Appendix A: Summary of evidence from surveillance

Summary of evidence from surveillance

Studies identified in searches are summarised from the information presented in their abstracts, including studies extracted into tables.

Feedback from topic experts who advised us on the approach to this surveillance review, was considered alongside the evidence to reach a view on the need to update each section of the guideline.

Evidence from an evidence update for this topic was also considered. Evidence updates were produced by NICE to highlight new evidence relating to published NICE guidelines.

1.1 Imaging options in occult hip fracture

1.1.1 Offer magnetic resonance imaging (MRI) if hip fracture is suspected despite negative X-rays of the hip of an adequate standard. If MRI is not available within 24 hours or is contraindicated, consider computed tomography (CT). [2011, amended 2014]

Surveillance proposal

No new information was identified at any surveillance review.

Imaging options in occult hip fracture

2013 surveillance summary
No relevant evidence was identified.

2015 surveillance summary
No relevant evidence was identified.

2019 surveillance summary
No relevant evidence was identified.
Intelligence gathering

There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement

There was no new evidence or intelligence found. The guideline recommendations will not be updated.

There was no new evidence.
1.2 Timing of surgery

1.2.1 Perform surgery on the day of, or the day after, admission. [2011]

1.2.2 Identify and treat correctable comorbidities immediately so that surgery is not delayed by:
   - anaemia
   - anticoagulation
   - volume depletion
   - electrolyte imbalance
   - uncontrolled diabetes
   - uncontrolled heart failure
   - correctable cardiac arrhythmia or ischaemia
   - acute chest infection
   - exacerbation of chronic chest conditions. [2011]

Surveillance proposal
This section of the guideline should not be updated.

Timing of surgery

2013 surveillance summary
A meta-analysis (1) of 35 studies (n=191,873; mean age=80 years) found that early surgery (defined by most studies as within 24 or 48 hours) appeared to be associated with a statistically significantly lower mortality risk than delayed surgery.

2015 surveillance summary
No relevant evidence was identified.

2019 surveillance summary
One RCT (2) (n=400) of a prehospital fast-track care (patient transferred directly to radiology from the ambulance) compared with standard care (patient taken from ambulance to A&E) for patients with suspected hip fracture found a statistically significant reduction in time to x-ray, but not start of surgery, proportion operated on in 24 hours, length of stay, postoperative complications or mortality.

Intelligence gathering
There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement
One study found that ambulance initiated fast-track to radiology provided faster time to x-ray but did not impact upon longer-term outcomes such as time to operation,
postoperative complications or mortality. One study found that early surgery was associated with reduced mortality compared with delayed surgery. This evidence does not contradict current recommendations within this section of the guideline, or provide evidence that would create new recommendations. This section of the guideline will not be updated. New evidence is unlikely to change guideline recommendations.
1.3 Analgesia

1.3.1 Assess the patient’s pain:
- immediately upon presentation at hospital and
- within 30 minutes of administering initial analgesia and
- hourly until settled on the ward and
- regularly as part of routine nursing observations throughout admission. [2011]

1.3.2 Offer immediate analgesia to patients presenting at hospital with suspected hip fracture, including people with cognitive impairment. [2011]

1.3.3 Ensure analgesia is sufficient to allow movements necessary for investigations (as indicated by the ability to tolerate passive external rotation of the leg), and for nursing care and rehabilitation. [2011]

1.3.4 Offer paracetamol every 6 hours pre-operatively unless contraindicated. [2011]

1.3.5 Offer additional opioids if paracetamol alone does not provide sufficient preoperative pain relief. [2011]

1.3.6 Consider adding nerve blocks if paracetamol and opioids do not provide sufficient preoperative pain relief, or to limit opioid dosage. Nerve blocks should be administered by trained personnel. Do not use nerve blocks as a substitute for early surgery. [2011]

1.3.7 Offer paracetamol every 6 hours postoperatively unless contraindicated. [2011]

1.3.8 Offer additional opioids if paracetamol alone does not provide sufficient postoperative pain relief. [2011]

1.3.9 Non-steroidal anti-inflammatory drugs (NSAIDs) are not recommended. [2011]

Surveillance proposal
This section of the guideline should not be updated.

---

Analgesia

2013 surveillance summary
A meta-analysis (3) of 83 studies (mean age ranged from 59 to 86 years) found a statistically significant effect on acute pain versus standard treatment (no blockade) for: epidural analgesia; femoral nerve blockade; psoas compartment nerve blockade; fascia iliac nerve blockade; and combined nerve blockades.

2015 surveillance summary
Multimodal pain management
One RCT (4) of multimodal pain management versus usual care in patients undergoing bipolar hip hemiarthroplasty found that multimodal pain management...
had a lower pain level on postoperative days 1 and 4, and a lower total amount of fentanyl used.

Nerve blocks
Three RCTs (5–7) found that nerve blocks statistically significantly reduced pain versus systemic analgesia, and reduced morphine use. One RCT (8) found that femoral nerve block provided statistically significantly superior preoperative analgesia and statistically significantly reduced need for morphine after the block, compared with fascia iliaca compartment block. One RCT (9) found that pain during positioning for spinal anaesthesia and time to perform anaesthesia were statistically significantly lower with femoral nerve block than fentanyl.

2019 surveillance summary

Opioids
One RCT found transdermal buprenorphine statistically significantly superior to oral tramadol on a range of outcomes such as resting pain scores and pain on movement, see Table 1.

Parecoxib
One RCT found no clear benefit of parecoxib plus propacetamol versus parecoxib, see Table 1.

