Disclaimer

The recommendations in this guideline represent the view of NICE, arrived at after careful consideration of the evidence available. When exercising their judgement, professionals are expected to take this guideline fully into account, alongside the individual needs, preferences and values of their patients or service users. The recommendations in this guideline are not mandatory and the guideline does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of the individual patient, in consultation with the patient and, where appropriate, their carer or guardian.

Local commissioners and providers have a responsibility to enable the guideline to be applied when individual health professionals and their patients or service users wish to use it. They should do so in the context of local and national priorities for funding and developing services, and in light of their duties to have due regard to the need to eliminate unlawful discrimination, to advance equality of opportunity and to reduce health inequalities. Nothing in this guideline should be interpreted in a way that would be inconsistent with compliance with those duties.

NICE guidelines cover health and care in England. Decisions on how they apply in other UK countries are made by ministers in the <u>Welsh Government</u>, <u>Scottish Government</u>, and <u>Northern Ireland Executive</u>. All NICE guidance is subject to regular review and may be updated or withdrawn.

1 Managing intracranial hypertension

Evidence review underpinning research recommendations in the NICE guideline.

1.1 Review question: What is the clinical and cost effectiveness of options for managing intracranial hypertension?

1.2 Introduction

In people with subarachnoid haemorrhage, intracranial pressure may be increased by hydrocephalus, haematoma, infection, or cerebral oedema. Raised intracranial pressure (intracranial hypertension) can impede blood flow to the brain and contribute to brain injury, in spite of a normal systemic blood pressure.

Several treatments for intracranial hypertension are in clinical use but there is variation in practice between neurosurgical centres. This review assesses the evidence to support medical and surgical interventions to treat intracranial hypertension.

1.3 PICO table

For full details see the review protocol in Appendix A:.

Table 1: PICO characteristics of review question

	• • • • • • • • • • • • • • • • • • •
Population	Inclusion: Adults (16 and older) with intracranial hypertension and a confirmed subarachnoid haemorrhage caused by a suspected or confirmed ruptured aneurysm.
Intervention	 Diuretics Hypertonic saline Surgical interventions: Decompressive Craniectomy External ventricular drain Sedation Hypertensive therapy
Comparison	Comparators: • To each other (within and between class comparison) • To no treatment
Outcomes	 Critical outcomes: Mortality Health and social-related quality of life (any validated measure) Degree of disability or dependence in daily activities, (any validated measure e.g. Modified Rankin Scale and patient-reported outcome measures) Important outcomes: Subsequent subarachnoid haemorrhage Return to daily activity (e.g. work, driving) Complications of intervention (any)
Study design	Change in intracranial pressure Randomised controlled trials (RCTs), systematic reviews of RCTs.
	, , , , , , , , , , , , , , , , , , ,

If insufficient RCT evidence is available, non-randomised studies will be considered if they adjust for key confounders (age), starting with prospective cohort studies

1.4 Clinical evidence

1.4.1 Included studies

Two studies were included in the review;^{6, 38} these are summarised in Table 2 below. Evidence from these studies is summarised in the clinical evidence summary below (Table 3).

1.4.2 Excluded studies

See the excluded studies list in Appendix J:.

1.4.3 Summary of clinical studies included in the evidence review

Table 2: Summary of studies included in the evidence review

Study	Intervention and comparison	Population	Outcomes	Comments
Bentsen 2006 ⁶	Hypertonic saline - was a 7.2% saline in 6% hydroxyethyl starch 200/0.5 solution (HyperHAES, Fresenius Kabi AG) The observation period lasted from 10 min before until 210 min after the start of the infusion. Need for rescue treatment was defined by treatment failure limits for ICP and CPP, which were an ICP of >20 > 20 mm HG and a CPP of 60 <60 mmHG. Unless these limits were reached during the observation period, the ventilation variables were kept unaltered, the infusion rates vasopressors, analgesics, sedatives, and fluids were stable, the resistance in the external ventricular drainage (EVD) was unchanged, and the patients were neither stimulated or moved. N=11 Control (placebo) - was 0.9% saline solution (Fresenius Kabi AG, Bad Hamburgh v.d.h), Germany. The observation period lasted from 10 mins before until 210 mins after the	Included intensive care patients with an acute spontaneous SAH with stable ICP in the range 10 - 20 mmHg. They needed to be >18 years of age, sedated, mechanically ventilated, have stable hemodynamics and serum sodium of <160 mmol/L Age: Intervention Group – 50.1 (10.5) Placebo group – 55.2 (10.8)	• Intracranial pressure	RCT

