Epilepsies in children, young people and adults: diagnosis and management

[18] Evidence review: Modifiable risk factors for epilepsy related mortality

NICE guideline NG217

Evidence reviews underpinning recommendations 10.1.1 to 10.1.4 and research recommendations in the NICE guideline.

April 2022

FINAL

Developed by the National Guideline Centre

Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and/or their carer or guardian.

Local commissioners and/or providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the <u>Welsh Government</u>, <u>Scottish Government</u>, and <u>Northern Ireland Executive</u>. All NICE guidance is subject to regular review and may be updated or withdrawn.

1 Modifiable risk factors for epilepsy-related mortality, including SUDEP, and the magnitude of risk of those factors

1.1 Review question

What are the modifiable risk factors for epilepsy-related mortality, including SUDEP, and what is the magnitude of risk of the factors?

1.1.1. Introduction

Epilepsy is associated with a number of risks, including a risk of injury, including head injury, and mortality in the form of drowning and accidents. One significant cause of epilepsy-related mortality is Sudden Unexpected Death in Epilepsy (SUDEP). Overall, the rate of SUDEP is around 1 in 1000 people with epilepsy per year.

This review examines modifiable risk factors for epilepsy-related mortality, including SUDEP, to inform the approach to the management of seizures and the provision of information to people with epilepsy, their families and carers.

1.1.2. Summary of the protocol

For full details see the review protocol in Appendix A.

Table 1: PICO characteristics of review question

able 1: PICO ci	naracteristics of review question
Population	Inclusion: People with a diagnosis of epilepsy.
	Exclusion: New-born babies with acute symptomatic seizures
Prognostic variable(s) under consideration	 Sleeping unsupervised/living alone Prone sleeping position Uncontrolled/frequent Generalised Tonic Clonic Seizures (GTCS) Nocturnal GTCS Substance abuse/alcohol dependence ASM polytherapy Other drug polytherapy Insufficient ASM therapy/any changes in prescription of drugs that could increase seizure rate
	Sleep deprivation/irregular sleep
Confounding factors	No key confounders that have to be adjusted for have been identified, but the analysis report must demonstrate that it has tried to avoid bias arising from plausible potential confounders (the modifiable factors listed above plus other non-modifiable factors) by an appropriate method
Outcomes	 Death, related to epilepsy SUDEP Follow up: any available but stratify according to: <1 yr., 1-5 yrs., >5 yrs.
Study design	A longitudinal design, such as prospective/retrospective cohort studies. Casecontrol studies will be allowed, provided they meet criteria.

1.1.3. Methods and process

This evidence review was developed using the methods and process described in <u>Developing NICE guidelines: the manual</u>. Methods specific to this review question are described in the review protocol in appendix A and the methods document.

Declarations of interest were recorded according to NICE's conflicts of interest policy.

1.1.4. Prognostic evidence

1.1.4.1. Included studies

Four cohort^{7, 10, 22, 30} studies and seven case-control^{15, 23, 26, 35, 36, 39, 40} studies assessing the modifiable risk factors for epilepsy-related mortality (including SUDEP) were included within the review.

The following modifiable risk factors were investigated, but not limited to:

- Sleeping unsupervised / living alone
- Prone sleeping position
- Uncontrolled/frequent Generalised Tonic Clonic Seizures (GTCS)
- Nocturnal GTCS
- Substance abuse/alcohol dependence
- Anti-seizure medication (ASM) polytherapy
- Other drug polytherapy
- Insufficient ASM therapy/any changes in prescription of drugs that could increase seizure rate
- Sleep deprivation / irregular sleep

Within the eleven studies included within the review, the risk factors considered were: different seizure types; comorbidities; seizure frequency; anti-seizure medications; changes to medications; substance abuse/alcohol dependence and psychosocial factors (education, living conditions and supervision).

Of the studies included, one³⁹ study looked at adults followed up over one to five years; three^{10, 26, 30} studies assessed adults who were followed up for longer than five years; one²² study investigated children who were followed up for over five years; one⁷ study which looked at a mixed population of children and adults followed up between one to five years and five^{15, 22, 35, 36, 40} studies with a mixed population who followed up the participants for over five years.

See also the study selection flow chart in Appendix A, study evidence tables in Appendix D, forest plots in Appendix E and GRADE tables in Appendix F.

1.1.4.2. Excluded studies

See the excluded studies list in Appendix J.

1.1.5. Summary of studies included in the prognostic evidence

Table 2: Summary of studies included in the evidence review - Adults >18 years (follow up 1 – 5 years)

Study	Population	Analysis	Prognostic variable(s)	Confounders	Outcomes	Comments
Walczak 2001 ³⁹	Cases = 20 Controls = 80 Participants were prospectively enrolled after evaluation at three upper mid-western epilepsy centres. A surveillance system was set up to identify deaths in this prevalence cohort.	Prospective case control study with multivariate analysis	Number of seizures (number per month) Number of tonic-clonic seizures (per year)	Number of seizures (number per month) Number of tonic- clonic seizures (per year)	Risk of SUDEP	

Table 3: Summary of studies included in the evidence review - Adults >18 years (follow up >5 years)

Study	Population	Analysis	Prognostic variable(s)	Confounders	Outcomes	Comments
Faught 2008 ¹⁰	N=33,658 The study population was selected based on ≥18 years of age; ≥ one neurologist visit with a diagnosis of epilepsy or nonfebrile convulsions; ≥ two pharmacy dispensing's for anti-seizure medications	Retrospective open cohort study design. Multivariate analysis with Cox regression models	Adherence Use of ASM polytherapy Epilepsy related comorbidity	Adherence status Gender Age Race Use of ASM polytherapy Epilepsy related co- morbidities	Mortality	

Study	Population	Analysis	Prognostic variable(s)	Confounders	Outcomes	Comments
Ryu 2015 ²⁶	N=104 individuals who had died, had a diagnosis of epilepsy registered on the death certificate and were treated for epilepsy at the centre in the study period, and met the criteria for SUDEP	Case control study with multivariate regression analysis	Seizure frequency Number of ASM's	Age at onset Duration of disease Aura Family history of epilepsy Psychiatric conditions Epilepsy classification Seizure frequency Seizure related to lesion on MR imagine Number of ASMs Type of ASM	Risk of SUDEP	
Si 2018 ³⁰	N = 456 The number of patients included in the study were those with epilepsy who died and deceased patients without epilepsy as comparison.	Prospective cohort study with logistic regression analysis	CNS infections Metastatic cancer Solid tumour without metastasis Depression Diabetes without complications Peripheral vascular disease Traumatic brain and head injuries	Age Gender CNS infections Metastatic cancer Renal disease Solid tumour without metastasis Anoxic brain injury Cardiac arrhythmias Encephalopathy Depression Paraplegia, hemiplegia Diabetes without complications Peripheral vascular disease Traumatic brain and head injuries	Mortality	