Nerve blocks
There was 1 Cochrane review and 10 RCTs of nerve blocks, see Table 1. Across the studies there was a trend that statistically significantly favoured nerve blocks for controlling pain, compared with no nerve blocks or conventional analgesia.

New evidence is unlikely to change guideline recommendations.

Intelligence gathering
There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement

Multimodal pain management
The evidence from 1 RCT identified in the 2015 surveillance review indicates that multimodal pain relief is superior to usual care, but limited detail was available in the abstract to determine what the multimodal pain management entailed. Currently the guideline recommends immediate analgesia (recommendation 1.3.2), with a stepped approach to controlling pain ranging from paracetamol (recommendation 1.3.4), to opioids (recommendation 1.3.5) and on to nerve blocks (recommendation 1.3.6). The evidence does not contradict guideline recommendations.

Opioids
The evidence from 1 RCT indicates that transdermal buprenorphine is superior to oral tramadol. However, the trial was only conducted in 50 patients. Currently the guideline recommendations do not provide specific advice on which opioid drugs to offer first, with recommendation 1.3.5 suggests offering additional opioids if paracetamol alone is not sufficient. This new evidence is not likely to change this recommendation or provide a more detailed recommendation on opioid drug choice.
New evidence is unlikely to change guideline recommendations.

**Parecoxib**

The evidence from 1 RCT found no clear benefit of parecoxib plus propacetamol versus parecoxib. Currently the guideline does not recommend NSAIDs (recommendation 1.3.9), and this new evidence is unlikely to change the recommendation.

New evidence is unlikely to change guideline recommendations.

**Nerve blocks**

The evidence from 16 studies identified across the 2015 and 2019 surveillance reviews found a trend that statistically significantly favoured nerve blocks for controlling pain, compared with no nerve blocks or conventional analgesia. This evidence is broadly in line with the guideline recommendation 1.3.6 which suggests adding nerve blocks if paracetamol and opioids do not provide sufficient pain relief.

New evidence is unlikely to change guideline recommendations.

IV = intravenous. n = number of participants. RCT = randomised controlled trial.
1.4 Anaesthesia

1.4.1 Offer patients a choice of spinal or general anaesthesia after discussing the risks and benefits. [2011]

1.4.2 Consider intraoperative nerve blocks for all patients undergoing surgery. [2011]

Surveillance proposal
This section of the guideline should not be updated.

Anaesthesia

2013 surveillance summary
No relevant evidence was identified.

2015 surveillance summary

General anaesthesia
An RCT (24) found that spinal anaesthesia provided better blood pressure stability than general anaesthesia. Two observational studies submitted by experts found no difference in 5-day or 30-day mortality between regional and general anaesthesia for hip fracture surgery, but hospital stay may be shorter with regional anaesthesia (25,26).

Depth of sedation
An RCT (27) found that mortality with light versus deep sedation was equivalent among all patients, however light sedation was safer than deep sedation among patients with serious comorbidities.

2019 surveillance summary

General anaesthesia
There was 1 Cochrane review and 3 RCTs considering the role and type of general anaesthesia (see Table 2). One Cochrane review found that there was no clear advantage of regional versus general anaesthesia across outcomes such as mortality and length of hospital stay, but regional anaesthesia may reduce deep vein thrombosis incidence. One RCT found an advantage of general laryngeal mask airway anaesthesia with lumbar plexus-sciatic nerve block compared with general anaesthesia with endotracheal intubation. One RCT found no difference of xenon anaesthesia compared with sevoflurane-based anaesthesia for fatal adverse events and delirium, but benefits in terms of serious adverse events. One RCT found an advantage of using SmartPilot view guided anaesthesia, compared with usual practice, in terms of outcomes such as length of stay and postoperative complications.

Spinal anaesthesia
There were 3 studies considering the dose and drug choice for spinal anaesthesia (see Table 2). Two RCTs considering the dose of bupivacaine found inconsistent effects, with benefits of both lower and higher doses. One RCT found levobupivacaine superior to bupivacaine for some outcomes, although the trial was only in a small number of participants.
Depth of sedation

There were 2 publications from 1 RCT considering the depth of sedation for spinal anaesthesia, which found no clear benefits of lighter depth sedation on mortality or delirium (see Table 2).

Intelligence gathering

There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement

General anaesthesia

Evidence from 5 studies considering the role and type of general anaesthesia were generally consistent with recommendation 1.4.1 that patients should be offered a choice of spinal or general anaesthesia after discussing the risks and benefits. A Cochrane review identified that across most outcomes regional and spinal anaesthesia were equivalent. Three trials found some benefits of specific techniques such as general laryngeal mask compared with endotracheal intubation, xenon anaesthesia compared with sevoflurane anaesthesia, and SmartPilot view guided anaesthesia compared with usual care. Currently the guideline does not provide advice on specific anaesthetic techniques, and this new evidence does not appear sufficient to warrant an update to the guideline. This section of the guideline will be revisited at subsequent surveillance time points to see if further evidence has become available that provides a stronger case for update.

New evidence is unlikely to change guideline recommendations.

Spinal anaesthesia

Evidence from 3 RCTs considering the dose and type of spinal anaesthesia were generally consistent with recommendation 1.4.1 that patients should be offered a choice of spinal or general anaesthesia after discussing the risks and benefits. Two RCTs considering the dose of bupivacaine found inconsistent effects. One RCT found levobupivacaine superior to bupivacaine for some outcomes, although the trial was only in a small number of participants. Currently the guideline does not provide specific recommendations on drug and dose for spinal anaesthesia and this new evidence does not appear sufficient to warrant an update to the guideline. This section of the guideline will be revisited at subsequent surveillance time points to see if further evidence has become available that provides a stronger case for update.

