NICE guideline NG100 Intervention evidence review July 2018

Final

This evidence review was developed by the National Guideline Centre

#### Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and, where appropriate, their careful or guardian.

Local commissioners and providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the <u>Welsh Government</u>, <u>Scottish Government</u>, and <u>Northern Ireland Executive</u>. All NICE guidance is subject to regular review and may be updated or withdrawn.

# **1** First line DMARDs

#### 1.1 Review questions:

In adults with Rheumatoid Arthritis (RA) who are DMARD naïve, which conventional DMARDs (alone or combined) are most clinically and cost effective?

In adults with RA who are DMARD naïve, which DMARD treatment strategy (monotherapy, sequential monotherapy, parallel combination therapy, step up therapy or step down therapy) is most clinically and cost effective?

#### 1.2 Introduction

DMARDs suppress disease activity and slow down radiological progression in rheumatoid arthritis, resulting in symptom improvement and reduced long-term disability. There are several conventional DMARDs that can either be prescribed as stand-alone monotherapy or combined. Treatment strategies include monotherapy, sequential monotherapy, parallel combination therapy, step-up therapy, and step-down therapy. At present it is unclear which DMARD or which DMARD treatment strategy is the most effective, both for newly diagnosed rheumatoid arthritis and further treatment.

#### 1.3 PICO table

For full details see the review protocol in appendix A.

Population Adults with RA who are DMARD naïve. Studies in adults with poor prognostic factors will be presented separately. Interventions methotrexate (oral) (MTX oral) methotrexate (subcutaneous) (MTX sc) hydroxychloroquine (HCQ) sulfasalazine (SSZ) leflunomide (LFN) combinations of the above sequential combinations of the above. Study treatment arms will be classified into one of the following classes: monotherapy (a single DMARD used for the duration of the trial) • sequential monotherapy (a single DMARD replaced with a different single DMARD in the case of inadequate response) • parallel combination (two or more DMARDs commenced at the same time without a step-down strategy) • step up (commencing with a single DMARD, followed by the addition of further DMARD(s) in the case of inadequate response) step down (two or more DMARDs commenced at the same time, with at least one drug tapered and stopped once disease is adequately controlled).

 Table 1: PICO characteristics of review question

Comparison	The intervention medications can be compared against each other or against placebo.
Outcomes	<ul> <li>CRITICAL</li> <li>Disease Activity Score (DAS) (continuous) at 6 and 12 months</li> <li>Quality of life (continuous) at 6 and 12 months</li> <li>Function (continuous) at 6 and 12 months</li> </ul>
	<ul> <li>Low disease activity (dichotomous) at 6 and 12 months</li> <li>Remission (dichotomous) at 6 and 12 months</li> <li>ACR50 response (dichotomous) at 6 and 12 months</li> <li>Pain (continuous) at 6 and 12 months</li> <li>Radiological progression (continuous) at 12 months</li> <li>Adverse events – mortality (dichotomous) at longest reported time point</li> <li>Withdrawal due to adverse events (dichotomous) at longest reported time point</li> <li>Withdrawal due to inefficacy (dichotomous) at longest reported time point</li> </ul>
Study design	Randomised controlled trials (RCTs)
	Systematic Review / Network Meta-Analysis of RCTs

Studies that enrol people who are not explicitly reported to be DMARD naïve were not excluded, except where: the study states that the only DMARD used previously is an antimalarial or hydroxychloroquine (as hydroxychloroquine is known to be a weak DMARD); or previous DMARDs have been used for no longer than 1 month. These populations were included on the basis that they would not differ substantially from a DMARD naïve population in terms of disease severity or likely response to DMARD treatment.

#### 1.4 Clinical evidence

#### 1.4.1 Included studies

An existing Cochrane review<sup>59,60</sup> by Hazelwood et al. comparing methotrexate monotherapy with methotrexate in combination with other DMARDs formed the basis of the evidence review. The protocol for the Cochrane review differed from the guideline review as to the population included in the guideline review was limited to people who are DMARD naïve and the Cochrane review to people who were naïve to or with an inadequate response speciofically to methotrexate. Additionally the Cochrane review included studies that investigated methotrexate monotherapy or in combination with any currently used conventional synthetic DMARD, biologic DMARDs, or tofacitinib. The included studies in that review were checked for inclusion in this evidence review based on the guideline's evidence review protocol. Searches were also conducted for randomised controlled trials and systematic reviews as follows:

- the Cochrane review search strategy was re-run to identify relevant trials published since the date of the Cochrane review searches; and
- a search was conducted to identify additional trials of non-methotrexate monotherapies and combinations that would not have been included in the Cochrane review. This was not date limited.

Twenty-one studies were included in the review; <sup>6</sup>,<sup>7</sup>,<sup>13</sup>,<sup>22</sup>,<sup>27</sup>,<sup>28</sup>,<sup>31</sup>,<sup>33</sup>,<sup>40</sup>,<sup>46</sup>,<sup>48</sup>,<sup>55</sup>,<sup>57</sup>,<sup>68</sup>,<sup>96</sup>,<sup>108</sup>,<sup>118</sup>,<sup>137</sup>, <sup>152</sup>,<sup>171</sup>,<sup>177</sup> these are summarised in Table 2. Evidence from these studies is summarised in the clinical evidence summaries below in Table 3 - Table 19.

The included studies covered 17 comparisons across a range of monotherapy, sequential monotherapy, parallel combination therapy, step-down therapy and step up therapy treatment regimens compared against each other and in some cases against placebo. All of the medicatios in the protocol were included within the included trials except for subcutaneous methotrexate for which no evidence was found.

See also the study selection flow chart in appendix C, study evidence tables in appendix D, forest plots in appendix E and GRADE tables in appendix H.

See the excluded studies list in appendix I.

#### 1.4.2 Summary of clinical studies included in the evidence review

Study	Intervention and comparison	Population	Outcomes	Comments
Monotherap	y versus placebo			
Anonymous 1992 <sup>7</sup>	Monotherapy: sulfasalazine versus placebo	People with RA for less than 12 months and no evidence of erosions in hands or feet N=122	<ul> <li>Pain</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	High dose medication in intervention arm. Short term glucocorticoid treatment not used.
Anonymous 1995 <sup>6</sup>	Monotherapy: hydroxychloroquine versus placebo	Adults with RA for less than 2 years. Persistent synovitis despite treatment with aspirin or NSAIDs. N=120	<ul> <li>Function</li> <li>Pain</li> <li>Quality of life</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	High dose medication in intervention arm. Short term glucocorticoid treatment used.
Clark 1993 <sup>22</sup>	Monotherapy: hydroxychloroquine versus placebo	Adults with active RA and ≤5 years since diagnosis and unsuccessful treatment with 2+ NSAIDs or salicylates. N=126	• Pain	High dose medication in intervention arm. Short term glucocorticoid treatment usage unclear.
Davis 1991 <sup>27</sup>	Monotherapy: hydroxychloroquine versus placebo	People with RA and palpable synovitis in the hands, wrists or feet N=104	Withdrawal: inefficacy	High dose medication in intervention arm. Short term glucocorticoids not used.
Hannonen 1993 <sup>57</sup>	Monotherapy: sulfasalazine versus placebo	People with active RA with disease symptoms for <12 months. N=80	<ul> <li>Radiological progression</li> <li>Adverse events - mortality</li> </ul>	High dose medication in intervention arm. Short term glucocorticoids used.

#### Table 2: Summary of randomised controlled trials included in the evidence review

	Intervention and			
Study	comparison	Population	Outcomes	Comments
Monotherap Ferraccioli 2002 <sup>40</sup>	y versus monotherapy Monotherapy: sulfasalazine versus monotherapy: methotrexate	People aged 17- 70 with active RA and at least 1 erosion and 4 month course of antimalarials. N=84	• ACR50 response	High dose medication in both arms. Short term glucocorticoids used. Considered indirect evidence due to previous course of antimalarials. Combination therapy of both interventions given to non- responders after 6 months.
Jaimes- hernandez 2012 <sup>68</sup>	Monotherapy: leflunomide versus monotherapy: methotrexate	Adults with active RA. N=85	<ul> <li>Disease Activity Score (DAS28)</li> <li>Function</li> <li>ACR50 response</li> <li>Remission</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	Low dose medication in both arms. Short term glucocorticoids used. 3% had prior DMARD treatment and had washout period. Committee agreed this percentage would not affect overall results.
Lisbona mp 2012 <sup>96</sup>	Monotherapy: leflunomide versus monotherapy: methotrexate	People with early RA: symptom duration for less than 1 year. N=78	<ul> <li>Disease Activity Score (DAS28)</li> <li>Function</li> <li>Pain</li> </ul>	High dose medication. Short term glucocorticoids used.
Nuver- zwart 1989 <sup>118</sup>	Monotherapy: hydroxychloroquine versus monotherapy: sulfasalazine	People aged 16- 75 years old with definite or classical and active RA. N=60	<ul> <li>Pain</li> <li>Pain</li> <li>Radiological progression</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	High dose medication in both arms. Short term glucocorticoids not used.
Van jaarsveld 2000 <sup>171</sup>	Monotherapy: hydroxychloroquine versus monotherapy: methotrexate	People with RA. Disease duration for less than 1 year. N=231	<ul> <li>Function</li> <li>ACR remission</li> <li>Pain</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	High dose medication in both arms. Short term glucocorticoids not used. Medications changed if adverse events made discontinuation inevitable.
	y versus other treatme	-		
COBRA trial: Boers	Step-down therapy: sulfasalazine and	Adults with active RA and	Disease Activity Score (DAS)	Mixed dose level in arm 1 and high dose

	Intervention and			
Study	comparison	Population	Outcomes	Comments
1997 <sup>13</sup>	methotrexate versus monotherapy: sulfasalazine	disease duration ≤2 years N=156	<ul> <li>Function</li> <li>Function</li> <li>Remission</li> <li>ACR50 response</li> <li>Pain</li> <li>Pain</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	study in high dose in arm 2. Short term glucocorticoid treatment used. Excluded patients previously or currently treated with DMARDs except antimalarials.
den Uyl 2014 <sup>31</sup>	Parallel combination therapy: methotrexate and sulfasalazine versus monotherapy – Methotrexate.	Adults with active RA. Disease duration for 2 years or less. N=164	<ul> <li>Disease Activity Score (DAS)</li> <li>Function</li> <li>ACR Remission</li> <li>ACR50 response</li> <li>Pain</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	High dose medication in both arms. Short term glucocorticoids used. Both arms given a regular dose of prednisone. Sequential change to parenteral methotrexate considered in group 2 though only utilised in 4% of participants.
Dougados 1999 <sup>33</sup>	3 treatment arms: Parallel combination therapy: methotrexate and sulfasalazine versus monotherapy: sulfasalazine versus monotherapy methotrexate	People with active RA. Disease duration less than 1 year. N=209	<ul> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	High dose medication in all arms. Short term glucocorticoids not used.
FIN-RACo trial: Mottonen 1999 <sup>108</sup>	Parallel combination therapy: sulfasalazine and methotrexate and hydroxychloroquine versus monotherapy: sulfasalazine	Adults with active RA and symptom duration <2 years. N=199	<ul> <li>Remission</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	Low dose medication in arm 1 and high dose medication in arm 2. Short term glucocorticoids used.
Haagsma 1997 <sup>55</sup>	3 treatment arms: Parallel combination therapy: methotrexate and sulfasalazine versus monotherapy: sulfasalazine versus monotherapy: methotrexate	Adults with active RA with disease duration less than 1 year. N=105	<ul> <li>Disease Activity Score (DAS)</li> <li>Disease Activity Score (DAS)</li> <li>Function</li> <li>Pain</li> <li>Pain</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: adverse events</li> </ul>	High dose medication in all arms. Short term glucocorticoids used. If dose was not effective after 24 weeks in study then participant withdrawn from study. Placebos utilised for blinding.

	Intervention and						
Study	comparison	Population	Outcomes	Comments			
Tascioglu 2003 <sup>152</sup>	Parallel combination therapy: methotrexate and sulfasalazine versus monotherapy: methotrexate	Adults with active RA and disease duration for less than 1 year. N=70	inefficacy • Function • Pain • Withdrawal: adverse events • Withdrawal: adverse events	Low dose medication. Short term glucocorticoids not used. Participants excluded from the study if treatment not effective after 12 weeks or if serious adverse events occurred.			
tREACH trial: de Jong 2013 <sup>28</sup>	Parallel combination therapy: methotrexate and sulfasalazine and hydroxychloroquine versus monotherapy: methotrexate	Adults with arthritis of 1 or more joints for less than 1 year. Results extracted for those with RA via 1987 ACR criteria. N=189	<ul> <li>Disease Activity Score (DAS)</li> <li>Function a</li> <li>Pain</li> <li>Remission</li> </ul>	High dose medication. Short term glucocorticoids used. Outcomes only extracted at time points prior to people beginning biologic treatment.			
Comparison	of non-monotherapy t	reatment strategie	S				
BeSt study: Goekoop- Ruiterman 2005 <sup>48</sup>	3 treatment arms: Step up therapy: methotrexate then add sulfasalazine then add hydroxychloroquine, then biologic DMARD combinations versus parallel combination therapy: methotrexate and sulfasalazine. Then step-up to biologic DMARD combinations versus sequential monotherapy: methotrexate to sulfasalazine to leflunomide, followed by biologic DMARD combinations.	Adults with active RA and disease duration ≤2 years N=380	<ul> <li>Function</li> <li>Radiological progression</li> </ul>	Outcomes only extracted at time points prior to people beginning biologic treatment. Participants DMARD naïve (other than antimalarials - 9%). High dose medication in all intervention arms. Short term glucocorticoid treatment used in arms 2 and 3. First two treatment arms are effectively methotrexate monotherapy for 6 months and outcomes extracted on that basis.			
Ghosh 2008 <sup>46</sup>	Parallel combination therapy: sulfasalazine and hydroxychloroquine versus parallel combination therapy: methotrexate and hydroxychloroquine	People with RA with disease duration for less than 6 months. N=110	<ul> <li>Disease Activity Score (DAS28)</li> <li>Remission</li> </ul>	Low dose medication in both arms. Short term glucocorticoids not used.			
Saunders	Step up therapy:	People aged 18	Disease Activity	High dose			

	Intervention and			
Study	comparison	Population	Outcomes	Comments
2008 <sup>137</sup>	sulfasalazine then methotrexate then hydroxychloroquine versus parallel combination therapy: methotrexate and sulfasalazine and hydroxychloroquine	to 80 with active RA N=96	Score (DAS28) <ul> <li>Quality of life</li> <li>Function at 12 months</li> <li>Low disease activity</li> <li>Remission</li> <li>ACR50 response</li> <li>Pain</li> <li>Radiological progression</li> <li>Withdrawal: adverse events</li> </ul>	medication in both arms. Short term glucocorticoids used. No previous DMARD treatment except for hydroxychloroquine.
Poor-progno	osis disease strata			
Verschuere n 2016 <sup>177</sup>	3 treatment arms: Step up therapy: methotrexate then leflunomide versus parallel combination therapy: methotrexate and leflunomide versus parallel combination therapy: methotrexate and sulfasalazine	People with RA with disease duration ≤1 year. Defined as "high risk" due to erosions, rheumatoid factor, ACPA, disease activity. N=289	<ul> <li>Disease Activity Score (DAS28)</li> <li>Disease Activity Score (DAS28)</li> <li>Function</li> <li>Function</li> <li>Low disease activity</li> <li>Low disease activity</li> <li>Remission</li> <li>Remission</li> <li>Radiological progression</li> <li>Withdrawal: adverse events</li> <li>Withdrawal: inefficacy</li> </ul>	High dose in arms 1 and 3, mixed dose in arm 2. Short term glucocorticoids used. Some participants took biologic medications outside of treatment protocol. Numbers range from 2% to 10% depending on treatment group.

See appendix D for full evidence tables.

#### 3 Quality assessment of clinical studies included in the evidence review

#### 1 Monotherapy versus placebo

#### Table 3: Clinical evidence summary: monotherapy: sulfasalazine (SSZ) compared to placebo

	No of			Anticipated absolute effects		
Outcomes	Participa nts (studies) Follow up	Quality of the evidence (GRADE)	Relati ve effect (95% CI)	Risk with Placebo	Risk difference with Monotherapy: SSZ (95% CI)	
Disease Activity Score at 6 or 12 months - not reported	-	-	-	-	-	
Quality of life at 6 or 12 months - not reported	-	-	-	-	-	
Function at 6 or 12 months - not reported	-	-	-	-	-	
Pain at 6 months VAS. Scale from: 0 to 100.	65 (1 study) 6 months	<ul> <li>⊕⊖⊖</li> <li>VERY</li> <li>LOW<sup>1,2</sup></li> <li>due to risk of bias,</li> <li>imprecision</li> </ul>		The mean pain (VAS) at 6 months in the control groups was 28.8	The mean pain (VAS) at 6 months in the intervention groups was 8.9 lower (19.07 lower to 1.27 higher)	
Radiological progression at 12+ months Modified Sharp score. Scale from: 0 to 32 or 64.	73 (1 study) 44-60 weeks	$\oplus \oplus \ominus \ominus$ LOW <sup>1,2</sup> due to risk of bias, imprecision		The mean radiological progression (modified Sharp score) at 12+ months in the control groups was 7.1	The mean radiological progression (modified Sharp score) at 12+ months in the intervention groups was 3.6 lower (8.21 lower to 1.01 higher)	
Adverse events - mortality	78 (1 study) 48 weeks	$\begin{array}{c} \bigoplus \ominus \ominus \ominus \\ VERY \\ LOW^{1,2} \\ due \text{ to risk of } \\ bias, \\ imprecision \end{array}$	RR 1.05 (0.07 to 16.24)	25 per 1000	1 more per 1000 (from 23 fewer to 381 more)	

	No of			Anticipated absolute effects	
Outcomes	Participa nts (studies) Follow up	Quality of the evidence (GRADE)	Relati ve effect (95% CI)	Risk with Placebo	Risk difference with Monotherapy: SSZ (95% CI)
Withdrawal: adverse events	105 (1 study) 6 months	⊕⊕⊖⊖ LOW <sup>1</sup> due to risk of bias	RR 3.43 (1.21 to 9.75)	77 per 1000	187 more per 1000 (from 16 more to 673 more)
Withdrawal: inefficacy	105 (1 study) 6 months	<ul> <li>⊕⊖⊖⊖</li> <li>VERY</li> <li>LOW<sup>1,2</sup></li> <li>due to risk of bias,</li> <li>imprecision</li> </ul>	RR 0.39 (0.08 to 1.93)	96 per 1000	59 fewer per 1000 (from 88 fewer to 89 more)

2 Downgraded by 1 increment if the confidence interval crossed one MID or by 2 increments if the confidence interval crossed both MIDs

#### Table 4: Clinical evidence summary: monotherapy: hydroxychloroquine (HCQ) compared to placebo

	No of			Anticipated absolute effects		
Outcomes	Participa nts (studies) Follow up	Quality of the evidence (GRADE)	Relati ve effect (95% CI)	Risk with Placebo	Risk difference with Monotherapy: HCQ (95% CI)	
Disease Activity Score at 6 or 12 months - not reported	-	-	-	-	-	
Quality of life at 12 months Global well being. ## 1.5 Economic evidence

#### 1.5.1 Included studies

Two health economic studies were identified with the relevant comparison and have been included in this review.<sup>157,162</sup> These are summarised in the health economic evidence profile below (Table 20) and the health economic evidence tables in appendix H.

#### 1.5.2 Excluded studies

One economic study relating to this review question was identified but was excluded due to combination of limited applicability and methodological limitations.<sup>139</sup> This is listed in appendix I, with reasons for exclusion given.

See also the health economic study selection flow chart in appendix G.

See also the health economic study selection flow chart in appendix G.

## 5.3 Summary of studies included in the economic evidence review

#### Table 20: Health economic evidence profile: multiple DMARD comparators

Study	Applicability	Limitation s	Other comments	Costs (a)	Effects (QALYs ) (a)	Increment al cost (b)	Incremental effects (b)	Cost effectiveness (b)	Uncertainty

Rheumatoid arthritis: Final First line DMARDs

Abbreviations: ICER: incremental cost-effectiveness ratio; QALY: quality-adjusted life years (a) Cost/effect in order of least to most effective intervention

(b) Full incremental analysis of available strategies: first strategies are ruled out that are dominated (another strategy is more effective and has lower costs) or subject to extended dominance (the strategy is more effective and more costly but the incremental cost effectiveness ratio is higher than the next most effective option and so it

would never be the most cost effective option); incremental costs, incremental effects and incremental cost effectiveness ratios are calculated for the remaining strategies by comparing each to the next most effective option.

- (c) Does not specify DMARDs but rather refers to treatment strategies, although authors note that a systematic review of monotherapy found no statistically significant difference between DMARDs. EQ-5D mapped from HAQ rather than directly elicited from patients in trials.
- (d) Patient covariates are not included to determine differences in clinical response or treatment withdrawal as both of these inputs are based on trials not a registry. Criteria set by NICE for biologic eligibility is failing 2 DMARDs (incl. methotrexate) and having a DAS >5.1. As model is HAQ based and conversion from HAQ to DAS is not possible, this requirement not included in model. This analysis is based on 5 of the 22 studies included for this question and includes 8 studies that were not included in the clinical review and so does not reflect full body of evidence and may provide treatment effect estimates that do not reflect that identified in the clinical review.
- (e) Costs components incorporated: Drug costs (including drugs, monitoring, review and administration where applicable); annual costs of managing RA stratified by HAQ score (hospital days, outpatient visits and joint replacements). Cost of adverse events not directly quantified, indirectly quantified through treatment withdrawal.
- (f) Evidence from a Dutch healthcare perspective. Discounting at 3% rather than 3.5% as required by the NICE reference case. Does not include a comparison of all possible treatment combinations identified in the clinical evidence.
- (g) 2 year follow-up unlikely to be sufficient to capture all downstream costs and treatment effects. Dutch unit costs may not reflect current NHS costs. Within trial analysis based on RCT BeST. This analysis is based on 1 of the 22 studies included for this question and so does not reflect full body of evidence.
- (h) 2008 Euro converted to UK pounds<sup>123</sup>. Cost components incorporated: medication costs, consultations, admissions and homecare.

#### 1.5.4 Unit costs

#### Table 21: UK costs of conventional DMARDs

Drug	Dosage	Cost – annual
Methotrexate, oral tablets	Max. 20mg weekly	£39.49
Methotrexate, subcutaneous, prefilled syringe	Max. 25 mg weekly	£960.96
Hydroxychloroquine, oral tables	200-400mg daily	£45.38
Sulfasalazine, gastro-resistant tablets	Max. 2-3g daily	£164.39
Leflunomide, oral tablet	10-20mg	£92.94

Sources: Dosage: BNF March 2017<sup>11</sup>; Unit cost: NHS Drug Tariff, March 2017.<sup>116</sup>

In addition to the cost of the drugs, there are also costs associated with monitoring of conventional DMARDs.

NICE technology appraisal TA375 has estimated that the monthly cost of monitoring methotrexate to be £134. This cost includes a full blood count, biochemical profile and a hospital outpatient appointment.

The British Society for Rheumatology and British Health Professionals in Rheumatology published a guideline for prescription and monitoring of non-biologic DMARDs in 2017. The standard laboratory monitoring schedule recommended is 9 monitoring blood tests in first 12 months. The blood tests include full blood count, creatinine/calculated GFR, ALT and/or AST and albumin. Table 22 below outlines a summary of monitoring requirements for each drug.

#### Table 22: Monitoring of conventional DMARDs

Drug	Laboratory monitoring	Other monitoring
Methotrexate	Standard monitoring schedule	None
Hydroxychloroquine	No routine laboratory monitoring	Annual eye assessment if continued >5 years
Sulfasalazine	Standard monitoring schedule for 12 months, then no routine monitoring needed	None
Leflunomide	Standard monitoring schedule	Blood pressure and weight at each monitoring visit

Source: BSR and BHPR monitoring guideline 201793

## 1.6 Resource costs

The recommendations made in this review are not expected to have a substantial impact on resources.

## **1.7 Evidence statements**

#### 1.7.1 Clinical evidence statements

Monotherapy: sulfasalazine compared to placebo

A benefit for sulfasalazine was found in radiological progression and withdrawal due to inefficacy though adversely there was a benefit for placebo in withdrawals due to adverse events. No difference was seen for pain at 6 months or mortality (low to very low quality evidence; 1 study for each outcome; n=65 to 105). No evidence was available for disease activity, quality of life or function.

• Monotherapy: hydroxychloroquine compared to placebo

Hydroxychloroquine showed a benefit in quality of life at 12 months, pain at 6 months and withdrawal due to adverse events or withdrawal due to inefficacy. No difference was seen between the treatments in terms of psychological function at 12 months (high to very low quality evidence; 1 to 2 studies for each outcome; n=100 to 215). No evidence was available for disease activity.

• Monotherapy: sulfasalazine compared to monotherapy: methotrexate

Methotrexate was beneficial for function at 12 months, ACR50 response at 6 months, withdrawal due to adverse events and withdrawal due to inefficacy. No difference between treatments was seen for disease activity at 6 or 12 months or pain at 6 or 12 months (very low quality evidence, 1 to 2 studies for each outcome, n=55 to 184). No evidence was available for quality of life data.

• Monotherapy: leflunomide compared to monotherapy: methotrexate

A benefit was found for leflunomide in function at 12 months and withdrawal due to inefficacy. Methotrexate was seen to be beneficial in withdrawal due to adverse events. No difference was seen between the treatments for disease activity at 6 or 12 months, function at 6 months, remission at 12 months or pain at 6 months (low to very low quality evidence; 1 study for each outcome; n=62 to 71). No evidence was available for quality of life data.

• Monotherapy: hydroxychloroquine compared to monotherapy: sulfasalazine

Sulfasalazine was beneficial in radiological progression and withdrawal due to inefficacy while hydroxychloroquine was more effective in terms of withdrawal due to adverse events. No difference was found in terms of pain at 6 or 12 months (low to very low quality evidence; 1 study; n=60). No evidence was available for disease activity, quality of life or function.

• Monotherapy: hydroxychloroquine compared to monotherapy: methotrexate

Methotrexate showed a clinical benefit in function at 12 months, ACR remission at 12 months and withdrawal due to inefficacy, while hydroxychloroquine was beneficial in withdrawal due to adverse events. No difference was seen for pain (low to very low quality evidence; 1 study; n=212). No evidence was available for disease activity or quality of life.

