

Neonatal parenteral nutrition

[C] Energy needs

NICE guideline tbc

Evidence reviews

September 2019

Draft for Consultation

These evidence reviews were developed by the National Guideline Alliance which is part of the Royal College of Obstetricians and Gynaecologists

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the [Welsh Government](#), [Scottish Government](#), and [Northern Ireland Executive](#). All NICE guidance is subject to regular review and may be updated or withdrawn.

1 Energy needs of preterm and term babies

2 Review question

3 How many kcal/kg/day should be given to preterm and term babies receiving parenteral
4 nutrition?

5 Introduction

6 Providing the optimal level of energy for babies receiving parenteral nutrition (PN) is very
7 important. If nutritional deficits occur during early postnatal life, there is an increased risk of
8 mortality and respiratory conditions, and detrimental effects on growth and
9 neurodevelopment. Conversely, providing energy in excess of needs has been associated
10 with impaired liver function, and increased adiposity. Determining the optimal energy needs
11 of preterm and term babies receiving PN as their main source of nutrition is therefore
12 important for optimal outcomes.

13 Summary of the protocol

14 Please see Table 1 for a summary of the Population, Intervention, Comparison and Outcome
15 (PICO) characteristics of this review.

16 Table 1: Summary of the protocol (PICO table)

Population	<ul style="list-style-type: none">• Babies born preterm, up to 28 days after their due birth date (preterm babies)• Babies born at term, up to 28 days after their birth (term babies)
Intervention	<ul style="list-style-type: none">• Different kcal/kg/day
Comparison	<ul style="list-style-type: none">• Each other
Outcomes	<p>Critical</p> <ul style="list-style-type: none">• Body composition (e.g., measured as lean mass, fat-free mass, fat mass, adipose tissue)• Nitrogen accretion• Growth/anthropometric measures<ul style="list-style-type: none">○ Head circumference○ Weight gain○ Height gain <p>Important</p> <ul style="list-style-type: none">• Mortality• Adverse effects of PN:<ul style="list-style-type: none">○ PN related liver disease (abnormal liver function, cholestasis, conjugated hyperbilirubinaemia, intrahepatocellular lipid)○ Hyperglycaemia○ Hypophosphataemia/hypercalcaemia• Energy intake (as the actual amount given)

17 *PN: Parenteral nutrition*

18 For full details see the review protocol in appendix A.

1 Clinical evidence

2 Included studies

3 As limited RCT evidence was available, we also included observational studies. Six studies
 4 were identified for inclusion in this review (Duffy 1981, Forsyth 1995, Morgan 2014, Pineault
 5 1988, Tan 2008, Zlotkin 1981).

6 Two Randomised controlled trials (RCTs) and 1 cross-over RCT compared high versus low
 7 energy intake (Forsyth 1995, Morgan 2014, Tan 2008).

8 Three studies had multiple groups within the high versus low energy comparison. One RCT
 9 compared high versus low energy intake for 2 different sources of amino acids (Duffy 1981).
 10 One observational study compared high versus low energy intake for 2 different energy
 11 sources (low fat and high fat; Pineault 1988). One observational study compared high versus
 12 low energy intake at different levels of nitrogen intake (Zlotkin 1981). For these studies,
 13 groups within high energy intake and low energy intake were combined for the purpose of
 14 analysis.

15 Although the actual energy intake differed across included studies, all studies were combined
 16 into one comparison of high versus low energy intake. This meant that for each individual
 17 study, the arm with the higher intake was included in the high energy arm and the arm with
 18 the lower intake was included in the low energy arm, even if the low energy arm of some
 19 studies was higher than the high energy arm of other studies. However, if there was
 20 significant heterogeneity on any outcome, the energy intakes of individual studies were
 21 examined to see if this might explain the difference between studies. RCT and observational
 22 evidence was analysed separately.

23 The included studies are summarised in Table 2.

24 See the literature search strategy in appendix B, study selection flow chart in appendix C,
 25 study evidence tables in appendix D, and GRADE tables in appendix F.

26 Excluded studies

27 Studies not included in this review are listed, and reasons for their exclusions are provided,
 28 in appendix K.

29 Summary of clinical studies included in the evidence review

30 Summaries of the studies that were included in this review are presented in Table 2.

31 **Table 2: Summary of included studies**

Study	Population	Intervention	Comparison	Outcomes	Comments
Duffy 1981	N= 24	<u>High energy</u> (n=12)	<u>Low energy</u> (n=12)	<ul style="list-style-type: none"> • Nitrogen balance • Nitrogen retention • Weight gain • Energy intake 	Vamin has a higher nitrogen content than Amigen, which affected nitrogen intake.
RCT	Preterm babies with BW <1600g	Target total calorie intake of 93 kcal/kg/day	Target total calorie intake of 68 kcal/kg/day		
Canada	<u>Mean GA</u> 29.6 weeks (SD 1.8)	Amigen (casein amino acid) or Vamin (crystalline amino acid)	Amigen (casein amino acid) or Vamin (crystalline amino acid)		The Vamin and Amigen groups were combined for the purpose of analysis in order to compare high