New evidence is unlikely to change guideline recommendations.

Depth of sedation

Across the surveillance time points there was evidence from 2 RCTs considering the depth of sedation for spinal anaesthesia, which found no clear benefits of lighter depth sedation on mortality or delirium (see Table 2). This new evidence is unlikely to impact on the recommendations as the guideline does not provide advice on the depth of anaesthesia.

New evidence is unlikely to change guideline recommendations.

1.6 Surgical procedures

Hip replacement

1.6.1 Operate on patients with the aim to allow them to fully weight bear (without restriction) in the immediate postoperative period. [2011]

1.6.2 Offer replacement arthroplasty (total hip replacement or hemiarthroplasty) to patients with a displaced intracapsular hip fracture. [2017]

1.6.3 Offer total hip replacement rather than hemiarthroplasty to patients with a displaced intracapsular hip fracture who:

- were able to walk independently out of doors with no more than the use of a stick and
- are not cognitively impaired and
- are medically fit for anaesthesia and the procedure. [2017]

Surveillance proposal

New evidence does not indicate that these recommendations need updating. However, an [NIHR suite of Cochrane reviews](https://www.cochranelibrary.com/cdsr/) including 4 reviews on surgical procedures for hip fracture is under development and due to publish in October 2020 and may be relevant to these recommendations. This new evidence will be considered when it becomes available.

Hip replacement

Recommendations 1.6.2 and 1.6.3 were updated in 2017 and full details are available in the [Full guideline addendum](https://www.cochranelibrary.com/cdsr/). The review questions that were updated were:

- What is the clinical and cost effectiveness of internal fixation compared with hemiarthroplasty compared with total hip replacement in people undergoing repair for a displaced intracapsular hip fracture?

- What is the clinical and cost effectiveness of conservative management compared with internal fixation compared with hemiarthroplasty compared with total hip replacement in people with an undisplaced intracapsular hip fracture?

Two studies identified during the 2013 surveillance process (37,38), and 16 studies identified during the 2015 surveillance process were available for consideration during update. (39–55).

2019 surveillance summary

One RCT with a 12 year follow up compared cemented hemiarthroplasty with cemented total hip replacement in 252 active patients aged >70 years with a displaced intracapsular fracture of the femoral neck was identified. (56) The trial found no statistically significant difference between groups in terms of mortality, revision rate, complications and Harris Hip
scores, however the follow up had small numbers at 12 years.

One RCT (57) (n=120 patients) of hemiarthroplasty compared with total hip arthroplasty for displaced femoral neck fractures found no statistically significant difference in terms of hip function, pain in the involved hip, health related quality of life, hip-related complications and reoperations, or daily living activities up to 2 years after surgery.

Impact statement

Recommendations 1.6.2 and 1.6.3 were updated in 2017 and full details are available in the Full guideline addendum.

Two RCTs in patients with a displaced fracture of the femoral neck were identified in the 2019 surveillance process, which showed no difference between arthroplasty and total hip replacement for displaced fractures of the femoral neck. A further larger RCT looking at total hip replacement versus hemiarthroplasty (the HEALTH study) is completed but publication date is unknown.

This new evidence does not contradict recommendation 1.6.2 which suggests offering replacement arthroplasty (total hip replacement or hemiarthroplasty) to patients with a displaced intracapsular hip, or sufficient to contradict recommendation 1.6.3 which outlines when a total hip replacement may be appropriate. As such, no update to these recommendations is suggested at this time.

However, an NIHR suite of Cochrane reviews including 4 reviews on surgical procedures for hip fracture is under development and due to publish in October 2020. The new evidence may be relevant to this recommendation and will be considered when it becomes available.

New evidence is unlikely to change guideline recommendations.
Types of implant

1.6.4 Use a proven femoral stem design rather than Austin Moore or Thompson stems for arthroplasties. Suitable designs include those with an Orthopaedic Data Evaluation Panel rating of 10A, 10B, 10C, 7A, 7B, 5A, 5B, 3A or 3B. [2011]

Surveillance proposal

Recommendation 1.6.4 should be updated as new evidence indicates that Thompson hemiarthroplasty may be equivalent to Exeter/Unitrax stem and head. There is also a NIHR suite of Cochrane reviews including 4 reviews on surgical procedures for hip fracture which is under development and due to publish in October 2020 and may be relevant to this recommendation. This new evidence will be considered when it becomes available.

Types of implant

2013 surveillance summary
No relevant evidence was identified.

2015 surveillance summary
No relevant evidence was identified.

2019 surveillance summary
The WHiTE3 RCT of 964 elderly patients with displaced intracapsular hip fractures showed no statistically significant difference between Thomson hemiarthroplasty and Exeter/Unitrax head and stem in terms of mortality, mobility or EQ-5D scores. (58)

Intelligence gathering
Feedback from a topic expert and stakeholders indicated that the WHiTE3 RCT was an important clinical trial likely to impact clinical practice and warrant an update to the NICE guideline CG124.

The ODEP committee identified a factual error in recommendation 1.6.4 highlighting that hemiarthroplasties are not currently rated. As such, an amendment will be made to this recommendation to remove any mention of ODEP rating.

Impact statement

One large RCT showed no difference between Thomson hemiarthroplasty and Exeter/Unitrax hemiarthroplasty for displaced intracapsular fractures. This trial was conducted in the UK and is part of the World Hip Trauma Evaluation Study. Currently recommendation 1.6.4 suggests using a proven femoral stem design rather than Austin Moore or Thompson stems. This new evidence indicates that Thomson stems may be equivalent to the Exeter/Unitrax stem and head. Thomson stems are cheaper than Exeter stems so this may save costs whilst maintaining equivalent outcomes.