• Step-down therapy: sulfasalazine, methotrexate compared to monotherapy: sulfasalazine

A benefit was found for the step-down therapy in Disease Activity Score at 6 months, function at 6 or 12 months in three of the four outcomes reported, ACR50 response at 6 months, pain at 6 months, withdrawal due to adverse events and withdrawal due to inefficacy. A benefit was found for sulfasalazine in terms of remission at 12 months and no clinical difference for Disease Activity Score at 12 months, one function outcome at 6 months and pain at 12 months (moderate to very low quality evidence; 1 study; n=156). No evidence was available for quality of life.

• Parallel combination therapy: methotrexate, sulfasalazine compared to monotherapy: sulfasalazine

A benefit for the parallel combination therapy for function at 12 months and withdrawal due to inefficacy and there was a benefit for sulfasalazine in withdrawal due to adverse events. There was no clinical difference for disease activity at 6 or 12 months or pain at 6 or 12 months (low to very low quality evidence; 1 to 2 studies for each outcome; n=55 to 183). No evidence was available for quality of life.

 Parallel combination therapy: methotrexate, sulfasalazine compared to monotherapy: methotrexate A clinical benefit was found for methotrexate in function at 6 or 12 months, withdrawal due to adverse events. Other outcomes indicated no difference between treatments: disease activity at 6 or 12 months, remission at 6 months, ACR50 response at 6 months, pain at 6 or 12 months and withdrawal due to inefficacy (moderate to very low quality evidence; 1 to 4 studies for each outcome; n=63 to 410). No evidence was available for quality of life.

• Parallel combination therapy: methotrexate, sulfasalazine, hydroxychloroquine compared to monotherapy: methotrexate

The parallel combination therapy was of clinical benefit in terms of remission at 6 months and pain at 6 months. Disease activity at 6 months and function at 6 months outcomes showed no difference between the treatments (moderate to very low quality evidence; 1 study; n=189). No evidence was available for quality of life.

• Parallel combination therapy: methotrexate, sulfasalazine, Hydroxychloroquine compared to monotherapy: sulfasalazine

A benefit was found for the parallel combination therapy in remission at 6 months but the other two withdrawal outcomes indicated no clinical difference (very low quality evidence; 1 study; n=199). No evidence was available for disease activity, quality of life or function.

• Step up therapy: methotrexate, sulfasalazine, hydroxychloroquine compared to sequential monotherapy: methotrexate, sulfasalazine, leflunomide

A benefit was found for the step-up therapy for radiographic progression but no clinical difference was found for function at 12 months (moderate quality evidence; 1 study; n=237). No evidence was available for disease activity or quality of life.

• Parallel combination therapy: sulfasalazine, hydroxychloroquine compared to parallel combination therapy: methotrexate, hydroxychloroquine

Parallel combination therapy utilising sulfasalazine and hydroxychloroquine showed a clinical benefit in disease activity at 6 months and remission at 6 months (very low quality evidence; 1 study; n=110). No evidence was available for quality of life or function.

• Step up therapy: sulfasalazine, methotrexate, hydroxychloroquine compared to parallel combination therapy: methotrexate, sulfasalazine, hydroxychloroquine

The step-up regime showed a clinical benefit in terms of disease activity at 12 months, function at 12 months, low disease activity at 12 months, remission at 12 months and radiographic progression. No clinical difference was found for quality of life at 12 months, ACR50 response at 12 months and pain at 12 months (moderate to low quality evidence; 1 study; n=96).

• Parallel combination therapy: methotrexate, leflunomide compared to parallel combination therapy: methotrexate, sulfasalazine in people with poor prognosis.

Parallel combination therapy utilising methotrexate and sulfasalazine showed a clinical benefit in terms of function at 6 or 12 months and parallel combination therapy utilising methotrexate and leflunomide showed a benefit through two withdrawal outcomes. No clinical difference was seen for disease activity at 6 or 12 months, remission at 6 or 12 months and radiological progression. (Low to very low quality evidence; 1 study; n=192). No evidence was available for quality of life.

• Step up therapy: methotrexate, leflunomide compared to parallel combination therapy: methotrexate, sulfasalazine in people with poor prognosis.

The parallel combination regime showed a clinical benefit in terms of function at 6 or 12 months though the step-up therapy regime was beneficial in radiological progression and two withdrawal outcomes. No difference was found for disease activity at 6 or 12 months and

remission at 6 or 12 months. (Low to very low quality evidence; 1 study; n=196). No evidence was available for quality of life.

• Step up therapy: methotrexate, leflunomide compared to parallel combination therapy: methotrexate, leflunomide in people with poor prognosis.

The parallel combination regime showed a clinical benefit in terms of function at 6 or 12 months and withdrawal due to adverse events. The step-up regimen showed a benefit through radiological progression and withdrawal due to inefficacy. No difference was seen between the treatments for disease activity at 6 or 12 months and remission at 6 or 12 months. (Low to very low quality evidence; 1 study; n=192). No evidence was available for quality of life.

#### 1.7.2 Health economic evidence statements

- One cost-utility analysis found that step-down combination DMARD therapy was dominant (less costly and more effective) for treating adults with recent onset rheumatoid arthritis compared to monotherapy DMARD, parallel combination DMARD and step-down combination DMARD. It was also found that step-down combination DMARD therapy was cost effective compared to intensive step-up combination DMARD (ICER: £27,392 per QALY). This analysis was assessed as partially applicable with potentially serious limitations.
- One cost-utility analysis found that step-down combination DMARD therapy was dominant (less costly and more effective) compared to sequential monotherapy for treating adults with early rheumatoid arthritis. This analysis was assessed as partially applicable with potentially serious limitations.

## **1.8** The committee's discussion of the evidence

#### 1.8.1 Interpreting the evidence

#### 1.8.1.1 The outcomes that matter most

The outcomes were the same across both reviews. The critical outcomes were agreed to be the Disease Activity Score (DAS), quality of life and function.

The important outcomes were agreed as the number of people achieving remission and low disease activity, using DAS thresholds. The committee agreed that data reported in this format are not as informative as continuous DAS data but still give an indication of symptom relief and disease activity improvement. Other important outcomes were mortality, the number of people who withdrew from trial due to adverse events or inefficacy, ACR50 response, as well as the level of pain and radiographic progression.

For most outcomes, 6- and 12-month data was sought to determine the short-term and longer-term benefits of different DMARDs and treatment strategies. The benefits in terms of radiographic progression were not expected earlier than 12 months and that outcome was restricted to data after 12 months or more of treatment. For mortality and withdrawal from trial, data covering the duration of the trial were sought.

In the first-line treatment review, no data were available for quality of life at 6 months. Some data were available for all other outcomes, though this was obtained across 16 different comparisons and so within each comparison there were significant gaps in the outcome data available for each DMARD.

In the further treatment review, no data were available for the outcomes of mortality, radiological progression, remission and quality of life.

#### 1.8.1.2 The quality of the evidence

#### **First-line treatment**

This review included 21 studies of first-line DMARD treatment, which spanned 17 comparisons of a range of different monotherapy, sequential monotherapy, parallel combination therapy, step-down therapy and step-up therapy regimens. Most studies compared different treatment regimens or reported different outcomes. Because of these differences, it was not possible to perform an NMA to compare all drugs and strategies to each other. It was not possible to create a strong, connected network using any of the outcomes the committee prioritised (such as DAS, ACR50 response, DAS remission or DAS low disease activity). Any network that could be connected was considered too limited in both the comparisons included (key comparators were not connected) and the amount of evidence for each comparison (data from only 1 study was available for each comparison) to inform a recommendation which DMARD or strategy to recommend.

A standard pair-wise meta-analysis was performed, though it was still not possible to pool much of the evidence due to the differences in treatment regimens and outcomes reported. In addition, where evidence was pooled, the committee noted there was variation in the DMARD doses and titration regimes used and variable use of glucocorticoids which could have influenced the relative effectiveness of the different regimens.

The quality of the evidence was varied, ranging from high to very low quality, with the majority of the outcomes graded either low or very low quality. The failure to blind participants and outcome assessors was a common source of risk of bias in the included studies, as many of the outcomes (including all of the critical outcomes) had a subjective element and therefore their scoring could be affected by knowledge of the treatment allocation. The other area where risk of bias was common was in terms of selection bias. Studies often failed to report allocation concealment or the method used to randomise people to treatment groups. Missing data also contributed as a source of risk of bias for many comparisons, in that significant numbers of participants left the trial, which could affect the reliability of the results. In addition, much of the evidence for each comparison was from single trials, leading to wide confidence intervals and uncertainty about whether a particular drug or strategy was more effective than another.

#### People with a poor prognosis

The committee had identified people with a poor prognosis as a population stratum to establish whether a different treatment strategy or different DMARDs should be used. People with a poor prognosis were considered to be those with one or more of the key prognostic factors identified in a separate review, which were anti-CCP positive status and the presence of erosions at baseline. Only 1 study was identified in people with a poor prognosis, which studied people identified as "high risk" due to erosions, rheumatoid factor, anti-CCP and disease activity. Similarly to the rest of the review, evidence was of low to very low quality due to risk of bias and imprecision. The main risk of bias issues stemmed from a lack of blinding and no reporting of adequate allocation concealment.

#### **Further treatment**

This review included 4 studies, all of which reported people who had an insufficient response to a specific DMARD monotherapy and were then treated by either adding another DMARD in a step-up strategy or switching to another DMARD monotherapy. While all participants in each study had previously been treated with the same DMARD, in some of the studies, people had tried (and presumably not responded to) a number of DMARDs *prior to* that specific DMARD. The committee acknowledged this was a limitation of the evidence base, as the populations were mixed. However, 1 of the 4 studies avoided this issue by recruiting and following people who were DMARD-naïve as they progressed through various treatment

strategies. As the results of this study were consistent with the results of the other studies, the committee considered all of the evidence to be direct and relevant to the review question.

The evidence quality was variable, ranging from moderate to very low quality across the outcomes and comparisons. Most of the evidence could not be pooled as the studies enrolled different populations, compared different drugs or treatment regimens or reported different outcomes. The evidence was generally at very high or high risk of bias due to incomplete outcome data (for example, unexplained or high numbers of missing data) and lack of blinding in the studies; only withdrawal due to adverse events, reported in 1 study, was at low risk of bias. One of the studies was also a post-hoc analysis of a subset of participants from an RCT, which was considered a further source of potential bias.

Further, for some of the important outcomes, there were small numbers of participants and low numbers of events, resulting in wide confidence intervals, meaning there was some uncertainty as to which treatment approach was superior.

#### 1.8.1.3 Benefits and harms

#### **First-line treatment**

The evidence demonstrated benefits for DMARD monotherapy compared to placebo and furthermore, when compared to parallel combination of 2 DMARDS monotherapy was equally effective or in some cases, demonstrated better results in terms of function and withdrawal due to adverse events. The remainder of the critical outcomes often showed no clinical difference between treatment arms; however where benefit was seen, it was not generalisable to a specific strategy. Similarly, the important outcomes did not uniformly support a treatment regimen; benefits were seen at times for varying strategies. Overall, the committee did not consider that the evidence indicated consistent benefits of any specific treatment strategy over another.

The committee reviewed the recommendations from the 2009 guideline, which recommended combination therapy on the basis of a network meta-analysis (NMA) and accompanying economic model. The committee concluded that the updated evidence review did not support the use of multiple DMARDs in combination as first-line treatment as there was no convincing evidence that it was more effective than monotherapy, and benefits were seen for monotherapy compared to placebo in terms of radiological progression, quality of life and reduction in pain. The committee also agreed that monotherapy would have fewer side effects than combination therapy, and starting with monotherapy would eliminate the challenge of identifying which drugs were causing side effects. It was therefore agreed that people newly diagnosed with rheumatoid arthritis should be offered DMARD monotherapy as first-line treatment.

The committee discussed the reasons for the change in the recommended approach to first line since the 2009 guideline.

Although this review was an update of an existing area of the guideline, the evidence that was included and the approach to analysing that evidence was different. Of note is that the internationally accepted methods for best practice systematic reviewing and appraisal of clinical evidence have changed in that time. In particular NICE now uses GRADE<sup>10</sup> to appraise evidence quality and formally considers whether the magnitude of any difference between treatments is clinically important, rather than whether it is statistically significant. More specifically, many of the studies included in the 2009 guideline used DMARDs that are no longer commonly used in UK practice (for example, ciclosporin). These studies were excluded from the update. In addition, the update included new evidence published after the 2009 guideline. Further, a different approach to the analysis was taken; the update aimed to identify not only which cDMARD strategy was most effective (monotherapy, sequential monotherapy, step-up therapy, step down therapy or parallel combination therapy), but also whether any of the cDMARDs were more or less effective than the others. In contrast, the

2009 guideline compared treatment strategies only, regardless of the particular DMARDs used in those strategies, and combined evidence within each treatment strategy. Other changes included a narrower population (studies were only included if they enrolled people who were DMARD naïve, rather than the only requirement being RA of recent onset, as the committee agreed that was the most important factor for the population of interest), and the exclusion of studies, study arms, or outcome data at particular time points where biological DMARDs formed part of the treatment strategy, due to biologics being outside the scope of the guideline.

Taken together, changes in the review approach, including those outlined above, meant that the evidence base included in the 2018 guideline was quite different to that included in 2009. Unlike in 2009, it was not possible to conduct an NMA or construct an economic model in the 2018 guideline. The results of the 2009 economic model were not considered to be influential by the committee, as they were based on a substantially different evidence base as described above.

The committee emphasised that for all people, the treatment strategy should be adjusted in the event of inadequate response to a particular DMARD monotherapy regimen, informed by the separate 'further treatment' and 'treat-to-target' reviews.

The recommendation to commence treatment as soon as possible was maintained as timing of treatment initiation was not within the scope of this review.

The committee discussed the relative effectiveness of the different DMARDs considered in the evidence review. It was agreed that the evidence review did not show consistent evidence in favour of any particular DMARD over another. In addition, there was no evidence to suggest that the adverse event profiles differed substantially between the different DMARDs.

The only possible exception to this was hydroxychloroguine, which the committee agreed might be a less effective drug based on the evidence reviewed. No clinically important benefit for hydroxychloroquine was seen over placebo in change in function. It was outperformed by methotrexate in terms of function and achieving remission and outperformed by sulfasalazine in radiological progression. In both cases, more people discontinued hydroxychloroguine due to ineffectiveness. That said, it showed no clinically important difference from methotrexate and sulfasalazine and was more effective than placebo, in terms of pain relief. It was also associated with fewer withdrawals due to adverse events than methotrexate, sulfasalazine and placebo. The committee agreed that generally, the choice of DMARD should be left to the discretion of the treating clinician and the person with rheumatoid arthritis. However, given the possibility that hydroxychloroguine may be less effective than other DMARDs, the committee acknowledged that, in many instances, it may not be the most suitable drug. The committee agreed that hydroxychloroquine is a drug that is low in toxicity which people find easier to take as there is no requirement for regular blood monitoring. Reduced side effects were supported by the evidence as withdrawal due to adverse events was the only outcome in which hydroxychloroquine demonstrated benefit over the other DMARDs. The committee suggested that it might therefore be helpful in people with mild disease or in palindromic rheumatoid arthritis and should be considered for this group.

No evidence was found for subcutaneous methotrexate, but the committee agreed that the effects may be superior and side effects fewer than with oral cDMARDs. However, because subcutaneous methotrexate is significantly more expensive than other cDMARD options, the committee was not able to recommend this without evidence of clinical benefit over oral cDMARDs. The committee decided to make a research recommendation to inform future guidance.

On balance, the committee decided that the recommendation should be to offer oral methotrexate, leflunomide or sulfasalazine as DMARD monotherapy, and to consider hydroxycholorquine as an alternative in people with mild or palindromic disease. The

recommendation was worded as a strong recommendation to offer the DMARD therapy rather than consider because DMARDs are the only effective first line treatment for rheumatoid arthritis and there are no alternative treatments that can be considered. This recommendation will not limit the choice of DMARDs, allowing rheumatologists to utilise their expertise and experience when deciding upon the most appropriate treatment with their patient.

#### People at risk of poor outcomes

The committee considered whether the evidence of people with a poor prognosis suggested that they should be treated any differently to the rheumatoid arthritis population as a whole. The committee noted that the evidence for this subpopulation was limited to a single study where 2 forms of parallel combination therapy were compared with each other and with step-up therapy. Most of the outcomes were of low or very low quality, and showed no clinical difference between the 2 strategies. Where a clinically important difference was seen between the strategies, it did not consistently favour one strategy over the other (for example, a small clinically important benefit for step-up therapy was seen in terms of radiological progression, and a small clinical benefit for parallel combination therapy over step-up therapy was seen for function assessed using HAQ). The data tended to have wide confidence intervals, which in some instances, ranged from a benefit of combination therapy to a benefit of step-up therapy. Similarly, there was no consistent evidence suggesting that a methotrexate and sulfasalazine combination therapy performed better or worse than a methotrexate and leflunomide combination in this subgroup.

The committee decided that this evidence did not support a recommendation to treat people with a poor prognosis any differently to the general rheumatoid arthritis population. As in all people with rheumatoid arthritis, the treatment strategy and/or DMARDs used should be adjusted in the event of inadequate response to a particular DMARD monotherapy regimen. The committee agreed that dose escalation and treatment to target should ensure that people with a poor prognosis receive effective DMARD treatment.

#### **Further treatment**

The data from the 4 RCTs provided evidence that after failing a DMARD, adding another DMARD ('step-up therapy') yielded better clinical results than replacing the DMARD ('sequential monotherapy') based on the differences in DAS, ACR50 response and low disease activity. However, some of the other important outcomes did not consistently show a difference between the interventions (for example, HAQ and pain), and the number of dropouts due to adverse events was lower in sequential monotherapy compared to step-up therapy in some trials. The committee agreed improvement in various disease activity measures was most important, as seen with step-up therapy. While the difference between the treatment strategies was not as consistent for other outcomes, there were no clinical outcomes for which sequential monotherapy performed better than step-up therapy.

A similar pattern was observed across the trials using different DMARDs, suggesting that it is not necessarily the choice of drug that leads to improvement in outcomes but rather the therapy strategy. The committee therefore agreed not to make a recommendation on which DMARD should be used after inadequate response to monotherapy; instead, the committee emphasised the treatment strategy.

Therefore in the event of inadequate response to monotherapy, the committee decided to recommend a step-up approach (adding another DMARD) rather than replacing the DMARD to which there had been insufficient response initially (sequential monotherapy). The committee acknowledged the possibility of increased adverse events when using step-up therapy rather than sequential monotherapy, but the committee considered that these could be managed, and often avoided, by appropriate drug monitoring; the committee thought that the clinical benefit outweighed this risk. For people who have experienced adverse events on

monotherapy or are at an increased risk of adverse events, switching to an alternative monotherapy may be preferable to adding a second drug.

The committee agreed that the selection of DMARD should be determined on a case-bycase basis, similar to the selection of first-line therapy.

#### 1.8.2 Cost effectiveness and resource use

Two health economic analyses were identified for first-line DMARD therapy. One was the cost-utility analysis that was conducted as part of the 2009 NICE rheumatoid arthritis guideline. This analysis compared 6 different strategies or regimens of conventional DMARD; only 5 of these comparators met the review protocol and were therefore reported. These were monotherapy, parallel combination, step-down combination and intensive step-up combination. The analysis found that step-down combination was the most cost-effective strategy for people who are newly diagnosed and DMARD naïve. This analysis was assessed as partially applicable with potentially serious limitations. This model did not specify DMARDs but rather refers to treatment strategies, although authors note that a systematic review of monotherapy conducted for the 2009 guideline found no statistically significant difference between DMARDs. EQ-5D was mapped from HAQ rather than directly elicited from people in trials. In terms of methodology, the key limitation was that this analysis is based on 5 of the 22 studies included in the clinical review. Furthermore, it includes 8 studies that were not included in the clinical review; therefore, it does not reflect the full body of evidence and may provide treatment effect estimates that do not reflect those identified in the clinical review. The committee agreed that the results of this analysis were not helpful in terms of evaluating which strategy would be most cost-effective.

The second study included was a cost-utility analysis of the BeST RCT. This analysis included 4 comparators but only 2 were reported, as the others did not meet the review protocol. The comparators reported were sequential monotherapy and step-up combination. Step-up combination dominated sequential monotherapy; that is, it was less costly and more effective. This analysis was assessed as partially applicable with potential serious limitations. The applicability of the analysis was downgraded primarily due to the Dutch healthcare perspective and lack of inclusion of comparison of all possible treatment combinations identified in the clinical evidence. In terms of methodological limitations, the follow-up was only 2 years, which was deemed unlikely to be sufficient to capture all downstream costs and treatment effects. Dutch unit costs may not reflect current NHS costs. Finally, this analysis is based on 1 of the 22 studies included for this question and so does not reflect the full body of evidence.

No health economic analyses were identified for second-line DMARD therapy.

The unit costs of individual conventional DMARDs were presented to the committee. These did not differ significantly (between £39 and £164 per year), with the exception of subcutaneous methotrexate. No clinical evidence in support of the use of subcutaneous methotrexate was identified, so no clinical recommendation was made. In addition to these drug costs, an estimate of the cost of drug monitoring was presented as well as the schedule for drug monitoring recommended by the British Society for Rheumatology and British Health Professionals in Rheumatology. The cost of monitoring, particularly in the first year, is likely to be greater than the drugs themselves but does not differ significantly between different conventional DMARDs or whether 1 or more conventional DMARDs are being prescribed.

The committee considered that the clinical evidence showed no evidence of superiority of any particular strategy or any individual drug for first-line therapy. As a result, the committee agreed to recommend monotherapy as the first-line approach, as this would achieve similar outcomes to combination treatment at a lower cost. The committee considered, however, the importance of frequently monitoring people receiving DMARDs to ensure outcomes are achieved (either remission or low disease activity score). The committee highlighted the importance of reflecting individual patient needs and agreed that if a person is not achieving their target, then a step-up approach is required, whereby the dose is escalated or additional, conventional DMARDs are added. The committee noted that this approach is not unusual and would not be a significant shift in current practice. This is also supported in part by the BeST trial economic analysis.

All other recommendations were ones that were carried over from the previous guideline in 2009. This includes considering reducing doses of conventional DMARDs in those who have a sustained and satisfactory level of disease activity.

Overall, it is not considered that these recommendations will have a significant impact on NHS resources. The committee do not think the previous guideline recommendation to initiate combination conventional DMARDs was being implemented nationally. This is partially due to reluctance to start on combination DMARDs. When combination DMARDs are initiated, there may be more adverse events that are difficult to attribute to a particular DMARD and are costly for the NHS to manage. Although in some areas prescribing conventional DMARDs for people newly diagnosed with rheumatoid arthritis may reduce, overall the committee considered it is likely to remain unchanged.

#### 1.8.3 Other factors the committee took into account

The 2009 guideline recommended that where a person's disease was adequately controlled, it may be appropriate to reduce drug doses or stop treatment with 1 or more DMARDs. While this area was not the focus of these update reviews, the committee noted that many of the included studies did allow or require tapering of drugs once the treatment target was achieved.

The committee agreed that reducing DMARD doses or tapering drugs in a step-down strategy may be appropriate in people who have maintained the treatment target (remission or low disease activity) for at least one year, without requiring glucocorticoid treatment in that time. The committee decided that this should be a 'consider' recommendation, as there are possible risks and benefits to be assessed on a case-by-case basis. Factors to consider would include the previous degree of response to the drug to be reduced or withdrawn and the severity of the person's disease prior to treatment. The committee noted that no evidence was found for subcutaneous methotrexate. The committee's view was that the effects are more immediate when administering via this route and there are reduced side effects. However, given it is significantly more expensive than the other DMARD options, without evidence demonstrating greater effectiveness, the committee was unable to provide advice about its use. It was agreed that this is an important topic for a research recommendation, as it may be a better option for some people who have failed to adequately respond to conventional DMARDs administered orally, especially if the alternative is progression to biologic DMARDs.

The management of rheumatoid arthritis in pregnancy was identified as an equalities issue in the equalities impact assessment. The committee agreed that it should be an individualised and consultant-led service, with involvement of obstetric services and broader rheumatology MDT as indicated. Patients and their rheumatology team need to consider many aspects of each individual patient's care. These include pre-conception advice and management of pharmacological therapies, assessment of potential impact of disease on the pregnancy, advice on disease course during pregnancy, and discussions regarding the disease and its treatment in the post-partum period. Particular attention should be paid to therapeutic management of rheumatoid arthritis, especially conventional DMARDs and biologic DMARDs, to ensure potentially teratogenic therapies are not continued in the pre-conception stage or into early pregnancy. Alternative management strategies should be considered, depending on each patient's level of disease control and symptoms, for the duration of the pregnancy.

# 2 Further treatment after first line DMARD treatment failure

2.1 Review questions:

In adults with RA who have had an inadequate response to, or failed treatment with, one or more conventional DMARDs, which conventional DMARDs (alone or combined) are most clinically and cost effective as subsequent treatments?

In adults with RA who have had an inadequate response to, or failed treatment with, one or more conventional DMARDs, which DMARD treatment strategy (monotherapy, sequential monotherapy, parallel combination therapy, step up therapy or step down therapy) is most clinically and cost effective as subsequent treatment?

## 2.2 Introduction

DMARDs suppress disease activity and slow down radiological progression in rheumatoid arthritis, resulting in symptom improvement and reduced long-term disability. There are several conventional DMARDs that can either be prescribed as stand-alone monotherapy or combined. Treatment strategies include monotherapy, sequential monotherapy, parallel combination therapy, step-up therapy, and step-down therapy. At present it is unclear which DMARD or which DMARD treatment strategy is the most effective, both for newly diagnosed rheumatoid arthritis and further treatment.

## 2.3 PICO table

For full details, see the review protocol in appendix A.

