National Institute for Health and Care Excellence

Draft for consultation

Chronic obstructive pulmonary disease in over 16s: diagnosis and management

[B] Oxygen therapy in people with stable COPD

NICE guideline Evidence review July 2018

Draft for consultation

These evidence reviews were developed by the NICE Guideline Updates Team

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the <u>Welsh Government</u>, <u>Scottish Government</u>, and <u>Northern Ireland Executive</u>. All NICE guidance is subject to regular review and may be updated or withdrawn.

Ambulatory and short burst oxygen

therapy for people not meeting the criteria for long term oxygen therapy

4 **Review question**

5 What is the effectiveness of oxygen therapy in people with stable COPD who are mildly 6 hypoxaemic or non-hypoxaemic at rest?

7 Introduction

8 The aim of this review was to determine whether ambulatory or short burst oxygen therapy 9 are effective at reducing breathlessness and improving quality of life in people with stable

10 COPD who are mildly hypoxaemic or non-hypoxaemic at rest, and do not meet the criteria for

11 long term oxygen therapy (not meeting the criteria was defined as having a mean arterial

12 oxygen $(PaO_2) > 7.3$ kPa, and not currently receiving long term oxygen therapy).

13 For the purposes of this question, ambulatory oxygen therapy is defined as the use of

supplemental oxygen during exercise and activities of daily living in mobile patients who are not sufficiently hypoxaemic to gualify for long term oxygen therapy but who desaturate on

16 exercise. It has historically been used to optimise saturations and short-term exercise

17 capacity. Ambulatory oxygen is also often supplied to long term oxygen therapy users, either

18 to allow those who are mobile outdoors to optimise their exercise capacity and achieve their

recommended hours per day usage, or to enable more immobile patients to leave the housein a wheelchair/scooter on occasion, for example for hospital appointments.

Short burst oxygen therapy is typically given to patients for the relief of breathlessness not
 relieved by any other treatments. It is used intermittently at home for short periods, for
 example 10–20 minutes at a time.

These definitions were obtained from the British Thoracic Society Home Oxygen Guidelines (2015).

This review identified studies that fulfilled the conditions specified in <u>Table 1</u>. For full details of the review protocol, see appendix A.

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for oxygen therapy in people with stable COPD DRAFT (June, 2018)

1 Methods and process

2 This evidence review was developed using the methods and process described in

3 Developing NICE guidelines: the manual. Methods specific to this review question are

described in the review protocol in appendix A, and the methods section in appendix B. In 4

5 particular, the minimally important differences (MIDs) used in this review are summarised in

- Table 8 in appendix B. These were selected based on the literature with input from the 6
- 7 committee.
- 8 The search strategies used in this review are detailed in appendix C.
- 9 Declarations of interest were recorded according to NICE's 2014 conflicts of interest policy.

10 Clinical evidence

11 Included studies - Oxygen therapy for breathlessness in people with stable COPD

12 This review was conducted as an update of the 2010 NICE COPD guideline (CG101). A

recent systematic review was incorporated and updated to help determine the efficacy of 13

14 oxygen therapy in people who have stable COPD.

15 The systematic review was carried out by the Cochrane Airways Group, published in 2016

and included 44 RCTs. The inclusion criteria stated that the participants were 18 years of 16

17 age or older who had COPD, had mild or no hypoxaemia (mean PaO2 > 7.3 kPa) and did not

receive long term oxygen therapy. For studies that also included participants without COPD, 18

19 the researchers obtained individual participant data for those with COPD and included only that data in the analyses. 20

21 Though the Cochrane review was directly applicable and of high quality, the data were 22 reanalysed in line with the methods and processes outlined in appendix B, and therefore the analyses presented in this review may be different from those in the published Cochrane 23

review. The summary of this systematic review is provided in Table 2. 24

25 A second set of searches was conducted at the end of the guideline development process for 26 all updated review questions using the original search strategies, to capture papers

- published whilst the guideline was being developed. These searches returned 3,100 27
- references in total for all the questions included in the update, and these were screened on 28
- title and abstract. One additional reference was identified and excluded at full text screening. 29
- 30 The process of study identification is summarised in the diagram in appendix D.
- 31 For the full evidence tables and the full GRADE profiles please see appendix E and appendix
- G. The references of individual included studies are given in appendix K. 32

33 Excluded studies

- 34 Since this review was based on evidence from a Cochrane review, please refer to this review
- for the list of studies excluded by the Cochrane group authors. Details of the study excluded 35
- at full text from the second search are given in Appendix J. 36

1 Summary of the systematic review included in the evidence review

2 The included systematic review is summarised in Table 2. Please see appendix E for the full evidence table and the characteristics of the included

3 studies from this systematic review.

4 Table 2 - Oxygen therapy for breathlessness

| Short Title | Interventions | Population | Outcomes |
|-------------------|--|--|---|
| Ekstrom (2016) | Oxygen therapy (delivered by a non-invasive method, delivered during exertion, continuously or as needed over a defined period, or short-burst oxygen before exertion (defined as therapy given during a short, defined period just before exertion)) Air (delivered by a non-invasive method at any inspired dose above that of ambient air (>21%)) | 44 randomised controlled trials Update of the 2011 systematic review Dates searched 2011 - 12 July 2016 18 years of age or older who had COPD Mild or no hypoxaemia (mean PaO2 > 7.3 kPa) | Level of breathlessness measured on any validated scale Health related quality of life measured on any validated scale Adverse events |

5

1 Quality assessment of clinical studies included in the evidence review

2 See appendix G for full GRADE tables.

3 Economic evidence

4 Included studies

- A single search was conducted to cover all review question topics in this guideline update. 5
- This search returned 16,299 records, of which 16,295 were excluded on title and abstract. 6
- 7 The remaining 4 papers were screened using a review of the full text and 0 were found to be
- 8 relevant for this review question.

9 Excluded studies

Details of the studies excluded at full-text review are given in Appendix J. 10

11 Summary of studies included in the economic evidence review

12 No economic evidence as identified for this review question.

13 Economic model

14 This topic was not prioritised for health economic modelling and no original analyses were 15 produced.

16 Evidence statements

- 17 The format of the evidence statements is explained in the methods in appendix B.
- 18 The evidence statements below only report numbers of participants where this data was
- available in the Cochrane review. 19

20 Oxygen therapy for breathlessness

21 Breathlessness – all trials

- 22 Moderate quality evidence from 32 RCTs reporting data from 865 people with stable COPD who were mildly or non-hypoxaemic at rest found no meaningful difference between people 23 offered oxygen therapy compared to pressurised air. There was also evidence of publication 24 bias, with studies showing more negative results with oxygen therapy being less likely to be 25 published. 26
- 27 Results were consistent across trials with different characteristics as detailed by the 28 subgroup analyses reported below.

29 Sub group analysis - Type of oxygen therapy - short burst and ambulatory oxygen 30 therapy

- 31 Low guality evidence from 4 RCTs reporting data from 90 people with stable COPD who
- were mildly or non-hypoxaemic at rest found no meaningful difference in breathlessness 32

- 1 between people offered short burst oxygen therapy before exercise compared to pressurised 2 air.
- 3 High guality evidence from 28 RCTs reporting data from 775 people with stable COPD who
- 4 were mildly or non-hypoxaemic at rest found no meaningful difference in breathlessness
- 5 between people offered ambulatory oxygen during exercise or daily activities compared to
- 6 pressurised air.

Subgroup analysis – with or without desaturation on exertion 7

- 8 Low quality evidence from 16 RCTs reporting data from people with stable COPD with
- 9 desaturation (defined as oxygen saturation (SaO₂) <88% at baseline or mean PaO2 < 8 kPa
- 10 on exertion) during exercise and moderate guality evidence from 15 RCTs reporting data
- from people with stable COPD without desaturation during exercise found no meaningful 11
- 12 difference in breathlessness between people offered oxygen therapy compared to
- 13 pressurised air.

14 Sub group analysis – mean arterial oxygen

- 15 Low quality evidence from 7 RCTs reporting data from people with stable COPD and a mean
- arterial oxygen (PaO₂) less than 9.3kpa at baseline and moderate quality evidence from 25 16
- RCTs reporting data from people with stable COPD and a mean arterial oxygen (PaO₂) 17
- 18 greater than 9.3kpa at baseline found no meaningful difference in breathlessness between
- 19 people offered oxygen therapy compared to pressurised air.

Sub group analysis – during exercise and in daily life 20

- 21 Moderate quality evidence from 30 RCTs reporting data from 591 people with stable COPD
- 22 found no meaningful difference in breathlessness during exercise between people offered
- 23 oxygen therapy compared to pressurised air.
- 24 High guality evidence from 2 RCTs reporting data from people with stable COPD found no
- 25 meaningful difference in breathlessness in daily life between people offered oxygen therapy
- 26 compared to pressurised air.

27 Sub group analysis – short term and long term oxygen training

- 28 Moderate quality evidence from 29 RCTs reporting data from people with stable COPD found no meaningful difference in breathlessness during an exercise test between people offered 29
- 30 oxygen therapy compared to air.
- 31 High quality evidence from 3 RCTs reporting data from people with stable COPD found no
- 32 meaningful difference in breathlessness with a long training period between people offered
- oxygen therapy compared to air for the same period. 33

Sub group analysis – oxygen dose 34

- High quality evidence from 26 RCTs reporting data from people with stable COPD found no 35
- meaningful difference in breathlessness between people offered oxygen therapy at a dose 36
- 37 greater than 2l/min compared to lower doses.
- 38 High quality evidence 5 RCTs reporting data from people with stable COPD found no
- meaningful difference in breathlessness between people offered oxygen therapy at a dose ≤ 39
- 40 2I/min compared to higher doses.

1 Health related quality of life

- 2 Low-quality evidence from 5 RCTs reporting data from 267 people with stable COPD who
- 3 were mildly or non-hypoxaemic at rest could not differentiate health-related quality of life
- 4 between people offered oxygen therapy compared to pressurised air.

5 Sensitivity analyses

6 Sensitivity analyses excluding all studies at high risk of bias did not meaningfully change the 7 results compared to when all studies were included.

8 Recommendations

9 Recommendations shaded in grey were not within the scope of the update. Evidence for

these was not reviewed and changes were made only to bring the wording in line with currentNICE style.

12 Oxygen therapy

13 Ambulatory oxygen therapy

- B1. Do not offer ambulatory oxygen to manage breathlessness in people with COPD who
 have mild or no hypoxaemia^b at rest. [2018]
- 16 B2. Consider ambulatory oxygen in people with COPD who have exercise desaturation and
- are shown to have an improvement in exercise capacity with oxygen, and have themotivation to use oxygen. [2004, amended 2018]
- B3. Prescribe ambulatory oxygen to people who are already on long-term oxygen therapy
 who wish to continue oxygen therapy outside the home, and who are prepared to use it
 [2004]
- B4. Only prescribe ambulatory oxygen therapy after an appropriate assessment has been

23 performed by a specialist. The purpose of the assessment is to assess the extent of

- desaturation, the improvement in exercise capacity with supplemental oxygen, and the oxygen flow rate needed to correct desaturation. **[2004]**
- B5. Small light-weight cylinders, oxygen-conserving devices and portable liquid oxygen
 systems should be available for people with COPD. [2004]
- B6. When choosing which equipment to prescribe, take account of the hours of ambulatory
 oxygen use and oxygen flow rate needed [2004]

30 Short-burst oxygen therapy

B7. Do not offer short-burst oxygen therapy to manage breathlessness in people with COPD
 who have mild or no hypoxaemia^b at rest. [2018]

33 Rationale and impact

34 Why the committee made the recommendations

The evidence for people with mild or no hypoxaemia showed that neither ambulatory oxygen nor short-burst oxygen provide a clinically meaningful improvement in breathlessness.