During the development of the original guideline, this recommendation was based on studies looking at hip replacement implants in patients with degenerative disease alongside expert opinion, as no randomised studies were found which
compared older stem designs with modern stem designs in patients with hip fractures. Furthermore, surveillance conducted in 2013 and 2015 did not find any studies that addressed this recommendation.

This new evidence is directly applicable to addressing a gap in the evidence base which underpins recommendation 1.6.4 and therefore, it is proposed that this section is updated. However, there is also an [NIHR suite of Cochrane reviews](#) including 4 reviews on surgical procedures for hip fracture which is under development and due to publish in October 2020 and may be relevant to this recommendation. This new evidence will be considered when it becomes available.

New evidence identified that may change current recommendations.
Cemented implants

1.6.5 Use cemented implants in patients undergoing surgery with arthroplasty.* [2011]

* The Association of Anaesthetists of Great Britain and Ireland, British Orthopaedic Association and British Geriatric Society have produced a safety guideline on reducing the risk from cemented hemiarthroplasty for hip fracture (2015). This safety guideline is not NICE accredited.

Surveillance proposal

New evidence does not indicate that this recommendation needs updating. However, an NIHR suite of Cochrane reviews including 4 reviews on surgical procedures for hip fracture is under development and due to publish in October 2020 and may be relevant to this recommendation. This new evidence will be considered when it becomes available.

Cemented implants

2013 surveillance summary
Evidence from 3 studies (59–61) indicated that functional outcomes and pain appeared to be equivalent with cemented and uncemented hemiarthroplasty, and that risk of death may be lower with cemented implants.

2015 surveillance summary
During the 2017 surveillance process there were 4 RCTs and 3 meta-analyses, as well as 2 observational studies submitted by experts (62–70). Cemented implants were superior to uncemented implants across most outcomes including pain, mobility and functioning, but there were safety concerns with cemented implants.

2019 surveillance summary
There were 5 trials of cemented versus uncemented stems, which showed a trend statistically significantly favouring cemented implants for some outcomes, see Table 3.

Intelligence gathering
There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement
Evidence from 17 studies of cemented versus uncemented stems generally favoured cemented stems. This evidence supports recommendation 1.6.5 which suggests using cemented implants in patients undergoing surgery with arthroplasty.

However, an NIHR suite of Cochrane reviews including 4 reviews on surgical procedures for hip fracture is under development and due to publish in October 2020. The new evidence may be relevant to this recommendation and will be considered when it becomes available. There is also the following study in progress and due to end October 2020: World hip trauma evaluation five: a randomised controlled trial comparing cemented and uncemented implants for the treatment of displaced intracapsular hip fractures, ISRCTN18393176.
New evidence is unlikely to change guideline recommendations.

### Surgical approach

1.6.6 Consider an anterolateral approach in favour of a posterior approach when inserting a hemiarthroplasty. [2011]

### Surveillance proposal

New evidence does not indicate that this recommendation needs updating. However, an NIHR suite of Cochrane reviews including 4 reviews on surgical procedures for hip fracture is under development and due to publish in October 2020 and may be relevant to this recommendation. This new evidence will be considered when it becomes available.

#### Surveillance 2013 summary

No relevant evidence was identified.

#### Surveillance 2015 summary

One RCT (76) found that mobility after 5 days and pain intensity after 16 days were statistically significantly improved with a minimally invasive (direct anterior) compared to a conventional (Watson-Jones anterolateral) approach.

#### Surveillance 2019 summary

One RCT of 190 elderly patients with femoral neck fractures showed no statistically significant difference between minimally invasive anterior muscle-sparing approach for hemiarthroplasty, compared with lateral hardening or transgluteral approach in terms of median duration of timed up and go at 3 weeks, blood transfusion, or soft tissue complications. (77)

### Intelligence gathering

There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

### Impact statement

Evidence from 2 RCTs showed mixed results of minimally invasive approach compared with lateral approach. Recommendation 1.6.6 suggests using an anterolateral approach in preference to a posterior approach when inserting a hemiarthroplasty. This new evidence does not contradict this recommendation or provide greater clarity on which approach to use.

However, an NIHR suite of Cochrane reviews including 4 reviews on surgical procedures for hip fracture is under development and due to publish in
October 2020. The new evidence may be relevant to this recommendation and will be considered as soon as it becomes available.

New evidence is unlikely to change guideline recommendations.

Type of fixation

1.6.7 Use extramedullary implants such as a sliding hip screw in preference to an intramedullary nail in patients with trochanteric fractures above and including the lesser trochanter (AO classification types A1 and A2). [2011]

1.6.8 Use an intramedullary nail to treat patients with a subtrochanteric fracture. [2011]

* The Association of Anaesthetists of Great Britain and Ireland, British Orthopaedic Association and British Geriatric Society have produced a safety guideline on reducing the risk from cemented hemiarthroplasty for hip fracture (2015). This safety guideline is not NICE accredited.

Surveillance proposal

New evidence does not indicate that these recommendations need updating. However, an NIHR suite of Cochrane reviews including 4 reviews on surgical procedures for hip fracture is under development and due to publish in October 2020. The WHITE four study looking at sliding hip screw versus X-Bolt Dynamic Plating System for trochanteric fractures is also in preparation for publication. The new evidence may be relevant to these recommendations and will be considered as soon as it becomes available.

Type of fixation

2015 surveillance summary

Screw and nail fixation

Eleven RCTs and 6 meta-analyses of various types of screw fixation for hip fracture found mixed results or non-statistically significant results (79–95). Two observational studies and a before and after study were also submitted by experts (96–98).