				Anticipated a	absolute effects
Outcomes	No of Participants (studies) Follow up	Quality of the evidence (GRADE)	Relative effect (95% CI)	Risk with no additional treatment	Risk difference with decompressive craniectomy (95% CI)
Mortality -	18 (1 study) death during hospitalisatio n	⊕⊖⊖ VERY LOW1,2 due to risk of bias, imprecision	RR 0.79 (0.38 to 1.64)	727 per 1000	153 fewer per 1000 (from 451 fewer to 465 more)
Mortality - (12 months)	18 (1 study) 12 months	⊕⊖⊖ VERY LOW1,2 due to risk of bias, imprecision	Peto OR 13.08 (0.23 to 729.15)	0 per 1000	140 more per 1000 (from 150 fewer to 440 more)
GOS grade 1-2 (12 months) scale 1-5; high score represents positive outcome	16 (1 study) 12 months	⊕⊖⊝⊝ VERY LOW1,2 due to risk of bias, imprecision	RR 1.04 (0.65 to 1.67)	800 per 1000	32 more per 1000 (from 280 fewer to 536 more)
GOS grade 3 (12 months) scale 1-5; high score represents positive outcome	16 (1 study) 12 months	⊕⊖⊖ VERY LOW1,2 due to risk of bias, imprecision	RR 1.67 (0.13 to 22)	100 per 1000	67 more per 1000 (from 87 fewer to 1000 more)
GOS grade 4-5 (12 months) scale 1-5; high score represents positive outcome	16 (1 study) 12 months	⊕⊖⊖ VERY LOW1 due to risk of bias	Peto OR 0.2 (0 to 11.57)	100 per 1000	78 fewer per 1000 (from 100 fewer to 462 more)

¹ Downgraded by 1 increment if the majority of the evidence was at high risk of bias, and downgraded by 2 increments if the majority of the evidence was at very high risk of bias

See Appendix G: for full GRADE tables.

² Downgraded by 1 increment if the confidence interval crossed one MID or by 2 increments if the confidence interval crossed both MIDs

1.5 Economic evidence

1.5.1 Included studies

No health economic studies were included.

1.5.2 Excluded studies

No relevant health economic studies were excluded due to assessment of limited applicability or methodological limitations.

See also the health economic study selection flow chart in Appendix H:.

1.5.3 Unit costs

Relevant unit costs are provided below to aid consideration of cost effectiveness.

Table 5: UK costs of treatments for decompressive craniectomy

Procedure	Description	Average cost
Decompressive craniectomy/ hemicraniotomy	Very Major Intracranial Procedures, 19 years and over [weighted average of NHS Reference Cost code AA52A-D]	£10,574

Source: NHS Reference Costs 2018/1940

1.6 Evidence statements

1.6.1 Health economic evidence statements

No relevant economic evaluations were identified.

1.7 The committee's discussion of the evidence

1.7.1 Interpreting the evidence

1.7.1.1 The outcomes that matter most

The committee considered mortality, quality of life (Glasgow outcome scale) and degree of disability or dependence in daily activities to be critical outcomes for decision-making. Other important outcomes included subsequent subarachnoid haemorrhage, return to daily activity, complications of intervention and reduction in intracranial pressure.

1.7.1.2 The quality of the evidence

No evidence was identified for managing intracranial hypertension using diuretics, sedation, external ventricular drain or hypertensive therapy.

Limited evidence was identified from two studies for hypertonic saline and decompressive craniectomy. The very small size of the studies (ranging from 18 to 22 participants) limited confidence in the strength of the evidence. The quality of evidence varied from high to very low; most of the evidence was downgraded due to risk of bias and/or imprecision. The RCT reported high quality evidence for the outcome of intracranial pressure, however the committee agreed that the evidence from this small study was insufficiently powered for clinical outcomes and could not support a recommendation. The outcomes from the

retrospective cohort study were at a high risk of bias due to their study design and were also downgraded due to imprecision.

1.7.1.3 Benefits and harms

The anticipated benefit of treating intracranial hypertension is to reduce the risk of mortality and subsequent neurological deterioration.