11

^b People who are not taking long-term oxygen and who have a mean PaO₂ greater than 7.3k Pa.

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for oxygen therapy in people with stable COPD DRAFT (June, 2018)

1 Impact of the recommendations on practice

- 2 Reducing the use of ambulatory and short-burst oxygen therapy in people who would not
- 3 benefit is likely to be cost saving and will allow resources to be invested in effective
- 4 treatments for breathlessness instead.

5 The committee's discussion of the evidence

6 Interpreting the evidence

7 The outcomes that matter most

8 The committee agreed that the most relevant outcome for this review question was quality of
9 life, with small improvements in breathlessness likely to be meaningful only if these
10 subsequently led on to improvements in quality of life. It was agreed that since the review
11 focused only on breathlessness in people who were mildly or non-hypoxaemic at rest, it was
12 important to restrict the recommendations made to that population, and that the evidence
13 reviewed would not be relevant to people being considered for ambulatory or short burst

14 oxygen for other indications.

15 The quality of the evidence

16 The committee agreed that the evidence presented was from a high quality systematic

17 review containing 44 randomised control trials. Some of the included studies were of low

- 18 quality with very small sample sizes, however the meta-analyses incorporated over 800
- 19 participants, which increased the power and precision of the evidence.
- 20 The committee acknowledged that the effect of oxygen therapy on breathlessness was
- 21 consistent between trials recruiting people with and without desaturation during exercise,
- studies with differing baseline mean arterial oxygen values, and studies using oxygen doses
- 23 greater or less than 2 litres per minute. It was therefore not possible to identify specific
- subgroups of people in which ambulatory or short burst oxygen therapy are more effective.

25 Evidence of possible publication bias was identified in the studies included in the review;

specifically that small, negative studies were less likely to have been published. The

- committee noted that if these studies had been published, it was likely the estimated
- effectiveness of ambulatory and short burst oxygen therapy would have been further reduced.
- 30 The committee agreed that overall the quality of evidence for the effect of oxygen compared
- 31 with air on breathlessness was of moderate quality with some variation depending on the
- 32 subgroup analysis. The consistency of the results across subgroup analysis added
- 33 confidence to the results observed.

34 Benefits and harms

35 Based on the evidence, the committee agreed that ambulatory oxygen therapy is not

- 36 indicated for the treatment of breathlessness of people who are mildly hypoxaemic or non-
- 37 hypoxaemic at rest. The evidence from 28 RCTs showed that ambulatory oxygen given
- 38 during exercise or daily activities reduced breathlessness when compared to pressurised air,
- 39 however the reduction was below a level that would be considered clinically meaningful. The
- 40 committee considered the reduction on breathlessness on the modified Borg scale and noted
- the published minimal clinically important difference on that scale is 2 points. The evidence

- 1 presented showed a mean improvement of 0.5, deemed too small to be meaningful to
- 2 someone experiencing breathlessness, and this was supported by the fact that no
- 3 improvements in quality of life were found in the studies. In addition, a large number of
- 4 subgroup analyses were carried out to try to identify subgroups of people that might benefit
- 5 from the therapy, but none of the subgroups showed an improvement in breathlessness
- 6 either. As a result, the committee were confident in making a do not offer recommendation
- that was generalizable across the whole COPD population. The committee noted that
 although ambulatory oxygen therapy was not effective at managing breathlessness, it could
- autough annouatory oxygen merapy was not enective at managing breatnessness, it could
 be beneficial under other circumstances, such as during exercise in people with exercise
- 10 desaturation, but this topic was outside of the scope of the evidence review.
- 11 The committee also amended a 2004 ambulatory oxygen recommendation to remove the
- term dyspnoea (breathlessness) as this was covered by the new recommendation. The rest
- 13 of the old 2004 recommendation was out of scope of this evidence review.
- 14 The committee concluded that short burst oxygen therapy was not indicated for treatment of
- 15 people who are mildly or non hypoxaemic at rest. Evidence from 4 RCTs, could not find a
- 16 difference in breathlessness or quality of life between people who were offered short burst
- 17 oxygen therapy and those offered pressurised air before exertion.

18 Cost effectiveness and resource use

- 19 No economic evidence was identified for this review question, and economic modelling was
- 20 not prioritised. The committee noted there were costs attached to the provision of oxygen
- 21 therapy. The evidence indicated that there would be no meaningful benefits arising from its
- 22 use and agreed that the recommendations not to offer short-burst oxygen therapy or
- ambulatory oxygen therapy to manage breathlessness in people with COPD who are mildly
- or non-hypoxaemic at rest were likely to be cost saving.

25 Other factors the committee took into account

26 No other factors were discussed.

Long-term oxygen therapy

2 Review question

In which subgroups of people is long-term oxygen therapy indicated, and is it a clinically and
 cost effective option for managing stable COPD in these subgroups?

5 Introduction

- 6 The aim of this review question was to determine the subgroups of people in which long term
- 7 oxygen therapy is indicated, and whether it represents an effective and cost-effective
- 8 treatment option in those groups.

9 For the purposes of this question, long term oxygen therapy (LTOT) is defined as oxygen 10 used for at least 15 hours per day. This definition was obtained from the British Thoracic 11 Society Home Oxygen Guidelines (2015), and is based on the original MRC trial of long term 12 oxygen therapy from the 1980s (which is included as part of this review). In UK clinical 13 practice, this is usually delivered by an oxygen concentrator, a machine that draws oxygen 14 from the air and concentrates it to deliver oxygen at higher concentrations to patients, thus 15 reducing the need for oxygen cylinders.

This review identified studies that fulfilled the conditions specified in Table 3. For full detailsof the review protocol, see appendix A

18 Table 3: PICO – Long-term oxygen therapy

| Population | People diagnosed with COPD |
|---------------|--|
| Interventions | Long-term oxygen therapy |
| Comparator | No interventionOptimal medical therapy |
| Outcomes | Mortality (primary outcome) Quality of life (primary outcome) Rates of pulmonary hypertension and cor pulmonale Exercise capacity/ tolerance Hospital admissions and readmissions Exacerbations Gas transfer (carbon monoxide diffusion capacity and arterial oxygen partial pressure, PaO2) Change in FEV1, rate of change in FEV1 Symptoms (including breathlessness) Adverse events – including trip risk from cables, burns Resource use and costs |

19 Methods and process

- 20 This evidence review was developed using the methods and process described in
- 21 Developing NICE guidelines: the manual. Methods specific to this review question are

described in the review protocol in appendix A, and the methods section in appendix B.

14

- 1 The search strategies used in this review are detailed in appendix C.
- 2 Declarations of interest were recorded according to <u>NICE's 2014 conflicts of interest policy</u>.

3 Clinical evidence

4 Included studies – Long-term oxygen therapy

A systematic literature search for randomised controlled trials (RCTs) and systematic reviews 5 6 with no date limit identified 5,141 references. No date limit was used as the previous guideline recommendations were not based on a systematic literature search. Additional 7 references were added from the old guideline (33) and the surveillance report (4) to give 8 5,178 references. Although priority screening was used for this review, all of the abstracts 9 were screened on title and abstract and 43 papers were ordered as potentially relevant 10 systematic reviews or RCTs based on the criteria in the review protocol. In particular, RCTs 11 (including those from identified systematic reviews) were excluded if they did not meet the 12 criteria of enrolling patients with COPD at baseline and did not have long term oxygen 13 14 therapy (at least 15 hours per day) as an intervention. Four papers were included after full text screening and all were RCTs. Summaries of the

Four papers were included after full text screening and all were RCTs. Summaries of the
 included studies are provided in <u>Table 4</u>.

17 A second search was conducted at the end of the guideline development process for all

- 18 updated review questions, to capture papers published whilst the guideline was being
- 19 developed. This search returned 3,100 references, which were screened on title and
- abstract. No additional relevant references were found for this review question.
- 21 The process of study identification is summarised in the diagram in appendix D.

22 For the full evidence tables and the full GRADE profiles please see appendix E and appendix

23 G. The references of individual included studies are given in appendix K.

24 Excluded studies

25 Details of the studies excluded at full text are given in Appendix J

1 Summary of clinical studies included in the evidence review

2 See appendix E for full evidence tables. One of the studies provided evidence on adverse events that could not be analysed in GRADE profiles,

3 and is therefore presented as evidence in appendix E (Table 12).

4 Table 4: Long-term oxygen therapy

| Short Title | Interventions | Population | Outcomes |
|------------------|---|--|---|
| Albert (2016) | Long term oxygen therapy - 24hrs/day Patients were prescribed 24 hour oxygen if their resting SpO2 was 89 - 93% or moderate exercise induced desaturation (during the 6 minute walking test, SpO₂ ≥ 80% for ≥5minutes and <90% for 10 seconds) All patients had stationary and portable oxygen systems and 2 litres of oxygen per minute during sleep and/or at rest. Patients were to use oxygen regardless of increase in the SpO₂ level No long term oxygen therapy Ambulatory dose of oxygen was individually prescribed and reassessed annually - 2 litres of oxygen per minute or adjusted higher to maintain an SpO₂ of 90% or more at least 2 minutes while the patient was walking no supplemental oxygen was to be used unless severe resting desaturation (SpO₂ ≤ 88%) or severe exercise induced desaturation (SpO₂<80% for >/= 1 minute) if either of these happened oxygen was prescribed and reassessed after 1 month | Sample size 737 Split between study groups Long term oxygen therapy – 368 (220 participants were on 24hour oxygen and 148 were prescribed oxygen during exercise and sleep only) No long term oxygen therapy – 370 participants %female LTOT - 28% No LTOT - 25% Mean age (SD) - LTOT - 68.3+/- 7.5 No LTOT - 69.3+/- 7.4 | Death/Mortality First readmission to hospital Incidence of COPD exacerbation Adherence to the supplemental oxygen Development of severe resting desaturation Development of severe exercise - induced desaturation The distance walked in 6 minutes St. George's Respiratory Questionnaire |

| Short Title | Interventions | Population | Outcomes |
|---|--|--|---|
| Gorecka (1996) | Long term oxygen therapy (received from an oxygen concentrator at a flow rate adjusted to raise resting PaO2 above 8.7kPa (65mmHg) prescribed for at least 17hrs/day and conventional therapy) No long term oxygen therapy (Conventional treatment was given same as the intervention group) | Sample size 135 participants Split between study groups <i>LTOT group - n=68 participants</i> <i>Control group - n= 67 participants</i> Loss to follow-up <i>No dropouts</i> %female 32 women (24%) Mean age (SD) 61.2 years (40-79 years) no S.D Current smokers <i>All participants declared to be</i> <i>non-smokers</i> | • Death/mortality |
| Medical Research Council working party (1981) | Long term oxygen therapy at least 15hrs/day (included sleeping hours, given via nasal prongs, at a flow rate of 2l/minute, or at a higher flow rate if this was necessary to achieve a PaO2>60mmHg. the delivery systems/cylinder varied across the patients.) No long term oxygen therapy (other treatments were given under the direction of a clinician and it included - diuretics, antibiotics and digoxin) | Sample size 87 patients Split between study groups Control group - 102 participants Intervention groups - 101 participants %female 21.2% Mean age – 65.7 (no SD) | Death/Mortality Rate of change - forced expiratory volume per second FEV1 Rates of change - arterial oxygen tension PaO₂ |

