Appendix 1

Scope of work

NATIONAL INSTITUTE FOR HEALTH AND CLINICAL EXCELLENCE

Scope of work (from original scope)

1 Guidance title

Obesity: the prevention, identification, assessment and management of overweight and obesity in adults and children.

1.1 Short title

Obesity

2 Background

a) The National Institute for Clinical Excellence ('NICE' or 'the Institute') has commissioned the National Collaborating Centre for Primary Care (NCC–PC) to work with the Health Development Agency (HDA) and develop guidance, for use in the NHS in England and Wales, on the prevention, identification, assessment, treatment and weight management of overweight and obesity in adults and children. This follows referral of the topic by the Department of Health and Welsh Assembly Government (see Annex). The guidance will provide recommendations for good practice that are based on the best available evidence of effectiveness, including cost effectiveness. The term 'guidance', rather than 'guideline' is used to reflect the broad nature of the task. The guidance has two key components. First, a guideline providing recommendations on the clinical management of overweight and obesity in the NHS will be developed through the NICE guideline development process. Second, advice on the prevention of overweight and obesity will be issued and will apply in both NHS and non-NHS settings.

b) The joint Institute and HDA guidance will support the implementation of National Service Frameworks (NSFs) (including those for Coronary Heart Disease, Diabetes, and the NHS Cancer Plan) in those aspects of care and prevention where a Framework has been published. The statements in each NSF reflect the evidence that was used at the time the Framework was prepared. The guidelines and technology appraisals published by the Institute after an NSF has been issued will update the Framework. The guidance will also support the implementation of the Priorities and Planning Framework 2003–6 and the new General Practitioner (GP) contract.

3 The need for the guidance

a) Obesity and overweight (pre-obese) are conditions in which weight gain has reached the point where it poses significant risks to health. Obesity is more than a lifestyle disorder. It may be considered as a disease and a risk factor for other diseases (for example, type 2 diabetes). In adults, the body mass index (BMI) is frequently used as a measure of overweight and obesity, with overweight being defined as a BMI 25-29.9 and obesity as a BMI ≥ 30. Epidemiological surveys of England indicate that the prevalence of overweight and obesity in adults has nearly trebled during the last 20 years. In 1980, 8% of adult women and 6% of adult men were classified as obese; by 2002 this had increased to 23% of women and 22% of men, with a further 43% of men and 34% of women being overweight. Therefore, around two-thirds of men and women, almost 24 million adults, were either overweight or obese in 2002. The Welsh Health Survey, undertaken in 1998, found that 1 in 6 adults in Wales were obese (nearly 15% of men and 17% of women). Compared with 1985 levels, obesity in Wales had doubled among men and increased by half among women by 1998. The prevalence of obesity differs according to age, socio-economic group and ethnic group. The National Audit Office (NAO) (2001) found that obesity:

- increases with age
- is more prevalent among lower socio-economic and lower income groups, with a particularly strong social class gradient among women
- is more prevalent among certain ethnic groups, particularly among African-Caribbean and Pakistani women (from Joint Health Surveys Unit, 2001)
- is a problem across all regions in England but shows some important regional variations.

In children, the prevalence of obesity is also rising. In England in 2002, over 16% of boys and girls aged 2–15 years were obese compared with 10% of males and around 12% of females in 1995 (defined as a BMI above the 95th percentile) (Health Survey for England [HSE] 2002). Around a further 14% of males and females were estimated to be overweight (defined as a BMI between the 85th and 95th percentiles) compared with around 13% of males and females in 1995. There are inequalities in the prevalence of obesity. The HSE (2002) found that obesity was more common in children, particularly girls, from lower social groups and the National Diet and Nutrition Survey (NDNS) (1997) of young people found that obesity was more common among Asian groups and children living in Wales.

Obesity occurs as a result of consuming more calories than are expended for daily energy needs. In adults, obesity is associated with an increased risk of diseases that are a major cause of morbidity and mortality, notably type 2 diabetes, coronary heart disease, hypertension, many cancers and osteoarthritis. In children and teenagers, the associated morbidities include hypertension, hyperinsulinaemia, dyslipidaemia, type 2 diabetes, psychosocial dysfunction, and exacerbation of existing conditions such as asthma. However, the persistence of obesity into adulthood is the most important concern; the risk of persistence increases with increasing age of the child and severity of obesity.

Obesity imposes a considerable economic burden. The National Audit Office (NAO) (2001), estimated that in 1998 obesity directly cost the NHS at least £0.5 billion, while the indirect cost of obesity on the wider economy was around £2 billion a year.

b) There is evidence of variability in the management of overweight and obese people in the NHS. The NAO (2001) identified no central guidance on management of obesity and, at local level, only 28% of Health Authorities had taken action to address obesity as a health problem. It was also noted that primary care played an important role in the management of obesity but that GPs and practice nurses used a wide range of different methods to manage overweight and obese patients and many were uncertain as to which interventions were most effective. The NAO also highlighted the need for joint working with different agencies to facilitate cross-government initiatives to prevent obesity at both national and local level and the need to consider the broader environment in terms of its potential to support behavioural change. As the key representative for health within Local Strategic Partnerships, Primary Care Trusts (PCTs) in England and Local Health Boards in Wales have a role to play which goes beyond the clinical setting and extends into the wider community through work in schools, workplaces and neighbourhoods.

c) National guidance is needed on the prevention of obesity and the identification, evaluation, and management of overweight and obese adults and children. The NAO (2001) noted that most general practices surveyed said they would find a national guideline for overweight and obesity useful. The reasons for needing guidance in this area are:
    - the rising prevalence of obesity and attendant rise in prevalence of diseases associated with obesity
    - the evidence of wide variations in care provided to adults and children with obesity, notably in primary care, and
    - the evidence that certain interventions can prevent excess weight gain, overweight and obesity .

4 The guidance

a) The guideline development process is described in detail in two booklets that are available from the NICE website (see 'Further information'). *The Guideline Development Process – An Overview for Stakeholders, the Public and the NHS* describes how organisations can become involved in the development of a guideline. *Guideline Development Methods – Information for National Collaborating Centres and Guideline Developers* provides advice on the technical aspects of guideline development.

b) This document is the scope. It defines exactly what this guidance will (and will not) examine, and what the guidance developers will consider. The scope is based on the referral from the Department of Health and Welsh Assembly Government (see Annex).

c) The areas that will be addressed by the guidance are described in the following sections.

4.1 Population

4.1.1 Groups that will be covered

a) This guideline will cover adults and children aged 2 years or older in following two categories: overweight or obese. This includes adults and children with established comorbidities, and those with or without risk factors for other medical conditions.

The following special groups will be considered, where there is good evidence of effectiveness of interventions targeted at these groups:
    - Black and minority ethnic groups
    - lower socio-economic groups
    - vulnerable groups, including older people and women of child-bearing age.

b) Currently a healthy weight (defined as being neither obese nor overweight), in order to support them in maintaining a healthy weight.

4.1.2 Groups that will not be covered

a) Children aged less than 2 years.

b) The medical management of related medical conditions. However, links will be made to other appropriate NICE guidance, such as that for type 2 diabetes and eating disorders.

4.2 Healthcare settings

a) The guidance will cover the care provided by NHS healthcare professionals working with overweight and obese adults and children in primary, secondary and, where appropriate, tertiary care (Specialised Morbid Obesity Services). The guidance will address areas that require collaboration between primary, secondary and tertiary care.
b) The HDA has a remit to work with a wide range of organisations and agencies – not just in the NHS but within national and local government, the voluntary and academic sectors and the private sector.

4.3 Areas that will be covered

The guidance will cover the following areas:

4.3.1 Clinical management of overweight and obesity in adults and children aged 2 years or older

a) The identification of overweight and obesity in adults and children in primary and secondary care. This will include advice on the following,
   i. The best way to discuss weight in the clinical setting.
   ii. The role of BMI and waist circumference as a method of measuring overweight and obesity, including an appropriate definition of overweight and obesity.
   iii. The role of serial measurements of height and weight in the clinical setting.
b) The assessment of overweight and obesity in adults and children in primary and secondary care. This will include advice on the following.
   i. Assessment of any weight-related comorbidities (for example, diabetes, coronary heart disease), including the adult's or child's clinical need to lose weight.
   ii. Assessment of risk factors strongly associated with overweight and obesity.
   iii. Determining the adult's or child's readiness and motivation to try to lose weight.
   iv. Consideration of lifestyle factors that are likely to explain why energy imbalance has occurred, including weight control history, usual dietary habits and physical activity levels.
c) The management of overweight and obesity in adults and children in primary and secondary care. This will include advice on the following.
   i. How practitioners should develop goals and treatment strategies with the adult or child with overweight or obesity (and their parent/family as appropriate). This will include, as appropriate, the goal of weight maintenance as well as weight loss.
   ii. The role of non-pharmacological interventions. Where there is good evidence of effectiveness, the following interventions will be considered:

- dietary advice including the role of low-fat, low-carbohydrate and very low-energy diets, the role of meal replacements and the role of ‘slimming clubs’
- physical activity
- psychological therapies
- professionally organised alternative therapies[1]

iii The role of pharmacological interventions. This will be limited to orlistat and sibutramine. These are currently the only anti-obesity drugs listed in the *British National Formulary* and available on prescription. The guidance will update the current NICE technology appraisals for these agents and when the guidance has been published the technology appraisals will be withdrawn.

- National Institute for Clinical Excellence (2001). *Guidance on the Use of Orlistat for the Treatment of Obesity in Adults*
- National Institute for Clinical Excellence (2001). *Guidance on the Use of Sibutramine for the Treatment of Obesity in Adults*

Note that guidance recommendations will fall within licensed indications: exceptionally, and only where clearly supported by evidence, can use outside a licensed indication be recommended. The guidance will assume that prescribers will use the Summary of Product Characteristics to inform their decisions for individual patients.

d) Morbid obesity in adults (BMI > 40) and children will be discussed in sufficient detail to inform primary and secondary care practitioners on best practice for referral to tertiary care (Specialised Morbid Obesity Services) and to identify key aspects of care for people with morbid obesity in tertiary centres. The following aspects of care will be considered.

i. The identification of morbid obesity in adults and children in primary and secondary care.

ii The criteria that should be used to determine when adults and children with morbid obesity should be referred to tertiary care.

iii. The assessment of morbid obesity in adults and children in tertiary care, including a health risk assessment based on presence of comorbidities.

iv. The management of morbid obesity in adults and children in tertiary care, including the role of an integral management approach aimed at weight loss and weight maintenance. The role of surgical treatment of morbid obesity will be addressed. The guidance will update the NICE technology appraisal on the use of surgery; when the guidance has been published the technology appraisal will be withdrawn.

- National Institute for Clinical Excellence (2002). *Guidance on the Use of Surgery to Aid Weight Reduction for People with Morbid Obesity*

4.3.2 The prevention of overweight and obesity in adults and children aged 2 years or older, who are currently of a healthy weight

a) The role of primary prevention approaches intended to support adults and children in maintaining a healthy weight. These approaches will be aimed mainly outside the clinical setting and will include advice on the following.

i. Raising awareness of what constitutes a healthy weight range and the need to stay within such a range.
ii. Identifying adults and children who should participate in prevention programmes based on their risk factors for obesity and readiness and opportunities to change their behaviour.
ii. Maintaining energy balance in adults and children of a healthy weight through a healthy diet and physical activity.
iv. Developing local strategies to prevent obesity and support weight maintenance in adults and children of a healthy weight. These will focus on multi-faceted interventions including:
   - community-based services including those to which individuals are referred from primary care services
   - broader environmental interventions in the community
   - interventions in workplaces
   - interventions in schools
   - interventions targeted at children aged 2–5 years
   - interventions targeted at black and minority ethnic groups, at vulnerable groups and at individuals at vulnerable life stages.

4.4 Areas that will not be covered

The guidance will not cover the following areas of clinical practice.

a) Population-based screening programmes for overweight or obesity.
b) Complementary therapy approaches to the treatment of overweight and obesity that are not included in the definition of 'professionally organised alternative therapies'.
c) Eating disorders, including binge-eating disorder.
d) In adults and children, the prevention or management of comorbidities (for example, type 2 diabetes) associated with overweight or obesity.
e) In children, the diagnosis and management of childhood syndromes (for example, Prader–Willi syndrome) or childhood diseases (for example, hypothyroidism) that lead to obesity.
f) In terms of prevention of overweight and obesity, the guidance will contribute to the evidence base leading to subsequent recommendations in national Government or European policies, including fiscal policy, food labelling policy and food advertising and promotion. The guidance is intended to support local practice whereas national or 'upstream' action will be addressed in the context of wider work such as the forthcoming Food and Health Action Plan.

4.5 Status

4.5.1 Scope

This is the final version of the scope.

4.5.2 Guidance

The development of the guidance recommendations will begin in September 2004.

---

[1] These are defined as: acupuncture, chiropractic, herbal medicine, homeopathy and osteopathy (House of Lords, 2000).

5 Further information

Information on the guideline development process is provided in:

- *The Guideline Development Process – An overview for Stakeholders, the Public and the NHS*

- *Guideline Development Methods – Information for National Collaborating Centres and Guideline Developers*

These booklets are available as PDF files from the NICE website (www.nice.org.uk). Information on the progress of the guideline will also be available from the website.

Annex – Referral from the Department of Health and Welsh Assembly Government

The Department of Health and Welsh Assembly Government asked the Institute:

"In consultation with the Health Development Agency, to prepare clinical guidance for the NHS in England and Wales for the prevention of obesity and for the identification, evaluation, and management of overweight and obese patients including the maintenance of weight loss. The guidance should:

- promote the best use of available NHS resources including workforce
- include a definition of obesity, standards for identification and evaluation, and guidance on effective methods of management and treatment, in primary care and other appropriate settings
- give appropriate emphasis to exercise, dietary approaches, group and individual behaviour modification, and to the scope for collaborative working between the NHS and other agencies
- make links to other appropriate NICE guidance."

Appendix 2

Questions and parameters

Key questions: public health

Raising awareness of what constitutes a healthy weight range and the need to stay within such a range

What is the effectiveness of public health interventions and the media to increase awareness of importance of staying a healthy weight?

What is the effectiveness of public health interventions and the media to increase awareness of behaviours associated with maintenance of a healthy weight (diet and activity)?

How can interventions best engage population/target groups?

Is an increase in awareness translated into action?

Sub-questions:

- Does the impact vary by gender, age, ethnicity, religious practices or social group.
- Is the source of delivery important?
- Is the mode of delivery important?
- Is there any negative impact?

Identifying adults and children who should participate in prevention programmes based on their risk factors for obesity and readiness and opportunities to change their behaviour

What is the effectiveness of public health interventions to identify individuals who would benefit from participation in prevention/public health interventions to manage weight?

What are the existing UK and non-UK guidelines/recommendation in relation to identifying individuals who would benefit from participation in prevention/public health interventions to manage weight?

Sub-questions:

- Does effectiveness vary by gender, age, ethnicity, religious practices or social group?
- What is the most effective source of delivery?
- What is the most effective mode of delivery?
- To what extent are public health interventions effective in identifying individuals for referral to/from primary care (clinical or non clinical setting)?
- Is there any negative impact?

Maintaining energy balance in adults and children of a healthy weight through a healthy diet and physical activity

What are the factors helping individuals to maintain energy balance/prevent overweight and obesity?

What are the factors helping individuals to increase their activity levels to an extent which will help maintain energy balance/prevent overweight and obesity?

What are the factors helping individuals to improve their diet in such a way to help maintain energy balance/prevent overweight and obesity?

Consideration of the above should be given for 'at risk' groups.
Sub-questions:

- Does this vary by gender, age, ethnicity, religious practices or social group?
- Do factors vary whether individuals previously lost weight?
- How is impact sustained?
- Is there any negative impact? (i.e. consider the flip side of healthy eating/physical activity health promotion messages – increased parental control and anxiety over eating/ link with eating disorders/parents displacing their own concerns over eating to their children)
- What was helpful/unhelpful?

Community-based services including those to which individuals are referred from primary care services

What is the effectiveness of interventions through community based public health services in terms of helping individuals/populations maintain a healthy weight/prevent overweight or obesity?
What is the effectiveness of interventions through community-based public health services in terms of helping individuals/populations improve behaviours associated with maintenance of a healthy weight (diet and activity)?