Hypertonic saline vs placebo

The committee were aware that administration of hypertonic saline may reduce intracranial pressure but is associated with a risk of metabolic derangement. The committee noted evidence from 1 small RCT that hypertonic saline lowers intracranial pressure when compared with normal saline, but the quality and quantity of the evidence was too low to draw any conclusions on the benefits or harms of this treatment and so no clinical recommendation was made.

Decompressive craniectomy vs no additional treatment

Evidence from 1 small cohort study showed a reduction in mortality (during hospitalisation) and less disability (GOS) with decompressive craniectomy compared with no decompressive craniectomy. This benefit was not sustained and at twelve months the study reported an increase in mortality with decompressive craniectomy compared to no decompressive craniectomy. The committee considered that the quality and quantity of the evidence was too low to draw any firm conclusions.

The committee noted from their clinical experience that a lower rate of mortality, but a higher rate of disability might be expected with decompressive craniectomy. The committee highlighted that there are recognised risks to an invasive procedure such as decompressive craniectomy, including haemorrhagic, infective, and CSF related complications. The committee agreed that no recommendation could be made for decompressive craniectomy.

The committee agreed that raised intracranial pressure is common in patients with aSAH, but intracranial hypertension that impedes blood flow to the brain and contributes to brain injury is generally only seen in the sickest group. These patients are usually unconscious or require ventilation on an intensive care unit, and the anticipated benefit of treating intracranial hypertension in these patients is to reduce the risk of death and disability. However, the committee acknowledged that management of this heterogeneous population varies widely in current practice, with some clinicians advocating routine monitoring of intracranial pressure to guide intervention to lower intracranial pressure and maintain cerebral perfusion (such as CSF drainage, hypertonic saline, or vasopressor therapy). By contrast, other clinicians favour management without intracranial pressure measurement.

The committee discussed the options for monitoring intracranial pressure and managing intracranial hypertension but could not agree whether intracranial pressure should be routinely measured or how raised intracranial pressure should be managed. The committee was therefore unable to make a consensus recommendation.

As the evidence available for this review and for the review on monitoring intracranial pressure (evidence review I) was limited, the committee decided to make a research recommendation to assess the clinical and cost effectiveness of interventions to monitor and reduce intracranial pressure in unconscious or ventilated people with aSAH in whom the poor clinical condition is attributed at least partly to raised intracranial pressure.

1.7.2 Cost effectiveness and resource use.

No published economic evaluations were identified for this review. Unit costs were presented to the committee for consideration of cost effectiveness. However, due to a lack of clinical

evidence the committee could not determine the clinical effectiveness of interventions to manage intracranial hypertension and therefore the cost effectiveness could not be assessed.

Due to the lack of evidence the committee made a research recommendation and therefore there will be no resource impact.

1.7.3 Other factors the committee took into account

There was no consensus within the committee whether intracranial pressure should be routinely measured or how raised intracranial pressure should be managed. The committee recognised the difference in management between traumatic brain injury and primary vascular injuries of the brain. It was noted by the committee that in traumatic brain injury, measuring intracranial pressure is a routine practice whereas in vascular injuries it is seldom performed. The committee added that there is significant variation in how intracranial hypertension is managed. A number of centres monitor and manage intracranial hypertension in aSAH in a manner similar to that for traumatic brain injury.

Due to the lack of evidence available for this review and for the review on monitoring intracranial pressure, the committee made a research recommendation to assess the impact of routine monitoring of intracranial hypertension on subsequent management and outcome in people with aneurysmal SAH who are unconscious or ventilated on ICU (see Appendix K).

Appendices

Appendix A: Review protocols

Table 6: Review protocol: Managing intracranial hypertension

lable	6: Review protocol: Managing	intracranial hypertension
ID	Field	Content
0.	PROSPERO registration number	CRD42019146786
1.	Review title	What is the clinical and cost effectiveness of options for managing intracranial hypertension?
2.	Review question	What is the clinical and cost effectiveness of options for managing intracranial hypertension?
3.	Objective	To determine which intervention to manage intracranial hypertension is the most clinically and cost-effective. Intracranial hypertension is recognised as a serious complication of aneurysmal subarachnoid haemorrhage associated with increased morbidity.
4.	Searches	The following databases will be searched:
		Cochrane Central Register of Controlled Trials (CENTRAL)
		Cochrane Database of Systematic Reviews (CDSR)
		Embase
		MEDLINE
		Searches will be restricted by:
		English language only
		The searches may be re-run 6 weeks before the final committee meeting and further studies retrieved for inclusion if relevant.
		The full search strategies will be published in the final review
5.	Condition or domain being studied	Aneurysmal subarachnoid haemorrhage
6.	Population	Inclusion: Adults (16 and older) with intracranial hypertension and a confirmed subarachnoid haemorrhage caused by a suspected or confirmed ruptured aneurysm.
		Exclusion:
		 Adults with subarachnoid haemorrhage caused by head injury, ischaemic stroke or an arteriovenous malformation.
		 Children and young people aged 15 years and younger.
7.	Intervention/Exposure/Test	Diuretics
		Hypertonic saline
		Surgical interventions:

	T	
		o Decompressive Craniectomy
		∘ External ventricular drain
		Sedation
		Hypertensive therapy
8.	Comparator/Reference	Comparators:
	standard/Confounding factors	To each other (within and between class comparison)
		To no treatment
9.	Types of study to be included	Randomised controlled trials (RCTs), systematic reviews of RCTs.
		If insufficient RCT evidence is available, non- randomised studies will be considered if they adjust for key confounders (age), starting with prospective cohort studies.
10.	Other exclusion criteria	Exclusions:
		Intracranial hypertension due to hydrocephalus.
		Non- English language studies
		Abstracts will be excluded as it is expected there will be sufficient full text published studies available.
11.	Context	
12.	Primary outcomes (critical	Mortality
	outcomes)	Health and social-related quality of life (any validated measure)
		Degree of disability or dependence in daily activities, (any validated measure e.g. Modified Rankin Scale and patient-reported outcome measures)
13.	Secondary outcomes (important	Subsequent subarachnoid haemorrhage
	outcomes)	Return to daily activity (e.g. work, driving)
		Complications of intervention (any)
		Change in intracranial pressure
		Outcomes will be grouped at <30 days, 30days-6 months, 6-12 months, and at yearly timepoints thereafter.
14.	Data extraction (selection and coding)	EndNote will be used for reference management, sifting, citations and bibliographies. All references identified by the searches and from other sources will be screened for inclusion. 10% of the abstracts will be reviewed by two reviewers, with any disagreements resolved by discussion or, if necessary, a third independent reviewer. The full text of potentially eligible studies will be retrieved and will be assessed in line with the criteria outlined above.
		EviBASE will be used for data extraction.
		If not an intervention review, add: A standardised form will be used to extract data

		the manual section 6.4).
15.	Risk of bias (quality) assessment	Risk of bias will be assessed using the appropriate checklist as described in Developing NICE guidelines: the manual.
		Systematic reviews: Risk of Bias in Systematic Reviews (ROBIS)
		Randomised Controlled Trial: Cochrane RoB (2.0)
		Non randomised study, including cohort studies: Cochrane ROBINS-I
		10% of all evidence reviews are quality assured by a senior research fellow. This includes checking:
		papers were included /excluded appropriately
		a sample of the data extractions
		correct methods are used to synthesise data
		a sample of the risk of bias assessments
		Disagreements between the review authors over the risk of bias in particular studies will be resolved by discussion, with involvement of a third review author where necessary.
16.	Strategy for data synthesis	Pairwise meta-analyses will be performed using Cochrane Review Manager (RevMan5).
		GRADEpro will be used to assess the quality of evidence for each outcome, taking into account individual study quality and the meta-analysis results. The 4 main quality elements (risk of bias, indirectness, inconsistency and imprecision) will be appraised for each outcome. Publication bias is tested for when there are more than 5 studies for an outcome.
		The risk of bias across all available evidence was evaluated for each outcome using an adaptation of the 'Grading of Recommendations Assessment, Development and Evaluation (GRADE) toolbox' developed by the international GRADE working group http://www.gradeworkinggroup.org/
		Where meta-analysis is not possible, data will be presented and quality assessed individually per outcome.
		Subgroups will be investigated separately if meta-analysed results show heterogeneity.
17.	Analysis of sub-groups	Strata:
		n/a Subgroups:
		Patient grade:
		∘ Good grade