1

| Short Title | Interventions | Population | Outcomes |
|---|--|--|--|
| Nocturnal Oxygen Therapy Trial Group (1980) | Long term oxygen therapy – (Average oxygen use of 17.7h/day (SD=4.8hr/day) Oxygen was administered by nasal prongs at a measured flow rate of 1 to 4 l/min. Each patient received the lowest flow in whole litres per minute that demonstrably increased resting semi recumbent arterial pO₂ at least 6 mmHg and maintained resting arterial pO₂ of 60 to 80 mmHg dose was increased by 11 in periods of exercise or sleep oxygen delivery systems varied All patients also treated with oral theophylline and inhaled beta antagonist. Diuretics and antibiotics were used as indicated) Nocturnal oxygen therapy (Oxygen therapy only during sleep - averaging 12h/day (SD=2.5hr/day) All patients were treated with oral theophylline and inhaled beta-2-agonists) | Sample size 203 patients Split between study groups Control group - 102 participants Intervention groups -101 participants %female 21.2% Mean age (SD) 65.7years (no S.D) | Death/Mortality Several subgroup analysis Comparison of PaO2 more/less than 55mmHg (7.3kPa) Comparison of PaCO2 more/less than 43 mmHg (5.7kPa) FEV1 more/less than 0.69I Comparison of sleep, mean oxygen saturation less/greater than 85% |

3 Economic evidence

4 Included studies

- 5 A single search was conducted to cover all review question topics in this guideline update.
- 6 This search returned 16,299 records, of which 16,295 were excluded on title and abstract.
- 7 The remaining 4 papers were screened on full test and 2 were found to be relevant for this
- 8 review question. No UK-based analyses were identified by the review, so inclusion criteria
- 9 were broadened to allow studies with a non-NHS perspective.

10 Excluded studies

11 Details of the studies excluded at full text are given in Appendix J

12 Summary of studies included in the economic evidence review

13 **Oba (2009)** conducted an economic analysis of two different oxygen therapy programmes, long-term continuous (COT) and nocturnal (NOT), compared with no oxygen therapy in 14 patients with COPD. The analysis considered 2 patient cohorts, 1 group with severe resting 15 hypoxaemia who were simulated to receive COT or no therapy, and another with nocturnal 16 desaturation who were simulated to receive either NOT or no therapy. A Markov model was 17 18 run for 3 and 5 years for both interventions, with a third-party payer perspective on costs (US Medicare). Costs and benefits were discounted at 3% per annum. One-way and probabilistic 19 sensitivity analyses were produced. The model describes 3 disease severity states as 20 defined by FEV1 ranges: stage 1 = FEV1 >50% of predicted; stage 2 = FEV1 of 30-50% of 21 predicted; stage 3 = FEV1 of <30% of predicted. Efficacy data were taken from a study using 22 23 EQ-5D to measure the HRQoL associated with COPD severity (as measured using FEV1). The model includes an all-cause mortality state, but does not explicitly model COPD 24 25 exacerbations because no trial evidence was available to suggest a reduction in 26 exacerbation rates in patients who were receiving LTOT.

27 Table 5 and Table 6 give the base-case results of the incremental cost-effectiveness analyses. During the 3-year (\$23,807 [~£16,700] per QALY) and 5-year (\$16,124 [£11,300] 28 per QALY) horizons, the ICER for COT in the severe resting hypoxaemia cohort was within 29 commonly accepted thresholds for cost effectiveness in US studies (<\$50,000 [~£35,100] per 30 QALY). In the severe resting hypoxaemia cohort, multiple 1-way sensitivity analyses showed 31 that all ICERs for COT were less than \$25,000 (~£17,600) per QALY, and the probabilistic 32 33 analysis showed a >95% probability that COT is associated with an ICER of \$50,000 (£35,100)per QALY or better. 34

Table 5Base-case cost-effectiveness results – Long-term continuous oxygen2therapy compared with no oxygen therapy in people with severe resting3hypoxaemia

| Пурохаонна | Absolute | | Incremental | | |
|--|---------------|-------|---------------|--------------------|----------------------|
| Strategy | Costs (\$) | QALYs | Costs (\$) | Effects (QALYs) | ICER (\$/QALY) |
| Three-year horizon | | | | | |
| Control | NR | 1.56 | - | - | - |
| Continuous oxygen therapy | NR | 1.84 | 6,567 | 0.28 | 23,807 (~£16,700) |
| Five-year horizon | | | | | |
| Control | NR | 2.07 | - | - | - |
| Continuous oxygen therapy | NR | 2.66 | 9,517 | 0.59 | 16,124 (~£11,300) |
| ICER = incremental cost-effectiveness ratio; NR = not reported; QALY = quality-adjusted life-year. | | | | | |

4 **Table 6** Base-case cost-effectiveness results – nocturnal oxygen therapy compared 5 with no oxygen therapy in people with nocturnal desaturation

| | Absolute | | Incremental | | |
|---|---------------|-------|---------------|--------------------|------------------------|
| Strategy | Costs (\$) | QALYs | Costs (\$) | Effects (QALYs) | ICER (\$/QALY) |
| Three-year horizon | | | | | |
| Control | NR | 1.87 | - | - | - |
| Nocturnal oxygen therapy | NR | 1.88 | 5,975 | 0.0125 | 477,929 (~£335,800) |
| Five-year horizon | | | | | |
| Control | NR | 2.68 | - | - | - |
| Nocturnal oxygen therapy | NR | 2.70 | 8,615 | 0.0281 | 306,356 (~£215,200) |
| ICER = incremental cost-effectiveness ratio: NR = not reported: $OALY = quality-adjusted life-year$ | | | | | |

ICER = incremental cost-effectiveness ratio; NR = not reported; QALY = quality-adjusted life-year.

In contrast, the ICER for NOT in the nocturnal desaturation cohort was \$477,929

7 (~£355,800) per QALY during a 3-year horizon and \$306,356 (~£215,200) per QALY during

8 a 5-year horizon. Results varied widely when the quarterly rate of death with NOT was varied

9 in 1-way sensitivity analysis. Quantitative results of the probabilistic sensitivity analysis are

10 not reported but, from the cost–utility scatter-plot provided, the probability that NOT is

11 associated with an ICER of \$50,000 (~£35,100) per QALY or better appears to be less than

12 10% at a 3-year time-horizon and less than 25% at the 5-year analysis.

This study was associated with a number of limitations. Firstly, HRQoL scores used were based on FEV1 states for patients with COPD, rather than focussing specifically on patients with hypoxaemia. Secondly, a number of aspects of the methodology are omitted; no cost for the control group is given, usual care is not defined, and distributions for the probabilistic sensitivity analysis are not provided. Finally, there is no grading of evidence of systematic reviews of costs and benefits used to inform the model. The study was classified as being partially applicable, as it was conducted from a non-NHS perspective.

Chronic obstructive pulmonary disease in over 16s: diagnosis and management: evidence reviews for Referral criteria for oxygen therapy in people with stable COPD DRAFT (June, 2018)

6

1 Chandra (2012) conducted a cost-utility analysis of a number of interventions for COPD, of 2 which one was long-term oxygen therapy (LTOT) delivered in an outpatient setting for around 15 hours per day compared to usual care in patients with severe hypoxaemia. The evaluation 3 was conducted from the perspective of the Canadian healthcare system, and used a lifetime 4 5 time horizon. The authors used a Markov model to simulate patients' progression through 6 four states of severity based on the GOLD classification system. For each annual cycle of the model, patients experienced a number of mild and severe exacerbations, according to their 7 8 disease severity. The assumption was made that severe hypoxaemia is equivalent to the 9 'very severe COPD' GOLD state, and so all patients started in this state.

- Data on baseline utility for patients in each health state were taken from a previous study of
 QoL in patients with a variety of COPD disease stages using visual analogue scale and time
 trade-off methods. Disutilities associated with moderate and severe exacerbations were
 applied to these as appropriate.
- Patients' baseline mortality was assumed to be 3.3 times that of the general population,
 based on a previous observational study of standardised mortality rates in people with
 COPD. For patients in the LTOT arm a relative risk for mortality was applied to this value,
 estimated using data from previous a 'mega-analysis' of chronic disease management
 conducted in Canada.
- An annual cost of CAD \$2,261 (~£1,260) for LTOT was used, based on healthcare system data. The model also included annual maintenance costs of COPD and costs per minor and major exacerbation, based on costs from previous economic analyses. However, since the model makes the assumption that LTOT only affects mortality, these costs do not differ between arms for living patients.
- Base case results showed that LTOT has an ICER of CAD \$38,993 (~£21,700) per QALY
 compared to usual care. Probabilistic sensitivity analysis indicated that LTOT is associated
 with a 71% probability of being cost effective at a threshold of CAD \$50,000 (~£27,900)
 QALY.
- This evaluation was classified as being partially applicable as it is not conducted from the perspective of the NHS and uses a discount rate of 5% for costs and health benefits. It was categorised as having potentially serious limitations. This was due to the assumption that patients with severe hypoxaemia are identical to those with very severe COPD according to the GOLD staging system. Furthermore, the analysis is potentially simplistic in some aspects – the assumption is made that LTOT only affects mortality, and that, other than the cost of intervention, treatment costs for living patients remain identical between arms.

35 Economic model

This topic was not prioritised for health economic modelling and no original analyses were produced.

38 Evidence statements

39 The format of the evidence statements is explained in the methods in <u>appendix B</u>.

1 Long term oxygen therapy vs no long term oxygen therapy

2 People with COPD and moderate resting or exercise-induced desaturation

3 Mortality

- 4 Low quality evidence from 1 RCT reporting data from 738 people with COPD and moderate
- 5 resting or exercise-induced desaturation (SpO₂ 89-93% approximately 7.5kPa 9.2kPa)
- 6 could not differentiate mortality rates between people offered long term oxygen therapy
- 7 compared to no long term oxygen therapy.

8 Mortality - subgroup analysis

Moderate quality evidence from 1 RCT reporting data from up to 289 people with COPD and
moderate resting or exercise-induced desaturation (SpO₂ 89-93% - approximately 7.5kPa –
9.2kPa) found reductions in mortality rates in people offered long term oxygen therapy who
were aged 71 or over, and in people with a COPD exacerbation in the 3 months prior to the
study enrolment, compared to people in the same groups who were not offered long term
oxygen therapy.