Study	Population	Intervention	Comparison	Outcomes	Comments
	Mean BW 1261g (SD 198)	mixture patterned on egg albumin)	mixture patterned on egg albumin)		energy and low energy groups.
Forsyth 1995 Cross-over RCT UK	N = 20 Inclusion criteria not reported Mean GA 30.9 weeks (SD 1.8) Mean BW 1314g (SD 291)	<u>High glucose regimen (n=20)</u> 12 g/kg/day (8.3 mg/kg/minute) of glucose	<u>Low glucose regimen (n=20)</u> 8 g/kg/day (5.5 mg/kg/minute) of glucose	<ul style="list-style-type: none"> • Energy intake 	After 24 hours, infants were changed to the alternative regimen which was continued again for 24 hours.
Morgan 2014 RCT UK	N = 135 Babies <29 weeks , weighing <1200g; admitted within 48 hours of birth Mean GA 26.7 weeks (SD 1.4) Mean BW 892g (SD 171)	<u>SCAMP (n=66)</u> Target total calorie intake of 108 kcal/kg/day	<u>Control (n=69)</u> Target total calorie intake of 85 kcal/kg/day	<ul style="list-style-type: none"> • Head circumference • Weight gain • Mortality • Hyperbilirubinaemia • Energy intake 	Study was not powered to assess differences in major complications.
Pineault 1988 Observational study Canada	N = 16 Appropriate- gestational- age babies with unchanging clinical conditions Mean GA 35 weeks (SD 2.8) Mean BW	<u>High energy (n=8)</u> Target total calorie intake of 80 kcal/kg- 1/d-1	<u>Low energy (n=8)</u> Target total calorie intake of 60 kcal/kg- 1/d-1	<ul style="list-style-type: none"> • Nitrogen balance • Nitrogen retention • Head circumference • Weight gain • Length gain • Energy intake 	All babies completed both a low fat (1g/kg-1/d- 1 lipids) and high fat (3g/kg-1/d- 1 lipids) nutrition phase. The high fat and low fat groups were combined (where analyses were not reported separately) for the purpose of analysis in order to compare high

Study	Population	Intervention	Comparison	Outcomes	Comments
	<u>2150g (SD 447)</u>				energy and low energy groups.
Tan 2008 RCT UK	N = 114 Babies <29 weeks; admitted within 7 days of birth <u>Mean GA</u> 26.1 weeks (SD 1.5) <u>Mean BW</u> 913g (SD 221)	<u>Hyperalimentation (n=55)</u> Target total calorie intake of 117 kcal/kg/day	<u>Control (n=59)</u> Target total calorie intake of 93 kcal/kg/day	<ul style="list-style-type: none"> • Head circumference (as measured by occipitofrontal circumference) • Weight gain • Length gain • Lower leg length • Mid-arm circumference • Energy intake 	Study was not powered to detect a difference in head circumference
Zlotkin 1981 Observational study Canada	N = 22 Premature babies that were appropriate size for gestational age <u>Mean GA</u> 29.2 weeks (Range 25-33) <u>Mean BW</u> Not reported	<u>High energy (n=18)</u> Target non-protein calorie intake 80 kcal/kg/day Nitrogen intake of 320, 480 or 640 mg/kg/day	<u>Low energy (n=12)</u> Target non-protein calorie intake 50 kcal/kg/day Nitrogen intake of 480 or 640 mg/kg/day	<ul style="list-style-type: none"> • Nitrogen retention • Weight gain • Length gain • Energy intake 	<p>Babies with hyperbilirubinaemia were assigned to the low energy group and babies without hyperbilirubinaemia were assigned to the high energy group; 8 babies were included in more than one group.</p> <p>A low energy, low nitrogen group was not included due to risk of very poor nitrogen retention and growth.</p> <p>The low, medium and high nitrogen groups were combined for the purpose of analysis in order to compare high energy and low energy groups.</p>

1 *BW: birthweight; GA: gestational age; RCT: randomised controlled trial; SCAMP: standardised, concentrated with*
2 *added macronutrients parenteral; SD: standard deviation.*

3 See appendix D for full evidence tables.

1 **Quality assessment of clinical outcomes included in the evidence review**

2 GRADE was conducted to assess the quality of outcomes. Evidence was identified for critical
3 and important outcomes. The clinical evidence profiles can be found in appendix F.

4 **Economic evidence**

5 **Included studies**

6 A systematic review of the economic literature was conducted but no economic studies were
7 identified which were applicable to this review question. A single economic search was
8 undertaken for all topics included in the scope of this guideline. Please see supplementary
9 material D for details.

