date on which the final literature search was undertaken should be specified.	No trial evidence was identified
Equality Does the research recommendation address equality issues? For example, does it focus on groups that need special consideration, or focus on an intervention that is not available for use by people with certain disabilities?	This recommendation does not exclude any patient group. However, special consideration should be given to very frail older people with a high prevalence of cognitive impairment.
<u>Study design</u> It should also specify the most appropriate study design to address the proposed question(s). Primary research or secondary research (for example, systematic reviews) can be recommended.	The study design for the proposed research would be best addressed by an RCT. This would ideally have three arms (3000 participants each) which looks at spinal versus spinal plus sedation versus general anaesthsia, this would separate those with regional anaesthesia from those with regional anaesthesia plus sedation. The study would also need to control for surgery, especially type of fracture, prosthesis

Γ	Г
	and grade of surgeon.
	A qualitative research component would also be helpful to study on patient preference for type of anaesthesia.
<u>Feasibility</u> Can the proposed research be carried out in a realistic timescale and at an acceptable cost? As part of cost-effectiveness analysis, formal value-of-information methods may also sometimes be used to estimate the value for money of additional research. Are there any ethical or technical issues?	Although the number of participants suggested is relatively high, it is worth considering that there are over 80,000 patients admitted with hip fractures each year. This should be feasible by conducting a multi-centre RCT.
Other comments Any other important issues should be mentioned, such as potential funders or outcomes of previous attempts to address this issue or methodological problems. However, this is not a research protocol.	Potential funders include : The National Institute for Health Research (NIHR), ASTRA foundation.
Importance How important is the question to the overall guideline? The research recommendation should be categorised into one of the following categories of importance:	High. The research is essential to inform future updates of key recommendations in the guideline.
 High: the research is essential to inform future updates of key recommendations in the guideline Medium: the research is relevant to the recommendations in the guideline, but the research recommendations are not key to future updates Low: the research is of interest and will fill existing evidence gaps. 	

1 21.3 Displaced intracapsular hip fractures

- 2 Research question:
- 3 What is the clinical and cost effectiveness of large head total hip replacement
- versus hemiarthroplasty on functional status, reoperations and quality of life in
 patients with displaced intracapsular hip fracture?
- 6 Why this is important:

7 Large head total hip replacement is a development of traditional total hip

- 8 replacement where a larger head makes the joint more stable and hence reduces
- 9 the risks of dislocation. Previous three small trials have shown traditional small
- 10 head total hip replacement have shown better outcomes and function yet with an

increased dislocation rate in selected groups of patients. The drawback with the large head arthroplasty is the additional implant cost and theatre time. This cost can

- large head arthroplasty is the additional implant cost and theatre time. This cost can
 account for up to 20% of current NHS tariff (up to £2000) and the study aims to
- 14 address whether this translates to improved patient outcome. The study design for
- 15 the proposed research would be best addressed by an randomised controlled trial.
- 16 This would have two arms which compares current standard care (using 17 hemiarthroplasty) with using large head total hip replacement for patients
- sustaining displaced intracapsular hip fractures. Primary outcome would be patient
 mobility at 1 year and secondary outcomes would include functional outcomes,
- 20 quality of life and cost effectiveness of the intervention.
- It would be expected that a sample size of approximately 500 patients would be
 required to show a significant difference in the mobility, hip function and quality of
- 23 life (assuming 80% power p<0.05). Recruiting centres through a trauma research
- 24 network it is estimated that 10 centres would be able to recruit 20 patients per
- 25 month (from 45 eligible patients) giving a recruitment period of 25 months.
- 26 Criteria for selecting high-priority research recommendations:

PICO questionEach research recommendation should be formulated as an answerable question or a set of closely related questions. This should use the PICO framework (patient, intervention, comparison and outcome)	Question: What is the clinical and cost effectiveness of large head total hip replacement versus hemiarthroplasty on functional status, reoperations and quality of life in patients with displaced intracapsular hip fracture?
	<i>Patients</i> : Patients sustaining displaced intracapsular hip fractures
	Intervention: Arthroplasty
	<i>Comparison</i> : Either hemiarthroplasty (half a hip replacement) or total hip replacement with a large head