Table 23: PICO C	naracteristics of review question
Population	Adults with RA who have failed one or more conventional DMARDs
Interventions	Methotrexate (oral; MTX oral)
	<ul> <li>Methotrexate (subcutaneous; MTX sc)</li> </ul>
	Hydroxychloroquine (HCQ)
	Sulfasalazine (SSZ)
	Leflunomide (LFN)
	Combinations of the above
	<ul> <li>Sequential combinations of the above</li> </ul>
	Study treatment arms will be classified into one of the following classes:
	<ul> <li>Monotherapy (a single DMARD used for the duration of the trial)</li> </ul>

#### Table 23: PICO characteristics of review question

	<ul> <li>Sequential monotherapy (a single DMARD replaced with a different single DMARD in the case of inadequate response)</li> </ul>
	<ul> <li>Parallel combination (two or more DMARDS commenced at the same time without a step-down strategy)</li> </ul>
	<ul> <li>Step up (commencing with a single DMARD, followed by the addition of further DMARD(s) in the case of inadequate response)</li> </ul>
	Step down (two or more DMARDs commenced at the same time, with drug doses and/or number of drugs reduced once disease is adequately controlled)
Comparisons	The above drugs will be compared against each other or against placebo.
Outcomes	CRITICAL • Disease Activity Score (continuous) at 6 and 12 months • Quality of life (continuous) at 6 and 12 months • Function (continuous) at 6 and 12 months
	<ul> <li>IMPORTANT</li> <li>Low disease activity (dichotomous) at 6 and 12 months</li> <li>Remission (dichotomous) at 6 and 12 months</li> <li>ACR50 response (dichotomous) at 6 and 12 months</li> <li>Pain (continuous) at 6 and 12 months</li> <li>Radiological progression (continuous) at 12 months</li> <li>Adverse events – mortality (dichotomous) at longest reported time point</li> <li>Withdrawal due to adverse events (dichotomous) at longest reported time point</li> <li>Withdrawal due to inefficacy (dichotomous) at longest reported time point</li> </ul>
Study design	RCTs Systematic Review / Network Meta-Analysis of RCTs

## 2.4 Methods and process

This evidence review was developed using the methods and process described in Developing NICE guidelines: the manual.<sup>10</sup> Methods specific to this review question are described in the review protocol in appendix A.

Declarations of interest were recorded according to NICE's 2014 conflicts of interest policy.

## 2.5 Clinical evidence

#### 2.5.1 Included studies

A search was conducted for randomised controlled trials and systematic reviews of randomised controlled trials comparing conventional DMARDs with each other following inadequate response to treatment with one or more conventional DMARDs in adults with rheumatoid arthritis. Four studies (5 papers) were included in the review;<sup>19,34,56,168,48</sup> these are summarised in Table 2 below. The studies reported populations who had failed to response to a variety of monotherapies and were subsequently prescribed a range of different DMARD treatments as either sequential monotherapy or step-up therapy:

• Two studies reported on people who had failed sulfasalazine monotherapy that were subsequently treated with either step-up therapy (a combination of methotrexate and sulfasalazine) or sequential monotherapy (replacement with methotrexate)

- One study treated people who had failed leflunomide monotherapy with either stepup therapy (combination of leflunomide and sulfasalazine) or sequential monotherapy (sulfasalazine)
- One study treated people who had failed methotrexate monotherapy with either step-up therapy (combination of methotrexate and sulfasalazine, with the further addition of hydroxychloroquine if continued inadequate response) or sequential monotherapy (sulfasalazine, replaced by leflunomide if continued inadequate response)

Evidence from these studies is summarised in the clinical evidence summary below (Table 25).

See also the study selection flow chart in appendix C, study evidence tables in appendix D, forest plots in appendix E and GRADE tables in appendix H.

#### 2.5.2 Excluded studies

See the excluded studies list in appendix I.

#### 2.5.3 Summary of clinical studies included in the evidence review

	Intervention and			
Study	comparison	Population	Outcomes	Comments
Capell 2007 <sup>19</sup>	Methotrexate plus sulfasalazine (n=56) versus methotrexate plus placebo (n=54)	Adults with active rheumatoid arthritis (RA; DAS >2.4) for whom sulfasalazine monotherapy failed age (mean): 55	<ul> <li>DAS at 12 months</li> <li>Health Assessment Questionnaire (HAQ) at 12 months</li> <li>ACR50 response at 12 months</li> <li>Withdrawal due to side effects at 12 months</li> <li>Withdrawal due to inefficacy at 12 months</li> </ul>	People who failed Sulfasalazine after 6 months of treatment (DAS≥2.4) were randomised to three treatment arms for 12 months: either sulfasalazine alone, methotrexate alone, or a combination of the two. Only the data of the latter two arms are relevant to this review and presented here. Unclear whether people were DMARD naïve before sulfasalazine treatment.
Dougados 2005 <sup>34</sup>	Leflunomide plus sulfasalazine (n=56) versus sulfasalazine plus placebo (n=50)	Adults with active RA and inadequate DAS28 response to leflunomide monotherapy Age (mean): 56	<ul> <li>HAQ change at 24 weeks</li> <li>Pain intensity change at 24 weeks</li> <li>ACR50 response at 24 weeks</li> <li>Withdrawal due to adverse events at 24</li> </ul>	People who had failed leflunomide monotherapy after 24 weeks open label phase were randomised to leflunomide plus sulfasalazine or sulfasalazine for 24 weeks. At the time of leflunomide

## 2.6 Economic evidence

#### 2.6.1 Included studies

No relevant health economic studies were identified.

#### 2.6.2 Excluded studies

No health economic studies that were relevant to this question were excluded due to assessment of limited applicability or methodological limitations.

See also the health economic study selection flow chart in appendix G.

#### 2.6.3 Unit costs

#### Table 28: UK costs of conventional DMARDs

Dosage	Cost – annual
Max. 20mg weekly	£39.49
Max. 25 mg weekly	£960.96
200-400mg daily	£45.38
Max. 2-3g daily	£164.39
10-20mg	£92.94
	Max. 20mg weekly Max. 25 mg weekly 200-400mg daily Max. 2-3g daily

Sources: Dosage: BNF March 2017<sup>11</sup>; Unit cost: NHS Drug Tariff, March 2017.<sup>116</sup>

In addition to the cost of the drugs, there are also costs associated with monitoring of conventional DMARDs.

NICE technology appraisal TA375 has estimated that the monthly cost of monitoring methotrexate to be £134. This cost includes a full blood count, biochemical profile and a hospital outpatient appointment.

The British Society for Rheumatology and British Health Professionals in Rheumatology published a guideline for prescription and monitoring of non-biologic DMARDs in 2017. The standard laboratory-monitoring schedule recommended is nine monitoring blood tests in first 12 months. The blood tests include full blood count, creatinine/calculated GFR, ALT and/or AST and albumin. Table 22 below outlines a summary of monitoring requirements for each drug.

#### Table 29: Monitoring of conventional DMARDs

Drug	Laboratory monitoring	Other monitoring
Methotrexate	Standard monitoring schedule	None
Hydroxychloroquine	No routine laboratory monitoring	Annual eye assessment if continued >5 years
Sulfasalazine	Standard monitoring schedule for 12 months, then no routine monitoring needed	None
Leflunomide	Standard monitoring schedule	Blood pressure and weight at each monitoring visit

Source: BSR and BHPR monitoring guideline 201793

## 2.7 Resource costs

The recommendations made in this review are not expected to have a substantial impact on resources.

## 2.8 Evidence statements

#### 2.8.1 Clinical evidence statements

• Step-up therapy (sulfasalazine plus leflunomide) versus sequential monotherapy (sulfasalazine plus placebo) in people who failed leflunomide monotherapy

Evidence from 1 study showed no clinically important difference between the therapies in terms of function and pain; however step-up therapy was associated with a clinically important benefit in terms of ACR50 response and withdrawal due to inefficacy. A clinically significant reduction in people on sequential monotherapy withdrawing due to side effects (low to very low quality; n=106). No evidence was available for disease activity or quality of life.

• Step-up therapy (methotrexate plus sulfasalazine) versus sequential monotherapy (methotrexate) in people who failed sulfasalazine monotherapy

Evidence from 1 study showed a clinically important benefit of step-up therapy over sequential monotherapy alone on function, pain and ACR50 response (2 studies, moderate to very low quality; range of n=40-110). Evidence for step-up therapy on disease activity was inconsistent, with the 6 month outcome showing a clinically important benefit associated with step-up therapy, but the 12 month outcome finding no clinically important difference (2 studies; range of n=40-110; moderate quality).No clinically importance difference was seen between the therapies for withdrawal due to side effects or inefficacy. No evidence was available for quality of life.

• Step-up therapy (methotrexate plus sulfasalazine, then adding hydroxychloroquine) versus sequential monotherapy (sulfasalazine, then replacing with leflunomide) in people who failed methotrexate monotherapy

Evidence from 1 study showed a clinically important benefit of step-up therapy in terms of low disease activity after the second 'step' of the protocol and over the full trial period. Withdrawal due to inefficacy after the second step in the protocol also showed a clinically important benefit in favour of step-up therapy. No clinically importance difference was seen between the therapies in terms of low disease activity or withdrawal due to inefficacy after the first step of the protocol. Sequential monotherapy was associated with fewer withdrawals due to adverse events after the first step of the protocol and over the full trial period, though no clinically important difference was seen after the second step of the protocol (low to very low quality, n=138). No evidence was available for disease activity, quality of life or function.

#### 2.8.2 Health economic evidence statements

• No relevant economic evaluations were identified.

## 2.9 The committee's discussion of the evidence

#### 2.9.1 Interpreting the evidence

#### 2.9.1.1 The outcomes that matter most

The outcomes were the same across both reviews. The critical outcomes were agreed to be the Disease Activity Score (DAS), quality of life and function.

The important outcomes were agreed as the number of people achieving remission and low disease activity, using DAS thresholds. The committee agreed that data reported in this format are not as informative as continuous DAS data but still give an indication of symptom relief and disease activity improvement. Other important outcomes were mortality, the number of people who withdrew from trial due to adverse events or inefficacy, ACR50 response, as well as the level of pain and radiographic progression.

For most outcomes, 6- and 12-month data was sought to determine the short-term and longer-term benefits of different DMARDs and treatment strategies. The benefits in terms of radiographic progression were not expected earlier than 12 months and that outcome was restricted to data after 12 months or more of treatment. For mortality and withdrawal from trial, data covering the duration of the trial were sought.

In the first-line treatment review, no data were available for quality of life at 6 months. Some data were available for all other outcomes, though this was obtained across 16 different comparisons and so within each comparison there were significant gaps in the outcome data available for each DMARD.

In the further treatment review, no data were available for the outcomes of mortality, radiological progression, remission and quality of life.

#### 2.9.1.2 The quality of the evidence

#### **First-line treatment**

This review included 21 studies of first-line DMARD treatment, which spanned 17 comparisons of a range of different monotherapy, sequential monotherapy, parallel combination therapy, step-down therapy and step-up therapy regimens. Most of studies compared different treatment regimens or reported different outcomes. Because of these differences, it was not possible to perform an NMA to compare all drugs and strategies to each other. It was not possible to create a strong, connected network using any of the outcomes the committee prioritised (such as DAS, ACR50 response, DAS remission or DAS low disease activity). Any network that could be connected was considered too limited in both the comparisons included (key comparators were not connected) and the amount of evidence for each comparison (data from only 1 study was available for each comparison) to inform a recommendation which DMARD or strategy to recommend.

A standard pair-wise meta-analysis was performed, though it was still not possible to pool much of the evidence due to the differences in treatment regimens and outcomes reported. In addition, where evidence was pooled, the committee noted there was variation in the DMARD doses and titration regimes used and variable use of glucocorticoids which could have influenced the relative effectiveness of the different regimens.

The quality of the evidence was varied, ranging from high to very low quality, with the majority of the outcomes graded either low or very low quality. The failure to blind participants and outcome assessors was a common source of risk of bias in the included

studies, as many of the outcomes (including all of the critical outcomes) had a subjective element and therefore their scoring could be affected by knowledge of the treatment allocation. The other area where risk of bias was common was in terms of selection bias. Studies often failed to report allocation concealment or the method used to randomise people to treatment groups. Missing data also contributed as a source of risk of bias for many comparisons, in that significant numbers of participants left the trial, which could affect the reliability of the results. In addition, much of the evidence for each comparison was from single trials, leading to wide confidence intervals and uncertainty about whether a particular drug or strategy was more effective than another. <u>People with a poor prognosis</u>

The committee had identified people with a poor prognosis as a population stratum to establish whether a different treatment strategy or different DMARDs should be used. People with a poor prognosis were considered to be those with one or more of the key prognostic factors identified in a separate review, which were anti-CCP positive status and the presence of erosions at baseline. Only 1 study was identified in people with a poor prognosis, which studied people identified as "high risk" due to erosions, rheumatoid factor, anti-CCP and disease activity. Similarly to the rest of the review, evidence was of low to very low quality due to risk of bias and imprecision. The main risk of bias issues stemmed from a lack of blinding and no reporting of adequate allocation concealment.

#### **Further treatment**

This review included 4 studies, all of which reported people who had an insufficient response to a specific DMARD monotherapy and were then treated by either adding another DMARD in a step-up strategy or switching to another DMARD monotherapy. While all participants in each study had previously been treated with the same DMARD, in some of the studies, people had tried (and presumably not responded to) a number of DMARDs *prior to* that specific DMARD. The committee acknowledged this was a limitation of the evidence base, as the populations were mixed. However, 1 of the 4 studies avoided this issue by recruiting and following people who were DMARD-naïve as they progressed through various treatment strategies. As the results of this study were consistent with the results of the other studies, the committee considered all of the evidence to be direct and relevant to the review question.

The evidence quality was variable, ranging from moderate to very low quality across the outcomes and comparisons. Most of the evidence could not be pooled as the studies enrolled different populations, compared different drugs or treatment regimens or reported different outcomes. The evidence was generally at very high or high risk of bias due to incomplete outcome data (for example, unexplained or high numbers of missing data) and lack of blinding in the studies; only withdrawal due to adverse events, reported in 1 study, was at low risk of bias. One of the studies was also a post-hoc analysis of a subset of participants from an RCT, which was considered a further source of potential bias.

Further, for some of the important outcomes, there were small numbers of participants and low numbers of events, resulting in wide confidence intervals, meaning there was some uncertainty as to which treatment approach was superior.

#### 2.9.1.3 Benefits and harms

#### **First-line treatment**

The evidence demonstrated benefits for DMARD monotherapy compared to placebo and furthermore, when compared to parallel combination of 2 DMARDS monotherapy was equally effective or in some cases, demonstrated better results in terms of function and withdrawal due to adverse events. The remainder of the critical outcomes often showed no clinical difference between treatment arms; however where benefit was seen, it was not generalisable to a specific strategy. Similarly, the important outcomes did not uniformly support a treatment regimen; benefits were seen at times for varying strategies. Overall, the

committee did not consider that the evidence indicated consistent benefits of any specific treatment strategy over another.

The committee reviewed the recommendations from the 2009 guideline, which recommended combination therapy on the basis of a network meta-analysis (NMA) and accompanying economic model. The committee concluded that the updated evidence review did not support the use of multiple DMARDs in combination as first-line treatment as there was no convincing evidence that it was more effective than monotherapy, and benefits were seen for monotherapy compared to placebo in terms of radiological progression, quality of life and reduction in pain. The committee also agreed that monotherapy would have fewer side effects than combination therapy, and starting with monotherapy would eliminate the challenge of identifying which drugs were causing side effects. It was therefore agreed that people newly diagnosed with rheumatoid arthritis should be offered DMARD monotherapy as first-line treatment.

The committee discussed the reasons for the change in the recommended approach to first line since the 2009 guideline.

Although this review was an update of an existing area of the guideline, the evidence that was included and the approach to analysing that evidence was different. Of note is that the internationally accepted methods for best practice systematic reviewing and appraisal of clinical evidence have changed in that time. In particular NICE now uses GRADE<sup>10</sup> to appraise evidence quality and formally considers whether the magnitude of any difference between treatments is clinically important, rather than whether it is statistically significant. More specifically, many of the studies included in the 2009 guideline used DMARDs that are no longer commonly used in UK practice (for example, ciclosporin). These studies were excluded from the update. In addition, the update included new evidence published after the 2009 guideline. Further, a different approach to the analysis was taken; the update aimed to identify not only which cDMARD strategy was most effective (monotherapy, sequential monotherapy, step-up therapy, step down therapy or parallel combination therapy), but also whether any of the cDMARDs were more or less effective than the others. In contrast, the 2009 guideline compared treatment strategies only, regardless of the particular DMARDs used in those strategies, and combined evidence within each treatment strategy. Other changes included a narrower population (studies were only included if they enrolled people who were DMARD naïve, rather than the only requirement being RA of recent onset, as the committee agreed that was the most important factor for the population of interest), and the exclusion of studies, study arms, or outcome data at particular time points where biological DMARDs formed part of the treatment strategy, due to biologics being outside the scope of the guideline.

Taken together, changes in the review approach, including those outlined above, meant that the evidence base included in the 2018 guideline was quite different to that included in 2009. Unlike in 2009, it was not possible to conduct an NMA or construct an economic model in the 2018 guideline. The results of the 2009 economic model were not [given much weight?] by the committee, as they were based on a substantially different evidence base as described above.

The committee emphasised that for all people, the treatment strategy should be adjusted in the event of inadequate response to a particular DMARD monotherapy regimen, informed by the separate 'further treatment' and 'treat-to-target' reviews.

The recommendation to commence treatment as soon as possible was maintained as timing of treatment initiation was not within the scope of this review.

The committee discussed the relative effectiveness of the different DMARDs considered in the evidence review. It was agreed that the evidence review did not show consistent evidence in favour of any particular DMARD over another. In addition, there was no evidence

to suggest that the adverse event profiles differed substantially between the different DMARDs.

The only possible exception to this was hydroxychloroquine, which the committee agreed might be a less effective drug based on the evidence reviewed. No clinically important benefit for hydroxychloroquine was seen over placebo in change in function. It was outperformed by methotrexate in terms of function and achieving remission and outperformed by sulfasalazine in radiological progression. In both cases, more people discontinued hydroxychloroquine due to ineffectiveness. That said, it showed no clinically important difference from methotrexate and sulfasalazine and was more effective than placebo, in terms of pain relief. It was also associated with fewer withdrawals due to adverse events than methotrexate, sulfasalazine and placebo.

The committee agreed that generally, the choice of DMARD should be left to the discretion of the treating clinician and the person with rheumatoid arthritis. However, given the possibility that hydroxychloroquine may be less effective than other DMARDs, the committee acknowledged that, in many instances, it may not be the most suitable drug. The committee agreed that hydroxychloroquine is a drug that is low in toxicity which people find easier to take as there is no requirement for regular blood monitoring. Reduced side effects were supported by the evidence as withdrawal due to adverse events was the only outcome in which hydroxychloroquine demonstrated benefit over the other DMARDs. The committee suggested that it might be helpful in people with mild disease or in palindromic rheumatoid arthritis and should be considered for this group.

No evidence was found for subcutaneous methotrexate, but the committee agreed that the effects may be superior and side effects fewer than with oral cDMARDs. However, because subcutaneous methotrexate is significantly more expensive than other cDMARD options, the committee was not able to recommend this without evidence of clinical benefit over oral cDMARDs. The committee decided to make a research recommendation to inform future guidance. On balance, the committee decided that the recommendation should be to offer oral methotrexate, leflunomide or sulfasalazine as DMARD monotherapy, and to consider hydroxycholorquine as an alternative in people with mild or palindromic disease. The recommendation was worded as a strong recommendation to offer the DMARD therapy rather than consider because DMARDs are the only effective first line treatment for rheumatoid arthritis and there are no alternative treatments that can be considered. This recommendation will not limit the choice of DMARDs, allowing rheumatologists to utilise their expertise and experience when deciding upon the most appropriate treatment with their patient.

#### People at risk of poor outcomes

The committee considered whether the evidence of people with a poor prognosis suggested that they should be treated any differently to the rheumatoid arthritis population as a whole. The committee noted that the evidence for this subpopulation was limited to a single study where 2 forms of parallel combination therapy were compared with each other and with step-up therapy. Most of the outcomes were of low or very low quality, and showed no clinical difference between the 2 strategies. Where a clinically important difference was seen between the strategies, it did not consistently favour one strategy over the other (for example, a small clinically important benefit for step-up therapy was seen in terms of radiological progression, and a small clinical benefit for parallel combination therapy over step-up therapy was seen for function assessed using HAQ). The data tended to have wide confidence intervals, which in some instances, ranged from a benefit of combination therapy to a benefit of step-up therapy. Similarly, there was no consistent evidence suggesting that a methotrexate and sulfasalazine combination therapy performed better or worse than a methotrexate and leflunomide combination in this subgroup.

The committee decided that this evidence did not support a recommendation to treat people with a poor prognosis any differently to the general rheumatoid arthritis population. As in all

people with rheumatoid arthritis, the treatment strategy and/or DMARDs used should be adjusted in the event of inadequate response to a particular DMARD monotherapy regimen. The committee agreed that dose escalation and treatment to target should ensure that people with a poor prognosis receive effective DMARD treatment.

#### **Further treatment**

The data from the 4 RCTs provided moderate to very low quality evidence that after failing a DMARD, adding another DMARD ('step-up therapy') yielded better clinical results than replacing the DMARD ('sequential monotherapy') based on the differences in DAS, ACR50 response and low disease activity. However, some of the other important outcomes did not consistently show a difference between the interventions (for example, HAQ and pain), and the number of dropouts due to adverse events was lower in sequential monotherapy compared to step-up therapy in some trials. The committee agreed improvement in various disease activity measures was most important, as seen with step-up therapy. While the difference between the treatment strategies was not as consistent for other outcomes, there were no clinical outcomes for which sequential monotherapy performed better than step-up therapy.

A similar pattern was observed across the trials using different DMARDs, suggesting that it is not necessarily the choice of drug that leads to improvement in outcomes but rather the therapy strategy. The committee therefore agreed not to make a recommendation on which DMARD should be used after inadequate response to monotherapy; instead, the committee emphasised the treatment strategy.

In the event of inadequate response to monotherapy, the committee decided to recommend a step-up approach (adding another DMARD) rather than replacing the DMARD to which there had been insufficient response initially (sequential monotherapy). The committee acknowledged the possibility of increased adverse events when using step-up therapy rather than sequential monotherapy, but the committee considered that these could be managed, and often avoided, by appropriate drug monitoring; the committee thought that the clinical benefit outweighed this risk. For people who have experienced adverse events on monotherapy or are at an increased risk of adverse events, switching to an alternative monotherapy may be preferable to adding a second drug.

The committee agreed that the selection of DMARD should be determined on a case-bycase basis, similar to the selection of first-line therapy.

#### 2.9.2 Cost effectiveness and resource use

Two health economic analyses were identified for first-line DMARD therapy. One was the cost-utility analysis that was conducted as part of the 2009 NICE rheumatoid arthritis guideline. This analysis compared 6 different strategies or regimens of conventional DMARD; only 5 of these comparators met the review protocol and were therefore reported. These were monotherapy, parallel combination, step-down combination and intensive step-up combination. The analysis found that step-down combination was the most cost-effective strategy for people who are newly diagnosed and DMARD naïve. This analysis was assessed as partially applicable with potentially serious limitations. This model did not specify DMARDs but rather refers to treatment strategies, although authors note that a systematic review of monotherapy conducted for the 2009 guideline found no statistically significant difference between DMARDs. EQ-5D was mapped from HAQ rather than directly elicited from people in trials. In terms of methodology, the key limitation was that this analysis is based on 5 of the 22 studies included in the clinical review. Furthermore, it includes 8 studies that were not included in the clinical review; therefore, it does not reflect the full body of evidence and may provide treatment effect estimates that do not reflect those identified in the clinical review. The committee agreed that the results of this analysis were not helpful in terms of evaluating which strategy would be most cost-effective.

The second study included was a cost-utility analysis of the BeST RCT. This analysis included 4 comparators but only 2 were reported, as the others did not meet the review protocol. The comparators reported were sequential monotherapy and step-up combination. Step-up combination dominated sequential monotherapy; that is, it was less costly and more effective. This analysis was assessed as partially applicable with potential serious limitations. The applicability of the analysis was downgraded primarily due to the Dutch healthcare perspective and lack of inclusion of comparison of all possible treatment combinations identified in the clinical evidence. In terms of methodological limitations, the follow-up was only 2 years, which was deemed unlikely to be sufficient to capture all downstream costs and treatment effects. Dutch unit costs may not reflect current NHS costs. Finally, this analysis is based on 1 of the 22 studies included for this question and so does not reflect the full body of evidence.

No health economic analyses were identified for second-line DMARD therapy.

The unit costs of individual conventional DMARDs were presented to the committee. These did not differ significantly, with the exception of subcutaneous methotrexate. No clinical evidence in support of the use of subcutaneous methotrexate was identified, so no clinical recommendation was made. In addition to these drug costs, an estimate of the cost of drug monitoring was presented as well as the schedule for drug monitoring recommended by the British Society for Rheumatology and British Health Professionals in Rheumatology. The cost of monitoring, particularly in the first year, is likely to be greater than the drugs themselves but does not differ significantly between different conventional DMARDs or whether 1 or more conventional DMARDs are being prescribed.

The committee considered that the clinical evidence showed no evidence of superiority of any particular strategy or any individual drug for first-line therapy. As a result, the committee agreed to recommend monotherapy as the first-line approach, as this would achieve similar outcomes to combination treatment at a lower cost. The committee considered, however, the importance of frequently monitoring people receiving DMARDs to ensure outcomes are achieved (either remission or low disease activity score). The committee highlighted the importance of reflecting individual patient needs and agreed that if a person is not achieving their target, then a step-up approach is required, whereby the dose is escalated or additional, conventional DMARDs are added. The committee noted that this approach is not unusual and would not be a significant shift in current practice. This is also supported in part by the BeST trial economic analysis.

All other recommendations were ones that were carried over from the previous guideline in 2009. This includes considering reducing doses of conventional DMARDs in those who have a sustained and satisfactory level of disease activity.

Overall, it is not considered that these recommendations will have a significant impact on NHS resources. The committee do not think the previous guideline recommendation to initiate combination conventional DMARDs was being implemented nationally. This is partially due to reluctance to start on combination DMARDs. When combination DMARDs are initiated, there may be more adverse events that are difficult to attribute to a particular DMARD and are costly for the NHS to manage. Although in some areas prescribing conventional DMARDs for people newly diagnosed with rheumatoid arthritis may reduce, overall the committee considered it is likely to remain unchanged.