Low quality evidence from 1 RCT reporting data from 618 people with COPD and moderate 15 16 resting or exercise-induced desaturation (SpO₂ 89-93% - approximately 7.5kPa – 9.2kPa) 17 could not differentiate mortality rates between people offered long term oxygen therapy compared to people not offered long term oxygen therapy in a range of subgroups based on: 18 19 treatment during sleep and exercise; the number of hours of long term oxygen therapy used 20 per day; desaturation gualifying for long term oxygen therapy at rest or during exercise or 21 under both circumstances; age < 71 years; race; sex; smoking status; levels of FEV1 % 22 predicted; body mass index; minimum oxygen saturations during 6 minute walking test; no COPD exacerbations in the 3 months prior to enrolment or history of anaemia. 23

24 Other outcomes

25 Very low to low quality evidence from 1 RCT reporting data from up to 738 people with

- 26 COPD and moderate resting or exercise-induced desaturation (SpO₂ 89-93% approximately
- 7.5kPa 9.2kPa) could not differentiate quality of life, rates of hospitalisations, room air
 oxygen saturation levels, room air 6 minute walking distance, post bronchodilator forced
- expiratory volume or partial arterial oxygen values between people offered long term oxygen
- 30 therapy compared to no long term oxygen therapy.
- Low quality evidence from 1 RCT reporting data from up to 738 people with COPD and
- 32 moderate resting or exercise-induced desaturation (SpO2 89-93% approximately 7.5kPa -
- 33 9.2kPa) found no meaningful difference between the risk of having an exacerbation between
- 34 people offered long term oxygen therapy compared to no long term oxygen therapy.

35 People with COPD and mild hypoxaemia

36 Mortality

- 37 Low quality evidence from 1 RCT reporting data from 135 people with COPD and mild
- 38 hypoxaemia (arterial oxygen tension (PaO₂) between 56 and 65 mmHg (7.4kPa to 8.7 kPa)
- 39 could not differentiate the risk of mortality between people offered long term oxygen therapy
- 40 compared to no long term oxygen therapy.

1 **People with COPD and cor pulmonale**

- 2 Low quality evidence from 1 RCT reporting data from 59 people with COPD and cor
- 3 pulmonale where arterial oxygen tensions is between 40 and 60mmHg (5.3kPa to 8kPa)
- 4 found improvements in partial pressure of arterial oxygen at 3 years follow-up in people
- 5 offered long term oxygen therapy compared to no long term oxygen therapy.
- 6 Very low guality evidence from 1 RCT reporting data from up to 87 people with COPD and
- 7 cor pulmonale where arterial oxygen tensions is between 40 and 60mmHg (5.3kPa to 8kPa)
- 8 could not differentiate the rate of change in FEV1 or mortality at 3 years follow-up between
- 9 people offered long term oxygen therapy compared to no long term oxygen therapy.

10 Health economic evidence

- 11 One partially applicable study with very serious limitations (Oba 2009) suggests that
- 12 continuous oxygen therapy is cost effective for patients with severe resting hypoxaemia. The
- 13 same study suggests that, in patients with nocturnal decompensation, the use of nocturnal
- 14 oxygen is unlikely to be cost effective unless mortality rates are low and the therapy is used
- 15 over a period of at least 5 years.
- 16 One partially applicable study with potentially serious limitations (Chandra 2012) suggests
- 17 that long-term oxygen therapy delivered in an outpatient setting for around 15 hours a day is
- 18 potentially cost effective, with an ICER of CAD \$38,993 (~£21,700) per QALY. However,
- 19 there is considerable uncertainty surrounding this finding.

20 Continuous oxygen therapy vs nocturnal oxygen therapy

21 People with COPD and moderate to severe hypoxaemia

Moderate quality evidence from 1 RCT reporting data from 203 people with moderate to
severe hypoxaemia found a reduced risk of mortality in people with COPD and moderate to
severe hypoxaemia (PaO2 of ≤ 55 mmHg (7.3kPa)) offered long term oxygen therapy
compared to nocturnal oxygen therapy. This improvement was also observed in moderate
quality evidence from subgroups with a baseline mean arterial oxygen ≥ 52 mmHg (6.9 kPa),
mean oxygen saturations < 85%, mean pulmonary arterial pressure < 27mmHg (3.6 kPa)
and mean arterial carbon dioxide ≥ 43mmHg (5.7 kPa).

- 29 Low quality evidence from 1 RCT reporting data from 203 people with moderate to severe
- 30 hypoxaemia could not differentiate the risk of mortality in people with COPD in the following
- 31 subgroups: PaO₂ <52 mmHg; FEV1 <0.69L or ≥ 0.69L; mean SaO2 ≥ 85%; mean pulmonary
- artery pressure ≥27mmHg (3.6kPa) or PaCO₂ < 43 mmHg (5.7 kPa).

33 Recommendations

- 34 Recommendations shaded in grey were not within the scope of the update. Evidence for
- 35 these was not reviewed and changes were made only to bring the wording in line with current
- 36 NICE style or to link the existing recommendation to a new one if the treatment pathway
- 37 changed.

38 Long term oxygen therapy

B8. Be aware that inappropriate oxygen therapy in people with COPD may cause respiratory depression. **[2004]**

- 1 B9. Assess the need for oxygen therapy in people with:
- 2 very severe airflow obstruction (FEV1 below 30% predicted)
- 3 cyanosis (blue tint to skin)
- polycythaemia 4
- 5 peripheral oedema (swelling)
- a raised jugular venous pressure 6
- oxygen saturations of 92% or less breathing air. 7
- 8 Also consider assessment for people with severe airflow obstruction (FEV1 30-49% 9 predicted). [2004]
- 10 B10. Assess people for long-term oxygen therapy by measuring arterial blood gases on 2 occasions at least 3 weeks apart in people who have a confident diagnosis of COPD, who 11 are receiving optimum medical management and whose COPD is stable. [2004] 12
- 13 B12. Consider long-term oxygen therapy for people with COPD who do not smoke and who:
- have a PaO₂ below 7.3 kPa when stable or 14
- 15 have a PaO₂ above 7.3 and below 8 kPa when stable, if they also have one of the 16 following:
- 17 secondary polycythaemia
- 18 o peripheral oedema
- 19 pulmonary hypertension. [2018]
- 20 B13. Conduct and document a structured risk assessment for people being assessed for 21 long-term oxygen therapy who meet the criteria in recommendation 1.2.53 (in the short guideline). As part of the risk assessment, cover the risks for both the person with COPD and 22 23 the people who live with them, including:
- the risks of falls from tripping over the equipment 24
- the risks of burns and fires, and the increased risk of these for people who live in homes 25 26 where someone smokes (including e-cigarettes).
- 27 Base the decision on whether long-term oxygen is suitable on the results of the structured risk assessment. [2018] 28
- 29 B14. For people who smoke or live with people who smoke, but who meet the other criteria for long-term oxygen therapy, ensure the person who smokes is offered smoking cessation 30 advice and treatment, and referral to specialist stop smoking services (see the NICE 31
- guidelines on stop smoking interventions and services and medicines optimisation). [2018] 32
- 33 B15. Do not offer long-term oxygen therapy to people who continue to smoke despite being offered smoking cessation advice and treatment, and referral to specialist stop smoking 34 35 services. [2018]
- 36 B16. Advise people who are having long-term oxygen therapy that they should breathe supplemental oxygen for a minimum of 15 hours per day. [2018] 37
- 38 B17. Do not offer long-term oxygen therapy to treat isolated nocturnal hypoxaemia caused by 39 COPD. [2018]
- 40 B18. To ensure everyone eligible for long-term oxygen therapy is identified, pulse oximetry
- 41 should be available in all healthcare settings. [2004]

- 1 B19. Oxygen concentrators should be used to provide the fixed supply at home for long-term 2 oxygen therapy. **[2004]**
- 3 B20. People who are having long-term oxygen therapy should be reviewed at least once per
- 4 year by healthcare professionals familiar with long-term oxygen therapy. This review should 5 include pulse oximetry. [2004]
- 6 Rationale and impact

7 Long term oxygen therapy

8 Why the committee made the recommendations

9 There is evidence that continuous long-term oxygen therapy improves survival in people with 10 more severe hypoxaemia, but not for people with mild hypoxaemia. The specific thresholds 11 for long-term oxygen therapy are taken from the trials that provided the evidence.

in long-term oxygen therapy are taken nom the thats that provided the evidence.

12 The recommendation that people should use supplemental oxygen for more than 15 hours a 13 day is based on the available evidence. There is also evidence that long-term oxygen

14 therapy was not effective for isolated nocturnal hypoxaemia caused by COPD.

- 15 The evidence showed risks of harm from the use of long-term oxygen, in particular burns and
- 16 fires as a result of smoking while using oxygen and falls from tripping over equipment. Given
- 17 these risks to the person with COPD and the people they live with, the committee agreed that
- 18 it is important to conduct a detailed risk assessment before offering this treatment.
- 19 The committee decided that there were 2 levels of risk posed by smoking around oxygen and 20 the recommendations they made reflect these differences:
- People with COPD who do not smoke but who live with people who smoke. Cigarettes could ignite the oxygen, but this risk is likely to be lower because the person who smokes can keep away from the oxygen. Oxygen therapy may benefit these people if they meet the eligibility criteria and the risk assessment is favourable.
- People with COPD who smoke. They will be smoking in close proximity to the oxygen,
 and the risks to them and the people they live with outweigh the potential benefits of long term oxygen therapy.

28 Impact of the recommendations on practice

These recommendations may result in an increase in demand for stop smoking services, but these are known to provide good value for money. Additional time may be needed to conduct risk assessments. As these should prevent people from being given oxygen therapy if they would not benefit or may be harmed by it, it would be an appropriate use of resources and should not lead to an overall increase in resource use. These recommendations may also reduce the cost of managing harms associated with oxygen use, including falls, burns and the wider costs of fires.

1 The committee's discussion of the evidence

2 Interpreting the evidence – Long term oxygen therapy

3 The outcomes that matter most

- 4 The committee agreed that the critical outcomes for this review were quality of life, mortality
- 5 and adverse events. Adverse events were defined as any harm incurred as a result of using
- long term oxygen therapy (including fires, burns, trips and falls). The committee noted that 6
- some of the outcomes reported in older studies, such as "the rate of change in arterial 7
- 8 oxygen" as reported in the MRC working group study (1981), were hard to relate to patient
- 9 experience and therefore difficult to interpret.

The quality of the evidence 10

11 The committee agreed that all four studies included were at risk of bias due to lack of blinding of participants and/or investigators. There were variations in the severity of COPD in 12 13 the included studies and the actual hours spent on oxygen use as all the studies relied on 14 self-reported accounts. The committee was also concerned about the validity of the MRC (1981) and the NOTT (1980) studies as they were carried out over thirty years ago and 15 medical practice has changed considerably since then. However, they acknowledged that 16 this is the best available evidence on long term oxygen therapy in people with moderate to 17 18 severe hypoxaemia.

19 The committee agreed that data from the USA (Albert 2016) provided useful evidence on 20 long term oxygen therapy in a modern context. However, it only included people with mild to 21 moderate hypoxaemia. There were concerns about the study design as some people in the control group used oxygen for ambulatory purposes, the lack of blinding could have 22 23 potentially influenced the participant self-reported outcomes, and adherence to oxygen was self-reported by the participants. 24

25 Overall the available evidence was of very low to moderate quality and was drawn from 4 randomised control studies with varying baseline populations in terms of disease severity 26 27 and administration of long term oxygen therapy. Due to these differences, the committee agreed that it was not appropriate to carry out any meta-analysis and consider each study 28 results in isolation and within context of its baseline population. The committee also agreed 29 that the low quality of the evidence meant that weaker recommendations would need to be 30 31 made for the use of long term oxygen therapy.