What strategies are effective in engaging a broad range of organisations and encouraging partnerships?
Sub-questions:

- Does effectiveness vary by gender, age, ethnicity, religious practices or social group?
- Do recommendations vary whether individuals have previously lost weight?
- Is the source of delivery important?
- Is the mode of delivery important?
- Is there any negative impact?
- What strategies are effective in engaging a broad range of organisations and encouraging partnerships?

Broader environmental interventions in the community

What is the effectiveness of broader environmental interventions in terms of helping individuals/populations maintain a healthy weight/prevent overweight or obesity?
What is the effectiveness of broader environmental interventions in terms of helping individuals/populations improve behaviours associated with maintenance of a healthy weight (diet and activity)?
What strategies are effective in engaging a broad range of organisations and encouraging partnerships?
Sub-questions:

- Does effectiveness vary by gender, age, ethnicity, religious practices or social group?
- Do recommendations vary whether individuals have previously lost weight?
- Is the source of delivery important?
- Is the mode of delivery important?
- Is there any negative impact?
- What strategies are effective in engaging a broad range of organisations and encouraging partnerships?

Interventions in workplaces

What is the effectiveness of workplace interventions in terms of helping individuals/populations to maintain a healthy weight/prevent overweight or obesity?
What is the effectiveness of workplace interventions in terms of helping individuals/populations improving behaviours associated with maintenance of a healthy weight (diet and activity)?
What strategies are effective in attracting workplaces to invest in the health and activity of their workforce?
Sub-questions:

- Does effectiveness vary by gender, age, ethnicity, religious practices or social group?
- Do recommendations vary whether individuals have previously lost weight?
- Is the source of delivery important?
- Is the mode of delivery important?
- Is there any negative impact?
- What strategies are effective in engaging a broad range of organisations and encouraging partnerships?

Interventions in schools

What is the effectiveness of school interventions in terms of helping individuals/populations maintain a healthy weight/prevent overweight or obesity?
What is the effectiveness of school interventions in terms of helping individuals/populations to improve behaviours associated with maintenance of a healthy weight (diet and activity)?
What strategies are effective in engaging schools to undertake interventions?
What are the essential elements of a ‘whole schools approach’?
Sub-questions:

- Does effectiveness vary by gender, age, ethnicity, religious practices or social group?
- Do recommendations vary whether individuals have previously lost weight?
- Is the source of delivery important?

- Is the mode of delivery important?
- Is there any negative impact?
- What strategies are effective in engaging a broad range of organisations and encouraging partnerships?

Interventions targeted at children aged 2–5 years

What is the effectiveness of interventions targeted at 2–5-year-olds, and their families/carers, in terms of helping children maintain a healthy weight/preventing overweight or obesity?

What is the effectiveness of interventions targeted at 2–5-year-olds, and their families/carers, in terms of helping children to improve behaviours associated with maintenance of a healthy weight (diet and activity)?

What strategies (identified in 8.1 or 8.2) are most effective in terms of participation and retention and which factors contribute to this success?

Sub-questions:

- Does effectiveness vary by gender, age, ethnicity, religious practices or social group?
- Do recommendations vary whether individuals have previously lost weight?
- Is the source of delivery important?
- Is the mode of delivery important?
- Is there any negative impact?
- What strategies are effective in engaging a broad range of organisations and encouraging partnerships?

Interventions targeted at black and minority ethnic groups, at vulnerable groups and at individuals at vulnerable life-stages

What is the effectiveness of interventions to help vulnerable groups maintain a healthy weight/prevent overweight or obesity?

What is the effectiveness of interventions to help vulnerable groups improve behaviours associated with maintenance of a healthy weight (diet and activity)?

What strategies (identified in 9.1 or 9.2) are most effective in terms of participation and retention and which factors contribute to this success?

Sub-questions:

- Does effectiveness vary by gender, age, ethnicity, religious practices or social group?
- Do recommendations vary whether individuals have previously lost weight?
- Is the source of delivery important?
- Is the mode of delivery important?
- Is there any negative impact?

- What strategies are effective in engaging a broad range of organisations and encouraging partnerships?

Interventions to manage overweight and obesity in non-clinical settings

What is the effectiveness of interventions in non-clinical settings (i.e. community-based and including commercial and self management) to help manage overweight or obesity?

What is the effectiveness of interventions in non-clinical settings (i.e. community-based and including commercial and self management) to help overweight and obese groups improve behaviours (diet and activity) associated with weight loss?

What non-clinical (i.e. community-based) strategies are associated with the maintenance of weight loss and continuation of improved behaviours (diet and activity) among overweight and obese individuals?

Additional questions on exercise referral in children

- What is the effectiveness of exercise referral programmes for children to help manage overweight or obesity?
- What is the effectiveness of exercise referral programmes for children to help increase physical activity to an extent that may aid the management of overweight and obesity?

General sub-questions:

- Does effectiveness vary by gender, age, ethnicity, religious practices or social group?
- Do recommendations vary whether individuals have previously lost weight?
- Is the source of delivery important?
- Is the mode of delivery important?
- Is there any negative impact?
- Does cost have an impact on effectiveness? (e.g. cost of attending slimming group compared with free group)
- What strategies are effective in engaging a broad range of organisations and encouraging partnerships?

Key questions: clinical management

NOTE: not all the ***Key clinical questions (KCQs)*** appear as individual reviews in the full guidance as some were used as background papers for the GuidelineDevelopment Group (GDG) and some were addressed using expert opinion of the GDG and co-optees. These questions are clearly identified in the Notes section of the table.

NEED TO CONSIDER ‘WHAT EFFECT WILL THIS HAVE IN PRACTICE’ – ELABORATE ON CARE PATHWAY
i.e. How will the questions and their answers (therefore recommendations) help the HCP ***(Health care professional***)saying ‘But what should I do?’

Review parameters: public health

Study year and type

- Rapid review to include search for interventions and evaluations and also cohort, qualitative and survey studies for corroborative evidence.

- In line with NICE methodology, if sufficient high quality, up-to-date evidence is found for a specific question, older studies and/or those using weaker designs will not be examined.

- English language papers only will be included.

- Papers not held at the British Library will be excluded.

Evidence of effectiveness

- Weight outcomes – include all RCTs and all controlled clinical (non-randomised) trials (CCTs) from 1990. To ensure that any key data published pre 1990 is not overlooked, an additional search of the Cochrane Trial database 1966–89 to be undertaken and any relevant RCTs included. In addition, where systematic reviews (published 1995 onwards) are identified, any included RCTs published before 1990 to be considered in rapid review. For topic areas with limited or no RCT/CCT evidence we will use the best available evidence.

- Intermediate outcomes (i.e. physical activity and diet) – include systematic review evidence from 1995 plus more recent RCTs and CCTs where available. For topic areas with limited or no systematic reviews, RCT/CCTs we will use the best available evidence.

- Cost outcomes – as intermediate outcomes (NB: this criteria for rapid reviews; additional search on costs likely to be undertaken).

- Changes in knowledge, attitudes and awareness *alone* will not be considered within the main body of reviews but will be considered in a separate ‘mini review’. This restriction is due to time constraints.

Cohort studies
(NB: of particular relevance to review addressing *The Determinants of Weight gain and Weight Maintenance*)

- Prospective cohorts of at least 12 months duration that assessed factors potentially associated with weight gain or weight control in adults and/or children who were not all obese at baseline and reported a weight outcome at baseline and follow-up included.

- There are no structured reporting requirements for observational longitudinal studies. Tooth et al. (2005) have recently developed and tested a checklist.

Corroborative evidence

- Evidence from UK to be included in all reviews. Relevance of evidence from outside UK to considered by question though ability to include constrained by time limitations.

Length of follow-up

- Minimum requirement for studies of effectiveness is at least one data point before and one after the intervention.

- Minimum time period of 3 months between baseline and repeat measures for interventions.

Treatment of systematic reviews

- To avoid ‘double counting’, where more than one systematic review is available to answer a question, the ‘best systematic review’ will be included. The ‘best’ will invariably be the most recent but older reviews will be included if better quality than more recent reviews. The excluded review(s) will be checked to ensure all appropriate studies included.

‘Unpicking’ individual studies within systematic reviews

- The need to ‘unpick’ the ‘best’ available systematic review to its individual study components should be considered on a ‘case-by-case’ basis.

- Where a review is judged to be of high quality and meets the NICE inclusion criteria, there is no need to unpick the review down to the components of individual studies. However, where the reviewers are in some doubt as to the quality of the review, or there are concerns about the lack of intervention detail presented within the review, then the review should be unpicked.

- The outcome measures and follow up time are critical in determining the need to unpick a review (i.e. a review that includes two different studies, one with a 2-week follow-up time and the other with 4-month follow-up should be unpicked).

- The benefits of 'unpicking' a review should be carefully balanced against time constraints.

Combining systematic reviews and individual studies

- Where a systematic review and a more recent individual study are identified, the approach should be to update the review rather than treating the review and study separately. However, how reviews and individual studies are combined should be the judgement of reviewers.

- NICE technical team to advise where there is some doubt as to how specific review(s) and studies should be combined.

Grading systematic reviews

- The grade of review should be based on the study type for which the conclusions are primarily based (i.e. if a review included five RCTs and fifteen CCTs but overall conclusions predominantly based on CCT evidence, then grade should be as a review of CCTs not as a review of RCTs).

Critical appraisal tools

- There is not currently a NICE appraisal tool for non-randomised controlled studies. Agreed that reviewers should use relevant EPOC forms as where NICE tools are not currently available.

Intention to treat

- To use the Cochrane Handbook definition of intention to treat (ITT) (see section 8.4; http://www.cochrane.dk/cochrane/handbook/hbook.htm).
- Contrary to current NICE guidelines, where RCTs do not include ITT the *quality* of the study should be downgraded, not the study type.
- It was agreed that the lack of ITT is a quality issue and not a design issue and that the current NICE methodology handbook is incorrect in implying that RCTs without ITT should be 'downgraded' to non-RCTs.

Review parameters: clinical management

Generic parameters applied for intervention studies are as below.
In summary, reviews included:

- Systematic reviews from 1995 and single studies (predominantly RCTs and non-randomised trials). No time restriction was applied for the Adult reviews, but Child reviews were limited to studies published since 1985.
- Studies which reported outcome measures of weight change (in kg for adults, and using any appropriate measure for children).
- Studies with at least 12-months follow-up for adults, and 6 months for children.

Where specific parameters were applied, the details are reported in the evidence review.

Appendix 3

The effectiveness of public health interventions to identify individuals who would benefit from participation in prevention/public health interventions to manage weight

EVIDENCE TABLE 1: IDENTIFYING ADULTS AND CHILDREN WHO SHOULD PARTICIPATE IN PREVENTION PROGRAMMES BASED ON THEIR RISK FACTORS FOR OBESITY AND READINESS AND OPPORTUNITIES TO CHANGE THEIR BEHAVIOUR

SUMMARY

Evidence for identification of individuals at risk of overweight and obesity:
Eight observational longitudinal studies, one retrospective cohort study and one ongoing prospective study were found providing evidence of interventions or potential interventions to identify those at risk of overweight and obesity. Eight studies examined interventions with children (or studies tracing from childhood to adulthood) and two studies examined interventions with adults. All studies had some confounders. Only one study (Metcalf 2002) was carried out in the UK.

Children
Eight moderate quality studies (Barba 2001; Freedman 2001; Maffeis 2001; Freedman 2002; Guo 2002; He 2002; Metcalf 2002; Toschke 2004) examined interventions to identify children at risk of overweight and obesity.
Two studies (Guo and He) found that growth and probability charts were useful tools to identify those who are at risk of becoming overweight and obese in adulthood. One small UK-based study (Metcalf) determined that accelerometers were a well-tolerated effective way to identify the habitually inactive child (mean age 4.8 years) who may be at risk of future obesity.
Of the four studies measuring anthropometric variables, one (Maffeis) concluded that measurement of waist circumference at 8 years may be a promising index to predict overweight at puberty, and two linked studies (Freedman; Freedman) concluded that a measurement of height could be used to identify more accurately children who are likely to become overweight adults, although this may only be true for those children already overweight. The fourth study (Toschke) concluded that although weight gain from birth to 24 months was the best predictor of overweight at school entry, a positive predictive value of 19% implied that 81% of children with large infant weight gain would receive an unnecessary intervention if action were taken.
A further study (Barba 2001), in which anthropometric variables were measured and lifestyle factors such as diet and physical activity (by self-reported responses to a questionnaire) were examined, concluded that large-scale involvement of primary schools in screening programmes could identify those children at risk of being overweight and obese in adulthood and for whom strategies to prevent overweight and obesity would be most effective.

Adults
Two studies with some confounders (St Jeor 1997; Kroke 2002); examined interventions to identify adults at risk of overweight and obesity. The large ($n = 18001$) study (Kroke 2002) evaluating the influence of recent weight changes on subsequent weight changes concluded that the data indicated a need for a thorough weight history assessment to identify those most likely to gain weight.

The smaller (*n* = 385) study (St Jeor 1997) studied natural weight changes to develop a weight classification system that could identify weight maintainers, gainers and losers. The authors concluded that a criterion of a 5 lb (2.3 kg) weight change to identify departures from weight maintenance should initiate early interventions and weight monitoring as strategies to prevent weight gain.

Cost-effectiveness data

No cost-effectiveness studies were found.

CHILDREN

Toschke 2004	Retrospective cohort study	3	+	German school children participating in the obligatory school entry health examination in 1999–2000. City and rural participants from six different areas in Bavaria, Germany. *n* = 6862 Age range 5.0–6.9 years. Full data available *n* = 4235 children and used for analysis.	**Aim:** To assess the best anthropometric predictor from birth to 2 years for later overweight. Measurements taken from paediatric preventive health care examinations at 6, 12 and 24 months, and at the school entry examination. Weight, kg, length in cm, body mass index (BMI) and ponderal index (kg/m^3) were all calculated and differences between	Retrospective study, but data used from 6 months to between 5.0 and 6.9 years.	Final sample consisted of only those with all measures (4235/6862 [62%]) Weight gain >9764 g from birth to 24 months was the best predictor of overweight at school entry, compared with length gain, BMI gain, or ponderal index gain. Two-year interval better predictor than shorter intervals. The odds ratio for overweight at school entry associated with weight gain greater than 9764 g was 5.7 (95% confidence interval [CI] 4.5, 7.1). This contrasts with a corresponding low positive likelihood ratio of 2.39 (95% CI	Only subjects with all measures included in sample. Bavaria, Germany. Probably generalisable to the UK. Cites Euro-growth study which doesn't find difference in growth patterns among populations of European infants.