## 2.9.3 Other factors the committee took into account

The 2009 guideline recommended that where a person's disease was adequately controlled, it may be appropriate to reduce drug doses or stop treatment with 1 or more DMARDs. While this area was not the focus of these update reviews, the committee noted that many of the included studies did allow or require tapering of drugs once the treatment target was achieved.

The committee agreed that reducing DMARD doses or tapering drugs in a step-down strategy may be appropriate in people who have maintained the treatment target (remission or low disease activity) for at least one year, without requiring glucocorticoid treatment in that time. The committee decided that this should be a 'consider' recommendation, as there are possible risks and benefits to be assessed on a case-by-case basis. Factors to consider would include the previous degree of response to the drug to be reduced or withdrawn and the severity of the person's disease prior to treatment. The committee noted that no evidence was found for subcutaneous methotrexate. The committee's view was that the effects are more immediate when administering via this route and there are reduced side effects. However, given it is significantly more expensive than the other DMARD options, without evidence demonstrating greater effectiveness, the committee was unable to provide advice about its use. It was agreed that this is an important topic for a research recommendation, as it may be a better option for some people who have failed to adequately respond to conventional DMARDs administered orally, especially if the alternative is progression to biologic DMARDs.

The management of rheumatoid arthritis in pregnancy was identified as an equalities issue in the equalities impact assessment. The committee agreed that it should be an individualised and consultant-led service, with involvement of obstetric services and broader rheumatology MDT as indicated. Patients and their rheumatology team need to consider many aspects of each individual patient's care. These include pre-conception advice and management of pharmacological therapies, assessment of potential impact of disease on the pregnancy, advice on disease course during pregnancy, and discussions regarding the disease and its treatment in the post-partum period. Particular attention should be paid to therapeutic management of rheumatoid arthritis, especially conventional DMARDs and biologic DMARDs, to ensure potentially teratogenic therapies are not continued in the pre-conception stage or into early pregnancy. Alternative management strategies should be considered, depending on each patient's level of disease control and symptoms, for the duration of the pregnancy.

## Appendices

## **Appendix A: Review protocols**

### Table 30: Review protocol: First-line DMARDs

ID	Field	Content
I	Review question	In adults with RA who are DMARD naïve, which conventional DMARDs (alone or combined) are most clinically and cost effective?
		In adults with RA who are DMARD naïve, which DMARD treatment strategy (monotherapy, sequential monotherapy, parallel combination therapy, step up therapy or step down therapy) is most clinically and cost effective?
П	Type of review	Intervention review.
	question	A review of health economic evidence related to the same review question was conducted in parallel with this review. For details see the health economic review protocol for this NICE guideline.
111	Objective of the review	To establish which conventional DMARDs, and which DMARD treatment strategy, is most clinically and cost effective in adults with newly diagnosed rheumatoid arthritis who are commencing DMARD therapy for the first time.
IV	Eligibility criteria – population /	Adults with RA according to validated classification criteria who are DMARD naïve.
	disease / condition / issue / domain	Studies in patients with prognostic factors indicating that their disease has a poor prognosis will be presented separately.
		Pregnant women will also be treated as a stratum.
V	Eligibility criteria – intervention(s) / exposure(s) / prognostic factor(s)	methotrexate (oral) (MTX oral)
		<ul> <li>methotrexate (subcutaneous) (MTX sc)</li> </ul>
		hydroxychloroquine (HCQ)
		• sulfasalazine (SSZ)
		leflunomide (LFN)     combinations of the above
		<ul><li> combinations of the above</li><li> sequential combinations of the above</li></ul>
		Study treatment arms will be classified into one of the following classes:
		• monotherapy (a single DMARD used for the duration of the trial)
		<ul> <li>sequential monotherapy (a single DMARD replaced with a different single DMARD in the case of inadequate response)</li> </ul>
		<ul> <li>parallel combination (two or more DMARDs commenced at the same time without a step-down strategy)</li> </ul>
		<ul> <li>step-up therapy (commencing with a single DMARD, followed by the addition of further DMARD(s) in the case of inadequate response)</li> </ul>
		<ul> <li>step-down therapy (two or more DMARDs commenced at the same time, with at least one drug tapered and stopped once disease is adequately controlled)</li> </ul>
		Studies will be combined regardless of whether glucocorticoids are used alongside the DMARD therapy.
		Studies using different doses of the same drug will be pooled in the meta-

	Field	Contont
ID	Field	Content analysis where drug doses or dosing strategies are the only difference
		between the study arms.
		Studies using biologic DMARDs or other DMARDs not listed above will be excluded, except where the out-of-scope DMARD is prescribed as part of a step-up treatment strategy and data is available prior to patients reaching that stage of the treatment escalation strategy.
VI	Eligibility criteria – comparator(s) / control or reference (gold) standard	The above drugs will be compared against each other or against placebo.
VII	Outcomes and	CRITICAL
	prioritisation	<ul> <li>Disease Activity Score (DAS) (continuous) at 6 and 12 months</li> <li>Quality of life (for example, EQ5D, SF-36, RA Quality of Life instrument) (continuous) at 6 and 12 months</li> </ul>
		<ul> <li>Function (for example, Health Assessment Questionnaire, activities of daily living) (continuous) at 6 and 12 months</li> </ul>
		IMPORTANT
		<ul> <li>Low disease activity (dichotomous) at 6 and 12 months</li> </ul>
		<ul> <li>Remission (dichotomous) at 6 and 12 months</li> </ul>
		<ul> <li>ACR50 response (dichotomous) at 6 and 12 months</li> </ul>
		<ul> <li>Pain (for example, Visual Analogue Scale) (continuous) at 6 and 12 months</li> </ul>
		<ul> <li>Radiological progression (continuous) at 12 months</li> <li>adverse events – mortality (dichotomous) at longest reported time point</li> </ul>
		<ul> <li>Withdrawal due to adverse events (dichotomous) at longest reported time point</li> </ul>
		<ul> <li>Withdrawal due to inefficacy (dichotomous) at longest reported time point</li> </ul>
VIII	Eligibility criteria – study design	Systematic Review / Network Meta-Analysis (NMA) of RCTs RCTs
IX	Other inclusion exclusion / criteria	Studies in mixed inflammatory arthritis populations will be excluded, unless the results are presented separately for RA patients.
		Studies in patients with RA as well as another rheumatic disease (e.g. lupus) will be excluded.
		Studies that enrol patients who are not explicitly stated to be DMARD naïve will be excluded, except where:
		<ul> <li>the study states that the only DMARD used previously is an antimalarial/HCQ (as HCQ is known to be a weak DMARD); or</li> </ul>
		<ul> <li>previous DMARDs have been used for no longer than 1 month.</li> </ul>
		These populations will be included on the basis that they would not differ substantially from a DMARD naïve population in terms of disease severity or likely response to DMARD treatment.
		Studies in which prior DMARD use is unclear or not reported will be excluded.

ID	Field	Content
X	Proposed sensitivity / subgroup analysis, or meta- regression	<ul> <li>Where a study reports multiple time points, the closest time point to the specified time points (6 months and 12 months) will be extracted.</li> <li>Data reported at time points less than 12 weeks will not be extracted.</li> <li>12 month data will be analysed in an NMA for outcomes prioritised by the committee where there is enough evidence to form treatment loops and sufficient homogeneity of data. The priority outcome for the NMA is DAS, if sufficient data is available. Otherwise, data on ACR50 response, DAS remission or DAS low disease activity may be analysed.</li> <li>The following DMARDs will be included only if necessary to connect the network:</li> <li>Ciclosporingold injections</li> <li>penicillamine</li> <li>azathioprine</li> <li>biologics</li> </ul>
XI	Selection process – duplicate screening / selection / analysis	A sample of at least 10% of the abstract lists were double-sifted by a senior research fellow and discrepancies rectified, with committee input where consensus could not be reached, for more information please see the separate Methods report for this guideline.
XII	Data management (software)	<ul> <li>Pairwise meta-analyses were performed using Cochrane Review Manager (RevMan5).</li> <li>GRADEpro was used to assess the quality of evidence for each outcome.</li> <li>Endnote was used for bibliography, citations, sifting and reference management</li> </ul>
XIII	Information sources – databases and dates	An existing Cochrane review <sup>59,60</sup> by Hazelwood at al. comparing methotrexate monotherapy with methotrexate in combination with other DMARDs formed the basis of the evidence review The included studies in that review were checked against the agreed evidence review protocol. Searches were also conducted for randomised controlled trials and systematic reviews. Firstly the Cochrane review search strategy was re- run to identify relevant trials published since the date of the Cochrane review searches and secondly a search was conducted to identify additional trials of non-methotrexate monotherapies and combinations, as well as strategy trials, that would not have been included in the Cochrane review. Clinical search databases: Medline, Embase and the Cochrane Library. Date limits for search: None Language: English Health economics search databases: Medline, Embase, NHSEED and
		HTA Date limits for search: Medline and Embase from 2014 NHSEED and HTA from 2001 Language: English
XIV	Identify if an update	This review is an update of a clinical area covered in NICE guideline: Rheumatoid arthritis in adults: management <sup>111</sup> published in 2009. However the protocol for this updated review differed from the previous review and thus the search was undertaken for all years.

# Table 31: Review protocol: Conventional DMARDs for rheumatoid arthritis – subsequent lines of treatment

ID	Field	Content
I	Review question	In adults with RA who have had an inadequate response to, or failed treatment with, one or more conventional DMARDs, which conventional DMARDs (alone or combined) are most clinically and cost effective as subsequent treatment?
		In adults with RA who have had an inadequate response to, or failed treatment with, one or more conventional DMARDs, which DMARD treatment strategy (monotherapy, sequential monotherapy, parallel combination therapy, step up therapy or step down therapy) is most clinically and cost effective as subsequent treatment?
II	Type of review question	Intervention review A review of health economic evidence related to the same review question was conducted in parallel with this review. For details see the health economic review protocol for this NICE guideline.
III	Objective of the review	To establish which conventional DMARDs, and which DMARD treatment strategy, is most clinically and cost effective in adults with rheumatoid arthritis who have already failed or inadequately responded to ("failed") one or more DMARDs.
IV	Eligibility criteria – population / disease / condition / issue / domain	Adults with RA according to validated classification criteria who have failed one or more conventional DMARDs. The review population will be stratified based on the particular DMARD(s) failed by the population enrolled in the trial.
		Pregnant women will also be treated as a stratum.
V	Eligibility criteria – intervention(s) / exposure(s) / prognostic factor(s)	methotrexate (oral) (MTX oral) methotrexate (subcutaneous) (MTX sc) hydroxychloroquine (HCQ) sulfasalazine (SSZ) leflunomide (LFN) combinations of the above sequential combinations of the above
		<ul> <li>Study treatment arms will be classified into one of the following classes:</li> <li>monotherapy (a single DMARD used for the duration of the trial)</li> <li>sequential monotherapy (a single DMARD replaced with a</li> </ul>

ID	Field	Content
		<ul> <li>different single DMARD in the case of inadequate response)</li> <li>parallel combination (two or more DMARDs commenced at the same time without a step-down strategy)</li> <li>step-up therapy (commencing with a single DMARD, followed by the addition of further DMARD(s) in the case of inadequate response)</li> <li>step-down therapy (two or more DMARDs commenced at the same time, with at least one drug tapered and stopped once disease is adequately controlled)</li> <li>Studies will be combined regardless of whether glucocorticoids are used alongside the DMARD therapy.</li> <li>Studies using different doses of the same drug will be pooled in the meta-analysis where drug doses or dosing strategies are the only difference between the study arms.</li> <li>Studies using biologic DMARDs or other DMARDs not listed above will be excluded, except where the out-of-scope DMARD is prescribed as part of a step-up treatment strategy and data is available prior to patients reaching that stage of the treatment escalation strategy.</li> </ul>
VI	Eligibility criteria – comparator(s) / control or reference (gold) standard	The above drugs will be compared against each other or against placebo.
VII	Outcomes and prioritisation	<ul> <li>CRITICAL</li> <li>Disease Activity Score (DAS or DAS28) (continuous) at 6 and 12 months</li> <li>Quality of life (for example, EQ5D, SF-36, RA Quality of Life instrument) (continuous) at 6 and 12 months</li> <li>Function (for example, Health Assessment Questionnaire, activities of daily living) (continuous) at 6 and 12 months.</li> <li>IMPORTANT</li> <li>Low disease activity (dichotomous) at 6 and 12 months</li> <li>Remission (dichotomous) at 6 and 12 months</li> <li>ACR50 response (dichotomous) at 6 and 12 months</li> <li>Pain (for example, Visual Analogue Scale) (continuous) at 6 and 12 months</li> <li>Radiological progression (continuous) at 12 months</li> <li>Adverse events – mortality (dichotomous) at longest reported time point</li> <li>Withdrawal due to inefficacy (dichotomous) at longest reported time point</li> </ul>
VIII	Eligibility criteria – study design	Systematic Review / Network Meta-Analysis (NMA) of RCTs RCTs
IX	Other inclusion exclusion criteria	Studies in mixed inflammatory arthritis populations will be excluded, unless the results are presented separately for RA patients.

ID	Field	Content
		Studies in patients with RA as well as another rheumatic disease (e.g. lupus) will be excluded.
		Studies where the enrolled patients have not all failed the same DMARD(s) will be excluded (for example, where some patients have failed MTX and others have failed SSZ).
х	Proposed sensitivity / subgroup	Where a study reports multiple time points, the closest time point to the specified time points (6 and 12 months) will be extracted.
	analysis, or meta-	Data reported at time points less than 12 weeks will not be extracted.
	regression	Data may be considered for analysis in an NMA for outcomes prioritised by the committee if there is enough evidence to form treatment loops and sufficient homogeneity of data within a specific population stratum. The priority outcome for the NMA is DAS, if sufficient data is available. Otherwise, data on ACR50 response, DAS remission or DAS low disease activity may be analysed.
		The following DMARDs will be included only if necessary to connect the network:
		Ciclosporingold injections
		penicillamine azathioprine biologics
XI	Selection process – duplicate screening / selection / analysis	A sample of at least 10% of the abstract lists were double-sifted by a senior research fellow and discrepancies rectified, with committee input where consensus could not be reached. For more information please see the separate Methods report for this guideline.
XII	Data management	<ul> <li>Pairwise meta-analyses were performed using Cochrane Review Manager (RevMan5).</li> </ul>

### Table 32: Health economic review protocol

	Review question	All questions – health economic evidence
Ī	Objectives	To identify health economic studies relevant to any of the review questions.
	Search criteria	Populations, interventions and comparators must be as specified in the clinical review protocol above.
		Studies must be of a relevant health economic study design (cost–utility analysis, cost-effectiveness analysis, cost–benefit analysis, cost–consequences analysis, comparative cost analysis).
		Studies must not be a letter, editorial or commentary, or a review of health economic evaluations. (Recent reviews will be ordered although not reviewed. The bibliographies will be checked for relevant studies, which will then be ordered.) Unpublished reports will not be considered unless submitted as part of a call for
		evidence. Studies must be in English.
	Search strategy	A health economic study search will be undertaken using population-specific terms and a health economic study filter – see appendix B below.
	Review strategy	Studies not meeting any of the search criteria above will be excluded. Studies published before 2001, abstract-only studies and studies from non-OECD countries or the USA will also be excluded.
		Each remaining study will be assessed for applicability and methodological limitations using the NICE economic evaluation checklist which can be found in appendix H of Developing NICE guidelines: the manual (2014).112
		Inclusion and exclusion criteria
		If a study is rated as both 'Directly applicable' and with 'Minor limitations' then it will be included in the guideline. A health economic evidence table will be completed and it will be included in the health economic evidence profile.
		If a study is rated as either 'Not applicable' or with 'Very serious limitations' then it will usually be excluded from the guideline. If it is excluded then a health economic evidence table will not be completed and it will not be included in the health economic evidence profile.
		If a study is rated as 'Partially applicable', with 'Potentially serious limitations' or both then there is discretion over whether it should be included.
		Where there is discretion
		The health economist will make a decision based on the relative applicability and quality of the available evidence for that question, in discussion with the guideline committee if required. The ultimate aim is to include health economic studies that are helpful for decision-making in the context of the guideline and the current NHS setting. If several studies are considered of sufficiently high applicability and methodological quality that they could all be included, then the health economist, in discussion with the committee if required, may decide to include only the most applicable studies and to selectively exclude the remaining studies. All studies excluded on the basis of applicability or methodological limitations will be listed with explanation in the excluded health economic studies appendix below.

Review question	All questions – health economic evidence
	The health economist will be guided by the following hierarchies. Setting:
	UK NHS (most applicable).
	OECD countries with predominantly public health insurance systems (for example, France, Germany, Sweden).
	OECD countries with predominantly private health insurance systems (for example, Switzerland).
	Studies set in non-OECD countries or in the USA will be excluded before being assessed for applicability and methodological limitations.
	Health economic study type:
	Cost–utility analysis (most applicable).
	Other type of full economic evaluation (cost–benefit analysis, cost-effectiveness analysis, cost–consequences analysis).
	Comparative cost analysis.
	Non-comparative cost analyses including cost-of-illness studies will be excluded before being assessed for applicability and methodological limitations. Year of analysis:
	The more recent the study, the more applicable it will be.
	Studies published in 2001 or later but that depend on unit costs and resource data entirely or predominantly from before 2001 will be rated as 'Not applicable'. Studies published before 2001 will be excluded before being assessed for applicability and methodological limitations.
	Quality and relevance of effectiveness data used in the health economic analysis: The more closely the clinical effectiveness data used in the health economic analysis match with the outcomes of the studies included in the clinical review the more useful the analysis will be for decision-making in the guideline.

## Appendix B: Literature search strategies

Searches were constructed using a PICO framework where population (P) terms were combined with Intervention (I) and in some cases Comparison (C) terms. Outcomes (O) are rarely used in search strategies for interventions as these concepts may not be well described in title, abstract or indexes and therefore difficult to retrieve. Search filters were applied to the search where appropriate.

Database	Dates searched	Search filter used
Medline (Ovid)	1946 – 06 October 2017	Exclusions Randomised controlled trials Systematic review studies
Embase (Ovid)	1974 – 06 October 2017	Exclusions Randomised controlled trials Systematic review studies
The Cochrane Library (Wiley)	Cochrane Reviews to 2017 Issue 10 of 12 CENTRAL to 2017 Issue 9 of 12 DARE, and NHSEED to 2015 Issue 2 of 4	None

## **B.1 Health Economics literature search strategy**

Health economic evidence was identified by conducting a broad search relating to rheumatoid arthritis population in NHS Economic Evaluation Database (NHS EED – this

ceased to be updated after March 2015) and the Health Technology Assessment database (HTA) with no date restrictions. NHS EED and HTA databases are hosted by the Centre for Research and Dissemination (CRD). Additional searches were run on Medline and Embase for health economics studies.

Table 34. Database date parameters and inters used			
Database	Dates searched	Search filter used	
Medline	2014 – 06 October 2017	Exclusions Health economics studies	
Embase	2014– 06 October 2017	Exclusions Health economics studies	
Centre for Research and Dissemination (CRD)	HTA - 2001 – 06 October 2017 NHSEED - 2001 – 31 March 2015	None

# Figure 2: Flow chart of clinical study selection for two reviews of first line and further DMARDs for rheumatoid arthritis

# **Appendix D: Clinical evidence tables**

# 1 First line DMARDs

Study (subsidiary papers)	Anonymous 1992 <sup>7</sup> (Danis 1992 <sup>25</sup> )
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=122)
Countries and setting	Conducted in Australia; Setting: 14 centres
Line of therapy	1st line
Duration of study	Intervention time: 6 months
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: Fulfilled the criteria for probable, definite or classical RA (Ropes 1958)
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	RA of less than 12 months duration and no evidence of bony erosions in hands and feet
Exclusion criteria	Patients with other significant acute or chronic disease likely to affect ability to participate, patients previously treated with SSZ or other SAARD, patients with history of sensitivity to salicylates or sulfa containing drugs, patients receiving systematic glucocorticoids, patients with significant renal or hepatic disease.
Recruitment/selection of patients	Recruitment from 1 June 1987 to 31 October 1988
Age, gender and ethnicity	Age - Mean (SD): 54 (13). Gender (M:F): NR. Ethnicity: NR
Further population details	
Extra comments	No. tender and swollen joints, mean (SD): 21.5 (12.2) Pain, mm, mean (SD): 32 (20) Ritchie index, mean (SD): 13.3 (9.2) ESR, mm/h, mean (SD): 28 (24)
Indirectness of population	No indirectness: No evidence of bony erosions
Interventions	(n=62) Intervention 1: Monotherapy - Monotherapy - specify. 2g / day (Salazopyrin EN-tabs). Duration 6 months. Concurrent medication/care: "Normal NSAID therapy". Indirectness: No indirectness

	Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids not used (Patients excluded from analysis for protocol violation if glucocorticoids used ). (n=60) Intervention 2: Placebo. Matching placebo. Duration 6 months. Concurrent medication/care: "Normal NSAID therapy". Indirectness: No indirectness Further details: 1. Dose: Not applicable 2. Use of glucocorticoids: Short term glucocorticoids not used (As above).
Funding	Study funded by industry ("Supported by Kabi-Pharmacia, Uppsala, Sweden and Sydney, Australia")

### RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: MONOTHERAPY - SULFASALAZINE versus PLACEBO

#### Protocol outcome 1: Pain at 6 months

- Actual outcome: Pain at 6 months; Group 1: mean 19.9 mm (SD 20.79); n=29, Group 2: mean 28.8 mm (SD 20.79); n=36; VAS 0-100 Top=High is poor outcome; Comments: SE of 5.19 calculated from mean (t value). Note: change scores also reported.

Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - Very high, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ITT analysis clearly used as no. analysed in placebo group was 36, which was higher than the number left after withdrawals. Method not specified. ; Indirectness of outcome: No indirectness ; Baseline details: Comparable for age, ESR, pain, morning stiffness, Ritchie index, no. tender/swollen joints; Blinding details: Patient was outcome assessor for outcome; Group 1 Number missing: 33, Reason: 9 - excluded from analysis for various reasons, 14 - adverse drug event, 2 lack of efficacy, 1 lost to follow up, 5 non-compliance, 1 protocol violation, 1 NR; Group 2 Number missing: 25, Reason: 8 - excluded from analysis for various reasons, 4 - adverse drug event, 5 lack of efficacy, 3 lost to follow up, 3 non-compliance, 2 protocol violation

Protocol outcome 2: Withdrawal/discontinuation: adverse events at Longest time period reported

- Actual outcome: Withdrawal: adverse events at 6 months; Group 1: 14/53, Group 2: 4/52

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ; Indirectness of outcome: No indirectness ; Baseline details: Comparable for age, ESR, pain, morning stiffness, Ritchie index, no. tender/swollen joints; Group 1 Number missing: 19, Reason: 9 - excluded from analysis for various reasons, 2 lack of efficacy, 1 lost to follow up, 5 non-compliance, 1 protocol violation, 1 NR; Group 2 Number missing: 21, Reason: 8 - excluded from analysis for various reasons, 5 lack of efficacy, 3 lost to follow up, 3 non-compliance, 2 protocol violation

- Actual outcome: Withdrawal: inefficacy at 6 months; Group 1: 2/53, Group 2: 5/52

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Very high, Outcome reporting - Low, Measurement -High, Crossover - Low, Comments - ; Indirectness of outcome: No indirectness ; Baseline details: Comparable for age, ESR, pain, morning stiffness, Ritchie index, no. tender/swollen joints; Group 1 Number missing: 31, Reason: 9 - excluded from analysis for various reasons, 14 - adverse drug event, 1 lost to follow up, 5 non-compliance, 1 protocol violation, 1 NR; Group 2 Number missing: 20, Reason: 8 - excluded from analysis for various reasons, 4 adverse drug event, 3 lost to follow up, 3 non-compliance, 2 protocol violation

Protocol outcomes not reported by the study	Disease Activity Score at 12 months; Disease Activity Score at 6 months; Quality of life at 12 months; Quality of life at 6 months; Function at 6 months; Function at 12 months; Pain at 12 months; Remission at 6 months; Remission at 12 months; Low disease activity at 6 months; Low disease activity at 12 months; Radiological progression at 12+ months; ACR50 response at 6 months; ACR50 response at 12 months; Adverse events -
	mortality at 12+ months; Withdrawal/discontinuation: inefficacy at Longest time period reported

Rheumatoid arthritis: Final References

Study (subsidiary papers)	Anonymous 1995 <sup>6</sup> (Tsakonas 2000 <sup>159</sup> )
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=120)
Countries and setting	Conducted in Canada; Setting: 6 centres in Canada.
Line of therapy	1st line
Duration of study	Intervention time: 36 weeks
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: 1987 ARA criteria
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	Adults with RA for less than 2 years. Persistent synovitis despite treatment with aspirin or NSAIDs for at least 6 weeks. ≥6 actively inflamed joints, 45 minutes or more of morning stiffness, ESR ≥25mm/h.
Exclusion criteria	Ara functional class IV disease, prior therapy with approved or experimental second line agent, use of IA or systemic glucocorticoids within 1 month of entry into study, ophthalmic abnormality, major surgery within 2 months of entry into study, Felty's syndrome, low platelet count, low white blood cell count, low polymorphonuclear leukocyte count, high serum creatinine level, proteinuria, bilirubin, high liver function tests, severe comorbid condition, women who might become pregnant.
Age, gender and ethnicity	Age - Mean (SD): 53. Gender (M:F): 75% female. Ethnicity: Not detailed
Further population details	
Indirectness of population	No indirectness
Interventions	<ul> <li>(n=60) Intervention 1: Monotherapy - Monotherapy - specify. Hydroxychloroquine (7mg/kg to maximum of 400mg per day). Smaller initial dose raised to full dose after 2 weeks. Treatment could be stopped for 4 weeks due to adverse events Duration 36 weeks. Concurrent medication/care: Current dose of NSAIDs or aspirin maintained. Some analgesics permitted. IA injections of glucocorticoids permitted from week 2 to week 24 Indirectness: No indirectness</li> <li>Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: &gt;15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used</li> <li>(n=60) Intervention 2: Placebo. Matching number of specially coated placebo tablets Duration 36 weeks.</li> </ul>
	Concurrent medication/care: Current dose of NSAIDs or aspirin maintained. Some analgesics permitted. IA injections of glucocorticoids permitted from week 2 to week 24 Indirectness: No indirectness Further details: 1. Dose: Not applicable 2. Use of glucocorticoids: Short term glucocorticoids used

Study (subsidiary papers)	BeSt study: 12 month outcomes trial: Goekoop-ruiterman 2005-1 <sup>48</sup> (Allaart 2007 <sup>4</sup> , Allaart 2006 <sup>5</sup> , Van der kooij 2009 <sup>169</sup> , De vries-bouwstra 2008 <sup>30</sup> )
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=380)
Countries and setting	Conducted in Netherlands; Setting: Rheumatologists in 18 peripheral and 2 university hospitals.
Line of therapy	1st line
Duration of study	Intervention time: 2 years
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: 1987 ACR criteria
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	Adults with RA with a disease duration $\leq 2$ years and active disease in a least 6 swollen and at least 6 tender joints, and either an ESR $\geq 28$ mm/hour or a global health score of $\geq 20$ mm on VAS (higher is worse).
Exclusion criteria	Previous treatment with DMARDs other than antimalarials, concomitant treatment with an experimental medication, malignancy within 5 years, bone marrow hypoplasia, serum aspartate aminotransferase level >3 times upper normal limit, serum creatinine level >150 µmoles per litre, estimated creatinine clearance <75 ml/minute. Diabetes, alcohol or drug abuse, pregnancy or wish to conceive during study or inadequate contraception.
Recruitment/selection of patients	Recruited from 2000-2002.
Age, gender and ethnicity	Age - Mean (SD): 54. Gender (M:F): 86% women. Ethnicity: Not detailed
Further population details	
Indirectness of population	No indirectness
Interventions	(n=126) Intervention 1: Sequential monotherapy - Sequential monotherapy - specify. Methotrexate at 15mg per week. Increasing to 30mg per week if DAS44 >2.4. If response insufficient therapy went through a sequence: sulfasalazine monotherapy, leflunomide monotherapy, methotrexate with infliximab, gold with methylprednisolone, methotrexate with ciclosporin A and prednisone. Outcomes extracted prior to people beginning treatments biologic treatment Duration 2 years. Concurrent medication/care: NSAIDs and intraarticular glucocorticoid injections permitted. Folic acid at 1mg per day during methotrexate treatment Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used

(n=121) Intervention 2: Step up therapy - Step up therapy - specify. Methotrexate at 15mg per week.