32 Benefits and harms

33 Based on the evidence, the committee agreed that continuous long term oxygen therapy can reduce mortality in people with moderate to severe hypoxaemia compared to nocturnal 34 oxygen therapy (NOTT 1980). They noted that this benefit might be even larger if continuous 35 long term oxygen therapy was compared to no oxygen therapy. They concluded that long 36 term oxygen therapy should be considered in those with arterial oxygen pressure of less than 37 7.3 kPa when stable or arterial oxygen pressure greater than 7.3 and less than 8 kPa when 38 stable and either secondary polycythaemia, peripheral oedema or pulmonary hypertension 39 40 are present, based on the inclusion criteria for this study.

- 41 However, they noted that there is a need for clear risk assessments in those being
- 42 considered for this therapy, in order to reduce the risk of harms both to the individual and 43
- those residing in the same household. The committee's main concern was the increased risk

of fires as a result of smoking whilst using oxygen or open flames near the oxygen flames, and risks of tripping over the equipment. The data on the adverse effects of using LTOT presented in the Albert study (2016, please see <u>Table 12</u> in this evidence review) supports the committee's concerns. 368 people were treated with long term oxygen therapy and there were a total of 51 adverse events attributed to using oxygen therapy. Twenty three reports of people tripping over equipment were made with 2 people requiring hospitalisation. Five people reported 6 cases of fires or burns and 1 of these cases required hospitalisation.

8 Based on this evidence, the committee agreed on the need for a thorough risk assessment 9 for anyone being considered for oxygen therapy. The committee noted that the increased risk 10 of fires or burns was not confined to the person with COPD and the assessment should include consideration of the risks for people living with the person on LTOT. The committee 11 were also concerned about the risk posed by others, and agreed it was important to consider 12 whether anyone within the household smokes, not just the person with COPD. They also 13 14 noted that the risk of fires was not confined to cigarettes and pipes, but that other electronic 15 devices (such as e-cigarettes) could potentially also produce sparks and ignite the oxygen 16 leading to a fire.

17 The committee agreed that as per current practice in the NHS, the risk assessment was likely to be performed by the oxygen supplier in conjunction with an oxygen assessment 18 19 team and that this assessment may also involve a representative from the local fire service. They noted that the <u>BTS oxygen guideline (pages i25-26, 2015)</u> provided information on who 20 should perform the assessment, how to perform the assessment and at what interval. They 21 also noted that the IHORM form summarises the initial risk assessment and that regular 22 23 follow up is important. This is likely to happen every few months initially, then every 6 months to a year if the person is stable. The committee also noted that the risks for people with 24 25 COPD (and the people they live with) may change over time, for example, if an ex-smoker with COPD relapses or a smoker with COPD guits and that it is appropriate for the risk 26 27 assessment to be carried out again under these circumstances.

28 Based on a discussion about the balance the risks and benefits posed by LTOT to people 29 with COPD and their families, the committee made separate recommendations concerning 30 the use of LTOT for people with COPD who do not smoke, but live with smokers, and for those groups of people with COPD who are current smokers. For the first group of people 31 32 with COPD, the committee agreed that the presence of smokers in the household still 33 constituted a fire risk, but that this could be potentially mitigated by awareness of the risks. They decided that for these people with COPD and their families the benefits of LTOT could 34 35 outweigh the risks and as a result, these people with COPD should have access to LTOT if they meet the criteria for this treatment and the results of the structured risk assessment are 36 37 favourable. However, in an attempt to reduce the fire risk still further, the committee also included a reference to NICE guidance on smoking cessation in another recommendation to 38 39 ensure that smokers who live in the same household as people with COPD who are being 40 considered for LTOT are offered services to help them guit smoking.

41 For people with COPD who are still smoking and meet the criteria for LTOT, the committee 42 emphasised the need to explore smoking cessation options to treat tobacco dependency to 43 reduce the risk of fires and burns. They agreed that smoking cessation has been shown to 44 be a highly cost-effective intervention, and does not have the same risks of harm as long term oxygen therapy. However, if the person with COPD is unable or unwilling to stop 45 smoking, the committee decided that it was too dangerous for them and their families to 46 47 allow them to access to LTOT. They made a do not offer recommendation to reflect the elevated risk of fires caused by people on LTOT who smoke. The committee agreed that is 48

important that clinicians explain fully to patients that the reasons for not prescribing LTOT to people who are still smoking are based solely on the risks to safety of the patients and other household members. The risk of fires in this situation was considered to be far greater than for people on LTOT who do not smoke, but have family members who smoke, as the oxygen and assures of a smark or firms are in much cleaser provinity in this same.

5 and source of a spark or flame are in much closer proximity in this case.

As the Albert and Gorecka studies did not find mortality benefits from using long term oxygen therapy in populations with less severe hypoxaemia, the committee agreed it would not be appropriate to extend the criteria for long term oxygen therapy to this more severe population. They also noted that, although benefits were seen in a small number of subgroups in that study, results were presented for a sufficiently large number of negative subgroups as well, and therefore they could not be confident these subgroup results

12 represented a real effect.

13 The committee agreed that to observe benefits, long term oxygen therapy should be 14 administered for at least 15 hours. This was based on the NOTT study (1980) which provided 15 evidence that oxygen therapy for at least 15 hours in people with moderate to severe hypoxaemia reduced the number of deaths when compared to those receiving oxygen 16 17 therapy just at night. In addition, the committee concluded that long term oxygen therapy 18 should therefore not be offered for treatment of overnight hypoxaemia in the absence of 19 other symptoms. They also considered evidence from the economic review that showed that 20 this oxygen therapy at night did not improve quality of life and did not provide an acceptable 21 balance between benefit and cost.

22 Cost effectiveness and resource use

The committee agreed that there were very serious limitations to the economic evidence identified, in particular a lack of clarity in the reporting, and the non-systematic way many of the parameters in the model were obtained. However, the committee agreed the results of the paper did support their conclusions that long-term oxygen therapy can be a cost-effective treatment for people with moderate to severe hypoxaemia, and that nocturnal oxygen therapy is unlikely to be a cost-effective alternative.

The committee noted that it is still the case that not all people with COPD who continue to smoke are offered appropriate smoking cessation interventions, which are likely to be the most effective way to improve their COPD. They agreed there might be an additional cost to fully rolling out these services to all people with COPD that smoke, but also agreed that by implementing the cost-effective smoking cessation interventions recommended in the NICE guideline on smoking cessation, this should represent an effective use of NHS resources.

35 Other factors the committee took into account

36 The committee discussed potential equalities issues surrounding smoking status. In 37 particular, they noted that smoking status is correlated with low socioeconomic status, and is 38 a factor that is both amenable to change and of particular importance for COPD disease 39 management and progression. They noted that it was inappropriate to make different 40 recommendations for people with COPD treatment based on their smoking status, unless the 41 treatment was less effective for smokers or posed an increased risk to them that outweighed 42 the potential benefits. In this particular review, the committee agreed it was appropriate to 43 make separate recommendations for the use of long term oxygen therapy in smokers and 44 non-smokers, based on the evidence of the elevated risks of fires and burns in people who smoke and their households. 45

1 The evidence on long term oxygen for people with COPD and cor pulmonale was also

2 considered in the evidence review on the management of pulmonary hypertension and cor

- 3 pulmonale. Recommendations on the management of cor pulmonale are reported in that
- 4 evidence review.

Appendices

2 Appendix A – Review protocols

3 Review protocol for ambulatory and short burst oxygen therapy

| Field (based on PRISMA-P) | Content | | |
|--|--|--|--|
| Review question | What is the effectiveness of oxygen therapy in people with stable COPD who are mildly hypoxaemic or non-hypoxaemic at rest? | | |
| Type of review question | Intervention | | |
| Objective of the review | To determine whether ambulatory or short burst oxygen therapy are effective at reducing breathlessness and improving quality of life in people with stable COPD who are mildly hypoxaemic or non-hypoxaemic at rest, and do not meet the criteria for long term oxygen therapy. | | |
| Eligibility criteria – population | People diagnosed with COPD who are not eligible for long term oxygen therapy. | | |
| Eligibility criteria – | Ambulatory oxygen therapy | | |
| interventions | Short burst oxygen given before exertion | | |
| Eligibility criteria – comparators | Pressurised air | | |
| Outcomes | Breathlessness | | |
| | Quality of life | | |
| | Resource use and costs | | |
| Eligibility criteria – study design | RCTs | | |
| Other exclusion criteria | Short burst oxygen given after exertion | | |
| | • Trials with a follow-up of less than 12 weeks | | |

1 Review protocol for long term oxygen therapy

| Field (based on <u>PRISMA-P</u>) | Content |
|-----------------------------------|--|
| Review question | In which subgroups of people is long-term oxygen therapy indicated, and is it a clinically and cost effective option for managing stable COPD in these subgroups? |
| Type of review question | Intervention |
| Objective of the review | To determine the effectiveness of long-term oxygen therapy for people with stable COPD, and to identify which subgroups of people benefit from treatment |
| Eligibility criteria – population | People diagnosed with COPD (by any means including Global Strategy for the Diagnosis, |

| | Management and Prevention of COPD, GOLD, guideline; American Thoracic Society criteria for COPD; European Respiratory Society criteria) |
|---|--|
| Eligibility criteria – interventions | Long term oxygen therapy (at least 15 hrs/day) |
| Eligibility criteria – comparators | No interventionRoutine medical therapyPlacebo |
| Outcomes | Mortality Exacerbations Hospital admissions, re-admissions and bed days Symptoms including breathlessness (e.g. Borg dyspnoea score, Modified MRC scale for dyspnoea) and orthopnoea Pulmonary hypertension and cor pulmonale Gas transfer (carbon monoxide diffusion capacity and arterial oxygen partial pressure, PaO2) Exercise capacity/ exercise tolerance (e.g. 6 minute walking distance, 6MWD, treadmill test and the shuttle walk test) Change in FEV1, rate of change in FEV1 Adverse events: all, severe, treatment discontinuation (including trip risk from cables, burns) Quality of life (e.g. St. George's respiratory questionnaire, SGRQ, overall score) Resource use and costs |
| Eligibility criteria – study design | RCTsSystematic reviews of RCTs |
| Other exclusion criteria | Trials with a follow-up of less than 12 weeks Non-English language publications |
| Proposed sensitivity/sub- group analysis, or meta- regression | Subgroups: |

| | Smoking status (smokers versus non-smokers or, data permitting, never smoked, ex-smokers and current smokers). Multimorbidities (including COPD with asthma, bronchopulmonary dysplasia, bronchiectasis, anxiety or depression) Partial pressure of oxygen dissolved in arterial blood (PaO2): mild hypoxaemia (arterial oxygen tension (PaO2) between 56 and 65 mmHg (7.4kPa to 8.7 kPa) mild to moderate (PaO2 between 40 and 60mmHg (5.3kPa to 8kPa)) moderate resting or exercise-induced desaturation (SpO2 89-93% - approximately 7.5kPa – 9.2kPa moderate to severe hypoxaemia (PaO2 of ≤ 55 mmHg (7.3kPa) Secondary polycythaemia Nocturnal hypoxaemia (oxygen saturation of arterial blood (SaO2) < 90% for > 30% of the time) Peripheral oedema Pulmonary hypertension and cor pulmonale Trials that recruited patients with at least one COPD exacerbation in the 12 months before study entry Subgroup analyses will only be conducted if the majority of trials report data for the listed categories in an accessible format. |
|---|---|
| Selection process – duplicate screening/selection/analysis | 10% of the abstracts were reviewed by two reviewers, with any disagreements resolved by discussion or, if necessary, a third independent reviewer. If meaningful disagreements were found between the different reviewers, a further 10% of the abstracts were reviewed by two reviewers, with this process continued until agreement is achieved between the two reviewers. From this point, the remaining abstracts will be screened by a single reviewer. |

| Data management (software) Information sources – databases and dates | This review made use of the priority screening functionality with the EPPI-reviewer systematic reviewing software. See Appendix B for more details. See Appendix B See Appendix C Main Searches: |

1

1 Appendix B – Methods

2 Priority screening

3 The reviews undertaken for this guideline all made use of the priority screening functionality

4 with the EPPI-reviewer systematic reviewing software. This uses a machine learning

5 algorithm (specifically, an SGD classifier) to take information on features (1, 2 and 3 word

6 blocks) in the titles and abstract of papers marked as being 'includes' or 'excludes' during the

title and abstract screening process, and re-orders the remaining records from most likely to
 least likely to be an include, based on that algorithm. This re-ordering of the remaining

9 records occurs every time 25 additional records have been screened.