	<i>Outcome</i> : Timely functional status, cost effectiveness, re-operations and quality of life at one year
Importance to patients or the population. What would be the impact of any new or altered guidance on the population? (for example, acceptability to patients, quality of life, morbidity or disease prevalence, severity of disease or mortality).	Presently there are over 30,000 who sustain a displaced intracapsular hip fracture per year in the United Kingdom. Whilst there is evidence that total hip replacement with a small femoral head gives some advantages in specific groups (3 small RCTs) the concern has been the risk of dislocations. The technology has advanced and it is now possible to perform large head (>36mm) total hip replacement which significantly reduces the risk of dislocation and may improve function. The drawback is the increased cost (between £1000 - £2000 or >10-20% of the tariff)
Relevance to NICE guidance How would the answer to this question change future NICE guidance (that is, generate new knowledge and/or evidence)?	Presently the NICE recommendations recommend replacement arthroplasty and is only specific about a defined group of cognitively unimpaired, previously mobile and with no significant comorbidities. There is currently widespread practice in arthroplasty and there is an increase use of more expensive prosthesis. Surgeons are beginning to adopt large head technology without evidence of effectiveness, cost benefit or consideration of complication rates. This recommendation is considered high by the NICE Hip Fracture Development Group as the results of this study would advise NICE on future recommendations for the large and
Relevance to the NHS What would be the impact on the NHS and (where relevant) the public sector of any new or altered guidance (for example, financial advantage, effect on staff, impact on strategic planning or service delivery)?	vulnerable group of patients The NHS would be in a better position to focus resources on those in most need. Better function of the large head total hip replacement may reduce care costs in both the acute setting and rehabilitation.
<u>National priorities</u> Is the question relevant to a national priority area (such as a national service framework or white paper)? The relevant document should	Improving the care of those suffering fragility fractures is a NHS priority. Hip fractures are the largest cost of this group and account for two thirds of all hospital days due to fractures and 87% of the costs (£385million 2007).

be specified.	
Current evidence base What is the current evidence base? What are the problems with the current evidence base? (that is, why is further research required?) Reference should be made to the section of the full guideline that describes the current evidence base, including details of trials and systematic reviews. The date on which the final literature search was undertaken should be specified.	One cohort study has been presented on large head total hip replacement and three previous RCTs on small head total hip replacements have been published
Equality Does the research recommendation address equality issues? For example, does it focus on groups that need special consideration, or focus on an intervention that is not available for use by people with certain disabilities?	Yes, very frail older people with a high prevalence of cognitive impairment.
<u>Study design</u> It should also specify the most appropriate study design to address the proposed question(s). Primary research or secondary research (for example, systematic reviews) can be recommended.	<i>Design</i> : A randomised controlled trial of displaced intracapsular fractures in previously mobile patients between hemiarthroplasty and large head total hip replacement. <i>Outcome</i> : Does large head arthroplasty improve recovery of mobility one year after surgical management of displaced intracapsular hip fracture
<u>Feasibility</u> Can the proposed research be carried out in a realistic timescale and at an acceptable cost? As part of cost-effectiveness analysis, formal value-of-information methods may also sometimes be used to estimate the value for money of additional research. Are there any ethical or technical issues?	The research would be ethically and technically feasible. The research costs would need to be considered in the context that participants would still need treatment if outside a trial which would set the research costs into proper context and perspective.
<u>Other comments</u> Any other important issues should be mentioned, such as potential funders or outcomes of previous attempts to address this issue or methodological problems. However, this is not a research protocol.	The National Institute for Health Research (NIHR) would be an appropriate funding source. Industry support would off lay excess implant costs
Importance How important is the question to the overall guideline? The research recommendation	High. The research is essential to inform future updates of key recommendations in the

should be categorised into one of the following	guideline.
categories of importance:	
 High: the research is essential to inform 	
future updates of key recommendations in the	
guideline	
 Medium: the research is relevant to the 	
recommendations in the guideline, but the	
research recommendations are not key to	
future updates	
• Low: the research is of interest and will fill	
existing evidence gaps.	

2 **21.4** Intensive rehabilitation therapies after hip fracture

- 3 Research question:
- What is the clinical and cost effectiveness of additional intensive physiotherapy
 and/or occupational therapy (for example progressive, resistance training) after hip
 fracture?
- 7 Why this is important:

8 The rapid restoration of physical and self care functions is a critical to recovery from 9 hip fracture, particularly where the goal is to return to the patient to pre-operative 10 levels of function and residence. Approaches that are worthy of future development 11 and investigation include progressive resistance training, progressive balance and 12 gait training, supported treadmill gait re-training, dual task training, and Activities of 13 Daily Living training. The optimal time point at which these interventions should be 14 started requires clarification.