Rheumatoid arthritis: Final References

	Increasing to 30mg per week if DAS44 >2.4. If response insufficient therapy went through an additive sequence: Sulfasalazine added, hydroxychloroquine added, prednisone added. If response still insufficient then participant switched to methotrexate with infliximab, methotrexate with ciclosporin A and prednisone, and finally to leflunomide. Outcomes extracted prior to people beginning treatments biologic treatment Duration 2 years. Concurrent medication/care: NSAIDs and intraarticular glucocorticoid injections permitted. Folic acid at 1mg per day during methotrexate treatment Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used (n=133) Intervention 3: Parallel combination therapy - Parallel combination therapy - specify. Methotrexate at 7.5mg per week, sulfasalazine at 2g per day, prednisone at 60mg per day reduced to 7.5mg per day after 7 weeks. If DAS44 >2.4 then methotrexate increased up to 30mg per week. If response was insufficient then treatment altered to methotrexate with ciclosporin A and prednisone, and then to methotrexate and infliximab, and then to leflunomide emotherapy, and then to gold with methylprednisolone, and finally to azathioprine with prednisone. Outcomes extracted prior to people beginning treatments biologic treatment Duration 2 years. Concurrent medication/care: NSAIDs and intraarticular glucocorticoid injections permitted. Folic acid at 1mg per day during methotrexate treatment Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoid injections permitted. Folic acid at 1mg per day during methotrexate treatment Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine:
Funding	Funding not stated

RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: SEQUENTIAL MONOTHERAPY - METHOTREXATE / SULFASALAZINE / LEFLUNOMIDE versus STEP UP THERAPY - METHOTREXATE

Protocol outcome 1: Function at 12 months

- Actual outcome: Change in function (HAQ) score at 12 months; Group 1: mean -0.7 (SD 0.7); n=122, Group 2: mean -0.7 (SD 0.7); n=115; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: SvdH score higher in step up group; Group 1 Number missing: 4; Group 2 Number missing: 6

Protocol outcome 2: Radiological progression at 12+ months

- Actual outcome: Change in radiographic score (Sharp van der Heijde) at 12 months; Group 1: mean 9 (SD 17.9); n=122, Group 2: mean 5.2 (SD 8.1); n=115; SvdH 0-448 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: SvdH score higher in step up group; Group 1 Number missing: 4; Group 2 Number missing: 6

Study	Clark 1993 <sup>22</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=126)
Countries and setting	Conducted in Mexico; Setting: Outpatient consultation clinic
Line of therapy	1st line
Duration of study	Intervention time: Six months
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: ARA 1987 criteria
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	≤ 5 years since diagnosis, ≥ 18 years of age, onset of RA > 16 years, 5+ actively inflamed joints, unsuccessful treatment with 2+ NSAIDs or salicylates.
Exclusion criteria	Current or previous treatment with second-line drugs or cytotoxic agents, current use of glucocorticoids, RA functional class IV.
Recruitment/selection of patients	Consecutive patients attending the clinic of the Rheumatology Service, Hospital General de Mexico, from June 1989 to August 1991, were enrolled.
Age, gender and ethnicity	Age - Other: Mean, years: HCQ - 39, placebo - 36. Gender (M:F): 10:116. Ethnicity: NR
Further population details	
Extra comments	Duration of disease, mean, months: HCQ - 30, placebo - 28. Functional class 1: HCQ - 80%, placebo - 82%. RF > 1:40 : hCQ - 48%, placebo 49% Pain, mean, mm: HCQ - 46.3, placebo - 40.6 ESR, mean, mm/h: HCQ - 35.7, placebo - 37.5 Radiographic erosions, 0-1: HCQ - 68%, placebo - 80% Radiographic erosions, >5: HCQ - 6%, placebo - 2%.
Indirectness of population	No indirectness
Interventions	(n=65) Intervention 1: Monotherapy - Monotherapy - specify. 400mg/day. Duration 6 months. Concurrent medication/care: NR. Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Not stated / Unclear
	(n=61) Intervention 2: Placebo. Matching placebo identical in shape, taste and colour. Duration 6 months. Concurrent medication/care: NR. Indirectness: No indirectness

Countries and setting	Conducted in Belgium, Netherlands; Setting: NR
Line of therapy	1st line
Duration of study	Intervention time: 56 weeks
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: ACR 1987 criteria
Stratum	Overall
Subgroup analysis within study	Stratified then randomised: Stratification by centre prior to randomisation
Inclusion criteria	Define
Exclusion criteria	Define
Recruitment/selection of patients	Patients recruited between May 1993 and May 1995 from 10 centres (nine in the Netherlands, one in Belgium).
Age, gender and ethnicity	Age - Mean (SD): MTX+SSZ - 49.5 (11.9), SSZ - 49.4 (12.3). Gender (M:F): Define. Ethnicity: 99% white
Further population details	
Extra comments	Median (range) disease duration, months: MTX+SSZ - 4 (1-24), SSZ - 4 (1-23) Previous treatment with antimalarials: MTX+SSZ - 21%, SSZ - 24% RF+: MTX+SSZ - 78%, SSZ - 72% Erosions: MTX+SSZ - 74%, SSZ - 79%.
Indirectness of population	No indirectness
Interventions	(n=77) Intervention 1: Step down therapy - Step-down therapy - specify. SSZ 500mg/day increased to 2000mg/day over 3 weeks; MTX 7.5mg / week, tapered to zero over weeks 40-56. If there was a flare, the medication was re-introduced Duration 56 weeks. Concurrent medication/care: Prednisolone 60mg, tapered to 7.5mg by week 7, tapered to zero over weeks 29-35. If there was a flare, the medication was re-introduced. NSAIDs and simple analgesics were allowed, discontinuation was actively pursued. A maximum of two intra-articular glucocorticoid injections was allowed in two periods after week 38 of the protocol, but not in the 6 week period preceding independent assessment. Other glucocorticoid interventions were not permitted. All patients received folic acid during MTX or placebo prescription. Vitamin D deficiency was also corrected Indirectness: No indirectness Further details: 1. Dose: Not applicable (SSZ - higher dose, MTX - lower dose). 2. Use of glucocorticoids: Short term glucocorticoids used (See above).

weeks. Matching placebo MTX Duration 56 weeks. Concurrent medication/care: Matching placebo prednisolone. NSAIDs and simple analgesics were allowed, discontinuation was actively pursued. A maximum of two intra-articular glucocorticoid injections was allowed in two periods after week 38 of the protocol, but not in the 6 week period preceding independent assessment. Other glucocorticoid intervention were not permitted. All patients received folic acid during MTX or placebo prescription. Vitamin D deficience was also corrected Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids not used (Ad hoc use of (see above)).	су

RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: STEP-DOWN THERAPY - SSZ+MTX, STEP DOWN TO SSZ versus MONOTHERAPY - SSZ

Protocol outcome 1: Disease Activity Score at 12 months

- Actual outcome: DAS at 56 weeks; Group 1: mean -1.4 (SD 1.2); n=76, Group 2: mean -1.3 (SD 1.4); n=79; Disease Activity Score 0-10 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - Data missing due to loss to follow-up were handled by a LOCF. For other missing data, values were interpolated if actual assessments were available at least every 38 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX -34%, SSZ - 48%). DAS similar at baseline (0.1 difference between groups).; Group 1 Number missing: 7, Reason: 1 ineligible at start, 5 adverse events, 1 loss of efficacy (none lost to follow up); Group 2 Number missing: 23, Reason: 6 adverse events, 12 loss of efficacy, 2 both, 3 other (5 of total lost to follow up)

- Actual outcome: DAS at 28 weeks; Group 1: mean -2.1 (SD 1.2); n=76, Group 2: mean -1.3 (SD 1.2); n=79; Disease Activity Score 0-10 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - Data missing due to loss to follow-up were handled by a LOCF. For other missing data, values were interpolated if actual assessments were available at least every 38 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX -34%, SSZ - 48%). DAS similar at baseline (0.1 difference between groups).; Group 1 Number missing: 2, Reason: 1 ineligible at start, 1 adverse event; Group 2 Number missing: 17, Reason: 5 adverse events, 9 loss of efficacy, 2 both, 1 other (3 of total lost to follow up)

Protocol outcome 2: Function at 6 months

- Actual outcome: Function (MACTAR) at 28 weeks; Group 1: mean 10 (SD 5); n=76,

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low,

Crossover - Low, Comments - Data missing due to loss to follow-up were handled by a LOCF. For other missing data, values were interpolated if actual assessments were available at least every 38 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX - 34%, SSZ - 48%). Outcome comparable at baseline (no difference between groups).; Group 1 Number missing: 2, Reason: 1 ineligible at start, 1 adverse events; Group 2 Number missing: 17, Reason: 5 adverse events, 9 loss of efficacy, 2 both, 1 other (3 of total lost to follow up) - Actual outcome: Function (HAQ) at 28 weeks; Group 1: mean -1.1 (SD 0.8); n=76, Group 2: mean -0.6 (SD 0.6); n=79; Health Assessment

Questionnaire 0-3 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - Data missing due to loss to follow-up were handled by a LOCF. For other missing data, values were interpolated if actual assessments were available at least every 38 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX -34%, SSZ - 48%). Outcome comparable at baseline (0.1 difference between groups).; Group 1 Number missing: 2, Reason: 1 ineligible at start, 1 adverse events; Group 2 Number missing: 17, Reason: 5 adverse events, 9 loss of efficacy, 2 both, 1 other (3 of total lost to follow up)

Protocol outcome 3: Function at 12 months

- Actual outcome: Function (MACTAR) at 56 weeks; Group 1: mean 7 (SD 7); n=76,

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - Data missing due to loss to follow-up were handled by a LOCF. For other missing data, values were interpolated if actual assessments were available at least every 38 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX -34%, SSZ - 48%). Outcome comparable at baseline (no difference between groups).; Group 1 Number missing: 7, Reason: 1 ineligible at start, 5 adverse events, 1 loss of efficacy (none lost to follow up); Group 2 Number missing: 23, Reason: 6 adverse events, 12 loss of efficacy, 2 both, 3 other (5 of total lost to follow up)

- Actual outcome: Function (HAQ) at 56 weeks; Group 1: mean -0.8 (SD 0.8); n=76, Group 2: mean -0.6 (SD 0.7); n=79; Health Assessment Questionnaire 0-3 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - Data missing due to loss to follow-up were handled by a LOCF. For other missing data, values were interpolated if actual assessments were available at least every 38 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX -34%, SSZ - 48%). Outcome comparable at baseline (0.1 difference between groups).; Group 1 Number missing: 7, Reason: 1 ineligible at start, 5 adverse events, 1 loss of efficacy (none lost to follow up); Group 2 Number missing: 23, Reason: 6 adverse events, 12 loss of efficacy, 2 both, 3 other (5 of total lost to follow up)

## Protocol outcome 4: Pain at 12 months

- Actual outcome: Pain (VAS) at 56 weeks; Group 1: mean -23 mm (SD 29); n=76, Group 2: mean -25 mm (SD 28); n=79; Visual Analogue Scale 0-100 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - Data missing due to loss to follow-up were handled by a LOCF. For other missing data, values were interpolated if actual assessments were available at least every 38 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX -34%, SSZ - 48%). Outcome comparable at baseline (1.0 difference between groups).; Group 1 Number missing: 7, Reason: 1 ineligible at start, 5 adverse events, 1 loss of efficacy (none lost to follow up); Group 2 Number missing: 23, Reason: 6 adverse events, 12 loss of efficacy, 2 both, 3 other (5 of total lost to follow up)

#### Protocol outcome 5: Pain at 6 months

- Actual outcome: Pain (VAS) at 28 weeks; Group 1: mean -34 mm (SD 25); n=76, Group 2: mean -20 mm (SD 30); n=79; Visual Analogue Scale 0-100 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - Data missing due to loss to follow-up were handled by a LOCF. For other missing data, values were interpolated if actual assessments were available at least every 38 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX -34%, SSZ - 48%). Outcome comparable at baseline (1.0 difference between groups).; Group 1 Number missing: 2, Reason: 1 ineligible at start, 1 adverse events; Group 2 Number missing: 17, Reason: 5 adverse events, 9 loss of efficacy, 2 both, 1 other (3 of total lost to follow up)

### Protocol outcome 6: Remission at 12 months

- Actual outcome: ACR remission at 56 weeks; Group 1: 1/70, Group 2: 3/56; Comments: Persistent remission at 56 weeks (not any remission over course of study)

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ; Indirectness of outcome: Serious indirectness, Comments: Remission not measured using DAS or other similar disease activity measure; Baseline details: Difference in % male (SSZ+MTX - 34%, SSZ - 48%). ; Group 1 Number missing: 7, Reason: 1 ineligible at start, 5 adverse events, 1 loss of efficacy (none lost to follow up); Group 2 Number missing: 23, Reason: 6 adverse events, 12 loss of efficacy, 2 both, 3 other (5 of total lost to follow up)

### Protocol outcome 7: ACR50 response at 6 months

- Actual outcome: ACR50 response at 28 weeks? (unclear); Group 1: 37/75, Group 2: 21/62; Comments: Time point unclear. From context, appears to be 28 week data.

Risk of bias: All domain - Very high, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - High, Measurement - Low, Crossover - Low, Comments - Time point outcome reported at unclear; Indirectness of outcome: No indirectness; Baseline details: Difference in % male (SSZ+MTX - 34%, SSZ - 48%).; Group 1 Number missing: 2, Reason: 1 ineligible at start, 1 adverse events; Group 2 Number missing: 17, Reason: 5 adverse events, 9 loss of efficacy, 2 both, 1 other (3 of total lost to follow up)

Protocol outcome 8: Withdrawal/discontinuation: adverse events at Longest time period reported

- Actual outcome: Discontinuation: adverse events at 56 weeks; Group 1: 5/75, Group 2: 8/64

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX - 34%, SSZ - 48%). ; Group 1 Number missing: 2, Reason: 1 ineligible at start, 1 loss of efficacy (none lost to follow up); Group 2 Number missing: 15, Reason: 12 loss of efficacy, 3 other (4 of total lost to follow up)

Protocol outcome 9: Withdrawal/discontinuation: inefficacy at Longest time period reported

- Actual outcome: Discontinuation: inefficacy at 56 weeks; Group 1: 1/71, Group 2: 14/70

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ; Indirectness of outcome: No indirectness ; Baseline details: Difference in % male (SSZ+MTX - 34%, SSZ - 48%). ; Group 1 Number missing: 6, Reason: 1 ineligible at start, 5 adverse events (none lost to follow up); Group 2 Number missing: 9, Reason: 6 adverse events, 3 other (3 of total lost to follow up)

Protocol outcomes not reported by the study

Disease Activity Score at 6 months; Quality of life at 12 months; Quality of life at 6 months; Remission at 6 months; Low disease activity at 6 months; Low disease activity at 12 months; Radiological progression at 12+ months; ACR50 response at 12 months; Adverse events - mortality at 12+ months

Study	Davis 1991 <sup>27</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=104)
Countries and setting	Conducted in United Kingdom; Setting: NR
Line of therapy	1st line
Duration of study	Intervention time: 12 months
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: 4 or more ARA criteria
Stratum	Overall
Subgroup analysis within study	Stratified then randomised: Stratification for presence or absence of erosions
Inclusion criteria	Presence of palpable synovitis but limited to hands, wrists and feet, ESR < 30mm/h and CRP < 2 mg/L.
Exclusion criteria	Previous use of disease suppressive therapy or oral glucocorticoids.
Recruitment/selection of patients	NR
Age, gender and ethnicity	Age - Median (IQR): HCQ - 46 (18), placebo - 46 (20). Gender (M:F): 36:67. Ethnicity: NR
Further population details

Study	Den uyl 2014 <sup>31</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=164)
Countries and setting	Conducted in Netherlands, Unknown
Line of therapy	1st line
Duration of study	Intervention + follow up: 2 years
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: 1987 ACR criteria
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	Adults with currently active RA, for 2 years or less. Active RA defined as at least 6 swollen or tender joints and either ESR $\geq$ 28 mm/h or global health score $\geq$ 20 on 0-100 VAS.
Exclusion criteria	Previous treatment with glucocorticoids or DMARD other than antimalarial agents, uncontrolled diabetes, heart failure, uncontrolled hypertension, ALT or AST more than 3 times upper limit of normal, reduced renal function, contraindications to glucocorticoids, positive tubercilin skin test.
Recruitment/selection of patients	Recruited from March 2008 to March 2011.
Age, gender and ethnicity	Age - Mean (SD): 52. Gender (M:F): 56% female. Ethnicity: Not detailed
Further population details	
Indirectness of population	No indirectness
Interventions	(n=81) Intervention 1: Parallel combination therapy - Parallel combination therapy - specify. COBRA therapy. Methotrexate (7.5mg per week), sulfasalazine (1g per day increased to 2g per day after 1 week), prednisolone (60mg per day, tapered to 7.5mg per day by week 6). Treatment adjusted if DAS44 was not less than 1.6. Increase MTX dose to 25mg per week after 13 weeks Duration 1 year. Concurrent medication/care: Folic acid 5mg per week. Daily calcium/vitamin supplementation. NSAID and IA glucocorticoid treatment permitted Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used
	(n=83) Intervention 2: Monotherapy - Monotherapy - specify. COBRA-light therapy. Methotrexate (10mg per week rising to 25mg per week by week 9), prednisolone (30mg per day, tapered to 7.5mg per day by week 6). Parenteral methotrexate considered after 13 weeks if DAS44 was not less than 1.6 Duration 1 year. Concurrent medication/care: Folic acid 5mg per week. Daily calcium/vitamin supplementation. NSAID and IA glucocorticoid treatment permitted Indirectness: No indirectness

	Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used

Ferraccioli 2002 <sup>40</sup>
RCT (Patient randomised; Parallel)
1 (n=84)
Conducted in Italy; Setting: Rheumatology Unit, University of Udine
1st line
Intervention time: 3 years
Adequate method of assessment/diagnosis: ACR criteria
Overall
Not applicable
Active disease (at least 3 of the following criteria for at least 3 months: ESR > 30 mm/h or CRP > 20 mg/L; > 6 swollen joints (of 66) or > 9 tender joints (of 68); moderate or severe pain on verbal scale as none, mild, moderate or severe; receiving prednisone at 5mg/day). All patients at least one erosion at baseline and all had received at least a 4 month course of antimalarials.
Age < 17 or > 70 years; comorbidities that might preclude any of the therapeutic approaches; previous treatment with immune suppressants; possible pregnancy or breastfeeding; psychiatric or neurological disease; hypertension under treatment.
Recruitment between June 1993 and June 1995
Age - Mean (SD): MTX - 59 (7.7), SSZ - 59 (15). Gender (M:F): 12:72. Ethnicity: NR
Disease duration, years, mean (SD): MTX - 1.2 (0.8), SSZ - 2.0 (1.0) Swollen joint count, mean (SD): MTX - 10 (12), SSZ - 9 (11) Tender joint count, mean (SD): MTX - 12 (13), SSZ - 10 (11) Pain, VAS, cm, mean (SD): MTX - 6.1 (0.9), SSZ - 6.3 (0.9) ESR, mm/h, mean (SD): MTX - 52 (30), SSZ - 43 (29) RF+: MTX - 73%, SSZ - 55% Prednisone, previous: MTX - 71%, SSZ - 76% (current use % same. Mean dose 5mg/day)
Serious indirectness: All patients had previously received at least a 4 month course of antimalarials
(n=42) Intervention 1: Monotherapy - Monotherapy - specify. 10mg/week, after 8 weeks the dose was increased monthly by 5mg, up to 20 mg/week. Duration 6 months. Concurrent medication/care: Attempts to decrease or stop the daily prednisone dose were performed throughout the study period. Paracetamol and NSAIDs were allowed concurrently. Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg,

Rheumatoid arthritis: Final References

	hydroxychloroquine: 400mg) 2. Use of steroids: Short term steroids used (Ad hoc, as above. ). Comments: After 6 months patients who had not shown ACR50 improvement had CsA added to their therapy. As this drug is out of scope, only data up to 6 months has been included in the review. (n=42) Intervention 2: Monotherapy - Monotherapy - specify. 1g/day, increased by 500mg each week for 5 weeks to reach 3g/day. Duration 6 months. Concurrent medication/care: Attempts to decrease or stop the daily prednisone dose were performed throughout the study period. Paracetamol and NSAIDs were allowed concurrently. Indirectness: No indirectness Further details: 1. Dose: 2. Use of steroids: Comments: After 6 months patients in the comparator arm had an out of scope drug added to their therapy. Therefore, only data up to 6 months has been included in the review.

Indirectness of population	No indirectness
Interventions	(n=34) Intervention 1: Monotherapy - Monotherapy - specify. Sulfasalazine (1g per day rising to 2g per day from day 10 in 500mg tablets). After week 16 dose could rise to 3g per day if efficacy inadequate. Placebo MTX tablets 3 times per week or 6 times per week if dose increased at 16 weeks. If higher dose was not effective after 8 weeks then participant withdrawn from study Duration 52 weeks. Concurrent medication/care: NSAID therapy at a dose that was preferable not altered. No systematically administered glucocorticoids permitted Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used (Systemic glucocorticoid treatment not permitted but local glucocorticoid treatment permitted).
	(n=35) Intervention 2: Monotherapy - Monotherapy - specify. Methotrexate (7.5mg per week in 3 2.5mg tablets). After week 16 dose could rise to 15mg per week if efficacy inadequate. Placebo SASP tablets each day matching possible SASP dose. If higher dose was not effective after 8 weeks then participant withdrawn from study Duration 52 weeks. Concurrent medication/care: NSAID therapy at a dose that was preferable not altered. No systematically administered glucocorticoids permitted Indirectness: No indirectness

Rheumatoid arthritis: Final References Funding

Study funded by industry (Study partly financed by Pharmacia AB. Methotrexate tablets and placebo provided by Pharmachemie BV. )

Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroguine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used (Systemic

Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg,

(n=36) Intervention 3: Parallel combination therapy - Parallel combination therapy - specify. Methotrexate (7.5mg per week in 3 2.5mg tablets) and Sulfasalazine (1g per day rising to 2g per day from day 9 in 500mg tablets). After week 16 MTX dose could rise to 15mg per week and SASP dose to 3g per day if efficacy inadequate. Stated to be a step-down-bridge strategy. If higher dose was not effective after 8 weeks then participant withdrawn from study. Duration 52 weeks. Concurrent medication/care: NSAID therapy at a

hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used (Systemic

dose that was preferable not altered. No systematically administered glucocorticoids permitted. .

glucocorticoid treatment not permirtted but local glucocorticoid treatment permitted).

glucocorticoid treatment not permitted but local glucocorticoid treatment permitted).

RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: MONOTHERAPY - SULFASALAZINE versus MONOTHERAPY - METHOTREXATE

Indirectness: No indirectness

Protocol outcome 1: Disease Activity Score at 12 months

- Actual outcome: DAS change from baseline at 52 weeks; Group 1: mean -1.8 (SD 1.2); n=22, Group 2: mean -2 (SD 1.03); n=33 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Baseline details: Similar for age, gender, disease duration, Rh factor, DAS, ESR, HAQ; Group 1 Number missing: 12, Reason: 9 AEs and 3 inefficacy; Group 2 Number missing: 2, Reason: 2 AEs

### Protocol outcome 2: Disease Activity Score at 6 months

- Actual outcome: DAS change over first 12 weeks at 12 weeks; Group 1: mean -1.1 (SD 0.48); n=22, Group 2: mean -1 (SD 0.59); n=33 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Baseline details: Similar for age, gender, disease duration, Rh factor, DAS, ESR, HAQ; Group 1 Number missing: 12, Reason: 9 AEs and 3 inefficay; Group 2 Number missing: 2, Reason: 2 AEs

### Protocol outcome 3: Function at 12 months

- Actual outcome: Function (HAQ) score change from baseline at 52 weeks; Group 1: mean -0.32 (SD 0.51); n=22, Group 2: mean -0.46 (SD 0.63); n=33; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Group 1 Number missing: 11, Reason: 9 AEs and 2 inefficacy; Group 2

#### Number missing: 2, Reason: 2 AEs

Protocol outcome 4: Pain at 12 months

- Actual outcome: Pain (VAS) score change from baseline at 52 weeks; Group 1: mean -25.2 (SD 26.8); n=22, Group 2: mean -25.1 (SD 22.72); n=33; VAS 100mm 0-100 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Group 1 Number missing: 11, Reason: 9 AEs and 2 inefficay; Group 2 Number missing: 2, Reason: 2 AEs

Protocol outcome 5: Pain at 6 months

- Actual outcome: Pain (VAS) score change over first 12 weeks at 12 weeks; Group 1: mean -18.1 (SD 16.87); n=22, Group 2: mean -12.3 (SD 19.64); n=33; VAS 100mm 0-100 Top=High is poor outcome

Hannonen 1993⁵ <sup>7</sup>
RCT (Patient randomised; Parallel)
1 (n=80)
Conducted in Sweden; Setting: Single centre
1st line
Intervention time: 48 weeks
Adequate method of assessment/diagnosis: ACR criteria for definite RA
Overall:
Not applicable
Duration of symptomatic disease < 12 months, never treated with DMARDs, stable dose of NSAIDs for at least previous 2 weeks, at least 2 of the following 3 criteria: ESR > 20mm/h, 6+ (of 30) joints with active RA, duration of morning stiffness > 45mins.
Other severe systemic diseases or previous allergic reaction to salicylates or sulfonamides. Originally, intention was to exclude patients with joint erosions, but 30 patients with some minor radiographic changes at baseline were included.
Consecutive patients with RA in the Medical Department of the Jvyaskyla Central Hospital
Age - Mean (range): SSZ - 52.1 (22-78), placebo - 50.5 (23-74). Gender (M:F): 28:50. Ethnicity: NR
Disease duration, months, mean (range): SSZ - 4.7 (2-12), placebo - 5.5 (2-12) RF+: SSZ - 66%, placebo - 68% Functional class I: SSZ - 11%, placebo - 8%; class II: SSZ - 84%, placebo - 93% No. of swollen joints, mean (SD): SSZ - 6.8 (3.3), placebo - 5.3 (3.3) Ritchie articular index, mean (SD): SSZ - 10.6 (5.2), placebo - 9.1 (4.2) Patient's global assessment, mean (SD): SSZ - 2.9 (0.8), placebo - 2.8 (0.7) Pain, mm, mean (SD): SSZ - 37 (20), placebo - 33 (18) ESR, mm/h, mean (SD): SSZ - 37.7 (21.3), placebo - 39.0 (18.9) CRP, mg/liter, mean (SD): SSZ - 26.7 (30.3), placebo - 23.6 (25.7)
No indirectness
(n=40) Intervention 1: Monotherapy - Monotherapy - specify. Starting dose of 500mg / day, increased by 500mg each week to total dose of 2g / day. In case of intolerance, the dosage was temporarily decreased Duration 48 weeks. Concurrent medication/care: Simultaneous treatment with NSAIDs, low-dose prednisolone (up to 7.5 mg/day) and local injections of glucocorticoids into the joints was permitted.

	Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used (glucocorticoids permitted but not prescribed routinely). (n=40) Intervention 2: Placebo. Identical tablet and dose escalation regime. Duration 48 weeks. Concurrent medication/care: Simultaneous treatment with NSAIDs, low-dose prednisolone (up to 7.5 mg/day) and local injections of glucocorticoids into the joints was permitted. Indirectness: No indirectness Further details: 1. Dose: Not applicable 2. Use of glucocorticoids: Short term glucocorticoids used (As above).
Funding	Study funded by industry ("Supported by Kabi-Pharmacia, Uppsala, Sweden")

### RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: MONOTHERAPY - SULFASALAZINE versus PLACEBO

### Protocol outcome 1: Radiological progression at 12+ months

- Actual outcome: Radiographic progression at 44-60 weeks; Group 1: mean 3.5 (SD 10.04); n=36,

Risk of bias: All domain - High, Selection - High, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - Missing data - patients who withdrew from the study were asked to obtain follow up radiographs at 48 weeks. 1 patient included in analysis was data at 24 weeks due to pregnancy at 48 weeks. ; Indirectness of outcome: No indirectness ; Baseline details: See population panel. Comparable for radiographic damage at baseline (SSZ -1.9, placebo - 2.1) ; Blinding details: Matched placebo. Outcome assessor also blinded. ; Group 1 Number missing: 4, Reason: 1 death, 2 withdrawn for protocol violations, 1 unknown; Group 2 Number missing: 3, Reason: 1 death, 1 lost to follow up, 1 unknown

Protocol outcome 2: Adverse events - mortality at 12+ months

- Actual outcome: Mortality at 48 weeks; Group 1: 1/38, Group 2: 1/40

Risk of bias: All domain - High, Selection - High, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ; Indirectness of outcome: No indirectness ; Baseline details: See population panel. ; Blinding details: Matched placebo. ; Group 1 Number missing: 2, Reason: 2 withdrawn for protocol violations; Group 2 Number missing: 1, Reason: 1 lost to follow up

Study	Jaimes-Hernandez 2012 <sup>67</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=85)
Countries and setting	Conducted in Mexico
Line of therapy	1st line
Duration of study	Intervention time: 52 weeks
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: 1987 ACR criteria
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	Adults with active RA. Active RA defined as >5 swollen joints and painful joints, morning stiffness for more than 30 minutes, ESR $\geq$ 20 mm/h. Any previous treatment with DMARDs was suspended for at least 1 month (3 months for methotrexate or leflunomide) prior to enrollment. Normal count of white blood cells, haemoglobin concentration of > 12g/dl, Albumin levels $\geq$ 3.5 g/d, normal liver function test. Negative pregnancy test.
Exclusion criteria	History of high alcohol consumption.
Age, gender and ethnicity	Age - Mean (SD): 42. Gender (M:F): 87% female. Ethnicity: No detailed
Further population details	
Indirectness of population	No indirectness
Interventions	(n=43) Intervention 1: Monotherapy - Monotherapy - specify. Leflunomide (starting at 100mg per day and reduced to 100mg per week after 3 days). Placebo utilised to achieve blinding. Treatment discontinued if participants did not achieve ACR20 improvement by week 16 Duration 52 weeks. Concurrent medication/care: Use of glucocorticoid treatment allowed though regular dose prednisolone or equivalent not exceeding 10mg daily for the shortest possible time Indirectness: No indirectness Further details: 1. Dose: Lower dose (sulfasalazine: 1 gm, methotrexate: <=15mg, leflunomide: 10mg, hydroxychloroquine: 200mg) 2. Use of glucocorticoids: Short term glucocorticoids used
	(n=42) Intervention 2: Monotherapy - Monotherapy - specify. Methotrexate (10mg per week). Placebo utilised to achieve blinding. Treatment discontinued if participants did not achieve ACR20 improvement by week 16 Duration 52 weeks. Concurrent medication/care: Use of glucocorticoid treatment allowed though regular dose prednisolone or equivalent not exceeding 10mg daily for the shortest possible time Indirectness: No indirectness Further details: 1. Dose: Lower dose (sulfasalazine: 1 gm, methotrexate: <=15mg, leflunomide: 10mg, hydroxychloroguine: 200mg) 2. Use of glucocorticoids: Short term glucocorticoids used

RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: MONOTHERAPY - METHOTREXATE versus MONOTHERAPY - LEFLUNOMIDE

Protocol outcome 1: Disease Activity Score at 6 months

- Actual outcome: Change in Disease Activity Score (DAS28) at 16 weeks; Group 1: mean -1.46 (SD 1.6); n=33, Group 2: mean -0.87 (SD 1.22); n=29; DAS28 2-10 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Baseline details: Not detailed; Group 1 Number missing: 8, Reason: Moved residence, declined to participate, loss of compliance of treatment, pregnancy desire; Group 2 Number missing: 4, Reason: Move residence, declined to participate, loss of compliance, pregnancy desire

#### Protocol outcome 2: Function at 6 months

- Actual outcome: Change in Health Assessment Questionnaire (HAQ) at 16 weeks; Group 1: mean -0.242 (SD 0.543); n=33, Group 2: mean -0.235 (SD 0.374); n=29; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Not detailed; Group 1 Number missing: 8, Reason: Moved residence, declined to participate, loss of compliance of treatment, pregnancy desire; Group 2 Number missing: 4, Reason: Move residence, declined to participate, loss of compliance, pregnancy desire

### Protocol outcome 3: Pain at 6 months

- Actual outcome: Change in VAS pain score at 16 weeks; Group 1: mean -13.2 (SD 18.1); n=33, Group 2: mean -9.6 (SD 20.5); n=29; VAS 0-100 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Not detailed; Group 1 Number missing: 8, Reason: Moved residence, declined to participate, loss of compliance of treatment, pregnancy desire; Group 2 Number missing: 4, Reason: Move residence, declined to participate, loss of compliance, pregnancy desire

Protocol outcomes not reported by the study	Disease Activity Score at 12 months; Quality of life at 12 months; Quality of life at 6 months; Function at 12 months; Pain at 12 months; Remission at 6 months; Remission at 12 months; Low disease activity at 6 months; Low disease activity at 12 months; Radiological progression at 12+ months; ACR50 response at 6 months; ACR50 response at 12 months; Adverse events - mortality at 12+ months; Withdrawal/discontinuation: adverse events at Longest time period reported; Withdrawal/discontinuation: inefficacy at Longest time period reported

Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=60)
Countries and setting	Conducted in Sweden
Line of therapy	1st line
Duration of study	Intervention time: 48 weeks
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: 1987 ACR criteria
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	People aged 16-75 years old with definite or classical RA. Active disease defined as at least 3 of the following ( $\geq$ 7 painful or tender joints in motion, $\geq$ 4 swollen joints, morning stiffness for at least 1 hour, ESR >28mm/1st h, anaemia) not adequately controlled by NSAIDs.
Exclusion criteria	People with serious complicating illnesses or previous reactions to sulphonamides or salicylates. People with a desire for children and previous treatment with second line medication.
Recruitment/selection of patients	From 5 participating clinics.
Age, gender and ethnicity	Age - Mean (SD): 53. Gender (M:F): 38 female, 22 male. Ethnicity: Not detailed
Further population details	
Indirectness of population	No indirectness
Interventions	(n=30) Intervention 1: Monotherapy - Monotherapy - specify. Hydroxychloroquine (200mg twice per day for 6 months and then 200mg once per day). Double dummy technique to ensure blinding Duration 48 weeks. Concurrent medication/care: glucocorticoid treatment not permitted 3 months previous to trial or during the trial. NSAID dose kept stable throughout the study Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids not used
	(n=30) Intervention 2: Monotherapy - Monotherapy - specify. Sulfasalazine (500mg per day increased to 2g per day after 2 weeks). Double dummy technique to ensure blinding Duration 48 weeks. Concurrent medication/care: glucocorticoid treatment not permitted 3 months previous to trial or during the trial. NSAID dose kept stable throughout the study Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids not used

Rheumatoid arthritis: Final References

# RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: MONOTHERAPY - HYDROXYCHLOROQUINE versus MONOTHERAPY - SULFASALAZINE

Protocol outcome 1: Pain at 12 months

- Actual outcome: Pain (VAS) at 48 weeks; Group 1: mean 33 (SD 23.4); n=29, Group 2: mean 32.8 (SD 28); n=28; VAS 0-100 Top=High is poor outcome

Risk of bias: All domain - High, Selection - High, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 1; Group 2 Number missing: 2

### Protocol outcome 2: Pain at 6 months

- Actual outcome: Pain (VAS) at 24 weeks; Group 1: mean 25.2 (SD 19.8); n=29, Group 2: mean 31.6 (SD 25.9); n=28; VAS 0-100 Top=High is poor outcome

Risk of bias: All domain - High, Selection - High, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Group 1 Number missing: 1; Group 2 Number missing: 2

Protocol outcome 3: Radiological progression at 12+ months

- Actual outcome: Change in radiological progressions (SvdH score) at 48 weeks; Group 1: mean 17.3 (SD 22.67); n=29, Risk of bias: All domain - High, Selection - High, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 1; Group 2 Number missing: 2

Protocol outcome 4: Withdrawal/discontinuation: adverse events at Longest time period reported

- Actual outcome: Discontinuation due to adverse events at 48 weeks; Group 1: 1/19, Group 2: 4/25

Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 11; Group 2 Number missing: 5

Protocol outcome 5: Withdrawal/discontinuation: inefficacy at Longest time period reported

- Actual outcome: Discontinuation due to inefficacy at 48 weeks; Group 1: 9/27, Group 2: 3/24

Risk of bias: All domain - High, Selection - High, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Group 1 Number missing: 3; Group 2 Number missing: 6

Study	Saunders 2008 <sup>137</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=96)
Countries and setting	Conducted in United Kingdom; Setting: 3 NHS teaching hospitals in Glasgow, Scotland.
Line of therapy	1st line
Duration of study	Intervention time: 1 year
Method of assessment of guideline condition	Unclear method of assessment/diagnosis: Unclear of criteria for diagnosis
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	People 18 to 80 years old with active RA as defined by DAS28 >5.1. Disease duration <5 years. No previous DMARD treatment except for hydroxychloroquine.
Exclusion criteria	Concurrent liver, renal, hematologic, severe respiratory disease. People who are pregnant or unwilling to use effective contraception.
Recruitment/selection of patients	Recruited from February 2003 to March 2005.
Age, gender and ethnicity	Age - Mean (SD): 55. Gender (M:F): 77% female. Ethnicity: Not detailed
Further population details	
Indirectness of population	No indirectness
Interventions	(n=49) Intervention 1: Parallel combination therapy - Parallel combination therapy - specify. Triple therapy: methotrexate (7.5mg per week), sulfasalazine (1g per day), hydroxychloroquine (200mg per day). If DAS28 ≥3.2 then sequential dose rises: MTX increased up to 25mg per week, next SSZ increased to 40mg/kg per day, then HCQ increased to 400mg per day Duration 1 year. Concurrent medication/care: IA glucocorticoid injections permitted. 5mg per week folic acid when using MTX Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used
	(n=47) Intervention 2: Step up therapy - Step up therapy - specify. Sulfasalazine (40mg/kg per day). After 3 months of DAS28 ≥3.2 methotrexate (7.5mg per week increased to maximum 25mg per week if required). If disease activity persistent then hydroxychloroquine (400mg per day) added Duration 1 year. Concurrent medication/care: IA glucocorticoid injections permitted. 5mg per week folic acid when using MTX Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids used

# RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: STEP UP THERAPY - SULFASALAZINE + METHOTREXATE + HYDROXYCHLOROQUINE versus PARALLEL COMBINATION THERAPY - METHOTREXATE + SULFSALAZINE + HYDROXYCHLOROQUINE

Protocol outcome 1: Disease Activity Score at 12 months

- Actual outcome: Change in Disease Activity Score (DAS28) at 12 months; Group 1: mean -4 (SD 1.8); n=44, Group 2: mean -3.3 (SD 1.6); n=47; DAS28 2-10 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Blinding details: High due to participant influence on DAS28 and not blinded; Group 1 Number missing: 3; Group 2 Number missing: 2

Protocol outcome 2: Quality of life at 12 months

- Actual outcome: Change in health related quality of life (SF-36) at 12 months; Group 1: mean 10 (SD 11); n=44, Group 2: mean 9 (SD 13); n=47; SF-36 0-100 Top=High is good outcome

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Blinding details: High due to participant influence and not blinded; Group 1 Number missing: 3; Group 2 Number missing: 2

Protocol outcome 3: Function at 12 months

- Actual outcome: Change in function (HAQ) at 12 months; Group 1: mean -0.9 (SD 0.7); n=44, Group 2: mean -0.8 (SD 0.7); n=47; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Blinding details: High due to participant influence and not blinded; Group 1 Number missing: 3; Group 2 Number missing: 2

Protocol outcome 4: Pain at 12 months

- Actual outcome: Change in pain score (VAS) at 12 months; Group 1: mean -42 (SD 32); n=44, Group 2: mean -43 (SD 34); n=47; VAS 0-100 Top=High is poor outcome

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness; Group 1 Number missing: 3; Group 2 Number missing: 2

Protocol outcome 5: Remission at 12 months

- Actual outcome: EULAR remission (DAS28 <2.6) at 12 months; Group 1: 21/47, Group 2: 16/49

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Blinding details: High due to participant influence on DAS28 and not

billided, Group T Number missing. , Group 2 Number missing.
Protocol outcome 6: Low disease activity at 12 months - Actual outcome: EULAR good response (DAS28 <3.2) at 12 months; Group 1: 28/47, Group 2: 20/49 Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Blinding details: High due to participant influence on DAS28 and not blinded; Group 1 Number missing: ; Group 2 Number missing:
Protocol outcome 7: Radiological progression at 12+ months - Actual outcome: Change in radiographic progression (Sharp score) at 12 months; Group 1: mean 6 (SD 5.3); n=44, Risk of bias: All domain - Low, Selection - Low, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 3; Group 2 Number missing: 2
Protocol outcome 8: ACR50 response at 12 months - Actual outcome: ACR50 response at 12 months; Group 1: 28/47, Group 2: 25/49 Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low,

Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Blinding details: High due to participant influence and not blinded; Group 1 Number missing: ; Group 2 Number missing:

Study	Tascioglu 2003 <sup>152</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=70)
Countries and setting	Conducted in Turkey
Line of therapy	1st line
Duration of study	Intervention time: 52 weeks
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: 1987 ACR criteria
Stratum	Overall
Subgroup analysis within study	Not applicable
Inclusion criteria	People ≥18 years old with active RA with disease duration for less than 1 year. Active was defined as at least 3 of the following criteria: >6 swollen joints, >9 tender joints, ESR >20 mm/hr in men or >30 mm/hr in women, morning stiffness ≥1 hour.
Exclusion criteria	Previous medication treatment for RA other than analgesics or NSAIDs. Hepatic, renal, hematologic, pulmonary, cardiovascular disease. Malignancy, peptic ulcers, presence of chronic infection, history of allergy to study medication, pregnancy or breast feeding. White blood cell count <3000 mm <sup>3</sup> or polymorphonuclear count <1500 mm <sup>3</sup> or platelet count <100000 mm <sup>3</sup> . Liver enzyme levels at least twice the limit of normal.
Recruitment/selection of patients	Not detailed
Age, gender and ethnicity	Age - Mean (SD): 46. Gender (M:F): 9 / 46 for participants completing the study. Ethnicity: Not detailed
Further population details	
Indirectness of population	No indirectness
Interventions	(n=35) Intervention 1: Monotherapy - Monotherapy - specify. Open label methotrexate. 7.5mg per week in three tablets taken as a single dose. Participants excluded from the study if treatment not effective after 12 weeks or if serious adverse events occurred Duration 52 weeks. Concurrent medication/care: NSAID usage not altered during study. Analgesic treatment permitted. No systemic or intraarticular corticosteroid use permitted Indirectness: No indirectness Further details: 1. Dose: Lower dose (sulfasalazine: 1 gm, methotrexate: <=15mg, leflunomide: 10mg, hydroxychloroquine: 200mg) 2. Use of steroids: Short term steroids not used
	(n=35) Intervention 2: Parallel combination therapy - Parallel combination therapy - specify. Open label methotrexate (MTS) and sulfasalazine (SSZ). MTX: 7.5mg per week in three tablets taken as a single dose. SSZ: 1g daily rising to 2g daily from week 2. Participants excluded from the study if treatment not effective

after 12 weeks or if serious adverse events occurred. Duration 52 weeks. Concurrent medication/care: NSAID usage not altered during study. Analgesic treatment permitted. No systemic or intraarticular corticosteroid use permitted. Indirectness: No indirectness Further details: 1. Dose: Not applicable (Dose levels differ between treatments). 2. Use of steroids: Short term steroids not used

Protocol outcome 1: Disease Activity Score at 6 months

- Actual outcome: Change in DAS at 3 months; Group 1: mean -1.55 (SD 0.9); n=65, Group 2: mean -1.41 (SD 1); n=59 Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher erosion number in treatment group. Higher CR in comparator group. ; Group 1 Number missing: 4; Group 2 Number missing: 8

Protocol outcome 2: Function at 6 months

- Actual outcome: Change in function (HAQ) at 3 months; Group 1: mean -0.47 (SD 0.54); n=54, Group 2: mean -0.42 (SD 0.52); n=52; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - Low, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher erosion number in treatment group. Higher CR in comparator group. ; Group 1 Number missing: 15; Group 2 Number missing: 11

### Protocol outcome 3: Pain at 6 months

- Actual outcome: Median pain (VAS) at 3 months;

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher erosion number in treatment group. Higher CR in comparator group. ; Group 1 Number missing: 4; Group 2 Number missing: 4

Protocol outcome 4: Remission at 6 months

- Actual outcome: Remission (DAS<1.6) at 3 months; Group 1: 28/65, Group 2: 19/59

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher erosion number in treatment group. Higher CR in comparator group. ; Group 1 Number missing: 4; Group 2 Number missing: 4

# RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: PARALLEL COMBINATION THERAPY - METHOTREXATE + SULFASALAZINE + HYDROXYCHLOROQUINE versus MONOTHERAPY - METHOTREXATE

Protocol outcome 1: Disease Activity Score at 6 months

- Actual outcome: Change in DAS at 3 months; Group 1: mean -1.77 (SD 1.04); n=55, Group 2: mean -1.41 (SD 1); n=59 Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher CR in comparator group. ; Group 1 Number missing: 4; Group 2 Number missing: 4

Protocol outcome 2: Function at 6 months

- Actual outcome: Change in function (HAQ) at 3 months; Group 1: mean -0.47 (SD 0.55); n=47, Group 2: mean -0.42 (SD 0.52); n=52; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - Low, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher CR in comparator group. ; Group 1 Number missing: 10; Group 2 Number missing: 11

### Protocol outcome 3: Pain at 6 months

- Actual outcome: Median pain (VAS) at 3 months;

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher CR in comparator group. ; Group 1 Number missing: 4; Group 2 Number missing: 4

### Protocol outcome 4: Remission at 6 months

- Actual outcome: Remission (DAS<1.6) at 3 months; Group 1: 24/55, Group 2: 19/59

Risk of bias: All domain - High, Selection - Low, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher CR in comparator group. ; Group 1 Number missing: 4; Group 2 Number missing: 4

12 months; Adverse events - mor	ession at 12+ months; ACR50 response at 6 months; ACR50 response at rtality at 12+ months; Withdrawal/discontinuation: adverse events at thdrawal/discontinuation: inefficacy at Longest time period reported

Study (subsidiary papers)	Van jaarsveld 2000 <sup>171</sup> (Van jaarsveld 20001 <sup>72</sup> , Verstappen 2003 <sup>181</sup> )
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=231)
Countries and setting	Conducted in Netherlands; Setting: Six rheumatological centres in Utrecht (1 university hospital and 5 general hospitals)
Line of therapy	1st line
Duration of study	Intervention time: 2 years
Method of assessment of guideline condition	Adequate method of assessment/diagnosis: ARA 1987 revised criteria
Stratum	Overall
Subgroup analysis within study	Not applicable:
Inclusion criteria	Disease duration < 1 year
Exclusion criteria	age, 17 years; comorbid conditions that might interfere with one of the therapeutic strategies (such as malignancy, cardiac, respiratory, hepatic, and renal insufficiency); previous or current treatment with SAARDs, glucocorticoids, cytotoxic or immunosuppressive drugs; possible pregnancy or breastfeeding; psychiatric or mental disturbances that make adherence to study protocol unlikely.
Recruitment/selection of patients	Since 1990 all patients with RA from the six centres were asked to participate
Age, gender and ethnicity	Age - Other: Mean (10-90 centiles): HCQ - 56 (37-74), MTX - 57 (37-73). Gender (M:F): 90:141. Ethnicity: NR
Further population details	
Extra comments	RF+: HCQ - 67%, MTX - 65% HAQ, mean (10-90 centiles): HCQ - 1.4 (0.5-2.5), MTX - 1.3 (0.3-2.4) Pain, mm, mean (10-90 centiles): HCQ - 46 (9-86), MTX - 44 (9-92) Radiological damage (0-448), mean (10-90 centiles): HCQ - 2 (0-12), MTX - 2 (0-13)
Indirectness of population	No indirectness
Interventions	(n=118) Intervention 1: Monotherapy - Monotherapy - specify. 400mg/day, with dose adjustment due to adverse reactions. Replacement with auranofin (6-9mg/day) if adverse reaction made discontinuation inevitable in the view of the attending doctor. If the patient fulfilled the remission criteria at three subsequent visits (6 months), the dosage was halved Duration 1 year. Concurrent medication/care: Use of NSAIDs and analgesics was allowed. Oral and IA injections of glucocorticoids were avoided Indirectness: Serious indirectness; Indirectness comment: Replacement with out of scope drug in case of adverse reaction Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg,

	hydroxychloroquine: 400mg) 2. Use of glucocorticoids: Short term glucocorticoids not used (As above). Comments: After 1 year, patients without improvement of at least 50% had HCQ replaced by auranofin. For that reason, only data up to 1 year has been included in this review. (n=113) Intervention 2: Monotherapy - Monotherapy - specify. 7.5-15mg/weekly. Replacement with SSZ (2- 3g/day) if adverse reaction made discontinuation inevitable in the view of the attending doctor. If the patient fulfilled the remission criteria at three subsequent visits (6 months), the dosage was halved Duration 1 year. Concurrent medication/care: Use of NSAIDs and analgesics was allowed. Oral and IA injections of glucocorticoids were avoided Indirectness: No indirectness Further details: 1. Dose: Lower dose (sulfasalazine: 1 gm, methotrexate: <=15mg, leflunomide: 10mg, hydroxychloroquine: 200mg) 2. Use of glucocorticoids: Short term glucocorticoids not used (See above). Comments: After 1 year, patients without improvement of at least 50% had MTX replaced by SSZ. In the comparator arm, an out of scope drug was used after 1 year for patients with inadequate response. For that reason, only data up to 1 year has been included in this review.
Funding	Academic or government funding ("Grant support: The Dutch League against Rheumatism")

### RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: MONOTHERAPY - HCQ versus MONOTHERAPY - MTX

Protocol outcome 1: Function at 12 months

- Actual outcome: Function (HAQ) at 12 months; Group 1: mean -0.3 (SD 0.79); n=107, Group 2: mean -0.4 (SD 0.52); n=105; Health Assessment Questionnaire 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ITT used for patients who discontinued strategy, patients lost to follow up excluded from analysis. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in outcome of 0.1 at baseline same magnitude as difference at follow up; Blinding details: Open label trial; Group 1 Number missing: 23, Reason: 11 lost to follow up and excluded from analysis (reasons overall only), 12 discontinued strategy due to ineffectiveness (treatment not in accordance with protocol); Group 2 Number missing: 19, Reason: 8 lost to follow up and excluded from analysis (reasons overall only), 11 discontinued strategy (4 for ineffectiveness, 4 for adverse reaction, 1 for both, 2 other) (treatment not in accordance with protocol)

### Protocol outcome 2: Pain at 12 months

- Actual outcome: Pain (VAS) at 12 months; Group 1: mean -21 (SD 32); n=107, Group 2: mean -24 (SD 26); n=105; Visual Analogue Scale 0-100 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ITT used for patients who discontinued strategy, patients lost to follow up excluded from analysis. ; Indirectness of outcome: No indirectness ; Baseline details: Difference in outcome of 2 at baseline less than magnitude of difference at follow up (3); Blinding details: Open label trial; Group 1 Number missing: 23, Reason: 11 lost to follow up and excluded from analysis (reasons overall only), 12 discontinued strategy (treatment not in accordance with protocol); Group 2 Number missing: 19, Reason: 8 lost to follow up and excluded from analysis (reasons overall only), 11 discontinued strategy (4 for ineffectiveness, 4 for adverse reaction, 1 for both, 2 other) (treatment not in accordance with protocol)

### Protocol outcome 3: Remission at 12 months

- Actual outcome: ACR remission at 12 months; Group 1: 17/107, Group 2: 25/105; Comments: Remission defined as: morning stiffness ≤ 15 mins, pain score ≤ 10 mm, joint score ≤ 1, ESR ≤ 30mm/h

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ITT used for patients who discontinued strategy, patients lost to follow up excluded from analysis. ; Indirectness of outcome: Serious indirectness, Comments: Does not use DAS or similar score; Baseline details: See pop panel; Blinding details: Open label trial; Group 1 Number missing: 23, Reason: 11 lost to follow up and excluded from analysis (reasons overall only), 12 discontinued strategy due to ineffectiveness (treatment not in accordance with protocol); Group 2 Number missing: 19, Reason: 8 lost to follow up and excluded from analysis (reasons overall only), 11 discontinued strategy (4 for ineffectiveness, 4 for adverse reaction, 1 for both, 2 other) (treatment not in accordance with protocol)

### Protocol outcome 4: Withdrawal/discontinuation: adverse events at Longest time period reported

- Actual outcome: Discontinuation of strategy: adverse events at 12 months; Group 1: 0/107, Group 2: 5/105

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ITT used for patients who discontinued strategy, patients lost to follow up excluded from analysis. ; Indirectness of outcome: No indirectness; Baseline details: See pop panel; Blinding details: Open label trial; Group 1 Number missing: 23, Reason: 11 lost to follow up and excluded from analysis (reasons overall only), 12 discontinued strategy due to ineffectiveness (treatment not in accordance with protocol); Group 2 Number missing: 14, Reason: 8 lost to follow up and excluded from analysis (reasons overall only), 6 discontinued strategy (4 for ineffectiveness, 2 other) (treatment not in accordance with protocol)

Protocol outcome 5: Withdrawal/discontinuation: inefficacy at Longest time period reported

- Actual outcome: Discontinuation of strategy: inefficacy at 12 months; Group 1: 12/107, Group 2: 5/105

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Comments - ITT used for patients who discontinued strategy, patients lost to follow up excluded from analysis. ; Indirectness of outcome: No indirectness ; Baseline details: See pop panel; Blinding details: Open label trial; Group 1 Number missing: 11, Reason: 11 lost to follow up and excluded from analysis (reasons overall only); Group 2 Number missing: 14, Reason: 8 lost to follow up and excluded from analysis (reasons overall only), 6 discontinued strategy (4 for adverse events, 2 other) (treatment not in accordance with protocol)

1 (n=289)
Conducted in Belgium
1st line
Intervention time: 2 years
Adequate method of assessment/diagnosis: ACR 1987 criteria
Poor-prognosis disease
Not applicable
People with RA with disease duration ≤1 year and DMARD/glucocorticoid unexperienced. Defined as "high risk" due to erosions, rheumatoid factor, ACPA, disease activity.
People with contraindications to intensive treatment with glucocorticoids.
Recruited in 13 Flemish rheumatology centres.
Age - Mean (SD): 52. Gender (M:F): 66% female. Ethnicity: Not detailed
No indirectness
(n=98) Intervention 1: Parallel combination therapy - Parallel combination therapy - specify. COBRA Classic: methotrexate (15mg per week), sulfasalazine (2g per day). MTX increased to 20mg per week if DAS ≤3.2 at week 8. Then, SSZ increased to 3g per day if DAS ≤3.2 at week 16. Duration 2 years. Concurrent medication/care: Oral prednisone in a step-down scheme (60mg to 7.5mg). Prophylactic treatment with folic

acid, calcium and vitamin D prescribed. IM or IA glucocorticoid injections are allowed once per 8 weeks but not in 4 weeks before W16, Q28, W40 or W52. Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroguine: 400mg) 2. Use of alucocorticoids: Short term alucocorticoids used

(n=98) Intervention 2: Step up therapy - Step up therapy - specify. COBRA Slim: methotrexate (15mg per week). MTX increased to 20mg per week if DAS ≤3.2 at week 8. Then, addition of Leflunomide (10mg per day) if DAS ≤3.2 at week 16. Duration 2 years. Concurrent medication/care: Oral prednisone in a stepdown scheme (60mg to 7.5mg). Prophylactic treatment with folic acid, calcium and vitamin D prescribed. IM or IA glucocorticoids injections are allowed once per 8 weeks but not in 4 weeks before W16, Q28, W40 or W52. . Indirectness: No indirectness

Further details: 1. Dose: Not applicable (MTX dose could be high but LEF dose was low). 2. Use of

RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: PARALLEL COMBINATION THERAPY - METHOTREXATE + SULFASALAZINE versus STEP UP THERAPY: METHOTREXATE + LEFLUNOMIDE

Protocol outcome 1: Disease Activity Score at 12 months

- Actual outcome for Poor-prognosis disease: Change in Disease Activity Score (DAS28) at 12 months; Group 1: mean -2.5 (SD 1.5); n=90, Group 2: mean -2.3 (SD 1.4); n=89; DAS28 2-10 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Group 1 Number missing: 8; Group 2 Number missing: 9

Protocol outcome 2: Disease Activity Score at 6 months

- Actual outcome for Poor-prognosis disease: Change in Disease Activity Score (DAS28) at week 16; Group 1: mean -2.8 (SD 1.2); n=98, Group 2: mean -2.6 (SD 1.2); n=98; DAS28 2-10 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 3: Function at 6 months

- Actual outcome for Poor-prognosis disease: Change in function (HAQ) at 16 weeks; Group 1: mean -0.8 (SD 0.6); n=98, Group 2: mean -0.6 (SD 0.6); n=98; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 4: Function at 12 months

- Actual outcome for Poor-prognosis disease: Change in function (HAQ) at 12 months; Group 1: mean -0.7 (SD 0.7); n=90, Group 2: mean -0.5 (SD 0.7); n=89; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low,

Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Group 1 Number missing: 8; Group 2 Number missing: 9

Protocol outcome 5: Remission at 6 months

- Actual outcome for Poor-prognosis disease: Remission (DAS28 <2.6) at 16 weeks; Group 1: 69/98, Group 2: 72/98 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 6: Remission at 12 months

- Actual outcome for Poor-prognosis disease: Remission (DAS28 <2.6) at 12 months; Group 1: 63/98, Group 2: 59/98 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 7: Low disease activity at 6 months

- Actual outcome for Poor-prognosis disease: Low disease activity (DAS28 ≤3.2) at 16 weeks; Group 1: 83/98, Group 2: 85/98 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 8: Low disease activity at 12 months

- Actual outcome for Poor-prognosis disease: Low disease activity (DAS28 ≤3.2) at 12 months; Group 1: 74/98, Group 2: 74/98 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 9: Radiological progression at 12+ months

- Actual outcome for Poor-prognosis disease: Change in radiological progression (SvdH) at 12 months; Group 1: mean -0.3 (SD 0.5); n=90, Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Group 1 Number missing: 8; Group 2 Number missing: 9

Protocol outcome 10: Withdrawal/discontinuation: adverse events at Longest time period reported

- Actual outcome for Poor-prognosis disease: Discontinuation due to adverse events at 16 weeks; Group 1: 2/93, Group 2: 1/97 Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 5; Group 2 Number missing: 1

Protocol outcome 11: Withdrawal/discontinuation: inefficacy at Longest time period reported

- Actual outcome for Poor-prognosis disease: Discontinuation due to inefficacy at 16 weeks; Group 1: 2/93, Group 2: 0/96 Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 5; Group 2 Number missing: 2

RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: PARALLEL COMBINATION THERAPY - METHOTREXATE +

### SULFASALAZINE versus PARALLEL COMBINATION THERAPY - METHOTREXATE + LEFLUNOMIDE

Protocol outcome 1: Disease Activity Score at 12 months

- Actual outcome for Poor-prognosis disease: Change in Disease Activity Score (DAS28) at 12 months; Group 1: mean -2.5 (SD 1.5); n=90, Group 2: mean -2.3 (SD 1.5); n=85; DAS28 2-10 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 8; Group 2 Number missing: 8

### Protocol outcome 2: Disease Activity Score at 6 months

- Actual outcome for Poor-prognosis disease: Change in Disease Activity Score (DAS28) at week 16; Group 1: mean -2.8 (SD 1.2); n=98, Group 2: mean -2.4 (SD 1.3); n=94

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

### Protocol outcome 3: Function at 6 months

- Actual outcome for Poor-prognosis disease: Change in function (HAQ) at 16 weeks; Group 1: mean -0.8 (SD 0.6); n=98, Group 2: mean -0.7 (SD 0.6); n=94

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

### Protocol outcome 4: Function at 12 months

- Actual outcome for Poor-prognosis disease: Change in function (HAQ) at 12 months; Group 1: mean -0.7 (SD 0.7); n=90, Group 2: mean -0.6 (SD 0.7); n=85

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 8; Group 2 Number missing: 8

### Protocol outcome 5: Remission at 6 months

- Actual outcome for Poor-prognosis disease: Remission (DAS28 <2.6) at 16 weeks; Group 1: 69/98, Group 2: 64/94

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 6: Remission at 12 months

- Actual outcome for Poor-prognosis disease: Remission (DAS28 <2.6) at 12 months; Group 1: 63/98, Group 2: 58/93

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 7: Low disease activity at 6 months

- Actual outcome for Poor-prognosis disease: Low disease activity (DAS28 ≤3.2) at 16 weeks; Group 1: 83/98, Group 2: 82/94 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 8: Low disease activity at 12 months

- Actual outcome for Poor-prognosis disease: Low disease activity (DAS28 ≤3.2) at 12 months; Group 1: 73/98, Group 2: 74/93 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 9: Radiological progression at 12+ months

- Actual outcome for Poor-prognosis disease: Change in radiological progression (SvdH) at 12 months; Group 1: mean 0.3 (SD 0.5); n=90, Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 8; Group 2 Number missing: 8

Protocol outcome 10: Withdrawal/discontinuation: adverse events at Longest time period reported - Actual outcome for Poor-prognosis disease: Discontinuation due to adverse events at 16 weeks; Group 1: 2/93, Group 2: 0/91 Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 5; Group 2 Number missing: 3

Protocol outcome 11: Withdrawal/discontinuation: inefficacy at Longest time period reported

- Actual outcome for Poor-prognosis disease: Discontinuation due to inefficacy at 16 weeks; Group 1: 2/93, Group 2: 1/92 Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 5; Group 2 Number missing: 1

RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: STEP UP THERAPY: METHOTREXATE + LEFLUNOMIDE versus PARALLEL COMBINATION THERAPY - METHOTREXATE + LEFLUNOMIDE

Protocol outcome 1: Disease Activity Score at 12 months

- Actual outcome for Poor-prognosis disease: Change in Disease Activity Score (DAS28) at 12 months; Group 1: mean -2.3 (SD 1.4); n=89, Group 2: mean -2.3 (SD 1.5); n=85; DAS28 2-10 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 9; Group 2 Number missing: 8

### Protocol outcome 2: Disease Activity Score at 6 months

- Actual outcome for Poor-prognosis disease: Change in Disease Activity Score (DAS28) at week 16; Group 1: mean -2.6 (SD 1.2); n=98, Group 2: mean -2.4 (SD 1.3); n=94; DAS28 2-10 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

### Protocol outcome 3: Function at 6 months

- Actual outcome for Poor-prognosis disease: Change in function (HAQ) at 16 weeks; Group 1: mean -0.6 (SD 0.6); n=98, Group 2: mean -0.7 (SD 0.6); n=94; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

### Protocol outcome 4: Function at 12 months

- Actual outcome for Poor-prognosis disease: Change in function (HAQ) at 12 months; Group 1: mean -0.5 (SD 0.7); n=89, Group 2: mean -0.6 (SD 0.7); n=85; HAQ 0-3 Top=High is poor outcome

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 9; Group 2 Number missing: 8

### Protocol outcome 5: Remission at 6 months

- Actual outcome for Poor-prognosis disease: Remission (DAS28 <2.6) at 16 weeks; Group 1: 72/98, Group 2: 64/94 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

### Protocol outcome 6: Remission at 12 months

- Actual outcome for Poor-prognosis disease: Remission (DAS28 < 2.6) at 12 months; Group 1: 59/98, Group 2: 58/93

Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

### Protocol outcome 7: Low disease activity at 6 months

- Actual outcome for Poor-prognosis disease: Low disease activity (DAS28 ≤3.2) at 16 weeks; Group 1: 85/98, Group 2: 82/94 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 8: Low disease activity at 12 months

- Actual outcome for Poor-prognosis disease: Low disease activity (DAS28 ≤3.2) at 12 months; Group 1: 74/98, Group 2: 74/93 Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: ; Group 2 Number missing:

Protocol outcome 9: Radiological progression at 12+ months

- Actual outcome for Poor-prognosis disease: Change in radiological progression (SvdH) at 12 months; Group 1: mean -0.4 (SD 1.1); n=89, Risk of bias: All domain - Very high, Selection - High, Blinding - High, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low, Other 1 - High; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 9; Group 2 Number missing: 8

Protocol outcome 10: Withdrawal/discontinuation: adverse events at Longest time period reported

- Actual outcome for Poor-prognosis disease: Discontinuation due to adverse events at 16 weeks; Group 1: 1/97, Group 2: 0/91 Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 5; Group 2 Number missing: 1

Protocol outcome 11: Withdrawal/discontinuation: inefficacy at Longest time period reported

- Actual outcome for Poor-prognosis disease: Discontinuation due to inefficacy at 16 weeks; Group 1: 0/96, Group 2: 1/92 Risk of bias: All domain - Very high, Selection - High, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - Low; Indirectness of outcome: No indirectness ; Baseline details: Higher symptom duration, ESR, CRP in comparator group; Group 1 Number missing: 2; Group 2 Number missing: 1

Study	Leflunomide failed trial: Dougados 2005 <sup>34</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=106)
Countries and setting	Conducted in Multiple countries; Setting: 24 week, double blind phase of a multi-centre, international RELIEF study, which followed an initial 24 week open label phase. The study was carried out in 162 cen in 14 countries across Europe, South America, Australia, and New Zealand.
Line of therapy	Mixed line
Duration of study	Other: Patients randomised to double blind phase for 24 weeks if initial 24 weeks of leflunomide had fail
Method of assessment of guideline condition	Adequate method of assessment/diagnosis
Stratum	LFN failed:
Subgroup analysis within study	Not applicable
Inclusion criteria	Male or female patients aged 18-75 years with active RA as defined by a DAS28>3.2, and with a function classification of I, II, or III according to the American Rheumatology Association (ARA) criteria were incluin the main study. Women of childbearing potential and men were required to use adequate contraception throughout the study. Patients with inadequate DAS28 response to leflunomide in the initial open label phase of the study were eligible for entry into the double blind phase.
Exclusion criteria	Patients of ARA functional class IV were not eligible for inclusion. Women who were pregnant or breastfeeding were also excluded.
Recruitment/selection of patients	In the initial open label phase of the study, after a 1-2 week screening period and interruption of any oth DMARD for at least a month, patients received a leflunomide loading dose of 100mg once daily for the f days followed by maintenance dose of 20mg once daily thereafter. Patients who were non-responders to leflunomide at the end of the first open label phase were randomly allocated to a further 24 weeks' treatment with either leflunide plus sulfasalazine or sulfasalazine plus placebo. Patients who were good or moderar responders in the first open label phase entered a second open label phase of 24 weeks leflunomide monotherapy, the results of which are not presented here. The protocol required treatment with other DMARDs to be discontinued at least 4 weeks before enrolment the initial phase of the study.
Age, gender and ethnicity	Age - Mean (SD): monotherapy (SSZ): 55.4; parallel therapy (SSZ+LFN): 56.3. Gender (M:F): 1/2. Ethn not specified but multi-centre, international study
Further population details	1. Disease duration: Not stated / Unclear

Rheumatoid arthritis: Final References

Extra comments	Before starting on Leflunomide in the first open label phase 66.1% of patients in the LFN+SSZ group and 68.0% in the SSZ+placebo group had already used other DMARDs (mean number of DMARDS: 1.7 and 1.3 respectively) previously.
Indirectness of population	No indirectness
Interventions	<ul> <li>(n=56) Intervention 1: Parallel combination therapy - Parallel combination therapy - specify. Patients who were non-responders to leflunomide monotherapy at the end of the 24 weeks open label phase and randomly allocated to the parallel combination therapy received leflunomide (20mg once daily) plus sulfasalazine (2g once daily starting at 0.5g increasing in weekly steps of 0.5g) . Duration 24 weeks. Concurrent medication/care: Stable doses of non-glucocorticoid anti-inflammatory drugs or oral glucocorticoids (max 10mg prednisone or glucocorticoid equivalent) were permitted as concomitant drugs. Intra-articular injections of glucocorticoids (max 60mg prednisone or equivalent) were to be avoided if possible, and were not permitted within the 4 weeks preceding the assessment. Analgesics were allowed, but were not to be taken in the 6 hours before joint examination Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: &gt;15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) (LFN (20mg) + SSZ (2g)). 2. Use of steroids: Not stated / Unclear (Stable doses of non-glucocorticoid anti-inflammatory drugs or oral glucocorticoids (max 10mg prednisone or glucocorticoids (max 60mg prednisone or equivalent) were to be avoided if possible, and were not permitted as concomitant drugs. Intra-articular injections of glucocorticoids (max 60mg prednisone or equivalent) were to be avoided if possible, and were not permitted within the 4 weeks preceding the assessment.).</li> <li>(n=50) Intervention 2: Monotherapy - Monotherapy - specify. Patients who were non-responders to leflunomide monotherapy at the end of the 24 weeks open label phase and randomly allocated to the monotherapy group received sulfasalazine (2g once daily starting at 0.5g increasing in weekly steps of 0.5g) plus placebo.</li> <li>Duration 24 weeks. Concurrent medication/care: Stable doses of non-glucocorticoid anti-inflammatory drugs or oral glucocorticoids (max 10mg prednisone or gluvalent) w</li></ul>

Study	Methotrexate failures in BeSt trial trial: Van der kooij 2007 <sup>168</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=138)
Countries and setting	Conducted in Netherlands; Setting: The BeSt study was conducted by rheumatologists participating in 18 peripheral and 2 university hospitals in the western part of the Netherlands.
Line of therapy	Mixed line
Duration of study	Intervention time: 2 years
Method of assessment of guideline condition	Adequate method of assessment/diagnosis
Stratum	MTX failed
Subgroup analysis within study	Not applicable
Inclusion criteria	BeSt study overall: Patients with disease duration of $\leq 2$ years, aged $\geq 18$ years, and have active disease with $\geq 6$ of 66 swollen joints, $\geq 6$ of 68 tender joints, and either an erythrocyte sedimentation rate (ESR) $\geq 28$ mm/hour or a global health score of $\geq 20$ mm on a 0-100 mm visual analogue scale. Sub-analysis: subset of patients from group 1 and group 2 of the BeSt study who failed MTX (persistent DAS>2.4)
Exclusion criteria	BeSt study overall: previous treatment with DMARDs other than antimalarials, concomitant treatment with an experimental drug, a malignancy within the last 5 years, bone marrow hypoplasia, a serum aspartate aminotransferase or alanine aminotransferase (ALT) level >3x the upper limit of normal, a serum creatinine level >150 µmoles/liter or an estimated creatinine clearance <75 ml/minute, diabetes mellitus, alcohol or drug abuse, concurrent pregnancy, wish to conceive during the study period, or inadequate contraception.
Recruitment/selection of patients	Patients with early RA (ACR1987) were recruited between April 2000 and August 2002.
Age, gender and ethnicity	Age - Mean (SD): 54 (13). Gender (M:F): 1/3. Ethnicity: not mentioned but study took place in the Netherlands
Further population details	1. Disease duration: early RA (<= 2 years) (≤2 years).
Extra comments	All patients were DMARD naive at the start of the BeSt trial.
Indirectness of population	No indirectness
Interventions	(n=69) Intervention 1: Sequential monotherapy - Sequential monotherapy - specify. All patients started therapy with methotrexate (MTX) 7.5mg/week, after 4 weeks instantly increased to 15mg/week, in combination with folic acid (1 mg/day). In the case of DAS>2.4 after 3 months, MTX was increased to 25 mg/week (or the highest tolerated dose). Patients with persistingDAS >2.4 on MTX 25 mg/week proceeded to next treatment steps (1 month overlap when switching from one single DMARD to the next). In the case of drug adverse events, the responsible drug was tapered to the lowest tolerable dose or discontinued if not

Rheumatoid arthritis: Final References tolerated at all. In this case, patients in the sequential monotherapy group proceeded to the next step in the treatment protocol.

If a DAS  $\leq$ 2.4 was achieved and maintained for  $\geq$ 6 months, medication was tapered to a single DMARD in maintenance dose: 2 g/day for SSZand 10 mg every other day for LFN. If the DAS increased to >2.4 after tapering to maintenance dose, the last effective dose of the last tapered drug was resumed. If DAS remained >2.4, the patient proceeded to the next treatment steps.

Next steps after failure of MTX for sequential monotherapy group: SSZ monotherapy (2-3 g/day), LFN monotherapy (20 mg/day).

Assessments were performed by a research nurse every 3 months.. Duration up to 2 years. Concurrent medication/care: Concomitant treatment with non-glucocorticoid anti-inflammatory drugs and intra-articular injections with glucocorticoids were permitted. Other parenteral glucocorticoids were not allowed. The use of DMARDs or oral glucocorticoids was only permitted as dictated by the treatment protocol. All patients received 1 mg/day folic acid during the treatment with MTX.. Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) (Step 1: SSZ 2-3g/day; if failed then Step 2: LFN 20 mg/day). 2. Use of s: Short term glucocorticoids not used (Concomitant treatment with non-steroidal glucocorticoid anti-inflammatory drugs and intra-articular injections with glucocorticoids were permitted. Other parenteral glucocorticoids were not allowed. The use of DMARDs or oral glucocorticoids were permitted as dictated by the treatment protocol. ).