Research is currently ongoing as to what are the appropriate thresholds where reviewing of abstract can be stopped, assuming a defined threshold for the proportion of relevant papers it is acceptable to miss on primary screening. As a conservative approach until that research has been completed, the following rules were adopted during the production of this guideline:

- In every review, at least 50% of the identified abstract (or 1,000 records, if that is a greater number) were always screened.
- After this point, screening was only terminated if a pre-specified threshold was met for
 a number of abstracts being screened without a single new include being identified.
 This threshold was set according to the expected proportion of includes in the review
- 19 (with reviews with a lower proportion of includes needing a higher number of papers
- 20 without an identified study to justify termination), and was always a minimum of 250.

As an additional check to ensure this approach did not miss relevant studies, the included

22 studies lists of included systematic reviews were searched to identify any papers not

23 identified through the primary search.

24 Incorporating published systematic reviews

25 For all review questions where a literature search was undertaken looking for a particular

26 study design, systematic reviews containing studies of that design were also included. All

27 included studies from those systematic reviews were screened to identify any additional

relevant primary studies not found as part of the initial search.

29 Quality assessment

Individual systematic reviews were quality assessed using the ROBIS tool, with each
 classified into one of the following three groups:

- High quality It is unlikely that additional relevant and important data would be identified
 from primary studies compared to that reported in the review, and unlikely that any
 relevant and important studies have been missed by the review.
- Moderate quality It is possible that additional relevant and important data would be
 identified from primary studies compared to that reported in the review, but unlikely that
 any relevant and important studies have been missed by the review.
- Low quality It is possible that relevant and important studies have been missed by the review.

- 1 Each individual systematic review was also classified into one of three groups for its
- 2 applicability as a source of data, based on how closely the review matches the specified 3 review protocol in the guideline. Studies were rated as follows:
- Fully applicable The identified review fully covers the review protocol in the guideline.
- Partially applicable The identified review fully covers a discrete subsection of the review protocol in the guideline.
- 7 Not applicable The identified review, despite including studies relevant to the review
- 8 question, does not fully cover any discrete subsection of the review protocol in the 9 guideline.

10 Using systematic reviews as a source of data

11 If systematic reviews were identified as being sufficiently applicable and high quality, they 12 were used as the primary source of data, rather than extracting information from primary 13 studies. The extent to which this was done depended on the quality and applicability of the review, as defined in Table 7. When systematic reviews were used as a source of primary 14 15 data, any unpublished or additional data included in the review which is not in the primary studies was also included. Data from these systematic reviews was then quality assessed 16 and presented in GRADE/CERQual tables as described below, in the same way as if data 17 had been extracted from primary studies. In questions where data was extracted from both 18 19 systematic reviews and primary studies, these were cross-referenced to ensure none of the 20 data had been double counted through this process.

21 Table 7: Criteria for using systematic reviews as a source of data

| Quality | Applicability | Use of systematic review |
|----------|----------------------|--|
| High | Fully applicable | Data from the published systematic review were used instead of undertaking a new literature search or data analysis. Searches were only done to cover the period of time since the search date of the review. |
| High | Partially applicable | Data from the published systematic review were used instead of undertaking a new literature search and data analysis for the relevant subsection of the protocol. For this section, searches were only done to cover the period of time since the search date of the review. For other sections not covered by the systematic review, searches were undertaken as normal. |
| Moderate | Fully applicable | Details of included studies were used instead of undertaking a new literature search. Full-text papers of included studies were still retrieved for the purposes of data analysis. Searches were only done to cover the period of time since the search date of the review. |
| Moderate | Partially applicable | Details of included studies were used instead of undertaking a new literature search for the relevant subsection of the protocol. For this section, searches were only done to cover the period of time since the search date of the review. For other sections not covered by the systematic review, searches were undertaken as normal. |

1 Evidence synthesis and meta-analyses

- 2 Where possible, meta-analyses were conducted to combine the results of studies for each
- 3 outcome. For mean differences, where change from baseline data were reported in the trials
- 4 and were accompanied by a measure of spread (for example standard deviation), these were
- 5 extracted and used in the meta-analysis. Where measures of spread for change from
- 6 baseline values were not reported, the corresponding values at study end were used and
- 7 were combined with change from baseline values to produce summary estimates of effect.
- 8 All studies were assessed to ensure that baseline values were balanced across the
- 9 treatment groups; if there were significant differences in important confounding variables at
- 10 baseline these studies were not included in any meta-analysis and were reported separately.

11 Evidence of effectiveness of interventions

12 Quality assessment

- 13 Individual RCTs and quasi-randomised controlled trials were quality assessed using the
- 14 Cochrane Risk of Bias Tool. Cohort studies were quality assessed using the CASP cohort
- 15 study checklist. Each individual study was classified into one of the following three groups:
- Low risk of bias The true effect size for the study is likely to be close to the estimated effect size.
- Moderate risk of bias There is a possibility the true effect size for the study is substantially different to the estimated effect size.
- High risk of bias It is likely the true effect size for the study is substantially different to the estimated effect size.
- Each individual study was also classified into one of three groups for directness, based on if there were concerns about the population, intervention, comparator and/or outcomes in the study and how directly these variables could address the specified review question. Studies were rated as follows:
- Direct No important deviations from the protocol in population, intervention, comparator and/or outcomes.
- Partially indirect Important deviations from the protocol in one of the population, intervention, comparator and/or outcomes.
- Indirect Important deviations from the protocol in at least two of the following areas:
 population, intervention, comparator and/or outcomes.

32 Methods for combining intervention evidence

- 33 Meta-analyses of interventional data were conducted with reference to the Cochrane
- 34 Handbook for Systematic Reviews of Interventions (Higgins et al. 2011).

Where different studies presented continuous data measuring the same outcome but using different numerical scales (e.g. a 0-10 and a 0-100 visual analogue scale), these outcomes

- 37 were all converted to the same scale before meta-analysis was conducted on the mean
- differences. Where outcomes measured the same underlying construct but used different
- instruments/metrics, data were analysed using standardised mean differences (Hedges' g).
- 40 A pooled relative risk was calculated for dichotomous outcomes (using the Mantel–Haenszel 41 method). Both relative and absolute risks were presented, with absolute risks calculated by

- 1 applying the relative risk to the pooled risk in the comparator arm of the meta-analysis (all
- 2 pooled trials). If hazard ratios and relative risks could both be calculated for a given outcome,
- 3 hazard ratios were used as the preferred outcome for assessing the quality of the evidence.

Fixed- and random-effects models (der Simonian and Laird) were fitted for all syntheses, with
the presented analysis dependent on the degree of heterogeneity in the assembled
evidence. Fixed-effects models were the preferred choice to report, but in situations where
the assumption of a shared mean for fixed-effects model were clearly not met, even after
appropriate pre-specified subgroup analyses were conducted, random-effects results are
presented. Fixed-effects models were deemed to be inappropriate if one or both of the
following conditions was met:

- Significant between study heterogeneity in methodology, population, intervention or
 comparator was identified by the reviewer in advance of data analysis. This decision was
 made and recorded before any data analysis was undertaken.
- The presence of significant statistical heterogeneity in the meta-analysis, defined as I²≥50%.

In any meta-analyses where some (but not all) of the data came from studies at high risk of
bias, a sensitivity analysis was conducted, excluding those studies from the analysis. Results
from both the full and restricted meta-analyses are reported. Similarly, in any meta-analyses
where some (but not all) of the data came from indirect studies, a sensitivity analysis was

- 20 conducted, excluding those studies from the analysis.
- 21 In situations where subgroup analyses were conducted, pooled results and results for the
- individual subgroups are reported when there was evidence of between group heterogeneity,
- 23 defined as a statistically significant test for subgroup interactions (at the 95% confidence
- 24 level). Where no such evidence as identified, only pooled results are presented.
- 25 Meta-analyses were performed in Cochrane Review Manager v5.3.

26 Minimal clinically important differences (MIDs)

27 The Core Outcome Measures in Effectiveness Trials (COMET) database was searched to

28 identify published minimal clinically important difference thresholds relevant to this guideline.

29 Identified MIDs were assessed to ensure they had been developed and validated in a

30 methodologically rigorous way, and were applicable to the populations, interventions and

31 outcomes specified in this guideline. In addition, the Guideline Committee were asked to

32 prospectively specify any outcomes where they felt a consensus MID could be defined from

33 their experience. In particular, any questions looking to evaluate non-inferiority (that one

treatment is not meaningfully worse than another) required an MID to be defined to act as anon-inferiority margin.

MIDs found through this process and used to assess imprecision in the guideline are given in
 Table 8. For other mean differences where no MID is given below the line of no effect is

38 used.

39 Table 8: Identified MIDs

| Outcome | MID | Source |
|---|---------------------|---|
| Borg dyspnoea (breathlessness) score | 2 units (-2, +2) | Ries AL. Minimally clinically important difference for the UCSD shortness of breath questionnaire, Borg |

| Outcome | MID | Source |
|---|------------------------------------|--|
| | | Scale, and Visual Analog Scale. J COPD 2005; 2: 105–110. |
| 6 minute walk distance | 26m (-26, +26) | Puhan MA, Chandra D, Mosenifar Z, et al. The minimal important difference of exercise tests in severe COPD. Eur Respir J (2011); 37: 784–790. |
| Total score in St. George's respiratory questionnaire | 4 points (-4,+4) | Schünemann HJ, Griffith L, Jaeschke R, et al. Evaluation of the minimal important difference for the feeling thermometer and the St. George's Respiratory Questionnaire in patients with chronic airflow obstruction. J Clin Epidemiol (2003); 56: 1170–1176. |
| Change in FEV1 | 100ml (or 0.1L) (-100ml, 100ml) | Cazzola M, MacNee W, Martinez M et al. Outcomes for COPD pharmacological trials: from lung function to biomarkers. Eur Respir J 2008; 31: 416–468. |

1 For standardised mean differences where no other MID was available, an MID of 0.2 was

used, corresponding to the threshold for a small effect size initially suggested by Cohen et al.
 (1988).

4 For breathlessness, the pooled mean difference was converted back to the Modified Borg

5 scale to allow for meaningful interpretation of the results. This was done by multiplying the

6 calculated standardised mean difference by the pooled standard deviation of all the studies

7 using the Borg scale (estimated standard deviation of 1.385). The resulting mean difference

8 was then used to rate imprecision using the MIDs stated in Table 8 above.