Intramedullary / extramedullary fixation

Three RCTs and 2 Cochrane reviews were found (99–103). The Cochrane reviews
found insufficient evidence to determine differences between designs of intramedullary nails for extracapsular hip fractures, or the use of external fixators.

2019 surveillance summary

Screw and nail fixation
There were 8 RCTs looking at various types of screw and nail fixation methods for a range of hip fracture types, see Table 4. The results were generally mixed or non-significant, although differences in populations and interventions makes comparisons difficult.

Intramedullary fixation
There were 5 RCTs looking at various methods and types of intramedullary fixation for a range of hip fracture types, see Table 4. The results were generally mixed or non-significant, although differences in populations and interventions makes comparisons difficult.

Intelligence gathering
There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement
Evidence from 19 studies looking at various types of screw, nail fixation, or intramedullary/extramedullary options for a range of hip fracture types found generally mixed or non-statistically significant results although the lack of detail in abstracts made it difficult to compare across studies. Currently recommendations 1.6.7 and 1.6.8 suggest using extramedullary implants such as sliding hip screw in patients with trochanteric fractures, and intramedullary nail for patients with subtrochanteric fractures. This new evidence does not contradict these recommendations or provide greater clarity on which approach to take.

However, an NIHR suite of Cochrane reviews including 4 reviews on surgical procedures for hip fracture is under development and due to publish in October 2020. The WHiTE four study looking at sliding hip screw versus X-Bolt Dynamic Plating System for trochanteric fractures is also in preparation for publication. The new evidence may be relevant to these recommendations and will be considered as soon as it becomes available

New evidence is unlikely to change guideline recommendations.

n = number of participants. RCT = randomised controlled trial.
1.7 Mobilisation strategies

1.7.1 Offer patients a physiotherapy assessment and, unless medically or surgically contraindicated, mobilisation on the day after surgery. [2011]

1.7.2 Offer patients mobilisation at least once a day and ensure regular physiotherapy review. [2011]

Surveillance proposal

This section of the guideline should not be updated.

---

Mobilisation strategies

2013 surveillance summary

A Cochrane review (117) was found which identified 1 trial assessing early assisted ambulation (within 48 hours) versus delayed assisted ambulation (after 48 hours) after surgery. However, this study had already been included in the guideline evidence review.

2015 surveillance summary

No relevant evidence was identified.

2019 surveillance summary

Three RCTs found that various forms of more intensive physiotherapy had some improvements in shorter term outcomes, such as functional assessment and length of hospital stay, see Table 5 for an overview of studies.

Intelligence gathering

There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement

Three RCTs identified during the 2019 surveillance review process found that various forms of more intensive physiotherapy had some improvements in shorter term outcomes, such as functional assessment and length of hospital stay. One trial indicated that 3 times daily physiotherapy was superior to once daily physiotherapy in terms of length of stay and discharge probability, but did not affect 6 month outcomes. This evidence does not contradict recommendation 1.7.2 which currently recommends offering early mobilisation at least once a day. As such, the guideline recommendations will not be updated.

New evidence is unlikely to impact guideline recommendations

---

1.8 Multidisciplinary management

1.8.1 From admission, offer patients a formal, acute, orthogeriatric or orthopaedic ward-based Hip Fracture Programme that includes all of the following:

- orthogeriatric assessment
- rapid optimisation of fitness for surgery
- early identification of individual goals for multidisciplinary rehabilitation to recover mobility and independence, and to facilitate return to pre-fracture residence and long-term wellbeing
- continued, coordinated, orthogeriatric and multidisciplinary review
- liaison or integration with related services, particularly mental health, falls prevention, bone health, primary care and social services
- clinical and service governance responsibility for all stages of the pathway of care and rehabilitation, including those delivered in the community. [2011]

1.8.2 If a hip fracture complicates or precipitates a terminal illness, the multidisciplinary team should still consider the role of surgery as part of a palliative care approach that:

- minimises pain and other symptoms and
- establishes patients' own priorities for rehabilitation and
- considers patients' wishes about their end-of-life care. [2011]

1.8.3 Healthcare professionals should deliver care that minimises the patient's risk of delirium and maximises their independence, by:

- actively looking for cognitive impairment when patients first present with hip fracture
- reassessing patients to identify delirium that may arise during their admission
- offering individualised care in line with NICE's guideline on delirium. [2011]

1.8.4 Consider early supported discharge as part of the Hip Fracture Programme, provided the Hip Fracture Programme multidisciplinary team remains involved, and the patient:

- is medically stable and
- has the mental ability to participate in continued rehabilitation and
- is able to transfer and mobilise short distances and
- has not yet achieved their full rehabilitation potential, as discussed with the patient, carer and family. [2011]
1.8.5 Only consider intermediate care (continued rehabilitation in a community hospital or residential care unit) if all of the following criteria are met:

- intermediate care is included in the Hip Fracture Programme and

- the Hip Fracture Programme team retains the clinical lead, including patient selection, agreement of length of stay and ongoing objectives for intermediate care and

- the Hip Fracture Programme team retains the managerial lead, ensuring that intermediate care is not resourced as a substitute for an effective acute hospital Programme. [2011]

1.8.6 Patients admitted from care or nursing homes should not be excluded from rehabilitation programmes in the community or hospital, or as part of an early supported discharge programme. [2011]

### Surveillance proposal

This section of the guideline should not be updated.

---

### Multidisciplinary management

#### 2013 surveillance summary

No relevant evidence was identified.