10 **Excluded studies**

11 No studies were identified which were applicable to this review question.

12 **Summary of studies included in the economic evidence review**

13 No economic evaluations were identified which were applicable to this review question.

14 **Economic model**

15 No economic modelling was undertaken for this review because the committee agreed that
16 other topics were higher priorities for economic evaluation

17 **Evidence statements**

18 **Clinical Evidence statements**

19 **Nitrogen accretion**

20 Nitrogen retention (%)

- 21 • Low quality evidence from 1 RCT (n=24) showed a clinically important difference in
22 nitrogen retention between babies who received high energy intake compared with low
23 energy intake, with increased nitrogen retention in the group of babies receiving high
24 energy intake. However, there was uncertainty around the effect: Mean difference (MD)
25 14.00% (95% CI 4.52 to 23.48).
26 • Very low quality evidence from 2 observational studies (n=66) showed a clinically
27 important difference in nitrogen retention between babies who received high energy intake
28 compared with low energy intake, with increased nitrogen retention in the group of babies
29 receiving high energy intake. However, there was uncertainty around the effect: MD
30 12.16% (95% CI 1.73 to 22.58).
31

32 Nitrogen balance (mg/kg/day)

- 33 • Low quality evidence from 1 RCT (n=24) showed a clinically important difference in
34 nitrogen balance between babies who received high energy intake compared with low
35 energy intake, with higher nitrogen balance in the group of babies receiving high energy
36 intake. However, there was uncertainty around the effect: MD 66.00mg/kg/day (95% CI
37 14.98 to 117.02).
38 • Very low quality evidence from 2 observational studies (n=62) showed a clinically
39 important difference in nitrogen balance between babies who received high energy intake
40 compared with low energy intake, with higher nitrogen balance in the group of babies

1 receiving high energy intake. However, there was uncertainty around the effect: MD
2 33.59mg/kg/day (95% CI 5.65 to 61.52).

3 **Head circumference**

4 Head circumference (mm) at 7, 14, 21 and 28 days and 36 weeks' corrected gestational age 5 (CGA)

- 6 • High quality evidence from 1 RCT (n=135) showed no clinically important difference in
7 head circumference at 7 days (MD 1.00mm [95% CI -3.39 to 5.39]) and 14 days (MD
8 2.00mm [95% CI -2.39 to 6.39]) between babies who received high energy intake
9 compared with low energy intake.
- 10 • Moderate quality evidence from the 1 RCT (n=135) showed no clinically important
11 difference between head circumference at 21 days (MD 4.00mm [95% CI -1.07 to 9.07])
12 and at 28 days (MD 6.00mm [95% CI 0.43 to 11.57]) between babies who received high
13 energy intake compared with low energy intake. However, there was uncertainty around
14 the effects.
- 15 • Very low quality evidence from 2 RCTs (n=240) showed no clinically important difference
16 in head circumference at 36 weeks' CGA in babies who received high energy intake
17 compared with low energy intake. However, there was uncertainty around the effect: MD
18 1.04mm (95% CI -6.80 to 8.88).

19 Head circumference z-score at 36 weeks' CGA

- 20 • Low quality evidence from 1 RCT (n=114) showed no clinically important difference in
21 head circumference z-score at 36 weeks' CGA in babies who received high energy intake
22 compared with low energy intake. However, there was uncertainty around the effect: MD -
23 0.20 (95% CI -0.62 to 0.22).

24 Head circumference gain (cm/week)

- 25 • Very low quality evidence from 1 observational study (n=15) showed a clinically important
26 difference in head circumference gain between babies who received high energy intake
27 compared with low energy intake, with greater head circumference gain in the group of
28 babies receiving high energy intake. However, there was uncertainty around the effect:
29 MD 0.40mm/week (95% CI 0.02 to 0.78).

30 **Weight gain**

31 Weight (g) at 7, 14, 21 and 28 days and 36 weeks' corrected gestational age (CGA)

- 32 • High quality evidence from 1 RCT (n=135) showed no clinically important difference in
33 weight at 7 days in babies who received high energy intake compared with low energy
34 intake: MD 31.00g (95% CI -8.22 to 70.22).
- 35 • Moderate quality evidence from 1 RCT (n=135) showed no clinically important difference
36 in weight at 14 days (MD 55.00g [95% CI 9.24 to 100.76]), 21 days (MD 75.00g [95% CI
37 20.78 to 129.22]) and at 28 days (MD 57.00g [95% CI -8.70 to 122.70]) in babies who
38 received high energy intake compared with low energy intake. However, there was
39 uncertainty around the effects. Moderate quality evidence from 2 RCTs (n=238) showed
40 no clinically important difference in weight at 36 weeks' CGA in babies who received high
41 energy intake compared with low energy intake: MD 77.31g (95% CI 8.89 to 145.74).

42 Weight gain (g/day)

- 43 • Very low quality evidence from 1 RCT (n=24) showed no clinically important difference in
44 weight gain in babies who received high energy intake compared with low energy intake.
45 However, there was high uncertainty around the effect: MD 10.00g/day (95% CI -21.7 to
46 41.7).