		 Poor grade Cause of intracranial hypertension: Haemotoma Cerebral oedema

25.	Review team members	From the National Guideline Centre:			

		M- CILDIA-LI-
		 Ms Gill Ritchie Mr Ben Mayer Mr Audrius Stonkus Mr Vimal Bedia Ms Emma Cowles
		Ms Jill Cobb
		Ms Amelia Unsworth
26.	Funding sources/sponsor	This systematic review is being completed by the National Guideline Centre which receives funding from NICE.
27.	Conflicts of interest	All guideline committee members and anyone who has direct input into NICE guidelines (including the evidence review team and expert witnesses) must declare any potential conflicts of interest in line with NICE's code of practice for declaring and dealing with conflicts of interest. Any relevant interests, or changes to interests, will also be declared publicly at the start of each guideline committee meeting. Before each meeting, any potential conflicts of interest will be considered by the guideline committee Chair and a senior member of the development team. Any decisions to exclude a person from all or part of a meeting will be documented. Any changes to a member's declaration of interests will be recorded in the minutes of the meeting. Declarations of interests will be published with the final guideline.
28.	Collaborators	Development of this systematic review will be overseen by an advisory committee who will use the review to inform the development of evidence-based recommendations in line with section 3 of Developing NICE guidelines: the manual . Members of the guideline committee are available on the NICE website.
29.	Other registration details	
30.	Reference/URL for published protocol	
31.	Dissemination plans	NICE may use a range of different methods to raise awareness of the guideline. These include standard approaches such as: • notifying registered stakeholders of
		publication
		publicising the guideline through NICE's newsletter and alerts
		issuing a press release or briefing as appropriate, posting news articles on the NICE website, using social media channels, and publicising the guideline within NICE.
32.	Keywords	Subarachnoid, intracranial hypertension, raised intracranial pressure

Table 7: Health economic review protocol

Review	
question	All questions where health economic evidence applicable
Objectives	To identify health economic studies relevant to any of the review questions.
Search criteria	 Populations, interventions and comparators must be as specified in the clinical review protocol above.
	 Studies must be of a relevant health economic study design (cost-utility analysis, cost-effectiveness analysis, cost-benefit analysis, cost-consequences analysis, comparative cost analysis).
	 Studies must not be a letter, editorial or commentary, or a review of health economic evaluations. (Recent reviews will be ordered although not reviewed. The bibliographies will be checked for relevant studies, which will then be ordered.)
	 Unpublished reports will not be considered unless submitted as part of a call for evidence.
	Studies must be in English.
Search strategy	A health economic study search will be undertaken using population-specific terms and a health economic study filter.
Review strategy	Studies not meeting any of the search criteria above will be excluded. Studies published before 2003, abstract-only studies and studies from non-OECD countries or the USA will also be excluded.
	Each remaining study will be assessed for applicability and methodological limitations using the NICE economic evaluation checklist which can be found in appendix H of Developing NICE guidelines: the manual. ³⁹
	Inclusion and exclusion criteria
	 If a study is rated as both 'Directly applicable' and with 'Minor limitations' then it will be included in the guideline. A health economic evidence table will be completed and it will be included in the health economic evidence profile.
	 If a study is rated as either 'Not applicable' or with 'Very serious limitations' then it will usually be excluded from the guideline. If it is excluded then a health economic evidence table will not be completed and it will not be included in the health economic evidence profile.
	 If a study is rated as 'Partially applicable', with 'Potentially serious limitations' or both then there is discretion over whether it should be included.
	Where there is discretion
	The health economist will decide based on the relative applicability and quality of the available evidence for that question, in discussion with the guideline committee if required. The ultimate aim is to include health economic studies that are helpful for decision-making in the context of the guideline and the current NHS setting. If several studies are considered of sufficiently high applicability and methodological quality that they could all be included, then the health economist, in discussion with the committee if required, may decide to include only the most applicable studies and to selectively exclude the remaining studies. All studies excluded based on applicability or methodological limitations will be listed with explanation in the excluded health economic studies appendix below.
	The health economist will be guided by the following hierarchies. Setting:
	 UK NHS (most applicable). OECD countries with predominantly public health insurance systems (for example, France, Germany, Sweden).
	 OECD countries with predominantly private health insurance systems (for example, Switzerland).

 Studies set in non-OECD countries or in the USA will be excluded before being assessed for applicability and methodological limitations.

Health economic study type:

- Cost–utility analysis (most applicable).
- Other type of full economic evaluation (cost–benefit analysis, cost-effectiveness analysis, cost–consequences analysis).
- · Comparative cost analysis.
- Non-comparative cost analyses including cost-of-illness studies will be excluded before being assessed for applicability and methodological limitations.