				No socio-economic data reported.	measures at the ages above were compared by receiver operating characteristic curves and predictive values. Unclear who delivered although all measures taken at standard 'well-child' check-ups or school entry examination. No power calculation provided. International Obesity Task Force (IOTF) BMI classifications used.		2.20, 2.59) and a positive predictive value of 19% (95% CI 17, 21), suggesting that only one of five children with a large weight gain in the first 2 years is overweight at school entry indicating poor predictability in the general population. The authors concluded that the results imply that 81% of children with large infant weight gain would undergo an unnecessary intervention, with potential adverse effects if intervention was based on large early weight gain.	
Freedman 2002	Observational Longitudinal Study	3	+	Subjects (*n* = 1055 of a possible 4043) from Louisiana, USA. Biracial (one-third black) community of approximately 43,000 residents. Included city and surrounding rural populations. Mean age at baseline	**Aim:** To determine whether childhood height is related to adult adiposity and whether the association is independent of childhood levels of BMI and triceps skinfold thickness. Anthropometric measures (height,	Mean follow-up: 18 years	Only those with both measurements included in analysis (*n* = 1055). Compared with children whose heights were below the gender- and age-specific median, a child with a height-for-age above the 95th percentile was approximately 2.5 times as likely to have a BMI ≥30 kg/m^2 and approximately five times as likely to have a skinfold thickness sum >90th	**Providers of intervention:** Bogalusa Heart Study. Only those with both measurements included in analysis (26.1% or original sample). Only examined 2–8-year-olds. Possibly only children who are already

				7 ± 1years Mean age at follow-up 24 ± 3 years 62% female 33% black From Bogalusa Heart Study – community-based study of cardiovascular disease risk factors among children and young adults.	weight and triceps skinfold thickness) taken at age 2–8 years (1973–82) and re-measured at adulthood, >18 years (1985–96). Longitudinal relations of childhood height to relative weight and skinfold thicknesses in adulthood examined. No power calculation provided. Probably Higher Education researcher delivered, but not stated. BMI-for-age percentiles calculated using a modification of the 'LMS technique'.		percentile in adulthood. Although height and adiposity among childhood were associated (*r* = 0.29) among children, the observed longitudinal relations persisted after controlling for BMI and the triceps skinfold thickness in childhood. Height in children ≥9 years was not related to adult adiposity. The authors concluded that it is possible that information on height could be used to identify more accurately children who are likely to be obese in later life. It is possible that tall, overweight children could be targeted with specific interventions aimed at preventing the development of adult obesity. Examines differences in height with the same BMI. Second checker.	overweight. Louisiana, USA – probably generalisable to the UK.
Guo 2002	Observational longitudinal study	3	+	Cohort of 166 males and 181 females* from the Fels longitudinal study, Ohio, USA 100% white	Study of the new Centers for Disease Studies (CDC) BMI charts and definitions of adult overweight and obesity to predict adult overweight and	On-going longitudinal study. Data used from birth to 35 years	The sensitivity and specificity of the chosen cut-off (50th percentile for overweight and 72nd percentile for obesity) were excellent for predicting overweight and obesity at 35 years of age from BMI values at 18 years of	Part of the (US) Fels Longitudinal study. US White subjects only for this study but the CDC charts were developed from data on

				Data collected from birth onwards. Many participants were from families where all members were enrolled in the study. No socio-economic data reported. Part of long-term large longitudinal study (Fels longitudinal study) (1929 – still ongoing. Serial multidisciplinary study, longest running in the World. Now part of Lifespan Health Research Center at Wright State University, Dayton, OH, USA.)	obesity. Update of previous report (1994) on use of CDC BMI-for-age growth charts to identify those who are likely to be overweight at 35 years. Logistic models were fitted to relate adult overweight and obesity to childhood and adolescent BMI values at each age (collected at 3-month intervals for the first year, 6-month intervals thereafter to age 18 years and every 2 years thereafter) No power calculation given. Probably Higher Education researcher delivered but not stated. BMI for overweight and obesity follow		age. The sensitivity and specificity at 3, 8 and 13 years of age were lower than those at 18 years of age for the chosen cut-off, and they were lower in the males than in the females. The authors concluded that this cut-off could facilitate public health screening programmes by detecting children and adolescents with a high probability of being overweight or obese at 35 years of age.	white and black children and adolescents at all ages, plus Mexican American from age 2 to 6 years. Sampling strategy unclear. US – probably generalisable to UK *'because of missed measurement at various ages, data are missing for some participants at some ages; thus at any age or for any age group, the number of participants varies and therefore differs slightly from the total number of participants.'

					definitions of WHO, National Heart, Lung and Blood Institute, the National institutes of Health and the US Department of Health and Human Services.			
He 2002	Longitudinal Growth Study	3	+	Healthy grade school children born in Gothenburg and surrounding areas in Sweden. *n* = 3650 Sample size for each gender varied between 582 and 1857 for various ages; at 18 years: Males *n* = 1849 Females *n* = 1801 No socio-economic data reported.	**Aim:** to develop a probability chart of adult overweight based on childhood BMI values and to evaluate BMI change during the BMI rebound period during childhood in different populations with the use of risk function curves. Weight and height values obtained from birth to 18 years. No power calculation provided. Delivered by four trained Higher Education investigators and two school nurses. IOTF BMI	Approx. 18 years Data were collected between April and November 1992 (97% of children born between 1973 and 1975).	A probability chart for reaching a BMI >23 kg/m^2 at 18 years was constructed for boys and girls. For example, a BMI of 18 kg/m^2 at 4 years of age is associated with a 0.70 probability of attaining a BMI >23 kg/m^2 at 18 years in boys: a BMI of 16 kg/m^2 at 4 years of age leads to a 0.40 probability of having a BMI >23 kg/m^2 at 18 years in girls. Children with an obvious BMI rebound before 8 years of age have a high risk of being overweight at 18 years of age. The authors concluded that probability charts for adult overweight developed in this study will provide a useful tool for paediatricians to identify those children who are at a high risk of becoming overweight in adulthood so that clinical intervention can be started as	Data were collected retrospectively from birth register and doctors and nurses notes. Some subjects excluded due to lack of presence of all measurements. Sampling strategy unclear (although exclusion criteria are stated, the number of children who did not meet the exclusion criteria and for each specified criterion is not confirmed). Sweden – probably generalisable to the UK.

					classifications used.		early as possible.	
Metcalf 2002	Observational longitudinal Study	3	+	Healthy children recruited at school entry from a random, stratified sample of schools in Plymouth, UK *n* = 100 Mean age 4.8 years. ‘Schools representing all socioeconomic groups.’ Part of ‘EarlyBird’ prospective cohort study monitoring effects of lifestyle on the metabolic status of healthy children.	Aim: To establish the range of physical activity (PA) undertaken by contemporary children; and to assess the feasibility of using activity monitors to screen for the habitually inactive child. Each child fitted with a CSA (computer science and applications) activity monitor to be worn, on the hip, during waking hours for 7 consecutive days (5 school days and both weekend days). This monitor is both lightweight and tamperproof. Records time and sums changes in acceleration for each 1 min interval, from which are displayed the timing, intensity, and duration of the child’s PA. Data	Not known – only baseline data available	82/100 children (37 boys and 45 girls) provided data for at least 4 weekdays and both weekend days and were included in the analysis. The authors concluded that accelerometers singled out habitually inactive children, most of them girls, who did little, whether at school or over the weekend. Accelerometers are of potential value in identifying, from an early age, children at risk of becoming obese. Accelerometer is well tolerated and generates quality data from >80% of children. Fourteen of the 16 children recording the lowest quintile of weekend activity were girls. Children who were inactive during the week were also inactive at the weekend. The authors also concluded that the activity monitor could prove an important tool for ‘assessment’ if schools are to take back responsibility for physical as well as academic education.	Providers of intervention: EarlyBird Research Centre (supported by a grant from the NHS Executive SW and by Roche Pharmaceuticals, the Henry Smith Foundation, the Child Growth Foundation, Eli Lilly, the London Law Trust and the EarlyBird Diabetes Trust). Analysis did not include all of starting sample. No confounders discussed.

					downloaded to PC and analysed according to week/weekend day and gender. No power calculation provided. Higher Education Researcher and research nurse delivered. Test–retest correlation (for CSA monitor output) over 12 months of *r* = 0.47 (<0.001)			
Barba 2001	Ongoing prospective study	3	+	All children of the II Circolo Didattico Primary School in Avellino, Italy were invited to participate; 509 (66.4%) accepted. Data here are from a preliminary analysis of 363 subjects for whom computerised data was available. Age: Males 8.7	Aim: to evaluate dietary habits and anthropometric factors in a sample of school children aged 6–12 years living in Southern Italy in the framework of an ongoing prospective study aimed and childhood obesity prevention. BRAVO project – part of an education programme on	N/a	Data from baseline: *n* = 363 (62% of eligible sample of this age group). The authors propose a strategy of evaluating dietary habits and anthropometric factors aiming at the identification of children in whom preventive strategies would be more effective. Data were pooled for boys and girls. For any age class, a considerable large proportion of children, almost 50%, had BMI above the age-specific centile	Part of a larger research project that includes an educational programme on nutrition for the teachers. Analysis does not take into account all of eligible sample. May be largely focussed on identification of childhood obesity as a risk factor for adulthood obesity.

				± 1.4 years; Females 8.86 ± 1.3 years Male *n* = 181 Female *n* = 182 No socio-economic data provided.	nutrition for the schoolchildren and their families. All participants underwent brief medical examination during which detailed anthropometry (including height and weight) were measured. Used standard balance beam with attached ruler. Children were examined by a trained dietitian under the supervision of a physician, within the school premises. A detailed questionnaire on medical history, lifestyle and dietary habits was filled in at home by the parents and checked during the visit. Prevalence of obesity was estimated according to the		that predicts the risk of being overweight in adult life. Among those at risk, many children – ranging from 20 to 30% across age-classes – were above the percentile curve that predicts the risk of overt obesity in adult life. Only half the sample (52.9%) regularly practised PA (as assessed by a questionnaire response), which was more common among girls in comparison to boys (56 vs. 44%, chi-square = 5.614, $p < 0.05$). Fruit intake appeared to be poor (10–20% ate fruit every day) whilst daily consumption of high-energy snacks was rather common among children (45%). The authors concluded that their data, though preliminary, suggest that the large-scale involvement of primary schools in screening programmes could represent an effective preventive strategy against the increased risk of childhood obesity. The study focused on the risk of children being overweight or obese in adult life, thus aiming at the identification of children in whom preventive strategies, involving	Southern Italy – probably generalisable to the UK. Screening in primary schools to identify those at risk of overweight and obesity.

					standard definition adopted by the IOTF. No power calculation provided.		targeted changes in dietary habits and lifestyle, would be more effective.	
Freedman 2001	Observational longitudinal study	3	+	Subjects (*n* = 105, of a possible 272) from Louisiana, USA. Biracial (one-third black) community of approximately 43,000 residents. Included city and surrounding rural populations. Age = 5 years in 1973 (beginning of study). From Bogalusa Heart Study – community-based study of cardiovascular disease risk factors among children and young adults. Sample demographics and socio-economic data not reported.	**Aim:** To examine whether the relation of adiposity rebound increases the risk for overweight in adulthood and whether this relation is independent of childhood BMI levels. Seven cross-sectional studies of children conducted during school years between 1973 and 1991. Total number of children studied in this analysis *n* = 105 comprising 5-year-olds who were examined in 1973, and were eligible for re-examination in 1974, 1975, 1976 and in 1987–91 (as 19–23-year-olds). Subjects had been examined at age 5 years, re-examined	14–18-year follow-up	105/272 subjects included in analysis (only those with sufficient data). Subjects who experienced rebound (age at which minimum BMI occurred – 'age_{min}") at ≤5 years were, on average, 4–5 kg/m^2 heavier in early adulthood than were subjects whose age_{min} was >7 years. Age_{min}, however, was also correlated with childhood BMI levels (r ~ –0.5), and age_{min} provided no additional information on adult overweight if the BMI level at age 7 years (or 8 years) was known. In contrast, childhood height, which was also correlated with age_{min} (r = –0.47), was independently related to adult BMI. Among relatively heavy (BMI = 16.0 kg/m^2) 5-year-olds, a child with a height of 120 cm was estimated to be 1.2 kg/m^2 heavier in adulthood than would a 104-cm tall child. **Conclusion:** Although an early BMI rebound was related to higher levels of	Small study sample (*n* = 105). Total sample and sampling frame have not been reported (although it is likely that this data has been reported in an earlier and/or companion study). USA – probably generalisable to the UK. The importance of childhood height needs to be examined in other longitudinal studies and research is needed to determine the possible mechanisms.

					at ages 19–23 years and had at least two (of three possible) measurements at ages 6, 7 and 8 years. No power calculation provided. Probably higher education researcher delivered, but not stated. No validation of measures discussed.		relative weight in adulthood, this association was not independent of childhood BMI levels. The relation of childhood height to adult BMI needs to be confirmed in other cohorts, but it is possible that childhood height may help identify children who are likely to become overweight adults. It is possible that childhood height could provide a simple tool in more accurately predicting which children are likely to become overweight adults.	
Maffeis 2001	Observational longitudinal study	3	+	Healthy pre-pubertal children recruited through questionnaires distributed to teachers at public and private primary schools in Italy. *n* = 112 Age = 8.7 ± 0.9 years Female = 58 Male = 54 100% White Response rate not stated.	**Aim:** To identify in a group of 8-year-old prepubertal children the anthropometric parameter with the highest prediction power of overweight, measured 4 years later. Four-year study with baseline and 4 year measurement of weight and body composition Measurements of	Baseline and 4 years	100% provided data at follow up. RelBMI (relative body mass index; %) at baseline showed significant correlation with waist circumference ($r = 0.89$; $p < 0.001$). Partial correlation analysis showed waist circumference had significant independent association with relBMI at follow-up, when basal BMI controlled for ($r = 0.23$, $p < 0.02$). Waist circumference measured at age 8 years is the best predictor of overweight (relBMI) at age 12 ($r^2 = 0.64$; $p < 0.001$). Each	All White children. No full description of recruitment. Parental BMI self-reported One of the funders Nestle Italiana Spa. Italy – probably generalisable to UK

					weight, height, skinfold thicknesses and waist circumference taken (on standardised equipment) at baseline and follow up at the hospital, and self-reported weight and height of the parents taken at baseline. No power calculation provided. Delivered by paediatricians in project laboratory at hospital.		centimetre increase of waist circumference at age 8 years doubles risk of having relBMI >120% at age 12 years. The authors concluded that the results of this study showed that waist circumference measured at the age of 8 years, which is simple to perform and easy to reproduce, may be a promising index to assess adiposity as well as to predict overweight at puberty.	

ADULTS

Kroke 2002	Observational longitudinal study	3	+	General population (those in the EPIC-Potsdam study, Germany), *n* = 18001 Males *n* = 6689; mean age 52 (range 24–69) years. Females *n* = 11312; mean age 49 (range 19–70) years Women: 57.36% with college or university degree. Men: 68.56% with college or university degree Sample selected from *n* = 27,548 in EPIC Potsdam study, after excluding those who did not respond to follow-up in 2000, those who smoked, those	**Aim:** To evaluate the influence of recent weight changes (weight gain, loss and cycling) on subsequent weight changes. Baseline information on lifestyle and health-related variables obtained from interviews. Baseline anthropometric measurements of body height and weight. Subjects questioned as to whether or not weight loss/gain was intended, to distinguish weight cyclers. Follow-up – self-assessment questionnaires for assessment of body weight and incident diseases. No power calculation provided.	2 years	Polytomous logistic regression (using stable weight group as the reference category and adjusting for potential confounders) demonstrated that weight cycling before baseline was strongest predictor of subsequent large weight gain (≥2 kg) with odds ratio (OR) 4.84 (95% confidence interval (CI) 3.34–7.02) in men. In women, prior weight loss was strongest predictor of subsequent large weight gain (OR 4.77; 95% CI 3.63–6.03) followed by weight cycling (OR 3.02; 95% CI 2.15–4.25). The authors concluded that these data indicate the need for thorough weight history assessment to identify those who are most likely to gain weight.	The subjects' weight-change variable derived from the difference between measured weight at baseline and self-reported weight at follow-up. This was otherwise a high quality study. Some subjects excluded from analyses due to lack of data. Germany – probably generalisable to the UK.

				with illness and pregnant women, and those with missing data. Providers of intervention: EPIC Potsdam Study.	Measurements taken by ‘trained personnel’, possibly Higher Education researchers. No validation of measure discussed.			
St Jeor 1997	Observational longitudinal study	3	+	USA, healthy subjects, including normal and overweight men and women. *n* = 508, mean age 44.1 ± 14.1 years. Of 385 included in analyses, 180 women (92 normal weight, 88 obese) and 205 men (105 normal weight, 100 obese). No socio-economic data reported.	**Aim:** To study natural weight changes and to develop a weight classification system that can identify weight maintainers, gainers and losers. Series of body composition measurements (done ‘according to established protocol’) taken annually in a clinic. Measures analysed to determine maintainers, losers and gainers (defined by changes in weight of ± 5 lbs [2.3 kg]) during the 5 years. No power calculation	5 years (1985–90).	Recruitment and response rate: 385/508 = 76% 46% maintainers, 34% gainers, 20% losers over total 4-year interval. Subjects more likely to become gainers over successively longer time periods ($p < 0.05$) for 4 years against 1 or 2. Only 22% were gainers in any given 1-year period. The authors concluded that weight changes of greater than ± 5 lb (2.3 kg) can classify a person as a weight maintainer, gainer or loser. Although annual weight changes were used in this study, a weight change of more than 5lb (2.3 kg) between any two points in time may suggest non-maintenance of weight or weight instability that needs further evaluation. The criterion of a 5 lb (2.3 kg)	Relationships of Energy, Nutrition, and Obesity to Cardiovascular Disease Study. Motivated, generally healthy population. Biased towards working men and women. Selection of ± 5 lb (2.3 kg) choice slightly arbitrary. Analysis did not include non-completers. USA – probably generalisable to UK.

					provided. Probably Higher Education researcher delivered, but not stated.		weight change to define departures from weight maintenance at any point should initiate early interventions and weight monitoring as strategies to prevent weight gain.