Table 4: Summary of studies included in the evidence review – Children <18 years (follow up > 5 years)

				io jouro (ionon up	c j cu. c,	
Study	Population	Analysis	Prognostic variable(s)	Confounders	Outcomes	Comments
Nickels 2012 ²²	n= 467 All children ages 1 month through 17 years diagnosed with new-onset epilepsy while resident in Olmsted County from 1980 to 2009 and had follow-up beyond the initial epilepsy diagnosis were included	Cohort study with multivariate Cox regression models	Abnormal neurological examination Abnormal cognitive function Status epilepticus, ever Metabolic/ structural aetiology	Neurologic examination cognitive function previous status epilepticus mode of onset, aetiology usage of ≥ 2 ASM's seizure frequency intractable at last follow up	Mortality	

Table 5: Summary of studies included in the evidence review - mixed population of children <18 years and adults >18 years (follow up 1 - 5 years)

Study	Population	Analysis	Prognostic variable(s)	Confounders	Outcomes	Comments
Chen 2005 ⁷	n=263 Participants were prospectively recruited patients with epilepsy who were at least 17 years old and newly referred to the outpatient epilepsy clinics	Prospective cohort study with Cox proportional hazards regression model	Aetiology of seizure / epilepsy	Age of onset Frequency Imaging Type of seizure Aetiology Medication Age Gender	Mortality	

Table 6: Summary of studies included in the evidence review - mixed population of children <18 years and adults >18 years (follow up >5 years)

Study	Population	Analysis	Prognostic variable(s)	Confounders	Outcomes	Comments
Langan 2005 ¹⁵	Cases = 151 Controls = 534	Case control study with backward	History of generalized tonic clonic seizures	History of generalized tonic clonic seizures	Risk of SUDEP	Supervision at night was defined as the presence in the

Study	Population	Analysis	Prognostic variable(s)	Confounders	Outcomes	Comments
	People with epilepsy who died suddenly between the ages of 16 and 50 years were identified by coroners and neurologists and by interviews with bereaved families	stepwise conditional logistic regression	No of tonic clonic seizures in previous 3 months Total number of anti- seizure medications Carbamazepine usage Supervision Asthma	No of tonic clonic seizures in previous 3 months Total number of anti- seizure medications Carbamazepine usage Supervision Asthma		bedroom of an individual of normal intelligence and at least 10 years old or the use of special precautions. Special precautions involved regular checks throughout the night or the use of a listening device.
Nilsson 1999 ²³	Cases = 57 Controls = 171 Cases were individuals who had died with a diagnosis of epilepsy registered on the death certificate and who after review of medical and necropsy records were found to meet SUDEP criteria.	Nested case control study with multivariate analysis	Seizure frequency during last year Epilepsy type Number of ASM Changes in dose of ASM per year Anxiolytic medication Antipsychotic medication	Seizure frequency during last year Epilepsy type Number of ASM Changes in dose of ASM per year	Risk of SUDEP	
Sveinsson 2020 ³⁶ (Sveinsson a)	Cases n = 255 Controls n=1148 All deaths with epilepsy written on the death certificate (n = 1,276), were eligible SUDEP cases.	Case control study with conditional logistic regression and individual modelling	ASM therapy Monotherapy Nonadherence	ASM therapy Medication Time since last dispensed ASM Nonadherence	Risk of SUDEP	Model 3 from analysis used within review: adjusted for the same variables as model 2 together with history of GTCS, GTCS frequency in the last year and nocturnal GTCS last year

Study	Population	Analysis	Prognostic variable(s)	Confounders	Outcomes	Comments
Sveinsson 2020 ³⁵ (Sveinsson b)	Cases n = 255 Controls n=1148 All deaths with epilepsy written on the death certificate (n = 1,276), were eligible SUDEP cases.	Case control study with conditional logistic regression and individual modelling	Type of Epilepsy Living conditions Highest education Alcohol dependence Substance abuse	Age Sex Generalized tonic- clonic seizures frequency and nocturnal generalized tonic-clonic seizures last year of observation Living conditions Antiepileptic drugs	Risk of SUDEP	Model 3 from analysis used within review: Adjusted for age, sex, generalized tonic- clonic seizure frequency and nocturnal generalized tonic- clonic seizures last year, living conditions and epileptic drugs.
Zhang 2016 ⁴⁰	Probable SUDEP n = 35 Control n = 105 Patients with convulsive epilepsy	Case control study with multivariate logistic regression analysis	Seizure frequency Seizure free prior (prior to SUDEP)	Onset age Seizure frequency at baseline (n/year) Seizure free prior to probable SUDEP (1 month)	Risk of probable SUDEP	

1.1.6. Summary of the prognostic evidence – Adults >18 years (follow up 1 – 5 years)

Table 7: Clinical evidence summary: one to five seizures per month

Outcomes	No of Participants (studies) Follow up	Quality of the evidence (GRADE)	Relative effect (95% CI)
SUDEP - Male	No seizures as reference		
	20 (1 study) 1 - 5 years	⊕⊖⊖ VERY LOW1,2,3,4 due to risk of bias, indirectness, imprecision	OR 3.40 (0.5 to 23.12)
SUDEP - Female	No seizures as reference

1.1.11. Economic evidence

1.1.11.1. Included studies

No health economic studies were included.

1.1.11.2. Excluded studies

No relevant health economic studies were excluded due to assessment of limited applicability or methodological limitations.

See also the health economic study selection flow chart in Appendix G.

1.1.12. Economic model

This area was not prioritised for a new cost-effectiveness analysis.

1.1.13. Evidence statements

1.1.13.1. Effectiveness

None.

1.1.13.2. Economic

No relevant economic evaluations were identified.

1.1.14. The committee's discussion and interpretation of the evidence

1.1.14.1. The outcomes that matter most

The two outcomes for this evidence review were death related to epilepsy or sudden unexpected death in Epilepsy (SUDEP). This was to ensure that the modifiable risk factors being assessed were in the context of the impact they would have on mortality and SUDEP. This was important as modifiable risk factors could be assessed in people who have been diagnosed with epilepsy, and the recommendations would potentially have the greatest impact for the person with epilepsy, their families, or carers, as well as the clinicians managing their epilepsy.

1.1.14.2. The quality of the evidence

The majority of results were of low or very low-quality evidence for all the stratifications for the outcomes of epilepsy-related mortality or SUDEP. The main reasons for this were: the risk of bias, indirectness for not adjusting for modifiable confounders and crossing of the null line. There were cohort studies and case-control studies included within this review. As all the studies were observational studies, they had to show adjustment was made for potential confounders. The evidence was downgraded if the study did not adjust for at least two of the four non-modifiable risk factors specified (age, gender, developmental/intellectual disability, and duration of epilepsy). Evidence of adjusting shows that the results are what they would be if all other variables were set to be the same across the risk factor and no risk factor group. In turn, this increases our confidence that the results are not confounded. Where the confidence interval of the odds, hazard or risk crossed one, or the null line, this signified that the result is consistent with no effect from the risk factor. This allowed the results to be divided into significant factors and non-significant factors. The committee took note of all

these different elements in the quality assessment of the evidence to decide on recommendations.