Year of analysis:

- The more recent the study, the more applicable it will be.
- Studies published in 2003 or later but that depend on unit costs and resource data entirely or predominantly from before 2003 will be rated as 'Not applicable'.
- Studies published before 2003 will be excluded before being assessed for applicability and methodological limitations.

Quality and relevance of effectiveness data used in the health economic analysis:

• The more closely the clinical effectiveness data used in the health economic analysis match with the outcomes of the studies included in the clinical review the more useful the analysis will be for decision-making in the guideline.

Appendix B: Literature search strategies

This literature search strategy was used for the following reviews;

 What is the clinical and cost effectiveness of options for managing intracranial hypertension?

The literature searches for this review are detailed below and complied with the methodology outlined in Developing NICE guidelines: the manual³⁹

For more information, please see the Methods Report published as part of the accompanying documents for this guideline.

B.1 Clinical search literature search strategy

Searches were constructed using a PICO framework where population (P) terms were combined with Intervention (I) and in some cases Comparison (C) terms. Outcomes (O) are rarely used in search strategies for interventions as these concepts may not be well described in title, abstract or indexes and therefore difficult to retrieve. Search filters were applied to the search where appropriate.

B.2 Health Economics literature search strategy

Health economic evidence was identified by conducting a broad search relating to subarachnoid haemorrhage population in NHS Economic Evaluation Database (NHS EED – this ceased to be updated after March 2015) and the Health Technology Assessment database (HTA) with no date restrictions. NHS EED and HTA databases are hosted by the Centre for Research and Dissemination (CRD). Additional searches were run on Medline and Embase.

Table 9: Database date parameters and filters used

Database	Dates searched	Search filter used
Medline	2003 – 23 June 2020	Exclusions Health economics studies
Embase	2003 – 23 June 2020	Exclusions Health economics studies
Centre for Research and Dissemination (CRD)	HTA - Inception – 23 June 2020	None

Appendix C: Clinical evidence selection

Figure 1: Flow chart of clinical study selection for the review of managing intracranial hypertension

Appendix D: Clinical evidence tables

Study	Bentsen 2006 ⁶
Study type	RCT (Patient randomised; Parallel)
Number of studies (number of participants)	(n=22)
Countries and setting	Conducted in Norway; Setting: single centre study, intensive care
Line of therapy	1st line
Duration of study	Intervention time : 210 minutes
Method of assessment of guideline condition	Adequate method of assessment/diagnosis
Stratum	Overall: n/a
Subgroup analysis within study	Not applicable: n/a
Inclusion criteria	Included intensive care patients with an acute spontaneous SAH with stable ICP in the range 10 -20 mmHg. They needed to be >18 yrs of age, sedated, mechanically ventilated, have stable hemodynamics and serum sodium of <160 mmol/L
Exclusion criteria	Not specified
Age, gender and ethnicity	Age - Mean (SD): Intervention group - 50.1(10.5); placebo - 55.2(10.8). Gender (M:F): 4/18. Ethnicity: not stated
Further population details	1. Cause of intracranial hypertension: Not stated / Unclear (spontaneous SAH). 2. Patient grade: Poor grade (Hunt and Hess median (range) intervention group - 5(3-5); place (2 -5)).
Indirectness of population	No indirectness
Interventions	(n=11) Intervention 1: Hypertonic saline. Hypertonic saline - was a 7.2% saline in 6% hydroxyethyl starch 200/0.5 solution (HyperHAES, Fresenius Kabi AG) The observation period lasted from 10 min before until 210 min after the start of the infusion. Need for rescue treatment was defined by treatment failure limits for ICP and CPP, which were an ICP of >20> 20 mm HG and a CPP of 60 <60 mmHG. Unless these limits were reached during the observation period, the ventilation variables were kept unaltered, the infusion rates vasopressors, analgesics, sedatives, and fluids were stable, the resistance in the external ventricular drainage (EVD) was unchanged, and the patients were neither stimulated or moved Duration 10 minutes before to 210 minutes after the infusion. Concurrent medication/care: n/a. Indirectness: No indirectness
	(n=11) Intervention 2: No treatment. Placebo - was 0.9% saline solution (Fresenius Kabi AG, Bad Homburgh v.d.h),