EVIDENCE TABLE 2: EXISTING UK AND NON-UK GUIDELINES/RECOMMENDATIONS IN RELATION TO IDENTIFYING INDIVIDUALS WHO WOULD BENEFIT FROM PARTICIPATION IN PREVENTION/PUBLIC HEALTH INTERVENTIONS TO MANAGE WEIGHT

SUMMARY

For the purposes of this review a clinical or practice guideline was defined as a document that aimed to identify, summarise and evaluate the best evidence and/or most current data about the prevention, management and/or identification of overweight or obesity or the prospective risk of developing overweight or obesity. Clinical guidelines were based on or likely to be based on a systematic review of the current research evidence.

Public/policy statements and recommendations were defined as documents that aimed to provide advice on or recommendations for the prevention, management and/or identification of overweight or obesity or the prospective risk of developing overweight or obesity. Public/policy statements and recommendations are likely to have been developed based on consensus agreement by an expert panel.

Guidance from UK guidelines/recommendations

No usable UK guidelines were identified.[4]

Evidence from four UK recommendations, all for children only, suggests that there is currently no consensus available for the screening of children for unhealthy weight gain. One policy statement (UK National Screening Committee, 2005), based on expert consensus opinion, recommended that screening should not be offered while the evidence from a briefing paper prepared by the Child Growth Foundation (2004) firmly recommended universal serial BMI monitoring for children at least until the end of primary school. One further report (House of Commons Select Committee on Health, 2004), supported the guidance suggested by the Child Growth Foundation and suggested that BMI measures should be recorded annually for school-aged children. Evidence underpinning the identified recommendations is not available or is of lower-level quality. Recently published guidance for Primary Care Trusts (Department of Health 2006 [4663]) recommends measurement of BMI in reception and year 6 children on an annual basis for the purpose of population monitoring. The guidance discourages giving out BMI to children or parents.

Quality assessment of UK guidance

According to the AGREE instrument for the appraisal of guidelines (see paper 9.3a, section 3.3.2) only three publications would be recommended (Child Growth Foundation 2004; UK National Screening Committee 2005; Department of Health 2006), two with provisos (UK National Screening Committee; Department of Health).

Guidance from non-UK guidelines/recommendations
Of the 11 identified guidance documents, overall evidence from nine non-UK recommendations suggests that periodic monitoring of weight status and BMI and waist circumference measurements should be routinely provided. One US-based practice guideline (US Preventive Services Task Force 2003) did not support screening for asymptomatic adults and one recommendation statement from Canada (Douketis 1999) concluded that there was insufficient evidence to recommend for or against BMI measurement in the periodic health examination of the general public.

Clinical practice guidelines
Five clinical practice, evidence-based guidelines were identified, of which four recommended recurrent screening for weight gain. Three of these were from the USA, one from Canada and one from Australia. Of the US-based recommendations, one (Institute for Clinical Systems Improvement 2004) recommended that height, weight and BMI measurements be taken annually for mature adolescents and adults, one (Expert Panel on the Identification, Evaluation and Treatment of Overweight in Adults, 1998) recommended that adults who are not overweight or who have no history of overweight should be screened for weight, BMI and weight circumference every 2 years, and one (US Preventive Services Task Force 2003) firmly recommended against screening for obesity for asymptomatic adults. The Canadian guideline (Registered Nurses' Association of Ontario 2005), based on expert opinion, advocated the inclusion of monitoring and surveillance data on nutrition, PA and measures of adiposity for children in public health policies. The Australian guideline (National Health & Medical Research Council 2003) recommended recurrent measurement of height and weight in a nationally representative sample of children and adolescents. Supporting evidence for clinical practice guidelines was obtained from controlled comparative studies, observational data and expert judgement from clinical experience.

Recommendation statements
Two recommendation statements, one US-based and one from Canada, proposed conflicting advice. The Canadian evidence-based statement (Douketis 1999) concluded that there was insufficient evidence to recommend for or against BMI measurement in the periodic health examination of the general public, while the US-based statement (Holcomb 2004), proposed an algorithm to determine a child's BMI at health visits. It recommended that good nutrition and exercise should be encouraged at health visits if a child's BMI <75th percentile and weight management advice should be provided if a child's BMI measurement is <85th percentile but >75th. No supporting evidence for the US statement is available and the frequency for health visits is not indicated.

Policy statements

---

[4] The results from the only UK clinical practice guideline for adults (Scottish Intercollegiate Guidelines Network 1996 [26]) cannot be included in the guidance summary. Robin Harbour, Quality & Information Director SIGN, confirmed that the link to the evidence in this guideline is not available and that it is currently under review to be updated or withdrawn (by telephone 9 August 2005). SIGN have advised us not to use it. SIGN Guidance for Children (2003 [25]) considered, but excluded it as it discusses identification of overweight and obesity only.

Three policy statements all supported serial assessments for weight monitoring. Two US-based statements recommended recurrent measurement of BMI, one of which (Krebs, 2003) recommended annual routine assessments to calculate and plot BMI measurements for children and the assessment of eating and activity patterns for excessive weight gain relative to linear growth. The other US-based statement (Nawaz, 2001) recommended periodic BMI measurement for all adults, independent of weight or BMI, along with consistent counselling about healthful dietary and PA patterns from primary care practitioners. There are no apparent links to supporting evidence for either of these statements. One evidence-based collaborative policy statement from Canada (Dietitians of Canada, Canadian Paediatric Society, The College of Family Physicians of Canada, Community Health Nurses Association of Canada, 2004) suggested that repeated height and weight measurements be part of scheduled well-baby and well-child health visits and that health maintenance visits for children be organised according to a child's immunisation schedule. Continued growth monitoring on an annual basis at primary care visits for older children and adolescents was also recommended. These recommendations were based on expert opinion only. BMI-for-age screening from age 2 years onwards to track and predict future risk of being overweight was also advised.

Taskforce report
One taskforce report from Australia (National Obesity Taskforce Secretariat 2003) recommended, as part of its national action agenda, regular tracking of height and weight status in the community as well as monitoring of knowledge, attitudes, intentions, behaviours and other indicators of healthy eating and active living. The recommendation from this report is not evidence-based.

Quality assessment of non-UK guidance
According to the AGREE appraisal criteria all five clinical practice guidelines would be strongly recommended. One guideline counsels against screening for adults (US Preventive Services Task Force 2003). The remaining four guidelines recommend screening for children (Registered Nurses' Association of Ontario 2005), children and adolescents (National Health & Medical Research Council, Australia, 2003), mature adolescents and adults (Institute for Clinical Systems Improvement, ICSI, USA, 2004) and adults (Expert Panel on the Identification, Evaluation and Treatment of Overweight in Adults, USA, 1998).

The five recommendation and policy statements are broadly recommended with provisos although one (Holcomb, 2004) is an identification algorithm only for children and adolescents and would not be recommended as a guideline. One recommendation document concludes that there is insufficient evidence for screening of adults (Douketis, 1999). The remainder recommend screening for children and adolescents (Holcomb, 2004), screening for adults (Nawaz, 2001), or monitoring for children (Krebs 2003; Dieticians of Canada,2004).

The taskforce report (National Obesity Taskforce Secretariat 2003) advises monitoring for children and their families but would not be recommended for use according to the AGREE criteria.

Cost-effectiveness data
No cost-effectiveness data were found.

EVIDENCE TABLE 2

UK GUIDELINES/RECOMMENDATIONS

First author	Guideline design/AGREE grading	Country of origin	Guideline topic Screening or monitoring Adults and/or children	Guidance/recommendation	Comments
Department of Health 2006 [4663]	Guideline. Recommend with provisos. Scope and purpose 100% Stakeholder involvement 63% **Rigour of development 36%** Clarity and presentation 75% Applicability 75% Editorial independence 63%	UK	Monitoring. Children.	The guidance recommends measurement of BMI in reception and year 6 children on an annual basis for the purpose of population monitoring. The guidance discourages giving out BMI to children or parents.	

UK National Screening Committee 2005	Policy statement **Recommend with provisos – policy statement, not guidelines** Scope and purpose 100% Stakeholder involvement 56% **Rigour of development 33%** Clarity and presentation 81% Applicability 50% Editorial independence 25%	All UK.	Screening Children	Screening should not be offered [to children].[1]	The NSC received the report of a consensus conference held at Coventry on 29 July 2000 and agreed that there is not enough evidence, at this time, to recommend screening for obesity. [1] Child Growth Foundation Seminar on the Epidemic of Obesity in Childhood – RCP London, 29–30 July 2000. The original conference consensus report states three main reasons for rejecting screening (see Appendix C – supporting information).
House of Commons Select Committee on Health 2004	Report **Would not recommend** Scope and purpose 50% Stakeholder involvement 25% **Rigour of**	All UK.	Monitoring. Population-wide (recommendation refers to children).	Throughout their time at school, children should have their BMI measured annually at school, perhaps by the school nurse, a health visitor or other appropriate health professional. Where appropriate, BMI measurement could be carried out alongside other health care interventions that are delivered at school, for example inoculation programmes.	Paragraph 369. No apparent link to evidence.

	development 25% Clarity and presentation 50% Applicability 25% Editorial independence 25%				
Child Growth Foundation, 2004	Briefing paper **Recommend** Scope and purpose 100% Stakeholder involvement 58% **Rigour of development 72%** Clarity & presentation 100% Applicability 100% Editorial independence 25%	All UK.	Monitoring. Children.	Universal serial BMI assessments must be recommended. Although those children at most risk of becoming obese can easily be targeted, only universal assessment will pick up the child who is in a healthy BMI range today but has been/may still be insidiously putting on weight and be obese 'tomorrow'. Monitoring should be implemented at a frequency* reasonably to allow a trend of significant unhealthy weight gain to be identified from birth and at any age thereafter. BMI monitoring should be the standard measure.[1] *A protocol outlining frequency is included in this briefing paper and recommends monitoring yearly through primary school (up to year 6)	Briefing paper prepared by pressure group [Guideline Development Group advice] for the clinical Guideline Development Group. [1] Hall D, Elliman D. *Health for All Children*. 4th Edn. Oxford: Oxford University Press, 2003.

NON-UK GUIDELINES/RECOMMENDATIONS

First author	Guideline design/AGREE grading	Country of origin	Guideline topic Screening or monitoring Adults and/or children	Guidance/recommendation	Comments

Registered Nurses' Association of Ontario 2005	Clinical practice guideline **Strongly recommend** Scope and purpose 75% Stakeholder involvement 69% **Rigour of development 96%** Clarity and presentation 100% Applicability 75% Editorial independence 100%	Canada	Screening and advice. Children.	Nurses advocate for healthy public policies that include monitoring and surveillance data at the population level regarding nutrition, PA and measures of adiposity including obesity and overweight status.[1]	Level of evidence IV. [1]Raine KD. *Overweight and obesity in Canada: a population health perspective*. Ottawa: Canadian Institute for Health Information, 2004.
Institute for Clinical Systems Improvement 2004	Clinical practice guideline **Strongly recommend** Scope and purpose 75% Stakeholder involvement 63% **Rigour of**	USA	Screening and advice. Mature adolescents and adults.	Measure height, weight and calculate BMI preferably annually for screening and as needed for management. A BMI calculation is worthwhile in the growing patient because it provides a reference point for future comparison. Subsequent observations establish a relative trajectory for this index of obesity.[1]	Supporting evidence is of classes D (cross-sectional study, case series, case report), R (consensus statement, consensus report, narrative review). [1]Barlow SE, Dietz WH. Obesity evaluation and treatment: expert committee recommendations. *Pediatrics* 1998;102:E29. (Class R).

	development 50% Clarity and presentation 100% Applicability 50% Editorial independence 100%				Algorithm 1 is currently being updated. It is anticipated that revisions will be completed by the end of September 2005. The Insitute for Clinical Systems Improvement (ICSI) will forward updated revisions as soon as they are available.
US Preventive Services Task Force 2003 US Preventive Services Task Force 2003	Clinical practice guideline **Strongly recommend** Scope and purpose 58% Stakeholder involvement 50% **Rigour of development 68%** Clarity and presentation 81% Applicability 50% Editorial independence 63%	USA	Screening and advice. Adults.	The USPSTF recommends against routinely providing [the service] (screening for obesity in adults) to asymptomatic patients. *The USPTF found at least fair evidence*[1] *that [the service] is ineffective or that harms outweigh benefits.*	[1]Fair evidence is sufficient to determine the effects on health outcomes, but the strength of the evidence is limited by the number, quality, or consistency of the individual studies; generalisability to routine practice; or indirect nature of the evidence on health outcomes. No apparent link to evidence.
Expert Panel on the Identification,	Clinical practice guideline	USA	Screening and advice. Adults.	Patients should receive periodic monitoring of their weight, BMI* and waist circumference. Patients who are not overweight or have no	*Only apparent evidence available is that linked to the recommendation for the

Evaluation and Treatment of Overweight in Adults 1998 National Institutes of Health 2000	***Strongly recommend*** Scope and purpose 83% Stakeholder involvement 44% **Rigour of development 79%** Clarity and presentation 81% Applicability 58% Editorial independence 63%			history of overweight should be screened for weight gain every 2 years. While this time span is not evidence-based, it is believed to be a reasonable compromise between the need to identify weight gain at an early stage and the need to limit the time, effort and cost of repeated measurements. *Practitioners should use the BMI to assess overweight and obesity.	measurement of BMI to assess overweight and obesity in the clinical setting. Evidence category C (evidence is from outcomes of uncontrolled or nonrandomised trials or from observational studies). Epidemiological and observational studies have shown that BMI provides an acceptable approximation of total body fat for the majority of patients. Because there are no published studies that compare the effectiveness of different measures for evaluating changes in body fat during weight reduction, the panel bases its recommendation on expert judgment from clinical experience. No apparent link to evidence.
National Health & Medical Research Council 2003	Clinical practice guideline **Strongly recommend** Scope and purpose 67%	Australia	Screening and advice. Children and adolescents.	The prevalence of overweight and obesity in children and adolescents in Australia is high enough to warrant both intervention and preventive action. Height and weight should be measured recurrently in a nationally representative sample of children and adolescents.	Evidence level III-2 evidence obtained from comparative studies with concurrent controls and allocation not randomised (cohort studies), case–control studies, or interrupted time series with a control group.

	Stakeholder involvement 50% **Rigour of development 82%** Clarity and presentation 75% Applicability 50% Editorial independence 100%				No apparent link to evidence.
Douketis 1999	Recommendation **Recommend with provisos** Scope and purpose 67% Stakeholder involvement 44% **Rigour of development 64%** Clarity and presentation 69% Applicability 50% Editorial independence	Canada	Screening and advice. Adults.	Because of lack of evidence supporting long-term effectiveness of weight-reduction interventions, there is insufficient evidence to recommend for or against BMI measurement in the periodic health examination of the general population (C).*	*C Grade There is poor evidence relating to the inclusion or exclusion of a condition or manoeuvre in a periodic health examination, but recommendations can be made on other grounds. (See Appendix C – supporting information for evidence.)