There were several outcomes within some of the stratifications that were of moderate or high-quality evidence. Within the adults (follow up over 5 years) adherence, polytherapy, neurological conditions and Charlson Comorbidity Index; mixed population (follow up 1 - 5 years) tumour aetiology; and mixed population (follow up over 5 years) undetermined seizures, substance abuse, alcohol, dependence, polytherapy (2 or more anti-seizure medications or more than 3 anti-seizure medications, use of levetiracetam, non-adherence and living conditions were all of moderate to high quality and significant outcomes. The committee discussed all of the factors in relation to their quality and significance and decided those that were modifiable were important to consider for recommendations.

1.1.14.3. Benefits and harms

People with epilepsy are at increased risk (approximately 7 - 12% cumulative lifetime risk) of premature mortality and SUDEP so the identification of risk factors, particularly modifiable risk factors is of benefit to people with epilepsy and their families and carers. This can provide important information of their own risk but also what steps can be taken to manage the risk.

In adults who were followed up from one to five years there did not appear to be a significant difference in risk of death or SUDEP resulting from 1-5 seizures a month, 2 seizures a month, 2 tonic clonic seizures per year or 2 tonic clonic seizures per year. However, for adults followed up over five years, being on more ASM's led to an almost doubling of the odds of SUDEP compared to less ASMs; non-adherence of ASM's led to an almost 3.5 times greater odds of death compared to being adherent to medications, and people with polytherapy (2 or more anti-seizure medications) had three-quarters the hazard of mortality as people not on polytherapy.

Comorbidities such as brain tumours, meningitis and stroke had almost two times the hazard of mortality compared to no neurological comorbidities. Although not modifiable risk factors, these conditions are important in a cumulative risk calculation.

Unexpectedly, the evidence showed that depression led to one-fifth of the risk of premature mortality compared to no depression, and having peripheral vascular disease led to approximately half the odds of mortality compared to the odds experienced without peripheral vascular disease. This is contrary to the understanding in current clinical practice that depression and peripheral vascular disease are modifiable risk factors that increase the risk of premature mortality. However, a higher score on the Charlson co-morbidity index, which is a measure of co-morbidities including cardiovascular disorders such as heart failure, stroke and peripheral heart disease as well as other chronic conditions, is associated with an increase in mortality. In children followed up for more than five years, having an abnormal neurological exam confers a hazard of mortality that is 12 times greater than the hazard experienced without an abnormal neurological exam and having abnormal cognitive function confers a hazard of mortality that is almost 4 times greater than the hazard experienced without abnormal cognitive function. Knowledge of the magnitude of these risk factors can contribute to the approach to epilepsy management.

Within a mixed population of children and adults who were followed up for one to five years, the evidence showed having a tumour has a hazard of mortality that is 4.5 times greater than the hazard experienced without having a tumour.

In studies of a mixed population followed up for over five years, there were several significant risk factors that had an impact on the risk of premature mortality. For example, having over ten seizures per year has almost six times greater odds of SUDEP than the odds experienced with less than ten seizures per year, and having a history of generalized tonic

clonic seizures has almost fourteen times greater odds of SUDEP than the odds experienced without a history of generalized tonic clonic seizures. In relation to medication and treatment of epilepsy, some results showed that three to five changes in dose of ASM per year has a risk of SUDEP that is nearly ten times greater than the risk experienced with no changes in ASM over a year and people on three ASM has an odds of SUDEP ten times greater than the odds experienced with monotherapy.

The committee agreed that these modifiable risk factors shown to have an impact on premature mortality or SUDEP could be grouped into a recommendation focused on treating seizures adequately with medication and adherence to medication. The committee agreed that focal to bilateral tonic-clonic seizures should be listed along with generalised tonic-clonic seizures as these more often cause convulsive seizures and are increasingly associated with drug-resistant epilepsy. In addition to this, social and lifestyle factors also showed an impact on premature mortality. For example, special supervision at night had about half of the odds of SUDEP compared to people with no supervision overnight and living alone has an odds of SUDEP that is five times greater than the odds when sharing a household and bedroom. The committee recognised the importance of these findings and included them as part of the recommendations to discuss whether night-time supervision might be helpful for some people who have seizures during sleep and are at higher risk of mortality. The committee discussed the challenges surrounding such an intervention and how it would not be feasible or appropriate in many circumstances but acknowledged parents or carers reported gaining some reassurance from the use of a night monitor in a child's room.

The committee noted the importance of ongoing dialogue between the person with epilepsy, their families or carers, and their clinicians about the general management of their epilepsy, medications and seizures, which can help in tailoring treatment and enhance adherence to medications. A person's risk of premature mortality or SUDEP can change at different stages in their life, which can be affected by how well their epilepsy is managed but also different environmental factors which indirectly affect their risks, such as stress and lifestyle choices. So, conversations around the risks of premature mortality need to be adapted according to risk factors which are relevant at the time of follow up.

The committee acknowledged it is important to note that the modifiable risk factors identified in the evidence are not the only risk factors that may have an impact on the risk of premature mortality and SUDEP. The committee agreed that the evidence base was limited with respect to many of the biologically plausible risk factors that had been included in the review protocol and were aware that absence of evidence did not equate to 'evidence of absence'. They, therefore, suggested that discussions about modifiable risk factors between clinician and patient should not be limited to those mentioned in the recommendations and may include other risk factors such as sleep deprivation or sleeping position, and drug polytherapy.

1.1.15. Cost effectiveness and resource use

No health economic evidence was identified for this review question.

The committee discussed the clinical evidence presented and noted that people with epilepsy should be supported to understand their individual risk of mortality, including SUDEP, from the time of their epilepsy diagnosis and throughout the duration of their care. The committee acknowledged that the prospect of SUDEP could be extremely worrying for people with epilepsy causing increased anxiety and depression, worsening people's quality of life. Therefore, support from health care professionals for people with epilepsy to understand their individualised risk is instrumental in improving patient's quality of life. In addition, for those patients who are at greater risk of premature mortality, the committee discussed that healthcare workers should work with patients to reduce this risk. The committee noted that these recommendations are reflective of current practice and so are not expected to result in a substantial resource impact.

The committee also discussed the modifiable risk factors and co-morbidities associated with the risk of epilepsy-related mortality. It was noted that modifiable risk factors and co-morbidities should be discussed with people upon an initial diagnosis of a person's epilepsy as well as throughout the duration of treatment. The committee acknowledged that in current practice, the degree to which modifiable risk factors are discussed with people varies. However, because the information provided on the modifiable risk factors of SUDEP is discussed at existing appointments people attend, this recommendation is not expected to result in a substantial resource impact.