47 Weight gain (g/kg/day)

- 1 • Very low quality evidence from 2 observational studies (n=46) showed a clinically
2 important difference in weight gain between babies who received high energy intake
3 compared with low energy intake, with greater weight gain in the group of babies receiving
4 high energy intake. However, there was uncertainty around the effect: MD 7.12g/kg/day
5 (95% CI -0.75 to 14.99).

6 Weight z-score at 36 weeks' CGA

- 7 • Low quality evidence from 1 RCT (n=114) showed no clinically important difference in
8 weight z-score at 36 weeks' CGA in babies who received high energy intake compared
9 with low energy intake. However, there was uncertainty around the effect: MD 0.10 (95%
10 CI -0.21 to 0.41).

11 Mid-arm circumference (cm) at 36 weeks' CGA

- 12 • Moderate quality evidence from 1 RCT (n=114) showed no clinically important difference
13 in mid-arm circumference at 36 weeks' CGA in babies who received high energy intake
14 compared with low energy intake: MD 0.10cm (95% CI -0.19 to 0.39).

15 **Height gain**

16 Length (cm) at 36 weeks' CGA

- 17 • Low quality evidence from 1 RCT (n=114) showed no clinically important difference in
18 length at 36 weeks' CGA in babies who received high energy intake compared with low
19 energy intake. However, there was uncertainty around the effect: MD 0.50cm (95% CI -
20 0.31 to 1.31).

21 Length gain (cm/week)

- 22 • Very low quality evidence from 2 observational studies (n=41) showed a clinically
23 important difference in length gain between babies who received high energy intake
24 compared with low energy intake, with greater length gain in the group of babies receiving
25 high energy intake. However, there was uncertainty around the effect: MD 0.29cm/week
26 (95% CI 0.12 to 0.46).

27 Length z-score at 36 weeks' CGA

- 28 • Low quality evidence from 1 RCT (n=114) showed no clinically important difference in
29 length z-score at 36 weeks' CGA in babies who received high energy intake compared
30 with low energy intake. However, there was uncertainty around the effect: MD 0.30 (95%
31 CI -0.16 to 0.76).

32 Lower leg length (cm) at 36 weeks' CGA

- 33 • Moderate quality evidence from 1 RCT (n=114) showed no clinically important difference
34 in lower leg length at 36 weeks' CGA in babies who received high energy intake
35 compared with low energy intake: MD 0.00cm (95% CI -0.26 to 0.26).

36 **Mortality**

- 37 • Low quality evidence from 1 RCT showed no clinically important difference in rate of
38 mortality at 28 days (Relative risk (RR) 1.17 [95% CI 0.45 to 3.07; n=150]) and at 36
39 weeks' CGA (RR 0.93 [95% CI 0.44 to 1.95; n=127]) in babies who received high energy
40 intake compared with low energy intake. However, there was high uncertainty around the
41 effects.

42

43 **Conjugated hyperbilirubinaemia (conjugated bilirubin > 50 mmol/L)**

- 44 • Low quality evidence from 1 RCT (n=135) showed a clinically important difference in rate
45 of conjugated hyperbilirubinaemia at 28 days between babies who received high energy
46 intake compared with low energy intake, with conjugated hyperbilirubinaemia associated

1 with receiving high energy intake. However, there was high uncertainty around the effect:
2 RR 0.78 (95% CI 0.29 to 2.14).

- 3 • Very low quality evidence from 1 RCT (n=127) showed no clinically important difference in
4 rate of conjugated hyperbilirubinaemia at 36 weeks' CGA in babies who received high
5 energy intake compared with low energy intake. However, there was high uncertainty
6 around the effect: RR 1.10 [95% CI 0.54 to 2.22).

7 **Energy intake**

8 Energy intake (kcal/kg/d) in the first 48 hours of life and at week 1, 2, 3 and 4

- 9 • Low quality evidence from 1 RCT (N=20) showed a clinically important difference in
10 energy intake in the first 48 hours of life between babies who received high energy intake
11 compared with low energy intake, with greater energy intake in the group of babies
12 receiving high energy intake. However, there was uncertainty around the effect: MD
13 15.30kcal/kg/day (95% CI 4.07to 26.53).
- 14 • High quality evidence from 1 RCT (n=135) showed a clinically important difference in
15 energy intake at week 1 (MD 7.00kcal/kg/day [95% CI 4.61 to 9.39]) and week 2 (MD
16 17kcal/kg/day [95% CI 9.87 to 24.13]), with greater energy intake in the group of babies
17 receiving high energy intake.
- 18 • Moderate quality evidence from 1 RCT (n=135) showed no clinically important difference
19 in energy intake at week 3 (MD 9.00kcal/kg/day [95% CI -2.35 to 20.35]) and week 4 (MD
20 5.00kcal/kg/day (95% CI -5.24 to 15.24]). However, there was uncertainty around the
21 effects.