	100%				
Holcomb 2004	Proposal for recommendations **Would not recommend as guideline – Algorithm for identification only** Scope and purpose 58% Stakeholder involvement 25% **Rigour of development 25%** Clarity and presentation 63% Applicability 50% Editorial independence 25%	USA	Algorithm for screening and identification. Children and adolescents.	Proposed identification and management algorithm for overweight and obese children. Determine child's BMI at each visit. If BMI is <75th percentile, continue to encourage good nutrition and exercise to parents and child. If BMI is <85th percentile but >75th percentile, instruct parents and child regarding weight management, diet, and exercise. Advise on limiting television to no more than 2 hours/day. Reassess the child annually.*	*No direct evidence linked to proposed algorithm. Supporting evidence may be Best Practice Group. *Best Practices in the Diagnosis and Treatment of Childhood Obesity*. Kansas: Metropolitan Health Council, 2003. Centers for Disease Control. BMI for Children and Teens. http://www.cdc.gov/nccdphp/dnpa/bmi/bmi-for-age.htm
Krebs 2003	Policy statement **Recommend with provisos – as position statement only** Scope and purpose 50%	USA	Monitoring Children	Calculate and plot BMI once per year in all children and adolescents. Use change in BMI to identify rate of excessive weight gain relative to linear growth. Routine assessments of eating and activity patterns in children and recognition of excessive weight gain relative to linear growth are	*Miller LA, Grunwald G, Johnson SL, Krebs NF. Disease severity at time of referral for pediatric failure to thrive and obesity: time for a paradigm shift? *Journal of Pediatrics* 2002;141:121–124.

	Stakeholder involvement 44% **Rigour of development 32%** Clarity and presentation 63% Applicability 67% Editorial independence 25%			essential throughout childhood. The CDC and Prevention percentile grids for BMI are important tools for anticipatory guidance and discussion of longitudinal tracking of a child's BMI.*	
Nawaz 2001]	Policy statement ***Recommend with provisos*** Scope and purpose 50% Stakeholder involvement 25% **Rigour of development 36%** Clarity and presentation 63% Applicability 50% Editorial independence 25%	USA	Screening and advice. Adults	Independent of weight or BMI, all adult patients should consistently receive counselling about healthful dietary and PA patterns in the context of primary care. Periodic measurement of BMI is recommended for all adults. Although an emphasis on health-promoting behaviours may be preferred to an emphasis on weight per se, weight monitoring is considered useful to both clinician and patient in gauging the adequacy of behavioural interventions.	No apparent link to evidence.

Dietitians of Canada, Canadian Paediatric Society, The College of Family Physicians of Canada, Community Health Nurses Association of Canada 2004	Collaborative policy statement **Recommend with provisos** Scope and purpose 67% Stakeholder involvement 50% **Rigour of development 50%** Clarity and presentation 63% Applicability 50% Editorial independence 100%	Canada	Monitoring. Assessment and monitoring growth (growth charts). Infants and children.	Serial measurements of recumbent length (birth to ages two or three) or height (age ≥2 years), weight and head circumference (birth to age 2 years) should be part of scheduled well-baby and well-child health visits in order to identify infants and children with disturbances in rates of weight gain or physical growth. Although the ideal number of health maintenance visits for children has not been established, current recommendations are that they be organised according to the immunization schedule with additional visits within the first month and also at 4, 6, 9, 12, 18, 24 months and 4–6 years. The frequency for monitoring older children and adolescents is unknown; however, it seems reasonable to continue monitoring growth on an annual basis at primary care visits for the early identification and referral of a child whose growth appears abnormal. To yield accurate measurements, weights and measures should be obtained using calibrated, well-maintained quality equipment and standardised measurement techniques. An individual child's measurements should be recorded in the data table of a consistent growth chart appropriate for age and gender, and then plotted to identify any disturbances in height or weight gain. BMI-for-age is recommended to screen children from age 2 years onwards to identify those who may be at risk for conditions and illnesses related to excess body fat. BMI-for-age provides a reference of overweight for older children and	I recommendation (i.e. based on 'expert opinion' as there is insufficient evidence in quantity or quality to make a recommendation; however, other factors may influence decision-making). (Canadian Task Force on the Periodic Health Examination. *The Canadian Guide to Clinical Preventive Health Care*. Ottawa: Supply and Services Canada, 1994; Saunders NR, Shouldice M. Health maintenance visits: a critical review. In: Feldman W, ed. *Evidence-based Pediatrics. Hamilton*: B.C. Decker Inc., 2000). B recommendation, (i.e. there is fair evidence to recommend this action). (World Health Organization. Physical status: the use and interpretation of anthropometry. Report of a WHO Expert Committee. *World Health Organization Technical Report Series* 1995; 834; Henry JJ. Routine growth monitoring and assessment of growth disorders. *Journal of Pediatric Health Care*

				adolescents that was previously not available. It is consistent with adult BMI, so it can be used continuously from age 2 years to adulthood and can therefore track body size throughout the lifecycle. In addition, BMI-for-age is also a predictor of health risks and future risk of being overweight. A Canadian Pediatric Nutrition Surveillance System should be developed for organised and ongoing collection of anthropometric measurements to follow growth and nutritional status of Canadian children and describe trends in key indicators of their nutritional status.	1992;6(5 Pt 2):291–301; US Department of Health and Human Services, Maternal and Child Health Bureau. Using the CDC growth charts: accurately weighing and measuring: equipment http://depts.washington.edu/ growth [accessed November 2003]). B recommendation, (i.e. there is fair evidence to recommend this action) (Whitaker RC, Wright JA, Pepe MS, Seider KD, Dietz WH. Predicting obesity in young adulthood from childhood and parental obesity. *New England Journal of Medicine* 1997;337(13):869–873). This recommendation is not graded.
National Obesity Taskforce Secretariat 2003	Report **Would not recommend** Scope and purpose 67% Stakeholder involvement 44%	Australia	Monitoring. Adults and children (families).	The NOTS national action agenda recommends improved regular tracking of height and weight status in the community as well as monitoring of knowledge, attitudes, intentions, behaviours and other indicators relating to healthy eating and active living; scope and develop specifications for national nutrition and PA monitoring and surveillance systems; design a comprehensive, regular, coordinated monitoring system for height and weight status (particularly of young	No supporting evidence available.

	Rigour of development 25% Clarity and presentation 50% Applicability 33% Editorial independence 63%			people) and a series of validated indicators of key behaviours and environments related to healthy eating and active living.

The determinants of weight gain and weight maintenance (‘energy balance’)

EVIDENCE SUMMARY TABLES

Table number **Page**

CHILDREN

ADULTS

EVIDENCE TABLE 1: MAINTAINING ENERGY BALANCE IN CHILDREN

SUMMARY

1.1 Dietary factors

Of the eighteen cohorts of children, ten longitudinal cohorts examined the association of dietary factors with weight change and one cross-sectional study (McConahy 2004) focused on portion size.

O'Loughlin et al. (2000) conducted a 2-year cohort study in 9–12-year-old children in Canada and reported no strong or consistent pattern of associations in either boys or girls for diet indicators and weight change (results not reported). Bogaert et al. (2003) conducted an analysis of 59 8-year-old Australian children and found no significant correlations between body mass index (BMI) over 12 months for any dietary variable.

Klesges et al. (1995) conducted a 2-year analysis of 3–5-year-old children and their parents in Tennessee and found that higher baseline percentages of energy as fat were associated with greater increases in BMI (0.168 kg/m^2 per 5%) and recent increases (year 2–3) in percentage of energy intake as fat were associated with greater increases in BMI (0.201 kg/m^2 per 5% change). Neither baseline total energy nor change in total energy increased variance in change in body mass.

The Growing Up Today Study (Berkey, 2000, 2003a, 2003b, Berkey 2005; Field, 2003, 2004; Taveras 2005) of 9–14-year-old US children included analyses of several potential determinants. Berkey et al. (2003) conducted an analysis of more than 10,000 children over 1 year and reported that for both boys and girls a larger rise in energy intake predicted larger BMI increase (girls 0.0059 per increase of 100 kcal [420 kJ]/day, boys 0.0082) and annual BMI increases were higher in girls with higher energy intakes (BMI increased by 0.061 kg/m^2 per 100 kcal [420 kJ]/day; $p > 0.02$). Over 2 years, boys with energy intake that increased more from the first to the second year predicted larger increases in BMI. In boys and girls no significant associations were noted for energy adjusted dietary fat or fibre and change in BMI ($p > 0.05$).

Overweight children who never ate breakfast lost BMI over 1-year compared with children who ate breakfast nearly every day (boys –0.66 kg/m^2, girls –0.50 kg/m^2). Normal weight children who never ate breakfast gained weight relative to peers who ate breakfast nearly very day (boys 0.21 kg/m^2, girls 0.08 kg/m^2).

Field (2003) conducted an analysis of more than 15,000 children over 3-years and after controlling for Tanner stage of development, age, height change, activity and inactivity (predictors of BMI), girls showed no relation between intake of fruits, fruit juice or vegetables (alone or combined) and subsequent changes in BMI *z*-score. In boys, intake of fruit and fruit juice was not predictive of changes in BMI. Although vegetables intake was inversely related to changes in BMI *z*-score ($p > 0.05$) after adjusting for energy intake, the magnitude of the effect was diminished and no longer significant.

There was no relation between intake of snack foods and subsequent changes in BMI *z*-score among the boys ($\beta = -0.004$), but snack foods had a weak inverse association ($\beta = -0.007$, $p > 0.05$) with weight change among the girls. However, the results were confounded by dieting status, which had a significant positive independent association with BMI change. After controlling for dieting status and whether the mother was overweight, the association between servings per day of snack foods and subsequent changes in BMI *z*-score were not significant in either gender (Field 2004).

Berkey (2005 GUTS) looked at the association between milk, dietary fat, dietary calcium and weight gain in the Growing Up Today Study (GUTS). Children who reported higher total milk intake experienced larger weight gains; children who drank more 1% and skimmed milk had larger weight gains than those who drank smaller amounts of 1% and skimmed; dietary calcium intake was positively correlated with weight gain; and dietary fat was not. The effects of milk and dietary calcium appeared to be explained by energy intake; however skimmed milk intake in girls remained marginally significant after adjustment for energy intake.

Taveras (2005, GUTS) looked at the association between overweight and frequency of family dinner in the Growing Up Today Study (GUTS). Whilst cross-sectional data showed children were less likely to be overweight if they ate dinner most days with their family, this relationship was not apparent in the longitudinal analyses over 2 years. This data was self-reported.

In the study by Thompson (2004) of girls (median age 9 years at baseline and followed for a median of 6 years), girls who ate quick-service food twice per week or more at baseline had the greatest means increase in BMI *z*-score at follow-up, and this change was significantly different from that seen in girls who ate quick-service food once or twice per week or not at all.

Burke (2005) investigated the relationships between different food categories and BMI at 8 years in 340 Australian children. Parents completed a food frequency questionnaire for their children at 6 years. An inverse relationship was found for 'cereals' and '% energy from total fat' (p = 0.046 and p = 0.025 respectively) and a positive relationship with 'takeaways' (p = 0.025).

Elgar (2005) found that skipping meals and snacking (not further defined) were associated with obesity, but did not predict change in BMI between the ages of 11-12 and 15-16 years in 355 Welsh adolescents.

Moore (2003) investigated the relationships between physical activity level, TV viewing and change in body fat in 106, 3-5-year-olds from the Framingham Children's Study over a period of eight years (from 2-5 years of age). Children with high fat diets (>34% calories from fat) exacerbated body fat gain in children watching TV for more than 3 hours per day. They gained approximately 30mm of body fat (sum of five skinfolds) compared with children who watched least TV (<1.75h per day) and consumed a lower-fat diet (<34% calories from fat).

Phillips (2004) investigated the relationship between energy dense snacks (EDS) and BMI z-scores in 196 non-obese pre-menarcheal girls 8 to 12 years old from the Massachusetts Institute of Technology Growth and Development Study (ethnicities included 75% white, 14% black and 11% other races) for four years after menarche. Categories of EDS foods considered were baked goods, ice cream, chips, sugar-sweetened carbonated drinks and sweets. No relationship was found between BMI z score or % body fat and total EDS food consumption. However, carbonated drinks were the only EDS food significantly related to BMI z-score over the 10-year study period (p-value for trend <0.001), but it was not related to % body fat.

Reilly (2005) examined 25 risk factors for obesity from the inter-uterine period to 7 years in the ALSPAC cohort (UK). Eight factors were associated with risk of obesity. None were dietary, although a 'junk food type dietary pattern' (not defined further) at 3 years was significant at the 10% level.

McConahy (2004) looked at dietary behaviours in 5447 children aged 2-5 years from the Continuing Survey of Food Intakes by Individuals across the US, over a two year period. Based on parental self-report, this cross-sectional study found that body weight, food portion size, number of eating occasions and number of foods accounted for 38% of the variance in 2-3-year-olds and 39% in 4-5-year-olds. Portion size as a single predictor explained 17% of the variance in 2-3-year-olds and 19% in 4-5-year-olds.

1.2 Physical activity

Of the eighteen cohorts of children, eight cohorts examined the association of physical activity (PA) factors with weight change. O'Loughlin et al. (2000) reported 1-year predictors of higher decile of change in BMI included no sports outside school (odds ratio [OR] 1.90; 95% confidence interval [CI] 1.18, 3.06) in girls. Two-year predictors of higher decile of change in BMI included no sports outside school (OR 2.14; 95% CI 0.96, 4.77) and least active (OR 2.18; 95% CI 1.01, 4.71) in boys.

Berkey et al. (2003) reported annual BMI increases were higher in girls with fewer hours of activity (BMI decreased by 0.284 kg/m^2 per hour per day of activity; $p > 0.05$) during the year between baseline and follow up. Boys who marginally, had less PA (–0.0261 kg/m^2 per hour of activity; $p = 0.094$) showed larger annual BMI increases. The number of gym classes per week was not associated ($p > 0.10$) with change in BMI in boys. Boys with higher metabolic equivalent tasks (METs) during the year between the two BMIs had marginally smaller ($p = 0.6$) increases in BMI.

Klesges et al. (1995) reported that higher baseline aerobic activity and increased leisure activity from years 2 to 3 were associated with BMI decreases.

Bogaert et al. (2003) reported no significant correlations between BMI over 12 months for any measures of energy expenditure, including hours of television (TV) viewing or percentage of time spent in low, moderate or high intensity activity. A significant correlation was found between activity and weight change for mothers and girls for percent time in moderate to high activity ($r = 0.44$, $p = 0.03$) and between fathers and children for percentage of time spent in low activity ($r = 0.43$, $p = 0.005$).

Datar et al. (2004) conducted a 1-year follow-up of primary school aged children in the USA and examined association between weight change and PA only. The study found that one additional hour of physical education in the first grade compared with the time allowed for physical education in kindergarten reduced BMI among girls who were overweight or at risk for overweight in kindergarten (*p* > 0.01) but had no significant effect among overweight or at risk for overweight boys (*p* = 0.02) or among boys (*p* = 0.31) or girls (*p* = 0.80) with a normal BMI.

Moore (2003) examined 106 children aged 3-5 years from the Framingham Children's Study with Caltrac motion sensors to assess physical activity levels. Children were categorised as having low, medium or high activity levels (based on average number of counts per hour and then averaged over the eight year study period). Children in the highest tertile for daily physical activity had consistently smaller gains in BMI, triceps and sum of 5 triceps throughout childhood. By 11 years, sum of 5 skinfolds was 95.1mm, 94.5mm and 74.1mm for the low, medium and high tertiles respectively (p-value for trend = 0.045). This relationship was evident for both sexes. Children with the lowest levels of PA and highest levels of TV viewing gained nearly 40 mm of body fat than children with highest levels of PA and least TV by 11 years.

Burke (2005) used parental questionnaires to assess levels of physical activity in 1430 Australian children at 6 years. Playing organised sport at age 6 was not predictive of BMI at age 8, but 'being slightly active' and 'active' at 8 years were (OR 0.44; 95 CI 0.28, 0.70 (p<0.001) and OR 0.23; 95 CI 0.14, 0.38 (p<0.001)) respectively. Duration of physical activity was not reported.

Elgar (2005) assessed the relationship between physical activity and change in BMI in 355 Welsh adolescents who were part of the Health Behaviour of School-aged Children Study. Physical activity questions were from the HBSC questionnaire and hours of sports participation was associated with lower increases in BMI (p<0.05) over the four year period (from 11-12 to 15-16 years). Details about amount of hours of sport were not reported.