- 15 The ideal study design is a randomised controlled trial. Initial studies may have to
- focus on proof of concept and be mindful of costs. A phase III randomised
 controlled trial is required to determine effectiveness and cost-effectiveness. The
- 17 controlled trial is required to determine effectiveness and cost-effectiveness. The
- 18 ideal sample size will be around, 400 500 patients, and the primary outcome
- 19 should be physical function and health related quality of life. Outcomes should also
- include falls. A formal sample size calculation will need to be undertaken. Outcomes
 should be followed over a minimum of 1 year, and compare if possible, either the
- should be followed over a minimum of 1 year, and compare if possible, either the
 recovery curve for restoration of function or time to attainment of functional goals.
- 23 Criteria for selecting high-priority research recommendations:

PICO question	<i>Question</i> : What is the clinical and cost effectiveness of additional intensive
Each research recommendation should be formulated as an answerable question or a set of closely related questions. This should use the PICO framework (patient, intervention,	physiotherapy and/or occupational therapy (for example progressive, resistance training) after hip fracture?
comparison and outcome)	<i>Patients</i> : All patients who have a fracture, studies should consider all forms of surgical treatment. Separate studies maybe needed for those with severe cognitive impairment and those without (depending on specifics of the intervention)
	Intervention: Progressive therapy protocols
	Comparison: Usual care therapy
	<i>Outcome</i> : Restoration of mobility, health related quality of life, falls, residence, ADL

	/IADL abilities, linked geriatric syndromes, resource use.
Importance to patients or the population. What would be the impact of any new or altered guidance on the population? (for example, acceptability to patients, quality of life, morbidity or disease prevalence, severity of disease or mortality).	Patients and their families value mobility very highly. The ability to walk even short distances, can mean the difference between being able to live at home, or not. The step between being able to walk outside and inside is greater still. The same can be said for key skills like dressing and bathing. The impact of improved mobility, strength, balance and function would have a substantial impact on the patient and their family, as well as the requirement for long term residential or at home care.
Relevance to NICE guidance How would the answer to this question change future NICE guidance (that is, generate new knowledge and/or evidence)?	It would enable NICE to come to a decision on whether to recommend more intensive physiotherapy and/or occupational therapy, by generating new evidence on clinical and cost effectiveness. This is very important to the guideline – at the moment we have made several statements about volume (frequency of therapy) but not of content. The guideline would be strengthened considerably with this additional information. The level would be high.
<u>Relevance to the NHS</u> What would be the impact on the NHS and (where relevant) the public sector of any new or altered guidance (for example, financial advantage, effect on staff, impact on strategic planning or service delivery)?	There would possibly be an increase in the amount of therapy time that is needed, and this would incur impacts on strategic planning and service delivery.
National priorities Is the question relevant to a national priority area (such as a national service framework or white paper)? The relevant document should be specified.	Yes the national service framework for older people.
<u>Current evidence base</u> What is the current evidence base? What are the problems with the current evidence base? (that is, why is further research required?) Reference should be made to the section of the full guideline that describes the current evidence base, including details of trials and systematic reviews. The date on which the	Very limited trial evidence, and no trial evidence for some interventions.

final literature search was undertaken should be specified.	
Equality Does the research recommendation address equality issues? For example, does it focus on groups that need special consideration, or focus on an intervention that is not available for use by people with certain disabilities?	Yes these are vulnerable older adults who need special consideration, particularly if they have cognitive impairment or frailty. These types of services are not currently provided to many hip fracture patients, and certainly not those with cognitive impairments
<u>Study design</u> It should also specify the most appropriate study design to address the proposed question(s). Primary research or secondary research (for example, systematic reviews) can be recommended.	<i>Design</i> : A randomised controlled trial of intensive therapy (to be specified) versus usual care therapy <i>Outcome</i> : Mobility, function, health related quality of life, resource use, and costs (health and social care)
Feasibility Can the proposed research be carried out in a realistic timescale and at an acceptable cost? As part of cost-effectiveness analysis, formal value-of-information methods may also sometimes be used to estimate the value for money of additional research. Are there any ethical or technical issues?	The research would be ethically and technically feasible. The outcome and research question is sufficiently important to merit a large scale randomised controlled trial
Other comments Any other important issues should be mentioned, such as potential funders or outcomes of previous attempts to address this issue or methodological problems. However, this is not a research protocol.	The National Institute for Health Research (NIHR) HTA would be an appropriate funding source.
Importance How important is the question to the overall guideline? The research recommendation should be categorised into one of the following categories of importance: • High: the research is essential to inform future updates of key recommendations in the guideline • Medium: the research is relevant to the recommendations in the guideline, but the research recommendations are not key to future updates • Low: the research is of interest and will fill	High. The research is essential to inform future updates of key recommendations in the guideline.

