Single Technology Appraisal

Amivantamab for treating EGFR Exon 20 insertion-positive non-small-cell lung cancer after platinum-based chemotherapy

Final scope

Remit/appraisal objective

To appraise the clinical and cost effectiveness of amivantamab within its marketing authorisation for treating EGFR Exon 20 insertion-positive non-small-cell lung cancer.

Background

Lung cancer is the third most common cancer and the most common cause of cancer death in the UK, accounting for 13% of all new cancer cases and 21% of all cancer deaths in 2017.¹ There are around 48,000 new lung cancer cases and 35,000 deaths from lung cancer in the UK every year. Around 85% of lung cancers are non-small-cell lung cancers (NSCLC).²

The majority of lung cancers are diagnosed at an advanced stage, when the cancer has spread to lymph nodes and other organs in the chest (locally advanced disease; stage III) or to other parts of the body (metastatic disease; stage IV), and usually cannot be surgically removed. In 2017, 88% (34,591) of people diagnosed with lung cancer had NSCLC in England, Wales, Jersey and Guernsey³. For the majority of people with NSCLC, the aims of therapy are to prolong survival and improve quality of life. Treatment choices are influenced by the presence of biological markers (such as mutations in epidermal growth factor receptor-tyrosine kinase (EGFR-TK), anaplastic-lymphoma-kinase (ALK) or PD-L1 status), histology (squamous or non-squamous) and previous treatment experience.

An estimated 10% to 35% of people with NSCLC have mutations to the protein epidermal growth factor receptor (EGFR).⁴ Exon 20 is part of the EGFR gene that can be mutated by an addition to the DNA sequence.

For people whose locally advanced or metastatic disease tests positive for the activating EGFR-TK mutation and who have not previously had treatment, NICE guidance recommends the tyrosine kinase inhibitors (TKIs) osimertinib, dacomitinib, afatinib, erlotinib, and gefitinib as treatment options (NICE technology appraisal guidance [654](#), [595](#), [310](#), [258](#), and [192](#) respectively).

Following disease progression with a TKI, osimertinib is available for EGFR T790M mutation-positive disease (NICE technology appraisal [653](#)). Otherwise, atezolizumab in combination and pemetrexed with carboplatin or other platinum doublet chemotherapy are treatment options (NICE technology appraisal [584](#) and NICE guideline [121](#)).

If disease continues to worsen after chemotherapy, atezolizumab, nintedanib with docetaxel or docetaxel monotherapy are treatment options (NICE technology appraisals [520](#), [347](#) and NICE guideline [121](#) respectively). Pembrolizumab and nivolumab (nivolumab is only available on the cancer drugs fund) are available for PD-L1 positive tumors (NICE technology appraisals [428](#), [484](#)).

Final scope for the appraisal of amivantamab for treating EGFR Exon 20 insertion-positive non-small-cell lung cancer after platinum-based chemotherapy

Issue Date: March 2021

There are currently no available therapies that specifically target EGFR Exon 20 insertion mutations.

The technology

Amivantamab (brand name unknown, Janssen-Cilag) is a human bispecific antibody that targets both EGFR and cMet. Amivantamab is administered as an intravenous infusion.

Amivantamab does not have a marketing authorisation in the UK for the treatment of EGFR mutation-positive NSCLC. It is being studied in a phase 1 & 2 study to treat metastatic or unresectable EGFR mutation-positive NSCLC. The first part of this study is dose-finding. The second part of this study aims to examine amivantamab as a monotherapy and combined with lazertinib. The study included people with several EGFR mutations including the Exon20 insertion mutation.

Intervention(s)	Amivantamab
Population(s)	Adults with EGFR Exon 20 insertion-positive non-small-cell lung cancer after previous platinum-based chemotherapy
Comparators	Established clinical management without amivantamab including: <ul style="list-style-type: none"> • atezolizumab • nivolumab (subject to an ongoing NICE appraisal) • pembrolizumab (for disease with PD-L1>1%) • chemotherapy such as docetaxel alone or with nintedanib, pemetrexed and carboplatin
Outcomes	The outcome measures to be considered include: <ul style="list-style-type: none"> • overall survival • progression-free or disease-free survival • response rate • time to treatment discontinuation • adverse effects of treatment • health-related quality of life.

<p>Economic analysis</p>	<p>The reference case stipulates that the cost effectiveness of treatments should be expressed in terms of incremental cost per quality-adjusted life year.</p> <p>The reference case stipulates that the time horizon for estimating clinical and cost effectiveness should be sufficiently long to reflect any differences in costs or outcomes between the technologies being compared.</p> <p>Costs will be considered from an NHS and Personal Social Services perspective.</p> <p>The availability of any commercial arrangements for the intervention, comparator and subsequent treatment technologies will be taken into account.</p> <p>The use of amivantamab is conditional on the presence of an EGFR mutation. The economic modelling should include the costs associated with diagnostic testing for EGFR in people with NSCLC who would not otherwise have been tested. A sensitivity analysis should be provided without the cost of the diagnostic test. See section 5.9 of the Guide to the Methods of Technology Appraisals.</p>
<p>Other considerations</p>	<p>Guidance will only be issued in accordance with the marketing authorisation. Where the wording of the therapeutic indication does not include specific treatment combinations, guidance will be issued only in the context of the evidence that has underpinned the marketing authorisation granted by the regulator.</p>