1.3 Other behavioural, psychological, social and environmental factors

1.3.1 Sedentary behaviours – television/video viewing

Ten cohorts examined the relationship between television (TV)/video viewing and weight change in children. Kaur (2003) analysed 3-year data from 12–17-year-old Californian adolescents and found that 1% variation in follow-up BMI% was explained by TV watching. Watching >2 hours TV per day was related to higher odds of being overweight at follow-up among adolescents at normal weight at baseline (OR 1.9; 95% CI 1.1, 3.5) and among adolescents overweight at baseline (OR 2.8; 95% CI 1.3, 6.3). For each additional hour of TV watching at baseline the average follow-up BMI% increased by 0.5, controlling for ethnicity and baseline BMI%. Forty-eight percent of new-onset overweight among adolescents not overweight at baseline was attributable to watching >2 hours TV per day.

O'Loughlin (2000) reported there was no strong or consistent pattern of association in either boys or girls for TV viewing. One-year predictors of higher decile of change in BMI included playing video games everyday (OR 2.48; 95% CI 1.04, 5.92) in girls.

Robinson (1993) conducted a 2-year analysis of 12-year-old Californian children and reported that hours of after-school TV viewing did not longitudinally predict change in ***sexual maturity index (SMI)*** -adjusted BMI (univariate Spearman *r* = 0.03, *p* = 0.62; multivariate regression co-efficient estimate = 0.05, *p* = 0.82). Hours of after-school TV viewing did not longitudinally predict change in SMI-adjusted triceps skinfold thickness (univariate Spearman *r* = 0.03, *p* = 0.54; multivariate regression co-efficient estimate = –0.19, *p* = 0.67).

Berkey (2003) reported that annual BMI increases were higher in girls with more hours of TV /video/games (BMI increased by 0.372 kg/m^2 per hour per day; *p* > 0.001) during the year between baseline and follow up. Boys who spent more time with TV/videos/games (0.384 kg/m^2 per hour per da***y***; *p* > 0.0001) showed larger annual BMI increases. Over 2 years, boys with higher means hours of TV/video/games were predicted to have larger increases in BMI.

Bogaert (2003) reported no significant correlations between BMI over 12 months for hours of TV viewing.

Burke (2005) examined the relationship between hours per day spent watching TV and BMI at 8 years with the Western Australian Pregnancy Cohort. Parental questionnaires were completed about their children's television viewing habits at age 6 and hours spent TV viewing at age 6 was predictive of BMI at 8 years; OR 1.53; 95 CI 1.16, 2.02 (p<0.002), ie more TV viewing resulted in higher BMI.

Elgar (2005) assessed the relationship between sedentary behaviour and change in BMI in 355 Welsh adolescents who were part of the Health Behaviour of School-aged Children Study. Sedentary behaviour (watching television or playing computer games) at Time 1 predicted BMI four years later ($p<0.05$), ie more sedentary behaviour resulted in higher BMI.

Moore (2003) used parental questionnaires in conjunction with Caltracs to estimate hours of TV viewing and video games per day in 106, 3-5-year-olds from the Framingham Children's Study. TV viewing was divided into tertiles of hours per day: <1.75h, 1.75 to <3.0h, >3.0h. At 11 years, those who watched 3.0h or more per day had a mean sum of 5 skinfolds of 106.2mm compared with 87.6mm for those watching 1.75 to <3.0h, and 76.5mm for those watching least ($p = 0.007$; p-value for trend = 0.028).

Reilly (2005) found two predictive factors for sedentary behaviours within the ALSPAC cohort. Watching more than 8 hours of television per week at age 3 was associated with risk of obesity (adjusted OR 1.55; 95 CI 1.13, 2.12) and short sleep duration (<10.5 hours) at age 3 was also identified as a risk (OR 1.45; 95 CI 1.10, 1.89).

Viner (2005) UK conducted an analysis of the 1970 British Birth cohort of over 8000 subjects followed up at 5, 10 and 30 years (30 year follow-up self-reported) examining the relationship between television viewing and BMI change. Weekend but not weekday TV viewing in early childhood independently predicted increased adult BMI.

Clearer relationships were found from ages 5 to 10 years than to 30 years. Mean hours of weekend TV and frequent TV watching at 10 were independently associated with higher BMI at 10: Using obesity at 10 as the outcome in logistic regression, each additional hour of TV watched on weekdays at 5 years increased the risk of obesity by 12% (OR 1.12; 95 CI 1.04, 1.21; $p = 0.002$); and each additional hour at weekends increased risk by 10% (OR 1.10; 95 CI 1.03, 1.18; $p = 0.003$).

1.3.2 Socio-economic status

Spiegelaere (1998) examined possible association between socio-economic status (SES) (statuses) and the rate of adiposity rebound in 3–5-year-old Belgium children and found that adiposity rebound before age 5 years was inversely related to body mass at age 3 years and was independent of social status. Parental income and education were not associated with change in BMI *z*-score in the study by Thompson et al. (2004).

Burke (2005) considered predictive factors for BMI at 8 years in 1430 Australian children. Categories of higher and lower incomes were based on total family income (categorised as lower = below $40,000, or higher = above $40,000). BMI was similar at 3 years but at 6 and 8 years, BMI was higher in lower income families ($p = 0.004$). A similar pattern was apparent for maternal education; BMI at 6 years was lower in tertiary educated mothers ($p = 0.001$) compared with mothers not educated beyond secondary schooling or having a technical qualification.

Elgar (2005) found that demographic factors and SES did not predict change in BMI in 355, Welsh adolescents (aged 11-14 years) over four years.

1.3.3 Age

Berkey (2003) examined the association between weight change and age and among boys under 12 years old, those who did more PA in the year between the BMI measurements had smaller annual increases in BMI (–0.0746 ± 0.0212).

1.3.4 Overweight biological parents

Klesges (1995) examined possible association between weight change and having one or two overweight biological parents. Boys with both parents overweight had increases in children's BMI (0.67 kg/m^2) and for girls those with just a father overweight showed BMI gains over 2 years (0.40 kg/m^2). O'Loughlin (2000) reported there were no strong or consistent pattern of associations in either boys or girls for family origin (results not reported). Parental BMI was not associated with change in BMI *z*-score in the study by Thompson et al. (2004).

Reilly (2005) found parental fatness was associated with risk of obesity at 7 years in the ALSPAC cohort. This was apparent if one parent was obese and increased If both parents were obese (OR 10.44; 95 CI 5.11, 21.32).

Burke (2005) looked at maternal weight and BMI in 1430, Australian 8-year-olds followed since 16 weeks gestation. BMI at 8 was predicted by maternal weight and maternal BMI and in a subset of 298 children with paternal data, each obese parent independently increased the risk of obesity at 8 by three times.

1.3.5 Birth weight

Reilly (2005) found four child weight related factors associated with obesity risk at 7 years in the ALSPAC cohort. Increasing birth weight was independently and linearly associated with obesity (p<0.001), as were early BMI or adiposity rebound (by 43 months) (OR 15.0; 95 CI 5.32, 42.3), catch-up growth (OR 2.6; 95 CI 1.09, 6.163) and weight gain in first year (OR 1.06; 95 CI 1.02, 1.10).

Burke (2005) also found that birth weight was positively associated with BMI at 8 (p<0.001) and an increasing likelihood of remaining overweight or obese with age.

1.3.6 Baseline body mass index

O'Loughlin (2000) reported that baseline BMI was the only consistent independent predictor of excess weight gain in all four multivariate models. One-year predictors of higher decile of change in BMI included BMI of 90th percentile or more (OR 2.66; 95% CI 1.80, 1.34) in boys and BMI of 90th percentile or more (OR 2.34; 95% CI 1.46, 3.76), in girls. Two-year predictors included baseline BMI of 90th percentile or more (OR 3.26; 95% CI 1.52, 7.01), and BMI of 90th percentile or more (OR 2.22; 95% CI 1.02, 4.81) in girls. Kaur (2003) reported nearly 50% variation in follow-up BMI% was explained by baseline BMI%.

1.3.7 Ethnicity

Two cohorts examined ethnicity and weight change, with one reporting that only 0.3% variation in follow-up BMI% was explained by ethnicity (Kaur 2003). Sixty-eight percent of the children were White, 5% African American, 20% Hispanic and 8% Asian with no other further details regarding ethnicity and weight change. Ambrosius (1998) performed a 14-year follow-up of children mean age 9–10 years at baseline (range 5–20 years) in Indianapolis. He reported that the rate at which BMI increased in Black children was significantly greater than in the White children ($p > 0.0001$). There were no gender differences in the rate of increase of BMI. No other details regarding ethnicity were reported.

1.3.8 Self-esteem

One cohort study examined the association between self-esteem and weight change in 12–15-year-old children in Minnesota (French 1996). Partial correlations were identified between baseline self-esteem and BMI at 3 years. In females, low physical appearance and low social acceptance self-esteem at baseline were associated with higher BMI 3 years later. In males, baseline self-esteem was unrelated to BMI 3 years later. Analyses examining relationships between baseline self-esteem and overweight status 3 years later showed high close friendship self-esteem in females and high physical appearance self-esteem in males were associated with decreased odds of overweight at 3-year follow-up. (All associations were significant but modest in magnitude.)

1.4 Parental fatness

A systematic review (Parsons et al. 1999) identified eight cohort studies that identified factors in childhood that may influence the development of obesity in adulthood. Offspring of obese parent(s) were consistently seen to be at increased risk of fatness, although few studies have looked at this relationship over longer periods of childhood and into adulthood. Data from one study suggested that this relationship may be stronger between mothers and their offspring than fathers and offspring, and that the mother-offspring relationship strengthens over time. One study found that parental obesity was a more important predictor of offspring obesity earlier in childhood (<6 years), becoming less important with increasing age. Data from another study showed that parental obesity influences tracking of the offspring's own obesity, which is much stronger if both parents are obese.

The relative contributions of genes and inherited lifestyle factors to the parent–child fatness association remains largely unknown.

1.5 Evidence of corroboration in the UK

Three of the 18 cohorts of children were conducted in the UK (Elgar 2005, Reilly 2005, Viner 2005) and the other cohorts were mainly conducted in the USA and generalisable to UK children. *(Evidence of implementation not valid for this review as not intervention studies.)*

EVIDENCE SUMMARY TABLES: DETERMINANTS OF WEIGHT GAIN/CONTROL IN CHILDREN

First author, design, aim	**Population**	**Intervention details, length of follow-up**	**Results**	**Confounders adjusted for/comments**
EVIDENCE OF ASSOCIATION BETWEEN DIETARY, PHYSICAL ACTIVITY AND OTHER FACTORS WITH WEIGHT CHANGE				
Parsons et al. (1999) **Aim:** To identify factors in childhood which may influence the development of obesity in adulthood 1++	Various, from eight cohort studies. **Baseline BMI:** Various.	**Year of baseline survey:** Various. **Duration of follow-up**: At least 1 year. **Outcome variable**: Measure of fatness. **Self-reported or measured weight:** Measured. **Statistical analysis**: Various.	Offspring of obese parent(s) were consistently seen to be at increased risk of fatness, although few studies have looked at this relationship over longer periods of childhood and into adulthood. Data from one study suggested that this relationship may be stronger between mothers and their offspring than fathers and offspring, and that the mother–offspring relationship strengthens over time. One study found that parental obesity was a more important predictor of offspring obesity earlier in childhood (<6 years), becoming less important with increasing age. Data from another study showed that parental obesity influences tracking of the offspring's own obesity, which is much stronger if both parents are obese. The relative contributions of genes and inherited lifestyle factors to the parent–child fatness association remains largely unknown.	**Adjusted for:** Various. **Author's conclusions:** Offspring of obese parent(s) were consistently seen to be at increased risk of fatness, and offspring of obese parents who themselves are fatter in childhood may be at particular risk.
Viner 2005 Prospective cohort, Aim: To examine the effects of duration, timing and type of television at 5 years on BMI in adult life.	1970 British Birth cohort of subjects (n = 16 567) living in Great Britain born 5-11th April, 1970. Cohort was representative of the UK population in childhood. At 30 years, 96.3% were white, 0.6% black, 1.8% South	Year of baseline examination and survey: Participants originally enrolled in the longitudinal growth and development study in 1970. Duration of follow-up: Participants were followed-up at 5, 10, 16, 26 and 29-30 years. Outcome variables:	**Attrition:** 32% **Weight change**: Obesity was found in 4.3% at 10 and 11.4% of the participants at 30 years. **Association of diet with weight change:** None reported. **Association of physical activity with weight change:** Higher frequency of playing sport at 10 years was independently associated with lower BMI z-score at 30: adjusted regression coefficient (95 CI) -0.08 (-0.12, -0.04; p<0.0001). **Association of other factors with weight change:** Higher duration of TV watching on weekdays and weekends were both	Adjusted for: Sex, social class, maternal education, birth weight, and BMI z-score of both parents. Also height at 5 and 10 years. Author's conclusions: Could not conclude that TV viewing in early childhood

	Asian, 0.8% Chinese and 0.6% other ethnic groups. At 5 years, data were obtained for 14,875 and 11,261 were interviewed at 29-30. Complete data on 8158.	Change in BMI z-score, calculated from the revised UK 1990 growth reference. Self-reported or measured: Both self-reported and measured. Height and weight measured by health care professionals at and 10 years. Self-report at 30 years. Statistical analysis: Linear regression and multivariate regression models.	significantly associated with higher BMI z-scores at 10 and 30 years. Mean hours of weekend TV and frequent TV watching at 10 were independently associated with higher BMI at 10: Using obesity at 10 as the outcome in logistic regression, each additional hour of TV watched on weekdays at 5 years increased the risk of obesity by 12% (OR 1.12; 95 CI 1.04, 1.21; p = 0.002); and each additional hour at weekends increased risk by 10% (OR 1.10; 95 CI 1.03, 1.18; p = 0.003). Strong maternal beliefs that TV was harmful to children at 5 years, predicted lower viewing at 10 years (p<0.001). Results at 30 years Mean daily hours of TV viewed at weekends predicted higher BMI z-score at 30 years (coefficient=0.03, 95% CI: 0.01, 0.05, P=.01) when adjusted for TV viewing and activity level at 10 years, sex, socioeconomic status, parental BMIs, and birth weight. Each additional hour of TV watched on weekends at 5 years increased risk of adult obesity (BMI > or =30 kg/m2) by 7% (OR=1.07, 95% CI 1.01, 1.13, P=.02). Weekday viewing, type of program and maternal attitudes to TV at 5 years were not independently associated with adult BMI z-score.	directly attributes to increased BMI.
Reilly 2005 Prospective cohort ALSPAC **Aim: To identify risk factors in early life for obesity in children**	8234 children aged 7 years and a sub-sample of 909 children with data on early growth related risk factors for obesity from the UK (Avon Longitudinal Study of Parents And Children). The original cohort of children was 13,971.	Year of baseline survey: April 1991 to December1992 Outcome variable: BMI. Duration of follow-up: 7+ years. Self-reported or measured weight: Measured. Statistical analysis: Multivariable binary logistic regression models in three stages. X^2 tests used for linear trend for ordered categorical	**Attrition:** 43% **Weight changes:** Increasing birth weight was independently and linearly associated with obesity (p<0.001); early adiposity rebound (by 43 months) (OR 15.0; 95 CI 5.32, 42.3); catch-up growth (OR 2.6; 95 CI 1.09, 6.163) and weight gain in first year (OR 1.06; 95 CI 1.02, 1.10). **Association of diet with weight change:** Food frequency questionnaires at 30 and 38 months, but dietary patterns at 3 years were not associated with risk of obesity at 7 years. Although in the final adjusted model, a 'junk food' diet reached significance at the 10% level. **Association of physical activity with weight changes:** No analysis. **Association of other factors with weight changes:** Watching more than 8 hours of television per week at age 3 was associated with risk of obesity (adjusted odds ratio 1.55; 95 CI 1.13, 2.12). Short sleep	Adjusted for: Maternal education, interuterine and perinatal factors, infant feeding and complementary feeding, family demography and lifestyle in early childhood. Author's conclusions: Early life environment implicated in findings. Interventions

		variables.	duration (<10.5 hours) at age 3 was also identified as a risk (1.45, 1.10 to 1.89). Parental obesity was associated with risk of obesity and when both parents obese (10.44; 5.11, 21.32). Maternal smoking between 28 and 32 weeks gestation was significantly associated with risk of obesity (independent of maternal education) at all intensities of smoking eg >20 (1.80, 1.01, 3.39). There was some evidence of a dose response relationship (X^2 test for linear trend 27.17).	might focus on environmental changes for short periods attempting to modify factors in utero, infancy or early childhood.
Elgar 2005 Prospective cohort Aim: To investigate the effect of sedentary behaviour and physical activity on changes in body mass	355 adolescents from the Health Behaviour of School-aged Children Study in Wales. Mean age at baseline was 12.30 (SD = 6.30).	Year of baseline survey: 1994 Outcome variable: Change in BMI. Duration of follow-up: 4+years. Self-reported or measured weight: Measured. Statistical analysis: Multiple regression was used for BMI predictors.	Attrition: 45.5% Weight changes: There were no significant changes in prevalence of overweight and obesity over the four year period for either sex. Association of diet with weight change: Analyses showed skipping meals and snacking were associated with obesity, but were not predictive of BMI change. Association of physical activity with weight changes: Hours of sports participation was associated with lower increases in BMI ($p<0.05$). Association of other factors with weight changes: Sedentary behaviours at 11 years predicted BMI at 15 years ($p<0.001$), but did not influence change in BMI over four years. Demographic and SES did not predict change in BMI at 15 years, but amount of pocket money earned did ($p<0.05$).	Adjusted for: BMI at 11 years Author's conclusion: Sedentary behaviour and physical activity in early adolescence influenced body mass in late adolescence.
Burke 2005 Prospective cohort **Aim: To examine predictors of BMI at age 8 years**	741 boys and 689 girls followed from 16th week of gestation from the Western Australia Pregnancy Cohort Study. The original	Year of baseline survey: May 1989 to November 1991 Duration of follow-up: 8+ years. Outcome variable: BMI. Self-reported or	Attrition: 33% Weight changes: Table shows percentages of overweight (including obese) using the IOTF definitions. Age (years) — Boys — Girls 1 — 22.1 — 25.1 3 — 13.5 — 14.0 6 — 12.6 — 17.9	Adjusted for: sex and maternal education Authors conclusions: Important to recognise role of adverse health-related