existing evidence gaps.	

1 21.5 Early Supported Discharge in Care Home patients

- 2 Research question:
- What is the clinical and cost effectiveness of early supported discharge on mortality,
 quality of life and functional status in patients with hip fracture who are admitted
 from a care home?
- 6 Why this is important:

7 Care and nursing homes residents account for 30% of all hip fracture patients 8 admitted to hospital. Two-thirds of these come from care homes and the remainder 9 from nursing homes. These patients are frailer, more functionally dependent and 10 have a higher prevalence of cognitive impairment than patients admitted from their 11 own homes. One third of those admitted from a care home are discharged to a 12 nursing home and a fifth are readmitted to hospital within 3 months. There are no 13 clinical trials to define the optimal rehabilitation pathway following hip fracture for 14 these patients and therefore represent a discrete cohort where the existing meta-15 analyses do not apply. As a consequence, many are denied structured rehabilitation 16 and are returned back to their care home or nursing home with very little or no 17 rehabilitation input.

- Given the patient frailty and comorbidities, rehabilitation may have no effect on clinical outcomes for this group. However, the fact that they already live in a home where they are supported by trained care staff, clearly provides an opportunity for a systematic approach to rehabilitation. Early multidisciplinary rehabilitation based in care homes or nursing homes would take advantage of the day-to-day care arrangements already in place and provide additional NHS support to deliver naturalistic rehabilitation, where problems are tackled in the patient's residential.
- Early supported multidisciplinary rehabilitation could reduce hospital stay, improve
 early return to function, and affect both readmission rates and the level of NHS funded nursing care required.
- 28 The research would follow a two-stage design: (1) an initial feasibility study to refine 29 the selection criteria and process for reliable identification and characterisation of 30 those considered most likely to benefit, together with the intervention package and 31 measures for collaboration between the Hip Fracture Programme team, care-home 32 staff and other community-based professionals, and (2) a cluster randomized 33 controlled comparison (with, say, two or more intervention units and matched 34 control units) set against agreed outcome criteria. The latter should include those 35 specified above, together with measures of the impact on care-home staff activity 36 and cost, as well as qualitative data from patients on relevant quality-of-life 37 variables.

Criteria for selecting high-priority research recommendations:

PICO question Each research recommendation should be formulated as an answerable question or a set of closely related questions. This should use the <u>PICO framework</u> (patient, intervention, comparison and outcome).	Patients: Elderly hip fracture patientsadmitted from a care/nursing homeIntervention: Structured multidisciplinaryrehabilitationComparison: Standard careOutcome: Reduction in hospital LOS, short
	and long-term functional improvement, reduction in readmission to hospital, reduction in upgrade from care to nursing home dependency.
Importance to patients or the population. What would be the impact of any new or altered guidance on the population? (for example, acceptability to patients, quality of life, morbidity or disease prevalence, severity of disease or mortality).	Reduced dependency
Relevance to NICE guidance How would the answer to this question change future NICE guidance (that is, generate new knowledge and/or evidence)?	The answer to this question is key to guidance on early supported discharge in hip fracture patients admitted from care home, who represent a significant proportion of patients
	With this information available NICE would be in a position to recommend early supported discharge in this group of patients. Importance : High
Relevance to the NHS What would be the impact on the NHS and	Reduction in hospital LOS will allow greater efficiency with respect to usage of trauma beds.
(where relevant) the public sector of any new or altered guidance (for example, financial advantage, effect on staff, impact on strategic planning or service delivery)?	Reduction in re-admissions, upgraded dependency to nursing homes represent significant cost savings
National priorities	A number of national guidelines now recommend the need for research in care
Is the question relevant to a national priority area (such as a national service framework or white paper)? The relevant document should be specified.	home patients following hip fracture (SIGN, Orthopaedic Blue Book, NIHR HTA review, Cochrane review).
<u>Current evidence base</u> What is the current evidence base? What are the problems with the current evidence base? (that is, why is further research	No trial evidence was identified.