(n=69) Intervention 2: Step up therapy - Step up therapy - specify. All patients started therapy with methotrexate (MTX) 7.5mg/week, after 4 weeks instantly increased to 15mg/week, in combination with folic acid (1 mg/day). In the case of DAS>2.4 after 3 months, MTX was increased to 25 mg/week (or the highest tolerated dose). Patients with persisting DAS >2.4 on MTX 25 mg/week proceeded to next treatment steps (1 month overlap when switching from one single DMARD to the next). In the case of drug adverse events. the responsible drug was tapered to the lowest tolerable dose or discontinued if not tolerated at all. In this case patients in the step-up group continued with the other drugs in the combination. If a DAS  $\leq$ 2.4 was achieved and maintained for  $\geq$ 6 months, medication was tapered to maintenance dose: 10 mg/week for MTX (tapering by 2.5mg/month), 2 g/day for SSZ and 10 mg every other day for LFN. If the DAS increased to >2.4 after tapering to maintenance dose, the last effective dose of the last tapered drug was resumed. If DAS remained >2.4, the patient proceeded to the next treatment steps. Next steps after failure of MTX for step-up combination therapy group: Step 1: MTX (25mg/week) + SSZ (2-3q/day); if failed then Step 2: MTX (25mg/week) + SSZ (2-3 q/day) + HCQ (400mg/day) Assessments were performed by a research nurse every 3 months.. Duration up to 2 years. Concurrent medication/care: Concomitant treatment with non-glucocorticoid anti-inflammatory drugs and intra-articular injections with glucocorticoids were permitted. Other parenteral glucocorticoids were not allowed. The use of DMARDs or oral glucocorticoids was only permitted as dictated by the treatment protocol. All patients received 1 mg/day folic acid during the treatment with MTX.. Indirectness: No indirectness

hydroxychloroquine: 400mg) (Step 1: MTX (25mg/week) + SSZ (2-3g/day); if failed then Step 2: MTX (25mg/week) + SSZ (2-3 g/day) + HCQ (400mg/day)). 2. Use of glucocorticoids: Short term glucocorticoids not used (Concomitant treatment with non-glucocorticoid anti-inflammatory drugs and intra-articular injections with glucocorticoid were permitted. Other parenteral glucocorticoids were not allowed. The use of DMARDs or oral glucocorticoids was only permitted as dictated by the treatment protocol.). Funding Study funded by industry RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: SEQUENTIAL MONOTHERAPY - SSZ THEN LFN versus STEP UP THERAPY - MTX+SSZ THEN MTX+SSZ+HCQ Protocol outcome 1: Low disease activity at 12 months - Actual outcome for MTX failed: LDA = DAS ≤2.4 after Step 1 (SSZ mono- or combination therapy) at during 2 years; Group 1: 15/69, Group 2: 15/69 Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - High; Indirectness of outcome: No indirectness; Group 1 Number missing: 0; Group 2 Number missing: 0 - Actual outcome for MTX failed: LDA = DAS ≤2.4 after Step 2 (SSZ failure, followed by LFN mono Group 1 or MTX+SSZ+HCQ Group 2) at during 2 years; Group 1: 7/54, Group 2: 16/44 Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - High; Indirectness of outcome: No indirectness; Group 1 Number missing: 0; Group 2 Number missing: 0 - Actual outcome for MTX failed: LDA = DAS ≤2.4 total ('successes' from Step 1 and Step 2 combined) at during 2 years; Group 1: 22/69, Group 2: 31/69 Risk of bias: All domain - Very high, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low, Subgroups - High, Comments - 54 patients in each group failed Step 1. All failures from group 1 but only 44 of group 2 failures moved onto Step 2 of treatment. The authors do not explain the reason for the 10 missing patients. Study	Methotrexate following failed sulphasalazine therapy trial: Haagsma 1994 <sup>56</sup>
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	1 (n=40)
Countries and setting	Conducted in Netherlands; Setting: Patients having RA who had an insufficient response to sulphasalazine (SSZ) according to their treating physician were considered for selection. In all patients SSZ treatment was stopped for 2 weeks. Patients were then randomised.
Line of therapy	Mixed line
Duration of study	Intervention time: 24 weeks
Method of assessment of guideline condition	Adequate method of assessment/diagnosis
Stratum	SSZ failed
Subgroup analysis within study	Not applicable
Inclusion criteria	<ol> <li>age 18 years and older</li> <li>RA according to the revised ACR criteria (1987)</li> <li>current SSZ treatment given for at least 6 months, but with insufficient effect</li> <li>active arthritis defined by: a DAS of minimally 3.0 (corresponding with a Ritchie score of 5 plus six swollen joints and an ESR of 30)</li> </ol>
Exclusion criteria	<ol> <li>preceding treatment with MTX</li> <li>contraindications for the use of MTX- insufficient kidney function defined as the estimated creatinine clearance (according to Cockroft) of less than 75 ml/min, liver disease, i.e. clinically significant hepatic impairment, liver enzymes more than twice the upper limit of the normal values or dormant serious liver disease (e.g. cirrhosis), uncontrolled diabetes mellitus (insulin dependent), severe congestive heart failure, interstitial lung disease, active peptic ulcers, inflammatory bowel disease, malignancies, leucopenia i.e. WBC count &lt;3.5x109/l, thrombocytopenia i.e. platelet count &lt;120 x109/l, pregnancy, intended pregnancy, breastfeeding or inability of adequate contraception, known or suspected alcoholism;</li> <li>the use of glucocorticoids</li> <li>no informed consent.</li> </ol>
Recruitment/selection of patients	Patients having RA who had an insufficient response to sulphasalazine (SSZ) according to their treating physician were considered for selection.
Age, gender and ethnicity	Age - Mean (SD): MTX group: 51.8 (13.9); MTX+SSZ group: 59.3 (12.3) . Gender (M:F): 1/3. Ethnicity: not mentioned
Further population details	1. Disease duration: established RA (> 2 years) (not mentioned specifically but induced from mean (SD) disease duration: MTX 5.3 (4.2); MTX+SSZ 4.7 (4.2)).

-	
Extra comments	Before starting on SSZ in the first phase of the study patients in both groups had used 1 median (range 0-4) DMARD previously.
Indirectness of population	No indirectness
Interventions	<ul> <li>(n=22) Intervention 1: Parallel combination therapy - Parallel combination therapy - specify. Methotrexate (MTX; 7.5 mg/week given in a single dose)combined with Sulphasalazine (SSZ; 2g/day in two divided doses). If there was insufficient improvement after 16 weeks of study and the medication was tolerated, the MTX dose was increased to 15mg/week in two divided doses with an interval of 24 hours. If unacceptable toxicity occurred, i.e. abnormal laboratory values as defined under the heading evaluation, measured on two occasions (the liver enzymes had to be greater than twice the normal value),severe skin rash, pulmonary abnormalities attributable to the study drugs or intolerable subjective side-effects, the MTX dose was reduced to 5mg/week and the SSZ dose to 1g or the medication was stopped, followed by a re-challenge depending on the severity of adverse drug reaction. If a dose reduction had insufficient effect, folic acid in a dose of 1mg daily was added in the case of minor toxicity.</li> <li>Patients were evaluated 2 weeks before entry, and on weeks0, 4, 8, 12, 16, 20 and 24 Duration 24 weeks. Concurrent medication/care: NSAIDs were given in a stable dose. No systemic glucocorticoids were allowed, one local injection of glucocorticoids was permitted but discouraged Indirectness: No indirectness Further details: 1. Dose: Lower dose (sulfasalazine: 1 gm, methotrexate: &lt;=15mg, leflunomide: 10mg, hydroxychloroquine: 200mg) (MTX 7.5mg/week given in a single dose (increased to 15mg/week in two divided doses). 2. Use of glucocorticoids: Short term glucocorticoids not used (glucocorticoid use was part of exclusion criteria).</li> </ul>
	<ul> <li>(n=18) Intervention 2: Monotherapy - Monotherapy - specify. Methotrexate (MTX; 7.5 mg/week given in a single dose). If there was insufficient improvement after 16 weeks of study and the medication was tolerated, the MTX dose was increased to 15mg/week in two divided doses with an interval of 24 hours. If unacceptable toxicity occurred, i.e. abnormal laboratory values as defined under the heading evaluation, measured on two occasions (the liver enzymes had to be greater than twice the normal value), severe skin rash, pulmonary abnormalities attributable to the study drugs or intolerable subjective side-effects, the MTX dose was reduced to 5mg/week or the medication was stopped, followed by a re-challenge depending on the severity of adverse drug reaction. If a dose reduction had insufficient effect, folic acid in a dose of 1mg daily was added in the case of minor toxicity.</li> <li>Patients were evaluated 2 weeks before entry, and on weeks 0, 4, 8, 12, 16, 20 and 24 Duration 24 weeks. Concurrent medication/care: NSAIDs were given in a stable dose. No systemic glucocorticoids were allowed, one local injection of glucocorticoids was permitted but discouraged Indirectness: No indirectness Further details: 1. Dose: Lower dose (sulfasalazine: 1 gm, methotrexate: &lt;=15mg, leflunomide: 10mg, hydroxychloroquine: 200mg) (MTX 7.5mg/week given in a single dose (increased to 15mg/week in two divided doses after 16 weeks if effect insufficient and MTX was tolerated) ). 2. Study	Sulfasalazine failed: followed by MTX+SSZ versus MTX trial: Capell 2007 <sup>19</sup>					
Study type	RCT (Patient randomised; Parallel)					
Number of studies (number of participants)	1 (n=110)					
Countries and setting	Conducted in United Kingdom; Setting: A randomised controlled study in eight Scottish NHS sites - four in Glasgow, three in Lanarkshire, and one in Inverness.					
Line of therapy	Mixed line					
Duration of study	Intervention time: 12 months					
Method of assessment of guideline condition	Adequate method of assessment/diagnosis					
Stratum	SSZ failed					
Subgroup analysis within study	Not applicable					
Inclusion criteria	Inclusion criteria were: aged 18-80 years and disease duration <10 years, with active disease defined by DAS of >2.4.					
Exclusion criteria	Patients were excluded if they had: prior exposure to either MTX or SSZ, known sulphonamide allergy, significant renal (creatinine >150 mmol/dl) or liver (alanine aminotransferase aspartate aminotransferase >80 IU/I, alkaline phosphatase >700 IU/I, Y-glulamyl transferase x3) disease, abnormal white cell count (<4x 109/I), pre-existing pulmonary fibrosis, known or planned pregnancy or use of oral glucocorticoids >7.5mg/day.					
Recruitment/selection of patients	Between May 1999 and June 2003, 687 patients with rheumatoid arthritis were recruited.					
Age, gender and ethnicity	Age - Mean (range): MTX+SSZ: 56 (30-78); SSZ: 55 (18-77); MTX: 53 (34-79). Gender (M:F): 1/3. Ethnicity: not mentioned specifically, but study conducted in Scotland					
Further population details	1. Disease duration: Not stated / Unclear (disease duration <10 years).					
Extra comments	Patients screened who did not meet the entry criteria or were not willing to participate in the study were documented. The authors do not specifically mention previous DMARD use other than one of the exclusion criteria being patients who had been on MTX or SSZ.					
Indirectness of population	No indirectness					
Interventions	(n=56) Intervention 1: Parallel combination therapy - Parallel combination therapy - specify. Continue SSZ at the dose achieved by 6 months with the addition of MTX initially 7.5mg/week (3x 2.5mg), increasing by 2.5mg/month (1x 2.5mg) until the maximal permitted dose of 25mg or toxicity occurred. Assessments were performed at 6, 9, 12, 15 and 18 months. Those patients whose DAS was considered 'too good' (DAS<2.4) to receive combination therapy and who continued with SSZ or an alternative drug were also assessed at 18 months Duration 12 months. Concurrent medication/care: Folic acid 5 mg/week					

	given 3 days after MTX/MTX placebo. Concomitant non-glucocorticoid anti-inflammatory drugs and other drugs were continued. Intra-articular or intramuscular glucocorticoid was permitted, but not within 1 month of the 6, 12 or 18 month assessments Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) (Continue SSZ at the dose achieved by 6 months (max dose of 4g/day) with the addition of MTX initially 7.5mg/week (3x 2.5mg), increasing by 2.5mg/month (1x 2.5mg) until the maximal permitted dose of 25mg or toxicity occurred.). 2. Use of glucocorticoids: Short term glucocorticoids used (Intra-articular or intramuscular glucocorticoid was permitted, but not within 1 month of the 6, 12 or 18 month assessments. Patients who used oral glucocorticoids >7.5mg/day were excluded.). (n=54) Intervention 2: Monotherapy - Monotherapy - specify. Placebo SSZ at the previously achieved number of tablets by6 months, with the addition of MTX, initially 7.5mg/week, increasing by 2.5mg/month until the maximal dose of 25 mg/week or toxicity occurred. Assessments were performed at 6, 9, 12, 15 and 18 months. Those patients whose DAS was considered 'too good' (DAS<2.4) to receive combination therapy and who continued with SSZ or an alternative drug were also assessed at 18 months Duration 12 months. Concurrent medication/care: Folic acid 5 mg/week given 3 days after MTX/MTX placebo. Concomitant non-glucocorticoid anti-inflammatory drugs and other drugs were continued. Intra-articular or intramuscular glucocorticoid was permitted, but not within 1 month of the 6, 12 or 18 month assessments Indirectness: No indirectness Further details: 1. Dose: Higher dose (sulfasalazine: 2 gm, methotrexate: >15 mg, leflunomide: 20mg, hydroxychloroquine: 400mg) (Placebo SSZ at the previously achieved number of tablets by 6 months, with the addition of MTX, initially 7.5mg/week, increasing by 2.5 mg/month until the maximal dose of 25 mg/week or toxi
Funding	Academic or government funding (but drugs provided by industry)

RESULTS (NUMBERS ANALYSED) AND RISK OF BIAS FOR COMPARISON: PARALLEL COMBINATION THERAPY - MTX+SSZ versus MONOTHERAPY - MTX+PLACEBO

Protocol outcome 1: Disease Activity Score at 12 months

- Actual outcome for SSZ failed: DAS (median and IQR; change from baseline/6 months to 18 months) at 12 months; MTX+SSZ: -0.67 (-1.38 to -0.21) MTX+placebo: -0.26 (-0.99 to 0);

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 17, Reason: intercurrent illness, side effects, lack of effect, non-

compliance/lost to follow-up; Group 2 Number missing: 16, Reason: intercurrent illness, side effects, lack of effect, non-compliance/lost to follow-up

Protocol outcome 2: Function at 12 months

- Actual outcome for SSZ failed: HAQ (median and IQR; change from baseline/6 months to 18 months) at 12 months; HAQ 0-100 Top=High is poor outcome; MTX+SSZ: -0.5 (-10.25 to 0.06)

MTX+placebo: -0.19 (-10.25 to 0.13);

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 17, Reason: intercurrent illness, side effects, lack of effect, noncompliance/lost to follow-up; Group 2 Number missing: 16, Reason: intercurrent illness, side effects, lack of effect, non-compliance/lost to follow-up

Protocol outcome 3: ACR50 response at 12 months

- Actual outcome for SSZ failed: ACR50 response (at 18 months) at 12 months; Group 1: 6/56, Group 2: 4/54 Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 17, Reason: intercurrent illness, side effects, lack of effect, noncompliance/lost to follow-up; Group 2 Number missing: 16, Reason: intercurrent illness, side effects, lack of effect, non-compliance/lost to follow-up;

Protocol outcome 4: Withdrawal/discontinuation: adverse events at Longest time period reported

Actual outcome for SSZ failed: withdrawal due to side effects (6 to 18 months) at 12 months; Group 1: 12/56, Group 2: 14/54
Risk of bias: All domain - Low, Selection - Low, Blinding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover
Low; Indirectness of outcome: No indirectness; Group 1 Number missing: 5, Reason: intercurrent illness, lack of effect, non-compliance/lost to follow-up;
Group 2 Number missing: 2, Reason: intercurrent illness, lack of effect, non-compliance/lost to follow-up
Actual outcome for SSZ failed: withdrawal due to lack of effects (6 to 18 months) at 12 months; Group 1: 2/56, Group 2: 2/54

Risk of bias: All domain - High, Selection - Low, Blinding - Low, Incomplete outcome data - High, Outcome reporting - Low, Measurement - Low, Crossover - Low; Indirectness of outcome: No indirectness ; Group 1 Number missing: 15, Reason: intercurrent illness, side effects, non-compliance/lost to follow-up; Group 2 Number missing: 14, Reason: intercurrent illness, side effects, non-compliance/lost to follow-up

patients, one at a time, along each of the	Start age: 54.8 years (SD: 13.6)	· · · /	column (95% CI: NR; p=NR)	5	£61,046	15.77	£27,392 per QALY	
alternative treatment pathways. This includes 6 month initial treatment response (ACR 20 and 50 response), duration of treatment strategy for responders, progression of disease (in terms of HAQ) while treatment continues, and future treatments (including biologics) likely to be provided over the remaining patient lifetime after withdrawal from initial DMARD	Male: 44.4% Intervention 1: Monotherapy: DMARD monotherapy (first line methotrexate 15mg/week, second line sulfasalazine 1g/day) Intervention 2: Parallel combination: two or more DMARDs given in combination at the same time	(95% CI: NR; p=NR) <b>Currency &amp; cost year:</b> 2007/8 UK pounds <b>Cost components</b> <b>incorporated:</b> Drug costs (including drugs, monitoring, review and administration where applicable); annual costs of managing RA stratified by HAQ score (hospital days, outpatient visits and joint replacements). Cost of adverse events not directly quantified, indirectly quantified		Analysis of uncertainty: Probabilistic sensitivity analysis conducted comparing all 6 interventions, not the 5 relevant interventions reported here. Results demonstrated: Probability Intervention 4 cost effective (£20K): 50% Probability Intervention 5 cost effective (£20K): 43% In addition, a range of one way sensitivity analyses were conducted to test robustness of results to the assumptions				

>Na

strategy. No treatment related mortality effect modelled. Perspective: UK NHS Time horizon: lifetime Treatment effect duration:<sup>(a)</sup> 6 months Discounting: Costs: 3.5%; Outcomes: 3.5%

Intervention 3: Step-up combination: Start on DMARD monotherapy, a second DMARD is added if inadequate response is observed (within first 6 months)

#### Intervention 4:

Step-down combination: initial parallel combination followed by downward dose titration and withdrawal

#### Intervention 5:

Intensive step-up combination: initial parallel combination and rapid dose increases (to above BNF recommended doses) made where an inadequate response is observed (within 6 months)

A sixth intervention was reported but does not meet the protocol (glucocorticoid plus monotherapy) and so is not reported.

All strategies used glucocorticoids 'as

through treatment withdrawal.

and measurement values used. Analyses included: alternative specifications of the relationship between HAQ and EQ-5D; patient baseline characteristics (HAQ and age), discount rates and frequencies of monitoring required while taking treatment. Assumption non-responders continue treatment until an adverse event or loss of efficacy is experienced. Assumption that there is no HAQ increase once achieved an ACR20 or 50 response for those receiving combination DMARDs (base-case assumed progression for all and was based on monotherapy evidence). Overall results were robust to all sensitivity analyses.

#### needed'.

#### Data sources

**Health outcomes:** Baseline characteristics from UK Early Rheumatoid Arthritis Study (Kobelt 2002), mortality from standard UK lifetables, initial 6-month treatment response (ACR 20 and ACR 50) and 6-month treatment withdrawal rate taken from a network meta-analysis of 13 RCTs identified through a systematic literature review. Of the 13 trials used to estimate the treatment effects, 8 of them were excluded from our clinical review either because they included ciclosporin A, a DMARD excluded from the protocol, or because the treatment arms of the trial were the same and only differed in the amount of monitoring received (TICORA). Therefore, only 5 of the trials used are included in the clinical review. Percentage HAQ improvement for a ACR 20 and 50 response taken from estimate published by the US National Databank for Rheumatic Diseases, annual HAQ progression (increase) taken from meta-analysis of natural disease data. Lifetime QALYs of biologic therapy taken from biologics economic model by Brennan et al 2007. Adverse events not directly quantified, indirectly quantified through treatment withdrawal.

**Quality-of-life weights:** HAQ converted to EQ-5D (UK tariff) using US National Databank for Rheumatic Diseases regression model. **Cost sources:** Resource use: Annual RA resource use stratified by HAQ taken from a UK cohort (Norfolk Arthritis Registry). Lifetime costs of biologics taken from biologics economic model (Brennan et al 2007). Unit costs: BNF 2008 and PSSRU 2007.

#### Comments

**Source of funding:** NICE as part of CG79. **Limitations:** Does not specify DMARDs but rather refers to treatment strategies, although authors note that a systematic review of monotherapy found no statistically significant difference between DMARDs. EQ-5D mapped from HAQ rather than directly elicited from patients in trials. Patient covariates are not included to determine differences in clinical response or treatment withdrawal as both of these inputs are based on trials not a registry. Criteria set by NICE for biologic eligibility is failing 2 DMARDs (incl. methotrexate) and having a DAS >5.1. As model is HAQ based and conversion from HAQ to DAS is not possible, this requirement not included in model. This analysis is based on 5 of the 21 studies included for this question and includes 8 studies that were not included in the clinical review and so does not reflect full body of evidence and may provide treatment effect estimates that do not reflect that identified in the clinical review. **Other:** None

#### **Overall applicability:**<sup>(b)</sup> Partially applicable **Overall quality:**<sup>(c)</sup> Potentially serious limitations

Abbreviations: 95% CI: 95% confidence interval; CUA: cost-utility analysis; EQ-5D: EuroQol 5 dimensions (scale: 0.0 [death] to 1.0 [full health], negative values mean worse than death); ICER: incremental cost-effectiveness ratio; NR: not reported; pa: probabilistic analysis; QALYs: quality-adjusted life years

(a) For studies where the time horizon is longer than the treatment duration, an assumption needs to be made about the continuation of the study effect. For example, does a difference in utility between groups during treatment continue beyond the end of treatment and if so for how long.

(b) Directly applicable / Partially applicable / Not applicable

(c) Minor limitations / Potentially serious limitations / Very serious limitations

Study	Van den Hout 2009 <sup>162</sup>					
Study details	Population & interventions	Costs	Health outcomes	Cost effectiveness		
<b>Economic analysis:</b> CUA (health outcome: QALYs)	<b>Population:</b> Adults with early RA (<2years) with active	Total costs (mean per patient): Intervention 1: £9,211	<b>QALYs (mean per patient):</b> Intervention 1: 1.29	Intervention 2 dominates intervention 1		

#### Study design: Withintrial analysis (RCT: BeST trial) Approach to analysis: Analysis of individual level data for EQ-5D and resource use. Unit costs applied. Perspective: Dutch healthcare system Follow-up: 2 years Treatment effect

duration:<sup>(a)</sup> n/a Discounting: Costs: 3%; Outcomes: 3% disease and who have not previously received DMARDs.

#### Cohort settings:

Start age: 54 years (SD: 13) Intervention1: Male: 32% Intervention 2: Male: 28%

#### Intervention 1:

Sequential monotherapy (MTX, then Sulfasalazine, then leflunomide, then MTX + infliximab, then gold with methylprednisolone, then MTX with ciclosporin A + prednisolone then azathioprine with prednisone)

#### Intervention 2:

Step-up combination (MTX, then MTX + sulfasalazine, then MTX with sulfasalazine and HCQ, then MTX, sulfasalazine+ HCQ + prednisone, then MTX + infliximab, then MTX with ciclosporin A +

prednisolone, then leflunomide, then azathioprine with Intervention 2: £7,053 Incremental (2–1): saves £2,158 (95% CI: NR; p=NR)

#### Currency & cost year:

2008 Euros (presented here as 2008 UK pounds<sup>(b)</sup>) **Cost components incorporated:** Medication costs, consultations, admissions

and homecare.

Intervention 2: 1.31 Incremental (2–1): 0.02 (95% CI: NR; p=NR) Analysis of uncertainty: Bootstrapping undertaken for all 4 interventions in study, not the 2 relevant interventions reported here. Results demonstrated: probability Intervention 2 cost effective (£20K threshold): ~50% (from a graph). Analysis was done including two additional comparators that did not meet the protocol. Results presented graphically only so values are approximate.

prednisone) For both 1 and 2, treatment was adapted based on DAS measured every 3 months, if >2.4 next treatment step started, if <2.4, present treatment continued and after 6 months the last added drug was tapered until one DMARD in a maintenance dose		
remained. Two more interventions were included in the trial but not reported here as they did not meet the review protocol (one included use of biologics and the other glucocorticoid as part of their combinations)		

#### **Data sources**

**Health outcomes:** Within trial analysis, EQ-5D data from BeST trial (same paper). QALYs calculated as the area under the curve. Other outcomes measured include HAQ and DAS but not used for analysis. **Quality-of-life weights:** EQ-5D UK tariff measured at baseline and every three months thereafter. **Cost sources:** Resource use from within trial, using case records and patient cost diaries filled quarterly. Unit costs were standard published Dutch prices.

#### Comments

**Source of funding:** Dutch Healthcare Insurance Board. **Limitations:** Evidence from a Dutch healthcare perspective. Discounting at 3% rather than 3.5% as required by the NICE reference case. Does not include a comparison of all possible treatment combinations identified in the clinical evidence. 2-year follow-up unlikely to be sufficient to capture all downstream costs and treatment effects. Dutch unit costs, may not reflect current NHS costs. Within trial analysis based on RCT BeST. This analysis is based on 1 of the 21 studies included for this question and so does not reflect full body of evidence. **Other:** None

**Overall applicability:**<sup>(c)</sup> Partially applicable **Overall quality:**<sup>(d)</sup> Potentially serious limitations

Abbreviations: 95% CI: 95% confidence interval; CUA: cost–utility analysis; EQ-5D: EuroQol 5 dimensions (scale: 0.0 [death] to 1.0 [full health], negative values mean worse than death); ICER: incremental cost-effectiveness ratio; NR: not reported; pa: probabilistic analysis; QALYs: quality-adjusted life years

(a) For studies where the time horizon is longer than the treatment duration, an assumption needs to be made about the continuation of the study effect. For example, does a difference in utility between groups during treatment continue beyond the end of treatment and if so for how long.

# **Appendix J: Research recommendations**

### J.1 Subcutaneous methotrexate

**Research question:** What is the clinical and cost effectiveness of subcutaneous methotrexate compared with oral methotrexate for adults with early onset rheumatoid arthritis starting a new DMARD?

#### Why this is important:

Methotrexate is an important drug in the treatment of RA. Subcutaneous administration is an alternative option for people who have side effects with oral treatment. Evidence on the effectiveness of subcutaneous methotrexate is lacking, but its effects may be superior, due to increased bioavailability, and side effects fewer than with oral drugs. Research on subcutaneous methotrexate will inform future guideline recommendations.

Criteria for selecting high-priority research recommendations:		
PICO question	Population: Adults with active RA commencing a new DMARD Intervention(s):Oral methotrexate Comparator: Subcutaneous methotrexate titrated rapidly to 20mg weekly Outcome(s):DAS 28, HAQ, Pain VAS, Quality of life	
Importance to patients or the population	If evidence were available demonstrating that subcutaneous methotrexate was a clinically and cost effective option, this could lead to improved efficacy for people with RA due to better tolerability of subcutaneous therapy.	
Relevance to NICE guidance	There was no evidence identified in the current evidence review included in this guideline to inform a recommendation for subcutaneous methotrexate. Therefore research in this area would inform future updates of this guidance.	
Relevance to the NHS	Subcutaneous methotrexate is currently prescribed by some rheumatologists. Whilst it is important maximise the benefit of treatment, subcutaneous preparations of methotrexate are considerably more expensive than oral therapy and evidence of its clinical and cost effectiveness is important so that its use within the NHS can be evidence based. As it is proposed to be better tolerated than oral preparations, it is possible that the increased costs of the drug are balanced by the improved management of the condition and hence a reduction in resource use.	
National priorities	N/A	
Current evidence base	There was no evidence identified in the review undertaken in this guideline for subcutaneous methotrexate compared to oral cDMARDS. See literature review in chapter F.	
Equality	Yes. Some patients who are have worse RA may not be offered this treatment currently, but it could be more beneficial to them.	
Study design	This should be a randomised controlled trial. Adults with active RA(DAS>5.0) who are DMARD naïve, randomised to oral or subcutaneous methotrexate in a double blind design. The suggested dose would be commenced at 15mg weekly and increased after 4 weeks to 20mg weekly. Standard assessments of disease activity (including HAQ, VAS pain and quality of life) and drug toxicity monitoring every 4 weeks for 12 months.	

#### Criteria for selecting high-priority research recommendations:

Feasibility	Yes. There are no anticipated feasibility issues if it is made clear to patients they can withdraw for side effects or inefficacy.
Other comments	Nil
Importance	<ul> <li>High: the research is essential to inform future updates of key recommendations in the guideline. This treatment could be cost effective for the NHS if it leads to better patient outcomes.</li> </ul>