Birth weight was positively associated with BMI at 8 (p<0.001).
Association of diet with weight change:
A subset of 340 children, parents completed a food frequency questionnaire and food categories derived via factor analysis. An inverse relationship was found for ‘cereals’ and ‘% energy from total fat’ (p = 0.046 and p = 0.025 respectively) and a positive relationship with the ‘takeaways’ factor (p = 0.025).
Association of physical activity with weight changes:
Playing organised sport at ages 6 and 8 were not significant. Subjective assessment of activity ‘being slightly active’ and ‘active’ at 8 were negatively associated with BMI at 8 years; OR 0.44; 95 CI 0.28, 0.70 (p<0.001) and OR 0.23; 95 CI 0.14, 0.38 (p<0.001) respectively.
Association of other factors with weight changes:
Obesity at 8 was associated with hours per day spent watching TV at age 6; OR 1.53; 95 CI 1.16, 2.02 (p<0.002).
BMI at 8 was predicted by maternal weight and maternal BMI and in a subset of 298 children with paternal data, each obese parent independently increased the risk of obesity at 8 by three times.
Mother being an ex-smoker or never smoked was negatively associated with BMI at 8 years; OR 0.57; 95 CI 0.38, 0.87 (p = 0.009) and OR 0.35; 95 CI

			0.22, 0.53 (p<0.001) respectively.	
			Children from higher income and lower income groups had similar BMI at 3 years but at 6 and 8 years, BMI was higher in lower income families (p = 0.004). Parental income was categorised as lower = below $40,000, or higher = above $40,000. BMI at 6 years was lower in tertiary educated mothers (p = 0.001). Mother's Educational level was categorised as	
			1 not higher than secondary schooling; 2 technical qualification; 3 tertiary qualification.	
Thompson 2004 **Design:** convenience sample from prospective cohort, 2+ **Aim:** To assess the relationship between eating food purchased away from home (FAH) and longitudinal change in BMI *z*-scores among girls, and to assess the longitudinal tracking of eating FAH from childhood to adolescence.	Healthy girls (*n* = 101) between the ages of 8 and 12 years at baseline and 11 and 19 years at follow-up participated in a longitudinal study of growth and development at the Massachusetts Institute of Technology. At baseline the median age was 9 years. 96% of participants had a baseline BMI *z*-score <85th percentile for age and sex. 4% of participants had a BMI ≥85th percentile.	**Year of baseline examination and survey:** Participants originally enrolled in the longitudinal growth and development study in 1990. **Duration of follow-up:** Time varied for all participants, follow-up records were completed a median of 6 years after baseline records were completed **Outcome variables:** Change in BMI z-score, defined as the number of standard deviation units that a person's BMI is from the mean or reference value. *z*-scores were computed with reference to sex and age-specific mean BMI	**Attrition:** 100% – no dropout. **Dietary patterns:** At baseline, 71% of participants ate FAH. At follow-up, this percent increased to 86% and the median number of total FAH occasions had increased from two to three times per week. There was slight FAH tracking from childhood through adolescence. Modest tracking was observed for those who ate quick service food and restaurant food, while no tracking was observed for those who ate at coffee shops. Few participants ate at coffee shops at baseline, but this number increased by 25% at follow-up. **Weight change:** In analysis of variance adjusted for unbalanced cell size, the weekly frequency of consuming quick service food at baseline was positively associated with change in BMI *z*-score ($F = 3.37$, $p \le 0.05$), and this relationship was strengthened after adjusting for baseline BMI *z*-score ($F = 6.49$, $p \le 0.01$). The frequency of eating at coffee shops and in restaurants at baseline was not associated with changes in BMI *z*-score. Duncan's multiple range test showed that participants who ate quick service food twice per week or more at baseline had the greatest means increase in BMI *z*-score at follow-up, and this change was significantly different from that seen in girls who ate quick-service food once or twice a week or not at all. Girls who were eating quick service food twice a week or more were consuming more energy on average than girls who were eating quick-service food once per week or not at all (73 kJ [304 kcal] and 51 kJ [213	**Adjusted for:** Baseline BMI *z*-score. **Author's conclusions:** Consuming quick service food appeared to predispose this sample of girls to increase their relative BMI. **Comments:** It is possible that the tracking observed in this study was as a consequence of increasing age, availability of spending money and/ or self-determination of teens. Most participants were middle to

	The majority of participants (60%) came from families earning at least US$50,000 per year. Most mothers and fathers had at least college level education (72 and 81%, respectively).	values and distributions using the Centers for Disease Control (CDC) and Prevention Growth Chart data. **Self-reported or measured:** Both self-reported and measured. Height and weight measured by health care professionals. Participants kept 7-day dietary records at two points in time, including the place and time for all foods consumed. Foods were classified as quick-service food, coffee-shop food or restaurant food. **Statistical analysis:** Analysis of variance was used to assess the relationship between change in BMI *z*-score and both the frequency of eating FAH and energy derived from eating FAH. The participants' baseline BMI *z*-score was a significant covariate and was controlled for in both	kcal], respectively), but this relationship was not significant **Association of physical activity with weight change:** At baseline 40% of participants considered themselves to be as active as their peers and 51% considered themselves to be more active than their peers PA was not significantly associated with change in BMI *z*-score, therefore was not included in any of the model. **Association of other factors with weight change:** Parental BMI, income and education were not associated with change in BMI *z*-score and so were not included in the models.	upper class White girls who reported being more physically active than their peers, although PA was not a significant covariate, it is possible that PA data were misclassified.

		models. Kappa coefficient was used to assess FAH tracking from childhood through adolescence.		
Phillips 2004 Prospective cohort Aim: To examine the longitudinal relationship of energy-dense snack (EDS) food intake with relative weight status and percentage body fat.	196 non-obese pre-menarcheal girls 8 to 12 years old from the Massachusetts Institute of Technology Growth and Development Study. Ethnicities included 75% white, 14% black and 11% other races.	Year of baseline survey: 1990 and 1993 Outcome variable: BMI z-score, body fat (%BF). Duration of follow-up: 4 years after menarche Self-reported or measured weight: Measured. Statistical analysis: Linear mixed effects modelling	Attrition: 9% Weight changes: None reported without reference to behaviours. Association of diet with weight change: Categories of EDS foods considered were baked goods, ice cream, chips, sugar-sweetened carbonated drinks and sweets, with data collected at annual follow-up visits. No relationship between BMI z score or %BF and total EDS food consumption was observed. Carbonated drinks were the only EDS food that was significantly related to BMI z score over the 10-year study period (p-value for trend <0.001), but it was not related to %BF.	Adjusted for: PA, parental overweight, ethnicity, and dietary variables. Author's conclusion: In initially non-obese girls, overall EDS food consumption does not seem to influence weight status or fatness change over the adolescent period.
Datar 2004 Prospective cohort 2+ **Aim:** To examine the effect of physical education instruction time on BMI change	9751 Kindergartens in the USA. **Baseline BMI or weight:** Boys overweight: 11.6 % Girls overweight: 9.8%	**Year of baseline survey:** 1998 **Duration of follow-up**: 1 year **Outcome variable**: BMI **Self-reported or measured weight:** Measured	**Attrition:** 49% **Weight changes**: Boys, non-Whites (particularly Hispanic children) whose mothers had an educational level of a high school diploma or less, and children from low-income families were significantly more likely to be overweight in kindergarten as well as first grade. **Association of diet with weight change:** No analysis **Association of physical activity with weight change:**	**Adjusted for**: Not reported. **Author's conclusions**: Increasing time spent on physical education programmes in schools, in the form in which they exist, may

<td>Growing Up Today study

Berkey, 2000, 2003a, 2003b; Berkey 2005; Field 2003, 2004; Taveras 2005;

Prospective cohort
2+

Aim:
This study examined the role of PA, inactivity and dietary patterns on annual weight changes among preadolescents and adolescents taking growth and development into account.</td>
<td>6149 girls and 4620 boys, aged between 9 and 14 years, from various parts of the USA (50 states who are offspring of Nurses health Study II).

94.7% were White (not Hispanic), 0.9% were Black (not Hispanic), 1.5% were Hispanic, 1.5% were Asian and 1.4% other (including Native American).

Baseline BMI/weight:
At baseline, 23.2% of the boys and 17.4% of the girls were overweight (>85th percentile BMI), while 7.2% of</td>
<td>**Year of baseline survey:**
1996

Duration of follow-up:
Three 1-year periods.

Outcome variable:
BMI.

Self-reported or measured weight:
Self-reported.

Statistical analysis:
Linear regression.</td>
<td>**Attrition:**
Girls 32%, boys 42%.

Weight changes:
Girls who were 11 years old at baseline and boys who were 12 years old had the largest mean annual increase in BMI.

The table below shows the mean annual change in BMI (kg/m^2) by age at baseline:
<table>
<tr><th>Age (years)</th><th>Boys</th><th>Girls</th></tr>
<tr><td>**9**</td><td>0.48</td><td>0.65</td></tr>
<tr><td>**10**</td><td>0.57</td><td>0.61</td></tr>
<tr><td>**11**</td><td>0.7</td><td>0.6</td></tr>
<tr><td>**12**</td><td>0.61</td><td>0.8</td></tr>
<tr><td>**13**</td><td>0.6</td><td>0.78</td></tr>
<tr><td>**14**</td><td>0.47</td><td>0.64</td></tr>
</table>
Weight changes:
At 3-year follow-up, changes in BMI were slightly greater among boys than among girls (0.7–0.8 units per year among the boys vs. 0.6–0.7 units per year among the girls (8203 girls and 6715 boys aged between 9 and 14 years of age from Boston USA).

Association of diet with weight change:
Annual BMI increases were higher in girls with higher energy intakes (BMI increased by 0.061 kg/m^2 per 100 kcal (4.2 kJ)/day; $p > 0.02$).

For both boys and girls a larger rise in energy intake predicted larger BMI increase (girls 0.0059 per increase of 100 kcal [4.2 kJ]/day, boys 0.0082).</td>
<td>**Adjusted for:**
Race, baseline BMI, annual change in height, menstrual history in girls, Tanner stage and age.

Authors' conclusions:
For both boys and girls, a 1-year increase in BMI was larger in those who reported more time with TV/videos/games during the year between BMI measurements and in those who reported that their energy intakes increased more from one year to the next. Larger annual increases in</td>
</tr>
</table>

	the boys and 8.6% of the girls were very lean (<10th percentile BMI).		In boys and girls no significant associations were noted between consumption of energy adjusted dietary fat or fibre and increase in BMI ($p > 0.05$). Overweight children who never ate breakfast lost BMI over 1 year compared with overweight children who ate breakfast nearly every day (boys –0.66 kg/m^2, girls –0.50 kg/m^2). Normal weight children who never ate breakfast gained weight relative to peers who ate breakfast nearly every day (boys 0.21 kg/m^2, girls 0.08 kg/m^2). Over 3 years, normal weight girls who ate breakfast 1–2 days a week gained more weight (+0.072 kg/m^2) than peers who ate breakfast daily. However, overweight boys and girls who skipped breakfast put on less weight than people who had breakfast every day (boys: no breakfasts –0.425 kg/m^2; 3–4 days –0.139; girls who ate breakfasts 1–2 days a week –0.114 and breakfasts on ***3-4*** days per week –0.177. **Association of diet with weight change:** At 3-year follow-up (8203 girls and 6715 boys aged between 9 and 14 years of age from Boston, MA, USA): after controlling for Tanner stage of development, age, height change, activity and inactivity (predictors of BMI), girls showed no relation between intake of fruits, fruit juice or vegetables (alone or combined) and subsequent changes in BMI *z*-score. In boys, intake of fruit and fruit juice was not predictive of changes in BMI. Although vegetables intake was inversely related to changes in BMI *z*-score ($p > 0.05$). However, after adjusting for energy intake, the magnitude of the effect was diminished and no longer significant (Field 2003). At 3-year follow-up (8203 girls and 6715 boys aged between 9 and 14 years of age from Boston, MA, USA): after controlling for Tanner stage of development, age, height change, activity and inactivity, there was no relation between intake of snack foods and subsequent changes in BMI *z*-score among the boys ($\beta = –0.004$), but snack foods had a weak inverse association ($\beta = –0.007$, $p > 0.05$) with weight change among the girls. However, the results were confounded by dieting status, which had a significant positive independent association with BMI change. After controlling for dieting status and whether the mother was overweight, the association between servings per day of snack foods and subsequent changes in BMI *z*-score were not significant in either gender.	BMI were also seen among girls who reported higher energy intakes and less PA during the year between the two BMI measurements. BMI decreased overweight children who never ate breakfast but normal weight children do not. From Berkey 2005; Drinking large amounts of milk may provide excess energy to some children.