required?) Reference should be made to the section of the full guideline that describes the current evidence base, including details of trials and systematic reviews. The date on which the final literature search was undertaken should be specified.	
Equality Does the research recommendation address equality issues? For example, does it focus on groups that need special consideration, or focus on an intervention that is not available for use by people with certain disabilities?	Yes, very frail older people with a high prevalence of cognitive impairment.
<u>Study design</u> It should also specify the most appropriate study design to address the proposed question(s). Primary research or secondary research (for example, systematic reviews) can be recommended.	This will comprise: a systematic literature review, focusing on rehabilitation in care homes; a qualitative interview study with care home residents, their families, care home staff, allied health professionals and inpatient orthopaedic staff regarding discharge planning and rehabilitation for these patients; and an evaluation of a pilot early supported multidisciplinary rehabilitation service compared to usual care.
<u>Feasibility</u> Can the proposed research be carried out in a realistic timescale and at an acceptable cost? As part of cost-effectiveness analysis, formal value-of-information methods may also sometimes be used to estimate the value for money of additional research. Are there any ethical or technical issues?	The research would be ethically and technically feasible, at an acceptable level of cost.
Other comments Any other important issues should be mentioned, such as potential funders or outcomes of previous attempts to address this issue or methodological problems. However, this is not a research protocol.	Potential funders include :The National Institute for Health Research (NIHR), BUPA, Alzheimer's Society
Importance How important is the question to the overall guideline? The research recommendation should be categorised into one of the following categories of importance: • High: the research is essential to inform future updates of key recommendations in	High. The research is essential to inform future updates of key recommendations in the guideline.

APPENDIX I	
------------	--

the guideline
 Medium: the research is relevant to the
recommendations in the guideline, but the
research recommendations are not key to
future updates
• Low: the research is of interest and will fill
existing evidence gaps.

1 22 Appendix J: Excluded studies

Chapter	Study ID	Reasons for exclusion
Diagnosis	Lubovsky et al (2005) ¹⁹⁴	The trial was excluded because of the very
		small sample size. Only 13 patients
		included and only 6 patients received CT
		and MRI. The results were reported in a
		way that did not allow calculations of
		sensitivity and specificity.
Timing of surgery	Davis et al (1988) ⁶⁶	No baseline characteristics, no adjustment
		for comorbidity.
Timing of surgery	Franzo et al (2005) ⁹⁹	No clear explanation of adjustment and no
		baseline characteristics for each group.
Timing of surgery	Gdalevich et al (2004) ¹⁰⁶	No baseline characteristics, no adjustment
		for comorbidity.
Timing of surgery	Hoenig et al (1997) ¹⁴⁴	Not only surgical delay investigated, unable
		to extract raw data.
Timing of surgery	Kenzora et al (1984) ¹⁷⁵	No baseline characteristics, no adjustment
		for comorbidity.
Timing of surgery	Mackenzie wt al (2006) ¹⁹⁶	Letter/short correspondence.
Timing of surgery	McGuire et al (2004) ²⁰⁷	The aim of the study is on day of the week
		of admission.
Timing of surgery	Moran et al (2005) ²¹³	No baseline characteristics, no adjustment
		for comorbidity.
Timing of surgery	Novack et al (2007) ²³⁵ Rae et al (2007) ²⁷²	Adjusted hazard ratios given.
Timing of surgery	Rae et al (2007) ²⁷²	Baseline characteristics not given for each
		group.
Timing of surgery	Rogers et al (1995) ²⁸²	No baseline characteristics, no adjustment
		for comorbidity.
Timing of surgery	Sebestyen et al (2008) ²⁹⁴	No adjustment for comorbidity.
Timing of surgery	Shabat et al (2003) ²⁹⁶	Inadequate methodology.
Timing of surgery	Sircar et al (2007) ³⁰⁴	No baseline characteristics, no adjustment
		for comorbidity.
Timing of surgery	Sund & Liski (2005) ³¹⁴	Adjusted odds ratios for provider
		characteristics.
Analgesia	Gorodetskyi et al	Not a study of nerve blocks.
	(2007) ¹²⁰	