#### 2015 surveillance summary

**‘Orthogeriatrician’ care**

Two meta-analyses (121,122) and 7 RCTs (123–129) found that generally the combination of orthopaedic and geriatric care led to improvements in a range of outcomes, including delirium, length of stay, and mortality rate.

**Rehabilitation**

**Patient-centred counselling in hospital**

An RCT (130) found that anxiety and depression had statistically significantly decreased after 30 days, and pain levels were statistically significantly lower on days 4 and 5 with counselling than among patients not receiving counselling.

**Anabolic steroids for rehabilitation**

A Cochrane review (131) of 3 trials found some functional improvement in people receiving anabolic steroids plus a nutritional supplement for rehabilitation after hip fracture, but the authors noted a high or uncertain risk of bias in studies.

**Home and community based rehabilitation**

An RCT (132) and a meta-analysis (133) found that home or community based rehabilitation reduced perceived difficulties in negotiating stairs and improved knee-extension strength, physical performance-based tests, timed ‘up & go’ test and fast gait speed.

#### 2019 surveillance summary

One systematic review and 10 RCTs were found that were of relevance to this section of the guideline.
'Orthogeriatrician' care

One Cochrane review found that, compared with usual care, comprehensive geriatric assessment provided some statistically significant benefits in terms of mortality and discharge, but did not impact on other outcomes such as delirium or readmission. A systemic review found that comprehensive geriatric assessment statistically significantly reduced delirium but no other outcomes. One RCT found that, compared with orthopaedic care, comprehensive geriatric care in a dedicated ward statistically significantly improved some functional outcomes, such as mobility at 4 months. See Table 6 for a summary of studies.

Postoperative orders

One RCT found that, compared with usual care, delirium-friendly printed postoperative orders statistically significantly improved delirium but did not impact upon mortality or discharge, see Table 6.

Rehabilitation

Enhanced rehabilitation for dementia

One Cochrane review found that, compared with usual care, enhanced rehabilitation statistically significantly improved some outcomes such as complications, but did not impact on delirium or functional outcomes, see Table 6.

Physical or geriatric rehabilitation

One RCT found that, compared with health centre hospital rehabilitation, physical rehabilitation statistically significantly improved 12 month mortality, and both physical rehabilitation and geriatric rehabilitation statistically significantly improved independent living at 12 months, see Table 6.

Home and community rehabilitation

Three RCTs found mixed results of home and nursing home rehabilitation, compared with usual care. See Table 6 for an overview of studies.

Intelligence gathering

There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement

'Orthogeriatrician' care

Across the surveillance time points, 11 studies indicated that comprehensive geriatric assessment and/or care provides some benefits in terms of mortality, delirium, and discharge, but the results were not consistent across studies. It should be noted that the type of orthogeriatrician care varied from simple assessment to dedicated wards, which makes interpreting results across studies difficult. However, this new evidence generally supports recommendation 1.8.1 that states that patients should be offered a package of care that includes orthogeriatric assessment. As such, this section of the guideline should not be updated.

New evidence is unlikely to change guideline recommendations.

Postoperative orders

One RCT found that delirium-friendly printed postoperative orders improved delirium but did not impact upon mortality or discharge. Currently recommendation
1.8.3 states that delirium should be reassessed during admission and individualised care offered in line with NICE’s guideline on delirium. This new evidence does not contradict that and as such no impact on the guideline is expected.

New evidence is unlikely to change guideline recommendations.

Rehabilitation
Across the surveillance time points, 12 studies provided a mixed picture of the effects of various different types of rehabilitation packages, including home rehabilitation, specific knee-strengthening training, anabolic steroids for rehabilitation, and rehabilitation packages specifically tailored to people with dementia. The impact of each specific type of rehabilitation package is discussed separately below.

Patient-centred counselling in hospital
An RCT found that patient-centred counselling throughout hospitalisation for hip fracture had a positive impact on quality of life, anxiety, depression and pain levels. Although the guideline does not specifically recommend counselling, this evidence is consistent with recommendation 1.8.1 that the Hip Fracture Programme should include liaison or integration with related services, including mental health.

Anabolic steroids for rehabilitation
A Cochrane review demonstrated some functional improvement in people receiving anabolic steroids plus a nutritional supplement for rehabilitation after hip fracture. However, because of the reported high or unclear risk of bias in all trials, the imprecise results and the likelihood of publication bias, the evidence is unlikely to impact on CG124 which does not currently discuss the use of anabolic steroids as part of rehabilitation.

Enhanced rehabilitation for dementia
A Cochrane review found that enhanced rehabilitation improved some outcomes such as complications, but did not impact on delirium or functional outcomes. This evidence does not contradict recommendation 1.8.1 which currently recommends early identification of individual goals for multidisciplinary rehabilitation to recover mobility and independence, and to facilitate return to pre-fracture residence and long-term wellbeing.

Physical or geriatric rehabilitation
One RCT found that physical rehabilitation improved 12 month mortality, and both physical rehabilitation and geriatric rehabilitation statistically significantly improved independent living at 4 months. However, the authors reported that the effects disappeared at 12 months, and there was no impact on walking ability. This evidence does not contradict recommendation 1.8.1 which currently recommends early identification of individual goals for multidisciplinary rehabilitation to recover mobility and independence, and to facilitate return to pre-fracture residence and long-term wellbeing.

Home and community rehabilitation
Four RCTs and a meta-analysis found mixed results of home and nursing home rehabilitation, compared with usual care. Currently recommendation 1.8.4 advises that early supported discharge should be
considered for appropriate patients (including those who are medically stable, have the appropriate mental ability, can transfer and mobilise short distances, and have not yet achieved full rehabilitation potential). This recommendation was based on committee extrapolation and interpretation of an evidence review of community based rehabilitation and economic modelling. This new evidence appears to be generally in line with previous evidence and as such no impact on the guideline is expected.