Night-time supervision for people with epilepsy was also discussed. The committee noted that night-time supervision could be especially beneficial for people who have seizures during their sleep and have been assessed to be at high risk of epilepsy-related mortality as intercepting a person's nocturnal seizure can be lifesaving. There are, however, significant implications associated with night-time monitoring. Night-time monitoring of people living in residential care should already be provided; however, the committee noted that, if possible, the level of supervision should be increased. This is because onset of a seizure when sleeping can start suddenly and unexpectedly, therefore without regular monitoring, there may be little benefit of monitoring at all. Overall, increasing the levels of monitoring of people residing in residential care should not result in a significant resource impact as there should already be night-time staff on shift able to conduct monitoring. The committee did, however, note that for places that do not currently provide regular monitoring, an additional member of staff may be required if the workload of night-staff is already high.

The committee acknowledged that night-time supervision for people with epilepsy not residing in care could be extremely challenging. Monitoring can be achieved through the use of baby monitors or other technologies which provide an alert to a parent, guardian, or partner when a person with epilepsy is experiencing a seizure. The purpose of the recommendation made by the committee is to inform people of the risks of night-time seizures and to make sure the correct approach to monitoring is adopted if appropriate. Advice on a person's individualised risks of night-time seizures and the best way to monitor these can be provided by health care professionals. In general, the cost of monitoring devices is incurred by careers, guardians, or patients. Therefore, this recommendation is not expected to lead to a significant resource impact.

The committee also discussed that monitoring may not be possible for adults living alone or in other settings such as living in a house with friends. The committee noted that in these circumstances, the risks and the benefits should be assessed with the help of a healthcare professional for the appropriate course of action to be taken.

1.1.16. Other factors the committee took into account

The committee acknowledged the importance of the 2020 MBRRACE-UK report, which focuses on improving the lives of pregnant women and mothers. The report highlighted that 13% of women died from epilepsy and stroke during or up to six weeks after their pregnancy. In relation to the recommendations made as part of this review, the report urges for the risk related to night-time seizures, uncontrolled seizures, and ineffective treatment to be discussed with pregnant women to reduce the risk of premature mortality and SUDEP.

1.1.17. Recommendations supported by this evidence review

This evidence review supports recommendations 10.1.1 – 10.1.4 in the NICE guideline.

1.1.17.1. 1.1.14.2 Economic evidence – included studies

[List references of studies included in the economic evidence review]

Appendices

Appendix A Review protocols

A.1 Review protocol for [add key area, for example, unplanned hospital admission]

ID	Field	Content
1.	Review title	Modifiable risk factors for epilepsy-related mortality, including SUDEP, and the magnitude of risk of those factors.
2.	Review question	What are the modifiable risk factors for epilepsy-related mortality, including SUDEP, and what is the magnitude of risk of the factors?
3.	Objective	To identify the modifiable variables that have an independent association with death, in a population of people who have a diagnosis of epilepsy. To identify the strength of those independent associations.
4.	Searches	The following databases from inception will be searched: Cochrane Central Register of Controlled Trials (CENTRAL) Cochrane Database of Systematic Reviews (CDSR) Embase MEDLINE

5.	Condition or domain being studied	Searches will be restricted by: • English language Other searches: • None The searches may be re-run 6 weeks before final committee meeting and further studies retrieved for inclusion if relevant. The full search strategies will be published in the final review.
6.	Population	Inclusion: People with a diagnosis of epilepsy.
7.	Risk factors (Although the ideal study would probably look at all these factors together, for inclusion a study need only look at one risk factor, though please note comments in row 8)	the following modifiable factors: • Sleeping unsupervised / living alone • Prone sleeping position • Uncontrolled/frequent Generalised Tonic Clonic Seizures (GTCS) • Nocturnal GTCS • Substance abuse / alcohol dependence • ASM polytherapy

		Other drug polytherapy
		Insufficient ASM therapy / any changes in prescription of drugs that could
		increase seizure rate
		Sleep deprivation / irregular sleep
8.	Key confounding factors (that have to be adjusted for)	No key confounders that have to be adjusted for have been identified, but the analysis
		report must demonstrate that it has tried to avoid bias arising from plausible potential
		confounders (the modifiable factors listed above plus other non-modifiable factors) by
		an appropriate method such as regression/ANCOVA, stratification, or propensity
		matching. If all plausible confounders are shown to be reasonably matched at baseline
		(if the study is a simple RF/no RF design) this will also be regarded as adequate.
		Some important confounders that we would ideally like to see accounted for are the
		modifiable factors listed above and the following 4 non-modifiable factors: age, gender,
		developmental intellectual disability, duration of epilepsy. If at least 2 of the modifiable
		factors [other than the index factor], and 2 of these 4 non-modifiable factors are not
		included in the analysis we will still include the study, but we will downgrade for
		indirectness.
9.	Types of study to be included	A longitudinal design, such as prospective/retrospective cohort studies. Case control
		studies will be allowed, provided they meet criteria in row 8.
10.	Other exclusion criteria	Cross-sectional studies

		Papers that have not attempted to adjust for key potential confounding variables
		Non-English language studies.
11.	Context	It is believed that epilepsy-related death (including SUDEP) may be preventable, partly by attention to altering modifiable risk factors. This review therefore sets out to identify the modifiable risk factors for epilepsy related death (including SUDEP).
12.	Primary outcomes (critical outcomes)	 Death, related to epilepsy SUDEP Follow up: any available but stratify according to: <1 yr., 1-5 yrs., >5 yrs.
13.	Secondary outcomes (important outcomes)	None
14.	Data extraction (selection and coding)	EndNote will be used for reference management, sifting, citations and bibliographies. All references identified by the searches and from other sources will be screened for inclusion. 10% of the abstracts will be reviewed by two reviewers, with any disagreements resolved by discussion or, if necessary, a third independent reviewer.
		The full text of these potentially eligible studies will be retrieved and assessed in line with the criteria outlined above.
		A standardised form will be used to extract data from the included studies (see Developing NICE guidelines: the manual section 6.4).

		10% of all evidence reviews are quality assured by a senior research fellow. This includes checking:
		papers were included /excluded appropriately
		a sample of the data extractions
		correct methods are used to synthesise data
		a sample of the risk of bias assessments
		Disagreements between the review authors over the risk of bias in particular studies will be resolved by discussion, with involvement of a third review author where necessary.
		Adjusted measures of effect (i.e., adjusted HRs, ORs) will be extracted, with a note of the variables adjusted for.
15.	Risk of bias (quality) assessment	Risk of bias quality assessment will be assessed using CASP.
		10% of all evidence reviews are quality assured by a senior research fellow. This includes checking:
		papers were included /excluded appropriately
		a sample of the data extractions
		correct methods are used to synthesise data
		a sample of the risk of bias assessments
		Disagreements between the review authors over the risk of bias in particular studies will be resolved by discussion, with involvement of a third review author where necessary.