22 Cumulative energy intake (kcal/kg) in the first 28 days of life

- 23 • Low quality evidence from 2 RCTs (n=249) showed no clinically important difference in
24 cumulative energy intake in the first 28 days of life in babies who received high energy
25 intake compared with low energy intake. However, there was uncertainty around the
26 effect: MD 165.26 (95% CI 93.78 to 236.73).

27 Energy intake (kcal/kg/day) – timeframe unclear

- 28 • Moderate quality evidence from 1 RCT (n=24) showed a clinically important difference in
29 energy intake between babies receiving high energy intake compared with low energy
30 intake, with greater energy intake in the group of babies receiving high energy intake: MD
31 25.00kcal/kg/day (95% CI 18.58 to 31.42).
- 32 • Very low quality evidence from 1 observational study (n=16) showed a clinically important
33 difference in energy intake between babies receiving high energy intake compared with
34 low energy intake, with greater energy intake in the group of babies receiving high energy
35 intake: MD 18.20kcal/kg/day (95% CI 15.65 to 20.75).

36 **Economic evidence statements**

37 No economic evidence was identified which was applicable to this review question.

38 **The committee's discussion of the evidence**

39 **Interpreting the evidence**

40 ***The outcomes that matter most***

41 The committee agreed that body composition, nitrogen accretion and anthropometric
42 measures should be included as critical outcomes as these are most directly influenced by
43 overall energy intake. Mortality rates, PN associated liver disease, hyperglycaemia,
44 hypophosphataemia, and hypercalcaemia were considered important outcomes, as these will
45 be influenced by energy intake and other factors. The actual energy intake received by the

1 baby was also selected as an important outcome because the actual intake could differ from
2 the provided energy.

3 ***The quality of the evidence***

4 The quality of the evidence for this review was assessed using GRADE methodology. The
5 observational evidence was very low quality due to risk of bias in the included studies and
6 uncertainty around the effects. The RCT evidence ranged from very low to high quality and
7 was mainly downgraded due to uncertainty around the effects. There was also some
8 heterogeneity across studies, selection bias, attrition bias and selective reporting bias.
9 Blinding of pharmacists and personnel involved in administering PN was not possible in the
10 RCTs due to safety reasons, however it was reported that this is unlikely to have affected
11 clinical care so evidence was not downgraded for this reason. One of the included studies
12 had a cross over design that only covered the first 48 hours after birth (Forsyth 1995), two
13 studies included enteral feeding as well as parenteral feeding (Morgan 2014; Tan 2008), and
14 one study assigned babies with hyperbilirubinaemia to the low energy arm (Zlotkin 1981).

15 The committee noted that the included studies differed according to the amount of
16 macronutrients and energy intake, thus were not entirely comparable, and that the protocols
17 in older studies did not reflect current practice.

18 ***Benefits and harms***

19 There was evidence from RCT and observational studies that nitrogen retention and balance
20 were higher in babies who received high energy intake compared with low energy intake;
21 however, there was uncertainty around the effects.

22 The RCT evidence showed no clinically important differences in head circumference
23 measured during the first 4 weeks of life and at 36 weeks' controlled for gestational age.
24 However, there was uncertainty around these effects and there was some observational
25 evidence of greater gains in head circumference with high energy intake compared with low
26 energy intake.

27 RCT evidence showed no clinically important differences between groups for any weight or
28 height outcomes; however, there was uncertainty around the effects. There was greater
29 weight and height gain shown in two observational studies but evidence was very low quality
30 and one study, which showed the greatest difference between groups, assigned babies with
31 hyperbilirubinaemia to low energy intake; therefore, it is unclear whether differences in
32 growth outcomes are due to energy intake or hyperbilirubinaemia.

33 There were no clinically important differences in mortality based on energy intake, although
34 there was high uncertainty around the effects. There was some evidence of reduced
35 hyperbilirubinaemia at 28 days in babies who received high energy intake compared with low
36 energy intake; however, there was uncertainty around the effect and this difference was not
37 observed at 36 weeks' CGA.

38 There was inconsistent evidence regarding whether babies who were prescribed high energy
39 intake actually received higher energy intake than those prescribed low energy intake.
40 Clinically important differences were observed in the first two weeks of life, but these
41 differences were not observed in the third and fourth week of life, or for cumulative energy
42 intake over the first 4 weeks of life. However, PN was decreased during the transition to
43 enteral feeding, and was discontinued when 50 to 75% of nutrition was received from enteral
44 feeds; therefore, differences may have been harder to detect during periods with lower PN.
45 Further evidence from 1 RCT and 1 observational study where the timeframe for nutritional
46 intake was unclear also showed higher energy intake in babies who were prescribed high
47 energy. Therefore, the committee agreed that the evidence showed it was feasible to provide
48 higher energy intakes.