9 The committee specified that any difference in mortality would be clinically meaningful, and 10 therefore the line of no effect was used as an MID. In this case, a 95% CI boundary of 1.00

11 for RR, OR and HR is taken as crossing the line of no effect.

12 For relative risks where no other MID was available, the GRADE default MID interval for

dichotomous outcomes of 0.8 to 1.25 was used. The line of no effect was specified as an
 MID for hazard ratios.

15 When decisions were made in situations where MIDs were not available, the 'Evidence to

16 Recommendations' section of that review should make explicit the committee's view of the

17 expected clinical importance and relevance of the findings.

18 GRADE for pairwise meta-analyses of interventional evidence

19 GRADE was used to assess the quality of evidence for the selected outcomes as specified in

20 'Developing NICE guidelines: the manual (2014)'. Data from RCTs was initially rated as high

21 quality and the quality of the evidence for each outcome was downgraded or not from this

22 initial point. If non-RCT evidence was included for intervention-type systematic reviews then

these were initially rated as either moderate quality (quasi-randomised studies) or low quality

- 24 (cohort studies) and the quality of the evidence for each outcome was further downgraded or
- not from this point, based on the criteria given in Table 9.

GRADE criteria Reasons for downgrading quality Not serious: If less than 33.3% of the weight in a meta-analysis came from Risk of bias studies at moderate or high risk of bias, the overall outcome was not downgraded. Serious: If greater than 33.3% of the weight in a meta-analysis came from studies at moderate or high risk of bias, the outcome was downgraded one level. Very serious: If greater than 33.3% of the weight in a meta-analysis came from studies at high risk of bias, the outcome was downgraded two levels. Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between studies at high and low risk of bias. Indirectness Not serious: If less than 33.3% of the weight in a meta-analysis came from partially indirect or indirect studies, the overall outcome was not downgraded. Serious: If greater than 33.3% of the weight in a meta-analysis came from partially indirect or indirect studies, the outcome was downgraded one level. Very serious: If greater than 33.3% of the weight in a meta-analysis came from indirect studies, the outcome was downgraded two levels. Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between direct and indirect studies. Concerns about inconsistency of effects across studies, occurring when there Inconsistency is unexplained variability in the treatment effect demonstrated across studies (heterogeneity), after appropriate pre-specified subgroup analyses have been conducted. This was assessed using the I² statistic. N/A: Inconsistency was marked as not applicable if data on the outcome was only available from one study. Not serious: If the I² was less than 33.3%, the outcome was not downgraded. Serious: If the I² was between 33.3% and 66.7%, the outcome was downgraded one level. Very serious: If the I² was greater than 66.7%, the outcome was downgraded two levels. Outcomes meeting the criteria for downgrading above were not downgraded if there was evidence the effect size was not meaningfully different between studies with the smallest and largest effect sizes. If MIDs (1 corresponding to meaningful benefit; 1 corresponding to meaningful Imprecision harm) were defined for the outcome, the outcome was downgraded once if the 95% confidence interval for the effect size crossed 1 MID, and twice if it crossed both the upper and lower MIDs. If the line of no effect was defined as an MID for the outcome, it was downgraded once if the 95% confidence interval for the effect size crossed the line of no effect (i.e. the outcome was not statistically significant), and twice if the sample size of the study was sufficiently small that it is not plausible any realistic effect size could have been detected. Outcomes meeting the criteria for downgrading above were not downgraded if the confidence interval was sufficiently narrow that the upper and lower bounds would correspond to clinically equivalent scenarios.

1 Table 9: Rationale for downgrading quality of evidence for intervention studies

2 The quality of evidence for each outcome was upgraded if any of the following five conditions3 were met:

- Data from non-randomised studies showing an effect size sufficiently large that it cannot be explained by confounding alone.
- Data showing a dose-response gradient.
- Data where all plausible residual confounding is likely to increase our confidence in the effect estimate.

6 Publication bias

- 7 Publication bias was assessed in two ways. First, if evidence of conducted but unpublished
- 8 studies was identified during the review (e.g. conference abstracts, trial protocols or trial
- 9 records without accompanying published data), available information on these unpublished
- 10 studies was reported as part of the review. Secondly, where 10 or more studies were
- 11 included as part of a single meta-analysis, a funnel plot was produced to graphically assess
- 12 the potential for publication bias.

13 Evidence statements

- For outcomes with a defined MID, evidence statements were divided into 4 groups asfollows:
- Situations where the data are only consistent, at a 95% confidence level, with an effect in one direction (i.e. one that is 'statistically significant'), and the magnitude of that effect is most likely to meet or exceed the MID (i.e. the point estimate is not in the zone of
- most likely to meet or exceed the MID (i.e. the point estimate is not in the zone of
 equivalence). In such cases, we state that the evidence showed that there is an effect.
- Situations where the data are only consistent, at a 95% confidence level, with an effect in one direction (i.e. one that is 'statistically significant'), but the magnitude of that effect is most likely to be less than the MID (i.e. the point estimate is in the zone of equivalence).
 In such cases, we state that the evidence showed there is an effect, but it is less than the defined MID.
- Situations where the confidence limits are smaller than the MIDs in both directions. In such cases, we state that the evidence demonstrates that there is no meaningful difference.
- In all other cases, we state that the evidence could not differentiate or detect a difference
 between the comparators.
- 30 For outcomes without a defined MID or where the MID is set as the line of no effect (for
- example, in the case of mortality), evidence statements are divided into 2 groups as follows:
- We state that the evidence showed that there is an effect if the 95% CI does not cross the
 line of no effect.
- The evidence could not differentiate between comparators if the 95% CI crosses the line of no effect.
- The number of trials and participants per outcome are detailed in the evidence statements, but in cases where there are several outcomes being summarised in a single evidence
- 38 statement and the numbers of participants and trials differ between outcomes, then the
- 39 number of trials and participants stated are taken from the outcome with the largest number
- 40 of trials. This is denoted using the terminology 'up to' in front of the numbers of trials and
- 41 participants.

- 1 The evidence statements also cover the quality of the outcome based on the GRADE table
- 2 entry. These can be included as single ratings of guality or go from one guality level to
- 3 another if multiple outcomes with different quality ratings are summarised by a single
- 4 evidence statement.

5 Health economics

6 Literature reviews seeking to identify published cost-utility analyses of relevance to the

- 7 issues under consideration were conducted for all questions. In each case, the search
- undertaken for the clinical review was modified, retaining population and intervention 8
- 9 descriptors, but removing any study-design filter and adding a filter designed to identify
- relevant health economic analyses. In assessing studies for inclusion, population, 10
- intervention and comparator, criteria were always identical to those used in the parallel 11 clinical search; only cost-utility analyses were included. Economic evidence profiles. 12
- including critical appraisal according to the Guidelines manual, were completed for included 13 14 studies.
- 15 Economic studies identified through a systematic search of the literature are appraised using a methodology checklist designed for economic evaluations (NICE guidelines manual; 2014). 16 This checklist is not intended to judge the quality of a study per se, but to determine whether 17 an existing economic evaluation is useful to inform the decision-making of the committee for 18 19 a specific topic within the guideline.

20 There are 2 parts of the appraisal process. The first step is to assess applicability (that is, the 21 relevance of the study to the specific guideline topic and the NICE reference case);

22 evaluations are categorised according to the criteria in Table 10.

| Level | Explanation |
|----------------------|---|
| Directly applicable | The study meets all applicability criteria, or fails to meet one or more applicability criteria but this is unlikely to change the conclusions about cost effectiveness |
| Partially applicable | The study fails to meet one or more applicability criteria, and this could change the conclusions about cost effectiveness |
| Not applicable | The study fails to meet one or more applicability criteria, and this is likely to change the conclusions about cost effectiveness. These studies are excluded from further consideration |

Table 10 Applicability criteria 23

24 In the second step, only those studies deemed directly or partially applicable are further

assessed for limitations (that is, methodological quality); see categorisation criteria in Table 25 26 11.

27 Table 11 Methodological criteria

| Level | Explanation |
|------------------------------------|---|
| Minor limitations | Meets all quality criteria, or fails to meet one or more quality criteria but this is unlikely to change the conclusions about cost effectiveness |
| Potentially serious limitations | Fails to meet one or more quality criteria and this could change the conclusions about cost effectiveness |

| Level | Explanation |
|--------------------------|---|
| Very serious limitations | Fails to meet one or more quality criteria and this is highly likely to change the conclusions about cost effectiveness. Such studies should usually be excluded from further consideration |

1 Studies were prioritised for inclusion based on their relative applicability to the development

2 of this guideline and the study limitations. For example, if a high quality, directly applicable

3 UK analysis was available, then other less relevant studies may not have been included.

4 Where selective exclusions were made on this basis, this is noted in the relevant section.

5 Where relevant, a summary of the main findings from the systematic search, review and

6 appraisal of economic evidence is presented in an economic evidence profile alongside the 7 clinical evidence

1 Appendix C – Literature search strategies

27 Identification of evidence

- 28 The population terms have been updated from the original guideline to include potential co-
- 29 morbidities such as asthma, bronchopulmonary dysplasia and bronchiectasis. These were 30 excluded in the original strategy.

- 1 In this update, several lines of the strategy have been focused with the use of the term
- 2 'chronic' to reduce retrieval of articles focusing on acute signs or symptoms.
- Additional acronyms for COPD have been included and on recommendation from the guideline committee, terms around 'breathlessness' have been added.

5 Searches were re-run in February 2018 and also included searching Medline epub ahead of 6 print.

7 Review question search strategy

- In which subgroups of people is long-term oxygen therapy indicated, and is it a
 clinically and cost effective option for managing stable COPD in these subgroups?
- 10 The MEDLINE search strategy is presented below. This was translated for use in all of the
- 11 other databases.
- 12