16.	Strategy for data synthesis	Where possible suitably adjusted data will be meta-analysed where appropriate. If meta-analysis is not possible, data will be presented as individual values in adapted GRADE profile tables and plots of un-pooled sensitivity and specificity from RevMan software.
17.	Analysis of sub-groups	Non-conditional stratification
		Follow up: <1 yr., 1-5 yrs., >5 yrs.
		Children (<18yrs) vs adult (18 yrs. or over)
		Conditional stratification
		Young stratum: <2, 2-11, 11-18; older stratum: 18-55, >55
		Learning disability vs none
		Head injury vs none
		Types of seizure
		gender

25.	Review team members	From the National Guideline Centre:		
		•		

26.	Funding sources/sponsor	This systematic review is being completed by the National Guideline Centre which receives funding from NICE.
27.	Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting, any potential conflicts of interest will be considered by the guideline committee Chair and a senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.
28.	Collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of Developing NICE guidelines: the manual . Members of the guideline committee are available on the NICE website: https://www.nice.org.uk/guidance/indevelopment/gid-ng10112/documents
29.	Other registration details	N/A
30.	Reference/URL for published protocol	
31.	Dissemination plans	NICE may use a range of different methods to raise awareness of the guideline. These include standard approaches such as: notifying registered stakeholders of publication
		publicising the guideline through NICE's newsletter and alerts

		issuing a press release or briefing as appropriate, posting news articles on the NICE website, using social media channels, and publicising the guideline within NICE.

A.2 Health economic review protocol

realtii et	conomic review protocol
Review question	All questions – health economic evidence
Objectives	To identify health economic studies relevant to any of the review questions.
Search criteria	 Populations, interventions and comparators must be as specified in the clinical review protocol above.
	 Studies must be of a relevant health economic study design (cost–utility analysis, cost-effectiveness analysis, cost–benefit analysis, cost–consequences analysis, comparative cost analysis).
	 Studies must not be a letter, editorial or commentary, or a review of health economic evaluations. (Recent reviews will be ordered although not reviewed. The bibliographies will be checked for relevant studies, which will then be ordered.) Unpublished reports will not be considered unless submitted as part of a call for evidence.
	Studies must be in English.
Search strategy	A health economic study search will be undertaken using population-specific terms and a health economic study filter.
Review strategy	Studies not meeting any of the search criteria above will be excluded. Studies published before 2004, abstract-only studies and studies from non-OECD countries or the USA will also be excluded.
	Studies published after 2004 that were included in the previous guideline(s) will be reassessed for inclusion and may be included or selectively excluded based on their relevance to the questions covered in this update and whether more applicable evidence is also identified.
	Each remaining study will be assessed for applicability and methodological limitations using the NICE economic evaluation checklist which can be found in appendix H of Developing NICE guidelines: the manual (2014). ²⁰
	Inclusion and exclusion criteria
	 If a study is rated as both 'Directly applicable' and with 'Minor limitations', then it will be included in the guideline. A health economic evidence table will be completed, and it will be included in the health economic evidence profile.
	 If a study is rated as either 'Not applicable' or with 'Very serious limitations', then it will usually be excluded from the guideline. If it is excluded, then a health economic evidence table will not be completed, and it will not be included in the health economic evidence profile.
	• If a study is rated as 'Partially applicable', with 'Potentially serious limitations' or both then there is discretion over whether it should be included.
	Where there is discretion
	The health economist will make a decision based on the relative applicability and quality of the available evidence for that question, in discussion with the guideline committee if required. The ultimate aim is to include health economic studies that are helpful for decision-making in the context of the guideline and the current NHS setting. If several studies are considered of sufficiently high applicability and methodological quality that they could all be included, then the health economist, in discussion with the committee if required, may decide to include only the most applicable studies and to selectively exclude the remaining studies. All studies excluded on the basis of applicability or methodological limitations will be listed with explanation in the excluded health economic studies appendix below.
	The health economist will be guided by the following hierarchies.

Setting:

- UK NHS (most applicable).
- OECD countries with predominantly public health insurance systems (for example, France, Germany, Sweden).
- OECD countries with predominantly private health insurance systems (for example, Switzerland).
- Studies set in non-OECD countries or in the USA will be excluded before being assessed for applicability and methodological limitations.

Health economic study type:

- Cost–utility analysis (most applicable).
- Other type of full economic evaluation (cost–benefit analysis, cost-effectiveness analysis, cost–consequences analysis).
- · Comparative cost analysis.
- Non-comparative cost analyses including cost-of-illness studies will be excluded before being assessed for applicability and methodological limitations.

Year of analysis:

- The more recent the study, the more applicable it will be.
- Studies published in 2004 or later (including any such studies included in the previous guideline(s)) but that depend on unit costs and resource data entirely or predominantly from before 2004 will be rated as 'Not applicable'.
- Studies published before 2004 (including any such studies included in the previous guideline(s)) will be excluded before being assessed for applicability and methodological limitations.

Quality and relevance of effectiveness data used in the health economic analysis:

 The more closely the clinical effectiveness data used in the health economic analysis match with the outcomes of the studies included in the clinical review the more useful the analysis will be for decision-making in the guideline.

Appendix B Literature search strategies

This literature search strategy was used for the following reviews:

- What are the modifiable risk factors for a further seizure after a first seizure, and what is the magnitude of risk of those factors?
- What are the modifiable risk factors for epilepsy-related mortality, including SUDEP, and what is the magnitude of risk of the factors?

The literature searches for this review are detailed below and complied with the methodology outlined in Developing NICE guidelines: the manual.²⁰

For more information, please see the Methodology review published as part of the accompanying documents for this guideline.

B.1 Clinical search literature search strategy

Searches were constructed using the following approach:

Population AND risk factor terms

B.2 Health Economics literature search strategy

Health economic evidence was identified by conducting a broad search relating to an Epilepsies population in NHS Economic Evaluation Database (NHS EED – this ceased to be updated after March 2015) and the Health Technology Assessment database (HTA) with no date restrictions. NHS EED and HTA databases are hosted by the Centre for Research and Dissemination (CRD). Additional searches were run on Medline and Embase for health economics and quality of life studies.