New evidence is unlikely to change guideline recommendations.

n = number of participants. RCT = randomised controlled trial. DVT = deep vein thrombosis.

* Note the Cochrane review also included 1 trial in elective cancer surgery.
1.9 Patient and carer information

1.9.1 Offer patients (or, as appropriate, their carer and/or family) verbal and printed information about treatment and care including:

- diagnosis
- choice of anaesthesia
- choice of analgesia and other medications
- surgical procedures
- possible complications
- postoperative care
- rehabilitation programme
- long-term outcomes
- healthcare professionals involved. [2011]

Surveillance proposal

No new information was identified at any surveillance review.

---

Patient and carer information

2013 surveillance summary
No relevant evidence was identified.

2015 surveillance summary
No relevant evidence was identified.

2019 surveillance summary
No relevant evidence was identified.

Intelligence gathering

There was no new intelligence from the 2019 surveillance process of relevance to this section of the guideline.

Impact statement

There was no new evidence or intelligence found. The guideline recommendations will not be updated. This section of the guideline will be revisited at the next surveillance timepoint.

There was no new evidence.
Areas not currently covered in the guideline

In previous and current surveillance, evidence was identified for areas not covered by the guideline. This new evidence has been considered for possible addition as a new section of the guideline.

Corticosteroids before surgery

Surveillance proposal

This section should not be added.

Corticosteroids before surgery

2015 surveillance summary

An RCT (144) of 82 patients found that administering single-dose methylprednisolone (125 mg intravenous) prior to intertrochanteric femoral fracture surgery statistically significantly reduced pain at rest, pain during 45 degree flexion of the hip, pain during walking after the surgery, and fatigue, compared with placebo. Nausea, vomiting and opioid consumption were not statistically significantly different.

2019 surveillance summary

An RCT (145) of 117 older hip fracture patients found that administering single-dose methylprednisolone (125 mg intravenous) prior to hip fracture surgery statistically significantly reduced cumulative postoperative fatigue scores and prevalence of postoperative delirium. There were no statistically significant differences in severity of delirium, 30- and 90-day mortality, rate of completing physiotherapy, postoperative pain, the administration of antipsychotic drugs, infection, or length of inpatient stay.

Intelligence gathering

No topic expert feedback was relevant to this section.

Impact statement

The evidence from 2 RCTs identified in the 2015 surveillance process did not find a consistent effect of methylprednisolone on delirium or pain. Topic experts did not raise this as a potential update area for the guideline. As such, this new evidence is not deemed sufficient to change current guideline recommendations and further robust evidence is required. This area will be revisited at subsequent surveillance review time points.

New evidence is unlikely to impact on the guideline.
Preoperative traction for hip fracture

Surveillance proposal
This section should not be added.

Preoperative traction for hip fracture

2013 and 2015 surveillance summary
A meta-analysis and an RCT concluded that preoperative traction did not reduce pain in hip fracture nor did it improve surgical outcomes. (3) (146)

2019 surveillance summary
No relevant evidence was identified.

Intelligence gathering
No topic expert feedback was relevant to this section.

Impact statement
The guideline currently does not recommend traction for pain management and this evidence is unlikely to affect the guideline.

New evidence is unlikely to impact on the guideline.

Single fluoroscope or 2 fluoroscopes

Surveillance proposal
This section should not be added.

Single fluoroscope or 2 fluoroscopes

2015 surveillance summary
An RCT found that using 2 fluoroscopes instead of 1 during closed reduction and internal fixation for stable intertrochanteric fracture reduced total radiation time and total operating time (24.3 vs 34.7 minutes). (147)

2019 surveillance summary
No relevant evidence was identified.

Intelligence gathering
No topic expert feedback was relevant to this section.

Impact statement
The guideline does not make recommendations on fluoroscopy.
technique, and although 2 fluoroscopes seem to have benefits, the evidence is from a single small trial and further evidence is needed.

New evidence is unlikely to impact on the guideline.

---

**Direct medical costs of hip fracture surgery**

**Surveillance proposal**

This section should not be added.

---

**Direct medical costs of hip fracture surgery**

**2015 surveillance summary**

An economic analysis indicated that the median cost per patient episode of hip fracture was £9,429 for people admitted from care homes in the UK in 2006. Of this, £7,129 (76%) was accounted for by hospital bed day costs, suggesting that interventions targeted at reducing hospital stay may be cost-effective.(148)

**2019 surveillance summary**

No relevant evidence was identified.

**Intelligence gathering**

No topic expert feedback was relevant to this section.

**Impact statement**

No interventions were specifically examined therefore although this information may be of use in future health economic evaluations undertaken during a guidance update, the evidence in isolation is unlikely to affect current recommendations. This study will be highlighted to the team developing the guideline during the proposed update of recommendation 1.6.4.

New evidence is unlikely to impact on the guideline.
The effect of hip fracture on health related quality of life

Surveillance proposal

This section should not be added.

The effect of hip fracture on health related quality of life

2015 surveillance summary

A prospective cohort study (149) examined 1-year patient-reported outcomes of 403 patients treated at a single major trauma centre in the United Kingdom who sustained a hip fracture between 2012 and 2014. Although quality of life (measured by EuroQol 5 Dimensions [EQ-5D]) improved during the year after the fracture, it was still statistically significantly lower than before injury irrespective of age group or cognitive impairment. Mean reduction in EQ-5D was statistically significantly greater in patients <80 years of age.