1 The committee decided that they could not make recommendations on a specific ideal
2 energy intake for all babies based on the limited evidence available. The committee also
3 noted that the composition of macronutrient intake differed between trial groups, which
4 makes it difficult to conclude if differences are based on energy intake or intake of other
5 macronutrients such as protein. The recommendations were therefore based on informal
6 consensus of the committee. They used their experience and expertise to conduct a
7 theoretical exercise, taking into account knowledge regarding physiological and metabolic
8 requirements of babies. In this exercise the committee worked backwards from the individual
9 nutrients (for which there was evidence for the ranges advised and in which they had greater
10 confidence – see section 1.4 of the guideline) and converted their respective dosages into
11 calories.

12 The committee discussed the number of days over which energy intake should increase to
13 reach the intended maintenance level, and agreed to align this with the recommendations on
14 lipid, carbohydrates and amino acid increases (see section 1.4 of the guideline). The
15 committee agreed that babies who start PN in the first 4 days after birth should have a
16 starting range and increase up to a maintenance range over approximately 4 days. This
17 timeframe was selected because fluid volume targets are commonly increased over the first
18 few days of life and this allows increasing amounts of nutrition to be given parenterally.
19 Babies starting PN after the first 4 days of life would then receive the maintenance amount
20 because their fluid volume targets would have already increased.

21 Based on committee knowledge that PN-related complications would be higher in term
22 babies that are critically ill or have just had surgery, they decided that giving energy intake in
23 the lower range would be more appropriate for these groups because term babies' energy
24 stores tend to be more replete.

25 **Cost effectiveness and resource use**

26 No economic studies were identified which were applicable to this review question.

27 The committee explained that recommendations pertaining to an optimal nutritional intake in
28 preterm and term babies who are receiving PN would not incur extra resource implications to
29 the health care system.

30 The committee noted that getting the right nutritional intake may result in avoiding additional
31 costs associated with nutritional deficit or providing energy in excess. For example, nutritional
32 deficits which may occur during PN are known to be negatively associated with mortality,
33 respiratory, growth and neurodevelopmental outcomes and may require expensive NHS care.
34 Similarly, providing energy in excess of needs is associated with impaired liver function, and
35 increased adiposity which also require expensive care.

36 The committee explained that recommendations in this area reflect practice across many units
37 and as such cost savings to the NHS, if any, are likely to be negligible.

1 Appendices

2 Appendix A – Review protocols

3 Review protocol for review question: How many kcal/kg/day should be given to preterm and term babies receiving parenteral nutrition?

Field (based on <u>PRISMA-P</u>)	Content
Review question	How many kcal/kg/day should be given to preterm and term babies receiving parenteral nutrition?
Type of review question	Intervention
Objective of the review	What are the energy needs of preterm and term babies receiving parenteral nutrition?
Eligibility criteria – population/disease/condition/issue/domain	<ul style="list-style-type: none"> • Babies born preterm, up to 28 days after their due birth date (preterm babies) • Babies born at term, up to 28 days after their birth (term babies)
Eligibility criteria – intervention(s)/exposure(s)/prognostic factor(s)	<ul style="list-style-type: none"> • Different kcal/kg/day
Eligibility criteria – comparator(s)/control or reference (gold) standard	<ul style="list-style-type: none"> • Each other
Outcomes and prioritisation	<p>Critical outcomes:</p> <ul style="list-style-type: none"> • Body composition (measured as lean mass, fat-free mass, fat mass, adipose tissue) • Nitrogen accretion • Growth/anthropometric measures <ul style="list-style-type: none"> ○ Head circumference ○ Weight gain ○ Height gain <p>Important Outcomes:</p> <ul style="list-style-type: none"> • Mortality • Adverse effects of PN: <ul style="list-style-type: none"> ○ PN related liver disease (abnormal liver function, cholestasis, conjugated hyperbilirubinaemia, intrahepatocellular lipid) ○ Hyperglycaemia ○ Hypophosphataemia/hypercalcaemia • Energy intake (as the actual amount given)

Field (based on <u>PRISMA-P</u>)	Content
Eligibility criteria – study design	<p>Systematic reviews of RCTs RCTs Comparative cohort studies (only if RCTs unavailable or limited data to inform decision making) Conference abstracts of RCTs will only be considered if no evidence is available from full published RCTs (if no evidence from RCTs or comparative cohort studies available and are recent i.e., in the last 2 years-authors will be contacted for further information).</p>
Other inclusion exclusion criteria	<p>No sample size restriction No date restriction Clinical settings that provide neonatal care or specialist paediatric care. UK and non-UK studies (non-UK studies from middle and high income countries according to WHO/World Bank criteria).</p>
Proposed sensitivity/sub-group analysis, or meta-regression	<p>Stratified analysis: Babies born preterm, up to 28 days after their due birth date (preterm babies) Babies born at term, up to 28 days after their birth (term babies)</p> <p>Subgroup analysis: The following groups will be considered for subgroup analysis: Age of baby (first 2 weeks versus later) Preterm (extremely preterm <28 weeks GA; very preterm: 28-31 weeks GA; moderately preterm: 32-36 weeks GA) Birthweight: low birthweight (<2500g); very low birthweight (<1500g) and extremely low birthweight (<1000g) Critically ill babies IUGR Specialist versus standard neonatal care</p> <p>Important confounders (when comparative observational studies are included for interventional reviews) Age of baby (first 2 weeks versus later) Birthweight: low birthweight (<2500g); very low birthweight (<1500g) and extremely low birthweight (<1000g) Actual dose received Other underlying conditions (e.g., chronic lung disease) Sex of baby Gestation (preterm vs. term)</p>
Selection process – duplicate screening/selection/analysis	<p>Sifting, data extraction, appraisal of methodological quality and GRADE assessment will be performed by the systematic reviewer. Quality control will be performed by the senior systematic reviewer.</p>