Table 84: Database date parameters and filters used

Appendix C Prognostic evidence study selection

Figure 1: Flow chart of clinical study selection for the review of modifiable risk factors for epilepsy related mortality

Appendix D Prognostic evidence

Reference	Walczak 2001 ³⁹	
Study type and analysis	nalysis Prospective case control study with multivariate analysis	
Number of participants	Cases = 20	
and characteristics	Controls = 80	
	Participants were prospectively enrolled after evaluation at three upper mid-western epilepsy centres. A surveillance system was set up to identify deaths in this prevalence cohort. All deaths were investigated to distinguish between SUDEP and other causes of death. Definite SUDEP required the following 1) a history of epilepsy (more than one epileptic seizure during a period of less than 5 years; 2) that the death occur suddenly; 3) that the death was unexpected; and 4) that the death remained unexplained after all investigative efforts, including autopsy. Probable SUDEP was considered with criteria 1 – 3. All deaths between June 1 1991 and December 31 1996 were analysed. Unclear how the controls were selected

Study type and analysis	Retrospective open cohort study design. Multivariate analysis with Cox regression models
Number of participants	N=33,658
and characteristics	

Reference	Faught 2008 ¹⁰		
	The study population was selected based on the following inclusion criteria: ≥18 years of age; ≥ one neurologist visit with a diagnosis of epilepsy or nonfebrile convulsions; ≥ two pharmacy dispensing's for ASMs (carbamazepine, ethosuximide, felbamate, gabapentin, lamotrigine, levetiracetam, oxcarbazepine, phenobarbital, phenytoin, pregabalin, primidone, tiagabine, topiramate, valproic acid, or zonisamide) following epilepsy/seizure diagnosis; and ≥6 months of continuous Medicaid enrolment before the first post epilepsy/seizure ASM dispensing (index date) to allow for a baseline period for assessing certain covariates. Patients from the three Medicaid databases who fulfilled all the above criteria with no subsequent gaps in enrolment were pooled together to form the study population. Health insurance claims data made available to the authors from the Florida (FL), New Jersey (NJ), and Iowa (IA) Medicaid programs were used for this analysis. The choice of states was driven solely by data availability. The datasets contain complete medical and pharmacy dispensing claims for eligible people during the covered years, including Medicare/Medicaid crossovers. Combined, the datasets spanned a period from January 1997 through June 2006, including 9 million covered lives. Adherence status was evaluated separately for each treated quarter using a variation of the medication possession ratio (MPR), a common means for assessing adherence in claims data. MPR = number of days in quarter with supplies for 1 ASM / number of days in quarter. A threshold of 0.80 was used to determine adherence.

Study type and analysis	Retrospective case control study with multivariate regression analysis
Number of participants	N=104
and characteristics	Inclusion criteria:
	Cases were individuals who had died, had a diagnosis of epilepsy registered on the death certificate and were treated for epilepsy at the centre in the study period, and met the criteria for SUDEP. SUDEP was defined according to the following criteria: 1) Patient has the disease of epilepsy, 2) unexpected death occurred while the patient was in a reasonable state of health, 3) death was sudden, 4) death occurred during normal activities and benign circumstances, 5) there was no evidence of an obvious medical cause of death, and 6) death did not occur as a result of direct insult of status epilepticus or seizure. SUDEP is typically classified as definite if an autopsy has been performed and probable if no autopsy has been performed. In Asian countries such as Korea, cultural customs and habits mean that is not common to perform an autopsy, so all SUDEP patients in the present study were classed as probable SUDEP.
	All included subjects were receiving ASM stationary at least more than 1 yr.
	Control subjects were living epilepsy patients matched for age, sex, and initial date of enrolment at our medical centre. Tree control participants were included for each case.
	Exclusion criteria:
	People were excluded if they were followed for less than 5 year and cases aged < 5 year or > 70 year, because unexpected death in these age groups may have many differential causes

Reference	Ryu 2015 ²⁶				
	The subjects in this study were patients who were registered and treated for epilepsy at Asan Medical Centre, University of Ulsan College of Medicine, Korea, the tertiary hospital in Korea, between 1993 and 2011. A total of 35,638 patients with epilepsy were enrolled. Epilepsy was defined as a history of two or more unprovoked seizures or a single seizure with evidence of epileptiform activity recorded by electroencephalogram or structural lesions documented by brain imaging. Medical records of patients were reviewed in detail and information on the cause of death was collected from the National Statistics Office database, which is matched to the hospital records using the unique national identification number of each patient.

and characteristics

Epilepsy is defined as recurrent seizures without an acute cause. Participants were prospectively recruited patients with epilepsy who were at least 17 years old and newly referred to the outpatient epilepsy clinics at the National Taiwan University Hospital (NTUH) between 1st January 1991 and 31 December 1991. The NTUH is the largest university teaching hospital and one of the major tertiary referral centres in Taiwan. All the patients underwent thorough clinical assessment to ensure that they had active epilepsy, this definition being restricted to patients with epilepsy who had experienced recurrent seizures within the past 5 years or who had been taking anticonvulsants within the last 5 years. Patients with seizures provoked by acute symptomatic causes were excluded. A total of 263 patients with active epilepsy formed the dataset for analysis.

This cohort was followed until 31 December 2000. The authors recorded 32 deaths out 263 patients. The cause of death was assessed in the light of documentary evidence, including medical charts, autopsy findings, and pathological reports. Sudden unexpected death (SUD) was defined as, non-traumatic death in a patient with epilepsy who had been previously healthy or had suffered from a disease

which would not normally be expected to result in immediate or sudden death, and those deaths not directly related to seizure or status epilepticus.

	The study is based on a cohort of people aged between 15 – 70 who during 1980 – 1989 had been admitted to and discharged with a diagnosis of epilepsy from any hospital in the county of Stockholm. The study population was followed up through the National Cause of Death Register until December 31 1991. Cases were individuals who had died with a diagnosis of epilepsy registered on the death certificate and who after review of medical and necropsy records were found to meet SUDEP criteria. Three control participants, who were living epilepsy patients matched for age and sex were selected from the same cohort for each case. All medical records were examined.

Sveinsson 2020 ³⁶ (Sveinsson a)
Case control study with conditional logistic regression and individual modelling
Cases n = 255
Controls n=1148
Using linkage to the National Cause of Death Registry (ICD-10 classified since 1994),18 9,605 deaths were identified from the study population during the follow-up time from July 1, 2006, to December 31, 2011. All deaths with epilepsy written on the death certificate (n = 1,276), together will all individuals who died during 2008 (n = 1,890), were eligible SUDEP cases. One neurologist reviewed all death certificates. Excluded from further analysis of case records were obvious non-SUDEP deaths such as malignancy, terminal illness, stroke, myocardial infarct, and post-mortem confirmed pneumonia (figure 1). For the remaining cases (n = 1,373), where SUDEP could potentially be the cause of death, patient records from family physicians, hospital records, nursing homes or other institutions, police records, and autopsy records were reviewed.
Controls:
From the study population, 5 epilepsy controls (n = 1,275) for each SUDEP case, of the same sex, who were alive at the case's
time of death were randomly selected by the National Board of Health and Welfare. The case's time of death served as an index
date for the controls, who thus were matched with the cases for sex and calendar time. We acquired medical records for 1,232
(97%) controls, of which 84 (6.8%) were adjudicated not to have epilepsy after case review. The remaining 1,148 individuals served as controls in the current study