Analgesia	Mannion et al (2005) ²⁰⁰	No 'control' group without the nerve block.
Analgesia	Marhofer et al (1998) ²⁰³	No 'control' group without the nerve block.
Analgesia	Mutty et al (2007) ²¹⁹	No proximal femoral fractures included.
Analgesia	Piangatelli et al (2004) ²⁶⁴	No 'control' group without the nerve block.
Analgesia	Schiferer et al (2007) ²⁹³	Inclusion of participants with other
Andigesia		conditions. The trialists were unable to
		provide separate results for only the hip
		fracture participants.
Analgesia	Turker et al (2003) ³²⁴	No 'control' group without the nerve block
Analgesia	Van Leeuwen et al (2000) ³³³	No 'control' group without the nerve block.
Anaesthesia	Alonso Chico et al (2003) ⁶	Not a trial of different types of anaesthesia
/ indestinesid		but a comparison of different drugs within
		one form of anaesthesia.
Anaesthesia	Barna (1981) ¹³	No randomisation of patients.
Anaesthesia	Ben-David et al (2000) ¹⁶	Not a trial of different types of anaesthesia
		but a comparison of different drugs within
		one form of anaesthesia.
Anaesthesia	Coleman et al (1988) ⁵⁴	The study was excluded as it involved a
		change in the types of drugs used only, not
		a change in the method of anaesthesia.
Anaesthesia	Critchley et al (1995) ⁵⁵	Not a trial of different types of anaesthesia
		but a comparison of different drugs within
		one form of anaesthesia.
Anaesthesia	Darling et al (1994) ⁶²	The study was excluded as it was not felt
		relevant to this review as no clinical
		outcomes were reported.
Anaesthesia	Dyson et al (1988) ⁷³	Lack of outcome data for the anaesthesia
		comparison.
Anaesthesia	El-Zahaar et al (1995) ^{77,326}	This trial was excluded because separate
		results for patients having surgery for a hip
		fracture were not presented.
Anaesthesia	Favarel-Garrigues et al	The trial was excluded as it was not
	(1996) ⁹⁰	considered a comparison of different forms
		of anaesthesia, only of a modification of
		anaesthetic technique.
Anaesthesia	Hemmingsen & Nielsen	Not a trial of different types of anaesthesia
	(1991) ¹⁴¹	but a comparison of different drugs within
	202	one form of anaesthesia.
Anaesthesia	Marhofer et al (1999) ²⁰²	Not a comparison of anaesthetic methods.
Anaesthesia	Matot et al (2003) ²⁰⁵	Compared techniques outside the scope of
Apposthes:-		this review.
Anaesthesia	Maurette et al (1993) ²⁰⁶	The trial was excluded as it was a trial of
		different drugs with the same anaesthetic
		technique, not a comparison of different
Anaesthesia	Naja et al (2000) ²²¹	types of anaesthesia.
Anaesthesia	Nishikawa et al (2002) ²³⁴	No randomisation of patients. Not a comparison of different types of
Allacollicold		anaesthesia.
		ลและรถแะรเล.