2 Long term oxygen therapy- Randomised controlled trials

| Short Title | Title | Study Characteristics | Risk of Bias and directness |
|---------------|---------------------------------|-----------------------------|--|
| Albert (2016) | A Randomized Trial of Long-Term | Study type | Random sequence generation |
| . , | Oxygen for COPD with Moderate | Randomised controlled trial | Low risk of bias |
| | Desaturation. | | The randomization schedule was |
| | | Study details | stratified by regional clinical centre |
| | | Study location | with randomly permuted blocks of |

| Short Title | Title | Study Characteristics | Risk of Bias and directness |
|-------------|-------|---|--|
| | | USA Study setting | sizes 2, 4, and 6. The data system generated the treatment |
| | | 14 regional clinical centres (a total of 47 centres) | assignment only if the electronic |
| | | Study dates | checks for conformance with the |
| | | January 2009 to August 2014 | eligibility criteria were passed. |
| | | Duration of follow-up | |
| | | 1 to 6 years (median follow up 18.4 months) | |
| | | Sources of funding National Heart, Lung and Blood Institute, National | Allocation concealment High risk of bias |
| | | Institutes of Health and Department of Health and | The trial-group assignment was not |
| | | , Human services, Centres of Medicare and Medicaid | masked |
| | | Services, Department of Health and Human Services. | |
| | | Inclusion criteria | Blinding of outcome assessment |
| | | All must be met | Unclear risk of bias |
| | | Age at least 40 | |
| | | At least 10 pack/day cigarette smoking history | |
| | | Modified Medical Research Council (MMRC)* dyspnoea (breathlessness) score ≥ 1 (short of breath | Incomplete outcome data Low risk of bias |
| | | when hurrying on | LOW TISK OF DIAS |
| | | Post-bronchodilator FEV1 / FVC < 0.70 | |
| | | Post-bronchodilator FEV1 <70% of the predicted | Selective reporting |
| | | normal value or > 70% of the predicted normal value | Low risk of bias |
| | | and Study Physician determines that there is | |
| | | radiologic evidence of emphysema Resting SpO2 89-93% (moderate resting hypoxemia) | |
| | | OR resting SpO2 94% or greater and desaturation | Other courses of hiss |
| | | during exercise defined as SpO2 below 90% for at | Other sources of bias Moderate risk of bias |
| | | least 10 seconds during the 6-minute walk test | |

| Short Title | Title | Study Characteristics | Risk of Bias and directness |
|-------------|-------|---|--|
| Short Title | Title | Study Characteristics (normal resting saturation but hypoxemia with exercise) Medicare Part A and Part B beneficiary, insurance willing to pay costs of treatment and costs of study procedures and visits, or willing to self-pay costs Approval by study physician for randomization to either treatment group No exacerbation requiring antibiotics or new/ increased dose of systemic corticosteroids in the 30 days prior to screening At least 30 days post-discharge from an acute care hospital for COPD or other condition prior to screening If patient regularly uses supplemental oxygen prior to screening, all of the following must be met before randomisation: - Patient agrees to stop using supplemental oxygen if randomized to no supplemental oxygen - Patient's physician agrees in writing to rescind order for supplemental oxygen if patient is randomized to no supplemental oxygen for the 4 calendar days prior to randomization and must report that he/she had no problems doing without the oxygen Signature of written contract agreeing not to smoke while using supplemental oxygen | Risk of Bias and directnessself-reported adherence may have been an over/underestimate of the participants actual oxygen use in both groups hospitalisation was recorded from self-reported accounts every 4 months - possibility of underestimating the number of hospitalisations. Excluded participants who were not able to pay for costs of treatment and study procedureOverall risk of bias Moderate risk – due to lack of blinding and self-reported adherence of oxygenDirectness Fully applicable - potential excluded the equivalent of the UK population that is most likely to smoke, as only included those who could pay for treatment – this was downgraded in the risk of bias section |
| | | None may be met | |

| COPD exacerbation requiring antibiotics, new or increased dose of systemic corticosteroids, or New prescription of supplemental oxygen after screening starts and before randomization Thoracic surgery or other procedure in the 6 months prior to evaluation likely to cause instability of pulmonary status Non-COPD lung disease that would affect oxygenation or survival Epworth Sleepiness Scale† score greater than 15 Desaturation below 80% for at least 1 minute during | |
|--|--|
| the 6-minute walk Disease or condition expected to cause death or inability to perform procedures for the trial or inability to comply with therapy within 6 months of randomisation, as judged by study physician Participation in another intervention study Sample characteristics Sample size 737 Split between study groups Long term oxygen therapy - 368(220 patients were on 24hour oxygen and 148 were prescribed oxygen during exercise and sleep only) No long term oxygen therapy - 370 %female LTOT - 28% No LTOT - 25% | |

| Short Title | Title | Study Characteristics | Risk of Bias and directness |
|-------------|-------|--|-----------------------------|
| | | LTOT - 68.3+/- 7.5 No LTOT - 69.3+/- 7.4 | |
| | | Interventions Long term oxygen therapy - 24hrs/day Patients were prescribed 24 hour oxygen if their resting SpO2 was 89 - 93% or moderate exercise induced desaturation (during the 6 minute walking test, Spo2 >/= 80% for >/=5minutes and <90% for 10 seconds) All patients had stationary and portable oxygen systems and 2 litres of Oxygen per minute during sleep and/or at rest. Patients were to use oxygen regardless of increase in the SpO2 level. Ambulatory dose of oxygen was individually prescribed and reassessed annually - 2 litres of oxygen per minute or adjusted high to maintain and SpO2 of 90% or more at least 2 minutes while the patient was walking. | |
| | | Control No long term oxygen therapy No supplemental oxygen was to be used unless severe resting desaturation (SpO2 = 88%) or<br severe exercise induced desaturation (SpO2<80% for >/= 1 minute) if either of these happened oxygen was prescribed and reassessed after 1 month Outcome measure(s) | |
| | | Death/Mortality First readmission to hospital | |

| Short Title | Title | Study Characteristics | Risk of Bias and directness |
|--|---|--|--|
| | | incidence of COPD exacerbation Adherence to the supplemental oxygen Development of severe resting desaturation Development of severe exercise -induced desaturation The distance walked in 6 minutes St. George's Respiratory Questionnaire | |
| Nocturnal Oxygen Therapy Trial group (1980) | Continuous or nocturnal oxygen therapy in hypoxemic chronic obstructive lung disease: a clinical trial. Nocturnal Oxygen Therapy Trial Group | Study details Randomised control trial Study location <i>USA</i> Study setting 6 treatment centres Study dates <i>unclear - before 1980</i> Duration of follow-up <i>at least 1 year</i> Sources of funding <i>Nocturnal Oxygen Therapy Trial Group</i> | Random sequence generation Low risk of bias Randomisation schedules were developed separately for each investigative centre. Treatment assignments were present in blocks of four with an equal number of patients receiving nocturnal oxygen and continuous oxygen therapy in each block. The order of treatment assignment was randomly computer generated within each block of four. |
| | | Inclusion criteria Post-bronchodilator FEV1 / FVC < 0.70 PaO2 = to 55mmHg (7.3 kpa)<br PaO2 = 59 mmHg (7.85 kPa) plus one of the<br following: | Allocation concealment Unclear risk of bias No information provided Blinding of outcome assessment Unclear risk of bias |

| Short Title | Title | Study Characteristics | Risk of Bias and directness |
|-------------|-------|---|---|
| | | Exclusion criteria Previous oxygen therapy, 12h/day for 30 days during previous 2 months, other disease that might be expected to influence mortality, morbidity, compliance | No information provided Selective reporting |
| | | with therapy, or ability to give informed consent | Low risk of bias |
| | | Sample characteristics Sample size 203 participants Split between study groups LTOT group - n=101 participants nocturnal group - n= 102 participants %female 21.2%Mean age (SD) 65.7years (no S.D) | Other sources of bias High risk of bias Self-reported use of oxygen in especially continuous oxygen therapy compared to nocturnal oxygen therapy. Only stationary oxygen cylinders had timers recording use of oxygen, therefore nocturnal oxygen therapy was recorded accurately but possible underestimating of continuous oxygen therapy. |
| | | Interventions Long term oxygen therapy Average oxygen use of 17.7h/day (SD=4.8hr/day) Oxygen was administered by nasal prongs at a measured flow rate of 1 to 4 l/min. Each patient received the lowest flow in whole litres per minute that demonstrably increased resting semi recumbent arterial Po2 at least 60 mmHg (7.98kPa) and | Overall risk of bias Moderate risk of bas <i>due to</i> <i>uncertainties regarding blinding and</i> <i>allocation concealment and the bias</i> <i>surrounding self-reported outcomes</i> |

| Short Title | Title | Study Characteristics | Risk of Bias and directness |
|--|--|---|--|
| | | maintained resting arterial Po2 of 60 to 80 mmHg (7.98 – 10.6kPa) dose was increased by 11 in periods of exercise or sleep oxygen delivery systems varied All patients also treated with oral theophylline and inhaled beta antagonist. Diuretics and antibiotics were used as indicated | Directness Directly applicable |
| | | Control Nocturnal oxygen therapy oxygen therapy only during sleep - averaging 12h/day (SD=2.5hr/day) All patients were treated with oral theophylline and inhaled beta-2- agonists | |
| | | Outcome measure(s) Mortality Several subgroup analysis PaO2 less/more than 55mmHg(7.3 kPa) PaCO2 less/more than 43 mmHg (5.7kPa) PH less/more than 7.40 FEV1 less/more than 0.69I Sleep, mean oxygen saturation less/greater than 85% | |
| Medical Research Council working party (1981) | Long term domiciliary oxygen therapy in chronic hypoxic cor pulmonale complicating chronic bronchitis and emphysema. Report of the Medical Research Council Working Party. | Study type Randomised controlled trial | Random sequence generation Low risk of bias |

** MD data used for estimation of imprecision using MID for Borg scale.

PaO₂ at baseline ranged from 7.7 to 11.3 kPa in 30/42 studies. The remaining 12 studies provided baseline oxygen saturation ranging from 90% to 97%

Doses of oxygen provided ranged from 2 to 6 L/min via nasal cannula, and FiO₂ ranged from 24% to 75% via mask/mouthpiece

1. >33% of weighted data from studies at moderate or high risk of bias

2. 95% confidence interval crosses one end of a defined MID interval

|--------------------------|-----------------|----------|
|--------------------------|-----------------|----------|

| Study | 1. Applicability 2. Limitations | Comparison(s) | Setting | Duration Discount rate(s) | Results / conclusion | Uncertainty |
|------------|---|----------------------------------|---------|-------------------------------------|--|--|
| Oba (2009) | Partially applicable Very serious limitations ^{a,b,c,d,e} | COT vs Control NOT vs Control | USA | 3 & 5 years 3% (costs, QALYs) | COT ICER 3yrs \$23,807 (~£16,700) COT ICER 5yrs \$16,124 (~£11,300) NOT ICER 3yrs \$477,929 (~£335,800) NOT ICER 5yrs \$306,356 (~£215,200) | In the SRH cohort, the multipl 1-way sensitivity analyses showed that all ICERs for CO were less than \$25,000 (~£17,600) per QALY, and the probabilistic analysis showed that the 95% CI elliptical of COT was below the \$50,000 (~£35,100) per QALY line. In the ND cohort, the ICER for NOT was sensitive to the quarterly mortality rate varying from \$18,267 (~£12,800) per QALY to being dominated by no oxygen therapy. The ICER for NOT also varied widely in the probabilistic sensitivity analysis. The estimated ICER was more than \$100,000 (~£70,300) per QALY in a large portion of the 95% CI elliptical |

(a) No cost for the control group was reported
(b) Usual care/alternatives to O₂ therapy not defined or explored
(c) No grading of evidence taken from systematic reviews of costs and benefits, and therefore lack of transparency in uncertainty
(d) PSA reported, but no detail of distributions fitted to parameters
(e) Model used a short time horizon (5 years)

| Study | 1. Applicability 2. Limitations | Comparison(s) | Setting | Duration Discount rate(s) | Results / conclusion | Uncertainty |
|-------------------|---|---|---------|---|--|--|
| Chandra (2012) | Partially applicable ^a Potentially serious limitations ^b | Long-term oxygen therapy versus usual care in patients with severe hypoxaemia | Canada | Lifetime time horizon 5% (costs and QALYs) | ICER for long-term oxygen therapy versus usual care: CAD\$38,993 (~£21,799) per QALY | Probabilistic sensitivity analysis showed that long-term oxygen therapy is associated with a 71% probability of being cost- effective at a threshold of CAD\$50,000 (~£27,900). |

(a) Analysis was conducted in a non-UK setting
 (b) The analysis makes the assumptions that patients with severe hypoxaemia are equivalent to patients with very severe COPD according to GOLD staging and that LTOT only affects mortality. The analysis only considers the cost of the LTOT intervention; other healthcare resource usage is not included in the model.