Field (based on <u>PRISMA-P</u>)	Content
	A random sample of the references identified in the search will be sifted by a second reviewer. This sample size will be 10% of the total, or 100 studies if the search identifies fewer than 1000 studies. All disagreements in study inclusion will be discussed and resolved between the two reviewers. The senior systematic reviewer or guideline lead will be involved if discrepancies cannot be resolved between the two reviewers.
Data management (software)	<p>Data Analysis</p> <p>Where data is available, pair-wise meta-analysis using a fixed effects model, will be used to combine results from similar studies, this will be performed using Cochrane Review Manager (RevMan5). Heterogeneity will be considered, and if a random-effects model is considered more appropriate, it will be conducted.</p> <p>Quality Assessment</p> <p>Appraisal of methodological quality will be conducted using the appropriate tool: ROBIS (systematic reviews and meta-analyses), Cochrane risk of bias tool for RCT (RCT or comparative cohort studies). Cochrane risk of bias tool, ROBINS-I (Non-randomised studies)</p> <p>The quality of evidence for each outcome will be assessed using GRADEpro: Outcomes will be downgraded if the randomisation and/or concealment methods are unclear or inadequate. Outcomes will also be downgraded if there is considerable missing data (if there is a dropout of more than 20%, or if there is a difference of >20% between groups). Heterogeneity will be assessed using the I², outcomes will be downgraded once if I² >50%, twice if I² >80%. Imprecision: Outcomes will be downgraded if the 95% CI is imprecise (i.e. crosses 0.8 or 1.25, (dichotomous) or -0.5 or 0.5 (continuous)). Outcomes will be downgraded two levels depending on how many lines of imprecision are crossed. If the clinical decision threshold is NOT crossed, we will consider whether the criterion for Optimal Information Size is met, if not we will downgrade one level for dichotomous outcomes with less than 300 events, and downgrade one level for continuous outcomes when less than 400 participants are included.</p> <p>Clinical effectiveness</p> <p>For dichotomous outcomes, minimal important differences will be considered using thresholds of RR >0.80 and <1.25. For continuous outcomes, minimal important differences will be considered 0.5 times the SD of the control group</p>
Information sources – databases and dates	<p>Sources to be searched: Medline, Medline In-Process, CCTR, CDSR, DARE, HTA, Embase.</p> <p>Limits (e.g. date, study design): All study designs. Apply standard animal/non-English language filters. No date limit.</p> <p>Supplementary search techniques: No supplementary search techniques were used.</p> <p>See appendix B for full strategies.</p>
Identify if an update	This is not an update.
Author contacts	Developer: The National Guideline Alliance

Field (based on <u>PRISMA-P</u>)	Content
	https://www.nice.org.uk/guidance/indevelopment/gid-ng10037
Highlight if amendment to previous protocol	For details please see section 4.5 of Developing NICE guidelines: the manual 2014 .
Search strategy – for one database	For details please see appendix B.
Data collection process – forms/duplicate	A standardised evidence table format will be used, and published as appendix D (clinical evidence tables) or H (economic evidence tables).
Data items – define all variables to be collected	For details please see appendix B.
Methods for assessing bias at outcome/study level	Standard study checklists were used to critically appraise individual studies. For details please see section 6.2 of Developing NICE guidelines: the manual 2014 . The risk of bias across all available evidence was evaluated for each outcome using an adaptation of the ‘Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox’ developed by the international GRADE working group http://www.gradeworkinggroup.org/
Criteria for quantitative synthesis (where suitable)	For details please see section 6.4 of Developing NICE guidelines: the manual 2014 .
Methods for analysis – combining studies and exploring (in)consistency	For details of the methods please see supplementary material C.
Meta-bias assessment – publication bias, selective reporting bias	For details please see section 6.2 of Developing NICE guidelines: the manual 2014 . If sufficient relevant RCT evidence is available, publication bias will be explored using RevMan software to examine funnel plots. Trial registries will be examined to identify missing evidence: Clinical trials.gov, NIHR Clinical Trials Gateway.
Assessment of confidence in cumulative evidence	For details please see sections 6.4 and 9.1 of Developing NICE guidelines: the manual 2014 .
Rationale/context – Current management	For details please see the introduction to the evidence review.
Describe contributions of authors and guarantor	A multidisciplinary committee developed the guideline. The committee was convened by the National Guideline Alliance and chaired by Joe Fawke (Consultant Neonatologist and Honorary Senior Lecturer, University Hospitals Leicester NHS Trust) in line with section 3 of Developing NICE guidelines: the manual 2014 . Staff from the National Guideline Alliance undertook systematic literature searches, appraised the evidence, conducted meta-analysis and cost-effectiveness analysis where appropriate, and drafted the guideline in collaboration with the committee. For details of the methods please see supplementary material C.
Sources of funding/support	The National Guideline Alliance is funded by NICE and hosted by the Royal College of Obstetricians and Gynaecologists.