	Germany. The observation period lasted from 10 mins before until 210 mins after the start of the infusion. Need for rescue treatment was defined by treatment failure limits for ICP and CPP, whichwere an ICP of >20> 20 mm HG and a CPP of 60 <60 mmHG. Unless these limits were reached during the observation period, the ventilation variables were kept unaltered, the infusion rates vasopressors, analgesics, sedatives, and fluids were stable, the resistance in the external ventricular drainage (EVD) was unchanged, and the patients were neither stimulated or moved. Duration 10 minutes before to 210 minutes after the infusion. Concurrent medication/care: n/a. Indirectness: No indirectness					
Funding	Funding not stated					
Protocol outcome 1: Complications of procedure - Actual outcome: intracranial pressure change s	AS FOR COMPARISON: HYPERTONIC SALINE versus NO TREATMENT e (any) score at 210 min after trhe intervention; Group 1: mean -3.3 (SD 2.6); n=11, Group 2: mean -0.3 (SD 1.3); n=11 linding - Low, Incomplete outcome data - Low, Outcome reporting - Low, Measurement - Low, Crossover - Low;					
Protocol outcomes not reported by the study	Mortality; Health and social quality of life; Degree of disability or dependence in daily activities, (e.g. Modified R Scale and patient-reported outcome measures); Subsequent subarachnoid haemorrhage; Return to daily activity work)					

Study	Nagel 2009 ³⁸
Study type	Non-randomised comparative study
Number of studies (number of participants)	1 (n=18)
Countries and setting	Conducted in Germany; Setting: n/a
Line of therapy	1st line
Duration of study	Intervention + follow up: 12 months
Method of assessment of guideline condition	Adequate method of assessment/diagnosis
Stratum	Overall: n/a
Subgroup analysis within study	Not applicable: n/a

Protocol outcome 1: Mortality

- Actual outcome: Mortality - Death while clinical stay at while clinical stay; Group 1: 4/7, Group 2: 8/11

Inclusion criteria	Any SAH patient developing intracranial hypertension with ICP values ≥20 mmHg for at least >6h after SAH and requiring treatment of elevated ICP was included. aSAH confirmed by CT; cerebral angiogram demonstrating intracranial aneurysm; patients underwent clipping followed by intraoperative insertion of the microdialysis catheter o patients underwent endovascular therapy of an aneurysm from the anterior circulation and additionally had an external ventricular drainage placed, so catheter placement through the existing burrhole allowed monitoring of the anterior cerebral artery territory.
Exclusion criteria	Patients were excluded if they were hemodynamically instable, presented with fixed and dilated pupils on admission of died within 24 hours after admission
Recruitment/selection of patients	n/a
Age, gender and ethnicity	Age - Mean (SD): intervention group - 48(3.4) control group 52(3.5). Gender (M:F): 4/14. Ethnicity: not stated
Further population details	1. Cause of intracranial hypertension: Not applicable (SAH). 2. Patient grade: Not applicable (WFNS grade: intervention/comparison: (grade1 - 2/1; grade2 - 0/0; grade3 - 2/0; grade4 - 0/4; grade5 - 3/6) Fisher grade - intervention/comparison: (grade1 - 0/0; grade2 - 0/0; grade3 - 4/1; grade4 - 3/10).
Indirectness of population	No indirectness
Interventions	(n=7) Intervention 1: Surgical interventions - Decompressive Craniectomy . decompressive craniectomy - Hemicraniectomy was performed in median on day 4(2-6) after SAH, in 2 of the 7 patients early after SAH. in 4 patients (57%) a dilating pupil was observed shortly before hemicraniectomy. Duration n/a. Concurrent medication/care: All patients underwent first line treatment. Second line treatment included barbiturate coma and forced hyperventilation in both groups. Moderate hyperventilation was performed in most patients (n=16, 89%) while forced hyperventilation was rare (n=5, 28%) most frequently, moderate hyperventilation was started on day 3 (10 out of 16 patients, 63 %, range 1-9 days) and forced hyperventilation on day 6 (4 of 5 patients, 80%, 1-8 days). Indirectness: No indirectness (n=11) Intervention 2: No treatment. no decompressive craniectomy. Duration n/a. Concurrent medication/care: All patients underwent first line treatment. Second line treatment included barbiturate coma and forced hyperventilation in both groups. Moderate hyperventilation was performed in most patients (n=16, 89%) while forced hyperventilation was rare (n=5, 28%) most frequently, moderate hyperventilation was started on day 3 (10 out of 16 patients, 63 %, range 1-9 days) and forced hyperventilation on day 6 (4 of 5 patients, 80%, 1-8 days). Indirectness: No indirectness
Funding	Funding not stated

Zhao 2015 ⁶⁸	Inappropriate population – no raised ICP

J.2 Excluded health economic studies

Published health economic studies that met the inclusion criteria (relevant population, comparators, economic study design, published 2003 or later and not from non-OECD country or USA) but that were excluded following appraisal of applicability and methodological quality are listed below. See the health economic protocol for more details.