2019 surveillance summary

No relevant evidence was identified.

Intelligence gathering

No topic expert feedback from the 2019 surveillance process was relevant to this section. In the 2015 surveillance process, topic experts considered that the cohort study presenting EQ-5D data may have implications for the health economic modelling in NICE CG124. NICE’s health economist suggested that the principal difference in this paper appears to be that the average hip fracture patient has a lower quality of life than previously assumed. The experts agreed that the economic analyses in the original guideline were robust and comprehensively modelled. The topic experts also noted the WHITE Study, an ongoing study evaluating the quality of life of around 8000 patients, which may add further information.

Impact statement

The new evidence may have implications for health economic modelling within NICE CG124, but the results of the World Hip Trauma Evaluation, which is intended to publish 2022, were deemed more value to include before revisiting the health economic modelling in the guideline. As such no impact on the guideline is expected. However, the publications related to the WHITE Study Group are being tracked and will be considered as soon as possible once published. This study will also be highlighted to the team developing the guideline during the proposed update of recommendation 1.6.4.

New evidence is unlikely to impact on the guideline.
Blood transfusion, cryocompression therapy and haemodynamic monitoring

Surveillance proposal
This section should not be added.

Blood transfusion, cryocompression therapy and haemodynamic monitoring

2019 surveillance summary

Blood transfusion
We identified 2 Cochrane reviews, and 3 RCTs that found no clear benefits of liberal red blood cell transfusion strategies, cryocompression therapy or invasive haemodynamic monitoring. See Table 7 below.

Intelligence gathering
No topic expert feedback was relevant to this section.

Impact statement
There were no clear benefits of liberal red blood cell transfusion strategies, cryocompression therapy or invasive haemodynamic monitoring. These are not currently covered in the guideline and topic experts did not raise these as new areas for consideration for guideline update. NICE also currently has a guideline on blood transfusion, that covers red blood cell transfusion across a range of patients. As such, this new evidence is unlikely to warrant an update.

New evidence is unlikely to impact on the guideline.

Research recommendations

In patients with a continuing suspicion of a hip fracture but whose radiographs are normal, what is the clinical and cost effectiveness of computed tomography (CT) compared to magnetic resonance imaging (MRI), in confirming or excluding the fracture?

Summary of findings

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

What is the clinical and cost effectiveness of regional versus general anaesthesia on postoperative morbidity in patients with hip fracture?

Summary of findings

A Cochrane review found no difference in regional and general anaesthesia in terms of a range of outcomes, including postoperative morbidity, but the evidence was unlikely to impact recommendations, see 1.4 Anaesthesia above. The review concluded that further research is needed and as such does not currently fully address the research recommendation. This research recommendation will be revisited at the next surveillance review to see if more evidence is available which fully addresses the recommendation.

For people with undisplaced (or non-displaced) intracapsular hip fracture, what features should be used to characterise the injury and what are the optimal clinical and cost-effective management strategies?

Summary of findings

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

What is the clinical and cost effectiveness of additional intensive physiotherapy and/or occupational therapy (for example progressive resistance training) after hip fracture?
Summary of findings

Three RCTs identified in the 2019 surveillance process found that various forms of more intensive physiotherapy had some improvements in shorter term outcomes, such as functional assessment and length of hospital stay, but the evidence was unlikely to impact recommendations, see 1.7 Mobilisation strategies above. This new evidence does not fully address the research recommendation. As such, this research recommendation will be revisited at the next surveillance review to see if more evidence is available.

What is the clinical and cost effectiveness of early supported discharge on mortality, quality of life and functional status in patients with hip fracture who are admitted from a care home?

Summary of findings

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

What is the clinical and cost effectiveness of surgery within 36 hours of admission compared to surgery later than 36 hours from admission in mortality, morbidity and quality of life in patients with hip fracture?

Summary of findings

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

What is the clinical and cost effectiveness of preoperative and postoperative nerve blocks in reducing pain and achieving mobilisation and physiotherapy goals sooner in patients with hip fracture?

Summary of findings

The evidence from 1 Cochrane review and 15 RCTs identified across the 2015 and 2019 surveillance reviews found a trend that favoured nerve blocks for controlling pain, compared with no nerve blocks or conventional analgesia. This evidence is broadly in line with the guideline recommendation 1.3.6 which suggests adding nerve blocks if paracetamol and opioids do not provide sufficient pain relief. See 1.3 Analgesia above. This new evidence does
not fully address the research recommendation. As such, this research recommendation will be revisited at the next surveillance review to see if more evidence is available.

---

What is the clinical and cost effectiveness of large-head total hip replacement versus hemiarthroplasty on functional status, reoperations and quality of life in patients with displaced intracapsular hip fracture?

**Summary of findings**

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

---

What is the clinical and cost effectiveness of intramedullary versus extramedullary fixation on mortality, functional status and quality of life in patients with reverse oblique trochanteric hip fracture?

**Summary of findings**

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

---

What is the clinical and cost effectiveness of a designated hip fracture unit within the trauma ward compared to units integrated into acute trusts on mortality, quality of life and functional status in patients with hip fracture?

**Summary of findings**

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

---

Do patients admitted to hospital with a fractured hip who live permanently in a care/nursing home have equal access to multidisciplinary rehabilitation as patients admitted from home?
Summary of findings

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

What quality of life value do individual patients and their carers place on different mobility, independence and residence states following rehabilitation?

Summary of findings

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.

What is the patient’s experience of being admitted to hospital with a hip fracture in relation to surgery, pain management, timeliness of information given, and rehabilitation?

Summary of findings

No new evidence relevant to the research recommendation was found and no ongoing studies were identified.