education

Sveinsson 2020³⁶ (Sveinsson a) Reference Together with each individual's personal identification number, the Swedish National Patient Register (SNPR) contains ICD codes for all patients hospitalized (starting in 1968, with total national coverage from 1987) or managed in hospitalbased ambulatory care since 2001.17 Our study population was composed of all individuals who were registered at any time during 1998–2005 in the SNPR with an ICD-10 code for epilepsy (G 40) (n = 78,424) who were alive on June 30, 2006 (n = 60,952)Cases (n=255) Controls (n=1148) No ASMs Monotherapy Polytherapy No ASMs Monotherapy Polytherapy 46 113 265 483 400 Total 96 21 (12 – 15) 16(7-41)Age at diagnosis 17(4-46)5(1-24)9(4-22)9(3-21)Duration, years 12(7-27)17 (9 – 31) 30(14-46)10(8-16)14 (8 - 25)21(12 - 36)33/13 65/48 56/40 170/95 274/109 236/164 M/F ratio Sharing bedroom 135 17 9 77 179 6 Generalized 8 17 12 68 131 68 Epilepsy Focal epilepsy 27 88 71 175 311 308 Generalized and 1 2 7 4 10 17 focal Intellectual disability 7 36 54 44 107 172 19 Substance Abuse 17 18 16 11 6 Alcohol dependence 5 13 8 8 13 13 Primary school 23 59 61 152 223 246

² Downgraded for indirectness as analysis did not adjust for at least two of the non-modifiable confounders

³ Downgraded by 1 increment if the confidence interval crossed the null line

⁴ Adjusted for seizure frequency during last year, age in years at epilepsy onset, epilepsy type, number of ASM, changes in dose of ASM per year

¹ Downgraded by 1 increment if the majority of the evidence was at moderate risk of bias, and downgraded by 2 increments if the majority of the evidence was at high risk of bias

Table 151: Antipsychotic medication

			Quality assessmen	t			No of patien	ıts	Effect			
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute		Importance
Antipsychot	ic medication (foll	ow-up >5 ye	ars)									
1		,	no serious inconsistency	serious ²	serious ³	none		-	RR 2.14 (0.9 to 5.09)	-	⊕OOO VERY LOW⁴	CRITICAL

Downgraded by 1 increment if the majority of the evidence was at moderate risk of bias, and downgraded by 2 increments if the majority of the evidence was at high risk of bias

Table 152: Anxiolytic medication

			Quality assess	sment			No of patie	nts	Effect			
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute		Importance
Anxiolytic n	medication (follow	v-up >5 year	rs)									
1	observational study	, ,	no serious inconsistency	serious²	no serious imprecision	none	-	1	RR 3.00 (1.16 to 7.76)	-	⊕OOO VERY LOW³	CRITICAL

² Downgraded for indirectness as analysis did not adjust for at least two of the non-modifiable confounders

³ Adjusted for seizure frequency during last year, age in years at epilepsy onset, epilepsy type, number of ASM, changes in dose of ASM per year

² Downgraded for indirectness as analysis did not adjust for at least two of the non-modifiable confounders

³ Downgraded by 1 increment if the confidence interval crossed the null line

⁴ Adjusted for seizure frequency during last year, age in years at epilepsy onset, epilepsy type, number of ASM, changes in dose of ASM per year

Table 153: Asthma

	Quality assessment							No of patients				
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute		Importance
Asthma (f	ollow-up >5 years)											
1	observational study	,	no serious inconsistency		no serious imprecision	none	-	-	OR 0.20 (0.1 to 0.4)	-	⊕OOO VERY LOW³	CRITICAL

Downgraded by 1 increment if the majority of the evidence was at moderate risk of bias, and downgraded by 2 increments if the majority of the evidence was at high risk of bias

Table 154: Sharing household but not sharing a bedroom

	Quality assessment							ents	Effect			
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute	•	Importance
Sharing ho	usehold only (fol	llow-up >5 years	3)					•		•	•	
		no serious risk of bias			no serious imprecision	none	-	-	OR 2.28 (1.14 to 4.56)	-	⊕⊕⊕⊕ HIGH¹	CRITICAL

Adjusted for age at onset, duration of epilepsy, type of epilepsy, causes of epilepsy, living conditions, highest education

Table 155: Living alone

Quality assessment No of p	patients Effect	Quality	Importance
----------------------------	-----------------	---------	------------

¹ Downgraded by 1 increment if the majority of the evidence was at moderate risk of bias, and downgraded by 2 increments if the majority of the evidence was at high risk of bias

² Downgraded for indirectness as analysis did not adjust for at least two of the non-modifiable confounders

³ Adjusted for seizure frequency during last year, age in years at epilepsy onset, epilepsy type, number of ASM, changes in dose of ASM per year

² Downgraded for indirectness as analysis did not adjust for at least two of the non-modifiable confounders

³ Adjusted for history of TCS, number of TCS in previous 3 months, total number of anti-seizure medications, carbamazepine usage, supervision, asthma

No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute		
Not sharing	g household (fo	llow-up >5 years)										
		no serious risk of bias			no serious imprecision	none	•	-	OR 5.01 (2.93 to 8.57)	-	⊕⊕⊕⊕ HIGH¹	CRITICAL

Adjusted for age at onset, duration of epilepsy, type of epilepsy, causes of epilepsy, living conditions, highest education

Table 156: Secondary education

	Quality assessment							No of patients				
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute	Quality	Importance
Secondary	education (follow	w-up >5 years)										
				no serious indirectness	Serious ¹	none	-	1	OR 1.59 (0.78 to 3.24)		⊕⊕⊕O MODERATE²	CRITICAL

Table 157: Primary education

	Quality assessment							No of patients				
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute	Quality	Importance
Primary edu	ucation (follow-u	p >5 years)										
				no serious indirectness	Serious ¹	none	-	-	OR 1.21 (0.58 to 2.52)		⊕⊕⊕O MODERATE²	CRITICAL

¹ Downgraded by 1 increment if the confidence interval crossed the null line ² Adjusted for age at onset, duration of epilepsy, type of epilepsy, causes of epilepsy, living conditions, highest education

Table 158: Same room supervision at night

	Quality assessment							No of patients Effect					
	No of tudies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute	_	Importance
Sar	ne room	supervision at ni	ght (follow-	up >5 years)									
1		observational study	, ,	no serious inconsistency		no serious imprecision	none	-	1	OR 0.40 (0.2 to 0.8)	-	⊕OOO VERY LOW³	CRITICAL

¹ Downgraded by 1 increment if the majority of the evidence was at moderate risk of bias, and downgraded by 2 increments if the majority of the evidence was at high risk of bias

Table 159: Special supervision at night (regular checks throughout the night or the use of a listening device)