Anaesthesia	Owen & Hutton (1982) ²⁴⁴	Not a comparison of anaesthetic techniques.
Anaesthesia	Sinclair et al (1997) ³⁰³	Not a comparison of different types of anaesthesia.
Anaesthesia	Sutcliffe & Parker (1994) ³¹⁵	No randomisation of patients.
Anaesthesia	Tonczar & Hammerle (1981) ³²¹	The study was excluded as it involved a neuroleptic anaesthesia and the only outcome measures were plasma catecholamines, cortisol, blood pressure and changes in heart rate.
Anaesthesia	Ungemach (1987) ³²⁵	The trial was excluded as it was a comparison of different drugs within one type of anaesthesia (general anaesthesia) and not a comparison of different anaesthetic techniques.
Surgeon Seniority	Claque et al (2002) ⁵⁰	Retrospective study, unclear if adjusted for confounders. Not stated how patients were allocated to surgeons.
Surgeon Seniority	Englesbe et al (2009) ⁸⁰	Compares outcomes at time when new trainees start compared to other times of the year. Not about surgeon seniority.
Surgeon Seniority	Evans et al (1979) ⁸⁵	No results or data for surgeon seniority analysis.
Surgeon Seniority	Faraj & Drakau (2007) ⁸⁸	No adjustment for confounders and no indication of how patients were allocated to surgeons.
Surgeon Seniority	Fung et al (2007) ¹⁰²	No outcome of interest.
Surgeon Seniority	Giannoudis et al (1998)	No outcome of interest.
Surgeon Seniority	Grimley et al (1980) ¹²⁴	Compares hospitals outcomes rather than surgeon seniority. Unclear if retrospective or prospective. No indication of how patients were allocated to surgeons.
Surgeon Seniority	Harper & Walsh (1985) ¹³³	Unclear if retrospective or prospective, no adjustment for confounders.
Surgeon Seniority	Holmberg et al (1987) ¹⁴⁷	Unclear if retrospective or prospective, no adjustment for confounders.
Surgeon Seniority	Holt et al (1994) ¹⁴⁹	No adjustment for confounders.
Surgeon Seniority	Levi & Gebuhr (2000) ¹⁹⁰	Unclear if retrospective or prospective, no adjustment for confounders, no outcomes measured by surgeon seniority only reports in words there was no difference between registrars and consultants.
Surgeon Seniority	Kukla et al (2001) ¹⁷⁹	Unclear if retrospective or prospective. Examines years of experience but inexperienced surgeons were supervised. Results presented as a continuous variable.
Surgeon Seniority	Parker et al (1994) ²⁶³	Not surgeon seniority, investigates the use of a special "Hip Fracture Team".
Surgeon Seniority	Sarvilinna et al (2002) ²⁹¹	Retrospective study, no adjustment for

		confounders.
Surgeon Seniority	Sehat et al (2006) 295	Not about surgeon seniority.
Surgeon Seniority	Weinrauch (2006) ³⁴¹	Not stated how patients were assigned to
subconsenionty		surgeons. Not stated the total number of
		surgeons involved nor how many involved
		in each category. Does not adjust for any
		confounders.
Internal fixation vs	Bhandari et al (2003) ²¹	Systematic review, used Cochrane review
arthroplasty		instead.
Internal fixation vs	Bjorgul et al (2006) ²⁵	Non-randomised study.
arthroplasty	2)0.9ul et ul (2000)	
Internal fixation vs	Bray et al (1988) ³⁵	Excluded from Cochrane review due to
arthroplasty		inadequate randomisation. Patients were
artinoplasty		allocated according to day of week and
		surgeon preference. In addition to the low
		numbers recruited five were lost to follow-
		up.
Internal fixation vs	El-Abed et al (2005) ⁷⁶	Excluded from Cochrane review as non-
arthroplasty		randomised study, type of procedure used
aremophasty		was by the preference of the attending
		surgeon on the day of admission.
Internal fixation vs	Gjertsen et al (2010) ¹¹⁶	Non-randomised study.
arthroplasty		
Internal fixation vs	Haentjens et al (2005) ¹²⁸	Non-randomised study.
arthroplasty		
Internal fixation vs	Heetveld et al (2009) ¹⁴⁰	Non-randomised study.
arthroplasty		
Internal fixation vs	Hunter (1974) ¹⁵⁴	Excluded from Cochrane review as non-
arthroplasty		randomised study.
Internal fixation vs	Hunter (1969) ¹⁵³	Excluded from Cochrane review as non-
arthroplasty		randomised study.
Internal fixation vs	Neander (2000) 230	Excluded from Cochrane review due to
arthroplasty		inadequate randomisation procedure. The
		first 20 patients were randomised with
		closed envelopes but the last 80 were
		allocated according to the day of week
		they were admitted (Monday to Thursday
		total hip replacement, Friday to Sunday
		reduction and fixation).
Internal fixation vs	Parker (1992) 253	Excluded from Cochrane review as non-
arthroplasty		randomised study.
Internal fixation vs	Riley (1978) 277	Excluded from Cochrane review as study
arthroplasty		provided no adequate data.
Internal fixation vs	Rodriguez et al (1987) ²⁸¹	Excluded from Cochrane review as non-
arthroplasty		randomised study.
Internal fixation vs	Rogmark & Johnell (2006)	Systematic review, used Cochrane review
arthroplasty	284	instead.
Internal fixation vs	Sikorski & Barrington	This comparison excluded from Cochrane
arthroplasty	(1981) ³⁰¹	review due to poor methodological quality.
Internal fixation vs	Stewart (1984) ³¹³	Excluded from Cochrane review as non-
arthroplasty		randomised study.