Table 14: Studies excluded from the health economic review

Reference	Reason for exclusion
None.	

Appendix K: Research recommendations

K.1 Intracranial hypertension

Research question: What is the impact of routine monitoring of intracranial hypertension on subsequent management and outcome in people with aneurysmal subarachnoid haemorrhage who are unconscious or ventilated on an intensive care unit?

Why this is important:

In people with subarachnoid haemorrhage the pressure inside the skull may be increased by hydrocephalus, haematoma or cerebral oedema. Raised intracranial pressure (intracranial hypertension) can impede blood flow to the brain even if the systemic blood pressure is normal. Raised intracranial pressure can be inferred in people with cerebral oedema or mass lesions on a CT head scan, particularly if focal brain herniation is present, but can only be established definitively by invasive measurement. This can be done by insertion of a pressure sensor into the cranial cavity, or by pressure measurement from a ventricular drain, and is generally only done in people with aSAH who are admitted to an intensive care unit. Current practice varies widely, and some clinicians have a low threshold for intra-cranial pressure monitoring and base management decisions on the intra-cranial pressure, while other clinicians determine management without measuring intra-cranial pressure.

Criteria for selecting priority research recommendations:

PICO question

Population: Adults (16 and older) with a confirmed subarachnoid haemorrhage caused by a ruptured aneurysm who are unconscious or ventilated on an intensive care unit.

Intervention(s):

- Routine monitoring of ICP
 - o Direct pressure measurement/intracranial pressure (ICP) monitoring
- Detection of raised ICP will facilitate early use of interventions to manage ICP including:
 - o Hypertonic saline
 - o External ventricular drain
 - Hypertensive therapy
 - o any other protocol therapy to reduce ICP.

Comparison:

No routine monitoring for ICP.

Interventions to manage ICP may still be used but will not be directed by direct monitoring of ICP.

Outcome(s):

- Mortality
- Health and social-related quality of life (any validated measure)
- Degree of disability or dependence in daily activities, (any validated measure e.g. Modified Rankin Scale and patient-reported outcome measures)
- Interventions to manage intracranial hypertension
- Return to daily activity (e.g. work, driving)
- · Complications of intervention (any)

Importance to patients or the population	The anticipated benefit of monitoring intracranial pressure and treating any intracranial hypertension is to reduce the risk of neurological deterioration and mortality. The anticipated benefit of not measuring pressure is to avoid the procedure-related morbidity associated with doing so.
Relevance to NICE guidance	There is currently no guidance on the direct monitoring and subsequent management of raised intracranial pressure in people with SAH. Further research may guidance to be developed within this area.
Relevance to the NHS	Practice for the monitoring and subsequent management of raised intracranial pressure currently varies across the UK. The proposed research may help to reduce this variation and inform the design of a randomised trial.
National priorities	Not relevant to a national priority area.
Current evidence base	There is little evidence on diagnosing and treating intracranial hypertension. The diagnostic accuracies of transcranial doppler and ultrasound measurement of optic nerve sheath diameter were considered too low by the committee for reliable detection of intracranial hypertension when compared with direct intracranial pressure measurement. The committee also highlighted that there is no evidence that interventions to lower intracranial pressure improve clinical outcome.
Equality	No equality issues
Study design	Data to be collected as part of a registry study.
Timeframe	Evidence should be carried out within 3-5 years to allow for a sufficient collection of data and follow-up time.
Feasibility	This research is considered to be feasible.
Other comments	The committee noted that currently clinicians may not have equipoise to randomise patients to routine monitoring and no routine monitoring, and a RCT in this area currently may not be feasible. The committee agreed that a registry-based study could inform practice and the design of future definitive research.
Importance	Medium: the research is relevant to the recommendations in the guideline, but the research recommendations are not key to future updates.