	Quality assessment								No of patients Effect			
No of studies	Design	Risk of bias	Inconsistency	Indirectness	Imprecision	Other considerations	Mixed (f/u >5 years)	Control	Relative (95% CI)	Absolute	Quality	Importance
Special sup	ervision at night ((follow-up >	5 years)									
		, ,	no serious inconsistency	serious²	no serious imprecision	none	-	-	OR 0.10 (0.03 to 0.3)	-	⊕OOO VERY LOW³	CRITICAL

Downgraded by 1 increment if the majority of the evidence was at moderate risk of bias, and downgraded by 2 increments if the majority of the evidence was at high risk of bias

¹ Downgraded by 1 increment if the confidence interval crossed the null line

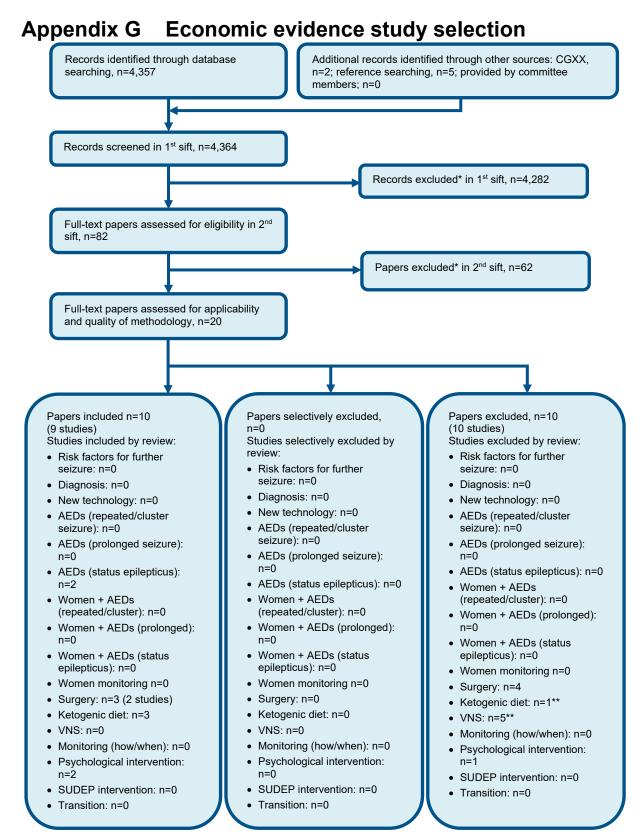

² Adjusted for age at onset, duration of epilepsy, type of epilepsy, causes of epilepsy, living conditions, highest education

² Downgraded for indirectness as analysis did not adjust for at least two of the non-modifiable confounders

³ Adjusted for history of TCS, number of TCS in previous 3 months, total number of anti-seizure medications, carbamazepine usage, supervision, asthma

² Downgraded for indirectness as analysis did not adjust for at least two of the non-modifiable confounders

³ Adjusted for history of TCS, number of TCS in previous 3 months, total number of anti-seizure medications, carbamazepine usage, supervision, asthma

^{*} Non-relevant population, intervention, comparison, design or setting; non-English language

^{**}Please note that 1 article related to two questions. For this reason, the numbers listed for each review may not total the number of full text articles assessed for applicability and quality of methodology.

Appendix H Economic evidence tables

None.

Appendix I Health economic model

No original economic modelling was undertaken for this review question.

Appendix J Excluded studies

J.1 Clinical studies

Table 160: Studies excluded from the clinical review

	uded from the clinical review
Reference	Reason for exclusion
Alvarez 2020 ¹	Inappropriate study design – narrative review of prognostic scores for status epilepticus.
Andrade-Machado 2015 ²	Inappropriate comparison – no relevant outcomes for extraction or analysis
Assis 2015 ⁴	Inappropriate study design – cross sectional study design
Blank 2021 ⁵	Inappropriate comparison – no relevant outcomes (analysis compares prognostic factors against no epilepsy)
Canoui-Poitrine 2011 ⁶	Inappropriate comparison – Multivariate analysis does not include modifiable risk factors
Dabla 2018 ⁸	Inappropriate population – people with epilepsy who sustained injuries; multivariate analysis not for mortality
Fangsaad 2019 ⁹	Inappropriate population – mixed population with neonates and multivariate analysis not for mortality or SUDEP
Hesdorffer 2011 ¹¹	Inappropriate study design – meta-analysis of four studies; individual papers ordered for analysis
Hesdorffer 2012 ¹²	Inappropriate study design – meta-analysis of four studies; individual papers ordered for analysis
Hitiris 2007 ³	Inappropriate study design – no multivariate analysis for risk factors for epilepsy related death
Hunt 2003 ¹³	Inappropriate population – correlation between sleeping position and sudden infant death syndrome
Lamberts 2015 ¹⁴	Inappropriate population and study design – correlation between cardiovascular conditions and possible SUDEP in epileptic and non-epileptic population
Li 2009 ¹⁶	Inappropriate study design – no modifiable risk factors included within multivariate analysis
Logroscino 2008 ¹⁷	Inappropriate population – risk of death after 1 st seizure or incident epilepsy
McCabe 2021 ¹⁸	Inappropriate study design – analysis of a checklist for SUDEP in the primary care compared to secondary care setting
McCarter 2018 ¹⁹	Inappropriate study design – investigation the risk of possible SUDEP in people with obstructive sleep apnoea
Ngugi 2014 ²¹	Inappropriate study design – population of people with active convulsive epilepsy and people with potentially undiagnosed epilepsy given treatment and monitored
Novak 2015 ²⁴	Inappropriate study design – double blind cross-over trial

Reference	Reason for exclusion
Odom 2018 ²⁵	Inappropriate study design – comparison of a risk score for possible SUDEP
Saetre 2018 ²⁷	Inappropriate study design – Systematic review; references checked
Saxena 2018 ²⁸	Inappropriate study design – Literature review; references checked
Shankar 2018 ²⁹	Inappropriate study design – analysis of a risk score for possible SUDEP
Sillanpaa 2013 ³¹	Inappropriate study design – no modifiable risk factors included within analysis with unclear methodology
Singh 2013 ³²	Inappropriate comparison – cardiovascular risk factors in relation to possible SUDEP
Sveinsson 2017 ³⁴	Inappropriate study design – incidence rates of psychological comorbidities in relation to SUDEP
Sveinsson 2018 ³³	Inappropriate study design – incidence rates of SUDEP
Tennis 1995 ³⁷	Inappropriate study design – multivariate analysis not for epilepsy related death or SUDEP
Waddy 2019 ³⁸	Inappropriate population – mortality related to end stage renal failure patients on dialysis and epilepsy

J.2 Health Economic studies

Published health economic studies that met the inclusion criteria (relevant population, comparators, economic study design, published 2004 or later and not from non-OECD country or USA) but that were excluded following appraisal of applicability and methodological quality are listed below. See the health economic protocol for more details.

Table 161: Studies excluded from the health economic review

Reference	Reason for exclusion
None.