Internal fixation vs arthroplasty	Wang et al (2009) ³³⁸	Systematic review, used Cochrane review instead.
Hemiarthroplasty vs total hip replacement	Goh et al (2009) ¹¹⁸	Systematic review, used Cochrane review instead.
Hemiarthroplasty vs total hip replacement	Haentjens et al (2005) ¹²⁸	Non-randomised study.
Hemiarthroplasty vs total hip replacement	Heetveld et al (2009) ¹⁴⁰	Non-randomised study.
Hemiarthroplasty vs total hip replacement	Kavcic et al (2006) ¹⁷⁰	Methodology not reported. Only mentions patients were randomly selected. No indication of allocation concealment, method of randomisation, blinding, or inclusion/exclusion criteria.
Cement	Ahn et al (2008) ²	Systematic review that includes randomised and non-randomised studies. Used Cochrane review.
Cement	Bajammal et al (2008) ¹⁰	Systematic review of cement use in appendicular fractures, not just hip fractures. Used Cochrane review.
Cement	Christie et al (1994) ⁴⁸	Excluded from Cochrane review as biometric study with no clinical outcome measures. No methods given for RCT, no outcomes from our protocol.
Cement	Clark et al (2001) 51	Excluded from Cochrane review as non- randomised study.
Cement	Dorr et al (1986) ⁷¹	Cemented vs uncemented hemiarthroplasty not a randomised comparison
Cement	Faraj & Branfoot (1999) ⁸⁷	Excluded from Cochrane review as non- randomised study, use of cement was at operating surgeon's preference.
Cement	Field & Rushton (2005) ⁹¹	Excluded from Cochrane review because of a limited number of cases using what is at present an experimental new cup.
Cement	Georgescu et al (2004) ¹⁰⁷	Excluded from Cochrane review because of a lack of reported results within the conference abstract
Cement	Gierer et al (2002) ¹¹⁰	Excluded from Cochrane review as non- randomised study, use of cement was at operating surgeon's preference.
Cement	Graf et al (2000) ¹²¹	Excluded from Cochrane review as non- randomised study.
Cement	Johnson et al (2001) ¹⁶²	Excluded from Cochrane review as non- randomised study.
Cement	Karpmann et al (1992) ¹⁶⁸	Excluded from Cochrane review as there was inadequate reporting of the trial. Attempts were made to contact the trialists for further information, without

Cement Khan et al (2002) ¹⁷⁶ Systematic review, excluded as used Cochrane review instead. Cement Lachiewicz et al (2008) ¹⁸² Ekcluded from Cochrane review as variations of cementing technique are not part of the protocol Cement Pitto et al (2000) ²⁶⁵ Excluded from Cochrane review as small numbers and only outcome measure is transoesophagel echocardiography shown embolism. No methods given for RCT, no outcomes from our protocol. Cement Sadr & Arden (1977) ²⁸⁷ Excluded from Cochrane review as unclear whether randomised, the use of Proplast. coated prosthesis is no longer prevalent, small study of 40 patients with limited reporting of outcomes form our protocol. Cement Vochteloo et al (2009) ³¹⁶ Protocol for a randomised, study, study not completed. Surgical approach to hemiarthroplasty Barden et al (2001) ¹²² Excluded from Cochrane review as not a comparison of different surgical approaches. Surgical approach to hemiarthroplasty Cashman & Cashman (2008) Elective hip replacement, patients. Surgical approach to hemiarthroplasty Enocson et al (2009) ⁸¹ Surgical approach to hemiarthroplasty Enocson et al (2009) ⁸² Surgical approach to hemiarthroplasty Enocson et al (2009) About ta minimumally invasive approach.			success.
CementLachiewicz et al (2008)Cochrane review instead.CementLeidinger et al (2002)Elective hip replacement patients, not hip fracture patients.CementLeidinger et al (2002)Excluded from Cochrane review as variations of cementing technique are not part of the protocolCementPitto et al (2000)Excluded from Cochrane review as small numbers and only outcome measure is transoesophagel echocardiography shown embolism.