Field (based on PRISMA-P)	Content
Name of sponsor	The National Guideline Alliance is funded by NICE and hosted by the Royal College of Obstetricians and Gynaecologists.
Roles of sponsor	NICE funds the National Guideline Alliance to develop guidelines for those working in the NHS, public health, and social care in England.
PROSPERO registration number	Not registered with PROSPERO.

Data for head circumference was missing for one baby in the 80 kcal/kg ⁻¹ /d ⁻¹ group; no other missing data.
Country/ies where the study was carried out					
Canada	<u>Age at study (days) - mean (SE)</u> 60 kcal/kg ⁻¹ /d ⁻¹ : 9 (1) 80 kcal/kg ⁻¹ /d ⁻¹ : 11 (2)	60 kcal/kg ⁻¹ /d ⁻¹ ; high fat: 5 g/kg ⁻¹ /day ⁻¹ glucose; 3g/kg ⁻¹ /d ⁻¹ lipids.	All infusions provided 150 mL/kg/day of total fluids, 3mmol/kg/day sodium, 2mmol/kg/day potassium, 2mmol/kg/day chloride, 1mmol/kg/day calcium, 0.125mmol/kg/day magnesium, 0.8mmol/kg/day phosphorus, 300µg/kg/day zinc, 40µg/kg/day copper and 2.5ml/day multivitamins.		Measurement of outcomes bias: Low risk. Unlikely that outcome assessors were blind to intervention for safety reasons but all outcomes are objective.
Study type					
Observational study (with cross-over component)					
(component of interest for this review question is based on two separate cohorts))	<u>Birthweight (g) - mean (SE)</u> 60 kcal/kg ⁻¹ /d ⁻¹ : 2293 (147) 80 kcal/kg ⁻¹ /d ⁻¹ : 2006 (169)	80 kcal/kg ⁻¹ /d ⁻¹ ; low fat: 17g/kg ⁻¹ /day ⁻¹ glucose; 1g/kg ⁻¹ /day ⁻¹ lipids		<u>Head circumference increment (cm/week) - mean (SE)</u> 60 kcal/kg ⁻¹ /d ⁻¹ (n=8): 0.50 (0.12) 80 kcal/kg ⁻¹ /d ⁻¹ (n=7): 0.90 (0.15)	Selection of the reported results bias: Moderate risk. Is it unclear why results are reported separately for low fat and high fat groups for nitrogen balance outcomes, but these groups are combined for growth outcomes.
Aim of the study					
To determine the influences of the quality (level and source) of infused energy on nitrogen metabolism.	<u>Weight at study (g) - mean (SE)</u> 60 kcal/kg ⁻¹ /d ⁻¹ : 2102 (153) 80 kcal/kg ⁻¹ /d ⁻¹ : 1850 (174)	80 kcal/kg ⁻¹ /d ⁻¹ ; high fat: 11g/kg ⁻¹ /day ⁻¹ glucose; 3g/kg ⁻¹ /day ⁻¹ lipids		<u>Weight gain (g/kg⁻¹/d⁻¹) - mean (SE)</u> 60 kcal/kg ⁻¹ /d ⁻¹ (n=8): 11.5 (2.3) 80 kcal/kg ⁻¹ /d ⁻¹ (n=8): 14.6 (2.0)	Other information Unclear wash-out period between interventions, suggesting potential for carry-over effect from one intervention to the other. However, as the comparison of interest for this review question is energy intake, not source of energy intake, any carry-over effect will not affect the results. The high fat and low fat groups were combined (where analyses were not reported separately) for the purpose of analysis in order to compare high energy and low energy groups.

No missing data.</p> <p>Measurement of outcomes bias: Low risk. Unlikely that outcome assessors were blind to intervention for safety reasons but all outcomes are objective.</p> <p>Selection of the reported results bias: Moderate risk. Insufficient reporting of head circumference and length gain was not reported for the high energy, high nitrogen group.</p> <p>Other information</p> <p>8 infants were included in more than one group. A low energy, low nitrogen group was not included due to risk of very poor nitrogen retention and growth (demonstrated in other studies). Three infants died from respiratory and/or haemorrhagic complications after completion of the study period; assigned treatment groups were not stated but the infants were all from different groups. The low, medium and high nitrogen groups were combined for the purpose of analysis in order to compare high energy and low energy groups.</p>