			From Berkey 2005; Children who reported higher total milk intake experienced larger weight gains; children who drank more 1% and skim milk had larger weight gains than those who drank smaller amounts of 1% and skim; dietary calcium intake was positively correlated with weight gain; and dietary fat was not. The effects of milk and dietary calcium appear to be explained by energy intake; however skim milk in girls remained marginally significant after adjustment for energy intake. From Taveras 2005; Frequency of family dinner and overweight was explored in the cohort. Subjects were classified as eating dinner with parents ‘never or some days’, ‘most days’ or ‘every day’. Whilst cross-sectional data showed children were less likely to be overweight if they ate dinner most days with their family, this relationship was not apparent over 2 years. **Association of physical activity with weight change:** Annual BMI increases were higher in girls with fewer hours of activity (BMI decreased by 0.284 kg/m^2/h per day of activity; $p > 0.05$) during the year between base line and follow-up. Boys who had marginally less PA (–0.0261 kg/m^2 per hour of activity; $p = 0.094$) showed larger annual BMI increases. The number of gym classes per week was not associated ($p > 0.10$) with change in BMI in boys. **Association of other factors with weight change:** Annual BMI increases were higher in girls with more hours of TV/video/games (BMI increased by 0.372 kg/m^2 per hour per day; $p > 0.001$) during the year between base line and follow up. Boys who spent more time with TV/videos/games (0.384 kg/m^2 per hour per day; $p > 0.0001$) showed larger annual BMI increases. Over 2 years, boys had higher means hours of TV/video/games, gym class participation that increased more from the first to the second year, and energy intake that increased more from the first to the second year predicted larger increases in BMI. Boys with higher METs (a way of measuring PA intensity) during the year between the two BMIs had marginally smaller ($p = 0.6$) increases in BMI. **Age:**	

			Among boys <12 years old, those who did more PA in the year between the BMI measurements had smaller annual increases in BMI (–0.0746 ± 0.0212).	
FRAMINGHAM CHILDREN'S COHORT Moore 2003 Proctor 2003 Moore 1995 Prospective cohort Aim: To examine the relationship between physical activity and TV viewing on body fat change during childhood	106 3-5-year olds from the Framingham Children's Study. These are from families who were third or fourth generation from the original Framingham Study Cohort.	Year of baseline survey: 1987 Outcome variable: BMI Duration of follow-up: 8+ years. Self-reported or measured weight: Measured. Statistical analysis: Various, but all used some form of regression analysis.	Attrition: 3% Weight changes: None reported without reference to behaviours. Association of diet with weight change: Children with the highest levels of TV viewing and high fat diets (>34% cals from fat) gained more body fat than children watching least TV and a lower-fat diet (<34% fat cals) gained less body fat by 11 years; mean sum of 5 skinfolds 99mm vs 69mm (data presented graphically). Association of physical activity with weight changes: Subjects were examined annually. Caltrac motion sensors were used to asses physical activity levels. Children were categorised as having low, medium or high activity levels based on average number of counts per hour for each period of recording. These were then averaged over the 8 years of the study. Children in the highest tertile for daily PA, had consistently smaller gains in BMI, triceps and sum of 5 triceps throughout childhood. By 11 years, sum of 5 skinfolds was 95.1mm, 94.5mm and 74.1mm for the low, medium and high tertiles respectively (p-value for trend = 0.045). This relationship was evident for both sexes. Children with the lowest levels of PA and highest levels of TV viewing gained nearly 40 mm of body fat than children with highest levels of PA and least TV by 11 years (data presented graphically). Association of other factors with weight changes: Questionnaires in conjunction with the Caltracs were used to estimate hours of TV viewing and video games per day. TV viewing was divided into tertiles of hours per day: <1.75h, 1.75 to <3.0h, >3.0h. At 11 years, those who watched 3.0h or more per day had a mean sum of 5 skinfolds of 106.2mm compared with 87.6mm for those watching 1.75 to <3.0h, and 76.5mm for those watching least (p = 0.007; p-value for trend = 0.028).	Adjusted for: sex, exact age and baseline BMI, total energy intake, % fat calories, mean PA level, parents age and education. Author's conclusion: Children who were in the highest level of activity showed less acquisition of body fat, whilst those watching most TV showed the greatest gains in body fat.
Bogaert 2003 Prospective cohort 2+	59 Australian children, aged between 6 and 9 years (mean age	**Year of baseline survey:** Not reported. **Duration of follow-up**:	**Attrition:** 31% **Weight changes:** No significant differences were found for initial, height, BMI percentile and	**Adjusted for:** Not reported. **Author's conclusions:**

Aim: To identify whether measures of energy intake and expenditure predict excessive weight gain over time in children.	8.6 ± 0.2 years) **Baseline BMI or weight:** Not reported.	12 months. **Outcome variable**: Weight (kg), BMI **Self-reported or measured weight:** Measured. **Statistical analysis**: Unpaired t test, Pearson's product moment correlation and Spearman's rank order correlation.	BMI z-scores over the 12 months. The boys BMI z-score was 0.3 ± 0.1 and the girls score was 0.5 ± 0.3. Percentage body fat was 18.4 ± 1.2 for boys and 25.8 ± 1.1 for girls, and percentage lean body mass was 81.6 ± 1.2 for boys and 74.2 ± 1.1 for girls. Girls had a significantly lower mean lean body mass ($p > 0.0001$) and a significantly greater mean fat mass than boys ($p > 0.0001$) after 12 months. **Association of diet with weight change:** No significant correlations were shown between BMI over 12 months for any dietary variable (% energy as protein, carbohydrate, fat, saturated fatty acids, monosaturated fatty acids and polyunsaturated fatty acids). **Association of physical activity with weight change:** No significant correlations were shown between change in BMI over 12 months and any measures of energy expenditure, including hours of television viewing or percent time spent in low, moderate or high intensity activity. A significant correlation was found both between mothers and daughters in percent time spent in moderate to high activity ($r = 0.44$, $p = 0.03$), and also between fathers and children for percent time spent in low activity ($r = 0.43$, $p = 0.005$), which suggests that parental activity levels can significantly affect their child's activity levels.	The study was unable to identify environmental predictors that indicate propensity to weight gain over time in this cohort of children, but has extended the evidence on lifestyle-influenced predictors that do. An overall lack of vigorous activity and correlations between parental and child activity and inactivity have been identified.
Kaur 2003 Prospective cohort 2+ **Aim:** To assess the effect of TV viewing on subsequent change in BMI percentiles in adolescence.	12–17 year olds, $n = 2223$, 52% male, 68% White, California, contacted by random-digit dialled computer-assisted telephone interviewing method as part of California Tobacco	**Year of baseline survey:** 1993 **Duration of follow-up**: 3 years **Outcome variable**: Change in age-specific and sex-specific BMI percentiles. **Self-reported or measured weight:** Self-report.	**Attrition:** 65.8% of sample had data for both time points. **Weight changes:** BMI at follow-up (mean [SD]): 22.57 (3.57); BMI% at follow-up (mean [SD]): 53.83 (26.92). **Association of diet with weight change:** **Association of physical activity with weight change:** Hours of TV viewed at baseline (mean/SD): 2.85 (1.98); model of TV at baseline and BMI% at follow-up explained 50% variation in follow-up BMI%; squared partial correlation coefficients were 0.495 for baseline BMI%, 0.008 for baseline TV, 0.003 for ethnicity; therefore nearly 50% variation in follow-	Adjusted for ethnicity and baseline BMI%. **Author's conclusions:** TV viewing leads to increase in BMI percentiles and overweight.

California Teen Longitudinal Survey of adolescents 12–17 years	Surveys. **Baseline BMI (kg/m^2), mean (SD):** 21.00 (3.52) BMI% 55.92 (26.78)	**Statistical analysis**: Multiple regression modelling and logistic regression.	up BMI% explained by baseline BMI%, 1% by TV, 0.3% by ethnicity. Watching >2 hours TV was related to higher odds of being overweight at follow-up among adolescents at normal weight at baseline (OR 1.9; 95% CI 1.1, 3.5) and among adolescents overweight at baseline (OR 2.8; 95% CI 1.3, 6.3). 48% new-onset overweight among adolescents not overweight at baseline was attributable to watching >2 hours TV per day. For each additional hour TV at baseline the average follow-up BMI% increased by 0.5, controlling for ethnicity and baseline BMI%.	
Ambrosius 2001 Prospective cohort 2+ **Aim:** To determine the rate of change in adiposity over time, making comparisons between racial and gender groups.	Healthy children aged 5–20 years (mean 9.5–10.5 years at baseline) recruited from schools in Indianapolis, USA. Schools were chosen to represent a range of SES. Total *n* = 773; 229 White and 157 Black boys, 213 White and 174 Black girls. Over the course of the study, 250 children (102 Black and 148 White) moved from the area, 114 (54 Black and 60 White) dropped out of the study, and 129 (36	**Year of baseline survey:** Study began 1985 and measurements ended in 1999. **Duration of follow-up**: 6 monthly visits; range 2 (6 months) to 26 visits (12.5 years). **Outcome variable**: Change in BMI and subscapular and triceps skinfold thicknesses. **Self-reported or measured weight:** Measured. **Statistical analysis**: Analysis of covariance was used to test for race and sex differences among the subjects at baseline, after adjusting for age.	**Attrition:** Approximately 39%. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change:** **BMI etc changes (units per year):** White (W), Black (B) **BMI (kg/m^2):** W boys (*n* = 229) 0.78; B boys (*n* = 157) 0.97 W girls (*n* = 213) 0.76; B girls (*n* = 174) 0.96 **Subscapular skinfold thickness (mm):** W boys 0.64; B boys 0.74 W girls 0.90; B girls 1.00 **Triceps skinfold thickness (mm):** W boys 0.12; B boys 0.13 W girls 0.70; B girls 0.71 **Waist-to-hip ratio:** W boys –0.0047; B boys 0.0006 W girls –0.0045; B girls 0.0008	Age. **Author's conclusions:** Body fat increases at a faster rate in Black children than in White children. It appears that racial and gender differences in prevalence of obesity originates in childhood.

	Black and 93 white) were lost to follow-up. **Exclusion criteria:** History of renal or cardiac disease, hypertension, diabetes mellitus. **Baseline BMI etc., mean (SD):** White (W) Black (B) **BMI (kg/m^2):** W boys 18.3 (4.7), B boys 20.0 (5.3) W girls 17.8 (3.6), B girls 20.3 (5.8) **Subscapular skinfold thickness (mm):** W boys 8.6 (7.7), B boys 11.0 (8.5) W girls 9.2 (6.2), B girls 13.2 (9.0) **Triceps skinfold thickness (mm):**	A random coefficient model was used for the main analysis.		
			Summary: The rate at which BMI increased in Black children was significantly greater than in the White children ($p > 0.0001$) There were no gender differences in the rate of increase of BMI. Results also presented for other measures of fatness. Supplementary analysis was carried out to examine the rates of change with age and educational attainment.	

	W boys 12.7 (6.8), B boys 13.8 (8.5) W girls 13.9 (5.7), B girls 15.6 (8.1) **Waist-to-hip ratio:** W boys 0.84 (0.07), B boys 0.81 (0.06) W girls 0.76 (0.06), B girls 0.77 (0.07**)**			
O'Loughlin 2000 Prospective cohort 2+ **Aim:** To identify 1- and 2-year predictors of excess weight gain amongst preadolescents.	2318 children at 1 year follow-up aged 9–12 years and 633 children aged 9–11 years with 2 years follow-up in 16 elementary schools located in multiethnic low-income neighbourhoods in Montreal, Canada; high ethnic diversity with 80% parents born outside Canada and 80% fathers unemployed **Baseline BMI:** 18.0–	**Year of baseline survey:** 1993–97 **Duration of follow-up**: 2 years **Outcome variable**: Change in BMI. **Self-reported or measured weight:** Measured. **Statistical analysis**: Multiple logistic regression analyses (dependent variable was whether or not the subject was in the highest age and gender specific decile of change in BMI.	**Attrition:** 57.7% available data at 1 year and 60.2% at 2 years **Weight changes:** Students in top decile of change in BMI increased 2–2.5 BMI units over 1 year compared with 1 BMI unit or less among those at the 50th percentile, over 2 years students in the top decile increased 3–4 units compared with 1–2 BMI units among those at the 50th percentile. **Association of diet with weight change:** **Association of physical activity with weight change:** One year predictors of higher decile of change in BMI included no sports outside school (OR 1.90; 95% CI 1.18, 3.06) in girls. Two-year predictors included no sports outside school (OR 2.14; 95% CI 0.96, 4.77) and least active (OR 2.18; 95% CI 1.01, 4.71) in boys. One year predictors of higher decile of change in BMI included BMI of 90th percentile or more (OR 2.66; 95% CI 1.80, 1.34) in boys and BMI of 90th percentile or more (OR 2.34; 95% CI 1.46, 3.76), and playing video games everyday (OR 2.48; 95% CI 1.04, 5.92) in girls. Two-year predictors included baseline BMI of 90th percentile or more (OR 3.26; 95% CI 1.52, 7.01), and only BMI of 90th percentile or more (OR 2.22; 95% CI 1.02, 4.81) in girls.	Cohort is comparison schools (control schools) in a heart health programme; children lost to follow-up lived in less advantaged families of non-Canadian origin. **Adjusted for:** Age at baseline, grade, year of cohort, school, dependence between observations of same subject (*n* = 549) in 1-year follow-up; **Author's conclusions:**

	20.0 kg/m^2.		**Summary of results:** Baseline BMI was only consistent independent predictor of excess weight gain in all four multivariate models; there were no strong or consistent pattern of associations in either boys or girls for family origin, diet indicators, school sports team or TV viewing	Results suggest need for interventions to promote PA in children.
Spiegelaere 1998 Cohort 2+ **Aim:** To determine whether social inequalities in obese adolescents can be partly explained by differences in the evolution of body mass during the critical period of adiposity rebound.	675 children born 1986–90 attending preventive medical services in Brussels, only Belgium children (immigrant children excluded). **Baseline BMI:** Prevalence of overweight (BMI >95th centile distribution for age and sex) 4.6%.	**Year of baseline survey:** Not reported. **Duration of follow-up**: 3 years (analysed retrospectively). **Outcome variable**: BMI change. **Self-reported or measured weight:** Measured . **Statistical analysis:** χ^2 and Kruskal–Wallis test.	**Attrition:** n/a, convenience sample **Weight changes:** Adiposity rebound (BMI at age 5 years greater than BMI at age 3 years) occurred in 30.4% of the children and did not differ between social groups; 205 of 675 had early adiposity rebound and mean BMI increased by 0.76 (0.82) kg/m^2. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change: Adiposity Rebound** After controlling for BMI at baseline, relationship between social status and presence of an early rebound remained non-significant; In lower socio-economic groups a greater proportion of children had an important increase in BMI between ages 3–5 years (>1.6 kg/m^2, above the 9th decile <0.05) 18.3% lower socio-economic group (active manual workers and not working), 7.1% intermediate social group (active self-employed and technicians) and 7.8% high socio-economic group (upper management and professionals).	**Adjusted for:** Early rebound adjusted for BMI at baseline. **Author's conclusions:** Adiposity rebound before age 5 years was inversely related to body mass at age 3 years and was independent of social status.
French 1996 Prospective cohort 2+ **Aim:** To estimate the change in BMI over 3 years in a cohort of adolescents, dependent on	All students aged 12 to 15 years (UK school years 8 to 10) at baseline in schools in a suburb of Minnesota. Total *n* = 1278 at 3 years; 656	**Year of baseline survey:** Unclear. **Duration of follow-up**: 3 years. **Outcome variable**: BMI. **Self-reported or measured weight:**	**Attrition:** Approximately 16%. **Weight changes:** Not reported separately. *Note:* all associations stated below were significant but modest in magnitude. **Association of diet with weight change:** No analysis.	**Adjusted for**: Fathers occupation, year at school, pubertal status and BMI at baseline. **Author's conclusions:** Self-esteem specific to

baseline self-esteem. Data for this study were collected as part of a longitudinal study on the development of eating disorders.	females and 622 males which represented approximately 84% of children invited to take part in the study. 89% White, 4% other or mixed, 3% Asian American. Approximately 48% fathers and 33% mothers held executive, administrative or professional occupations. **Baseline BMI (kg/m^2), mean (SD):** Males 20.1 (3.7); females 20.5 (3.6) 20.6 % of males and 17.6 % of females were overweight.	Measured. **Self esteem:** The Harter Self-Perception Profile for Adolescents. Pubertal status was assessed. **Statistical analysis**: Prospective relationships between self-esteem at baseline and BMI 3 years later were examined using partial correlations. In addition, a series of logistic regressions were run using overweight status as the independent variable and self-esteem subscales as independent variables.	**Association of physical activity with weight change:** No analysis. **Association of other factors with weight change: self-esteem** Partial correlations between baseline **self-esteem** and BMI 3 years (Table 3 in paper). In females, low physical appearance and low social acceptance self-esteem at baseline were associated with higher BMI 3 years later. In males, baseline self-esteem was unrelated to BMI 3 years later. Analyses examining relationships between baseline self-esteem and overweight status 3 years later showed high close friendship self-esteem in females and high physical appearance self-esteem in males were associated with decreased odds of overweight at 3 year follow-up.	physical appearance is modestly associated with BMI.
Klesges 1995 Prospective cohort 2+ **Aim:** To determine the dietary, PA,	Parents of 146 (110 boys and 93 girls) aged 3–5 years (mean 4.4 years boys, 4.3 years girls) recruited to participate in longitudinal	**Year of baseline survey:** Not reported. **Duration of follow-up**: 3 years (analysed change over 2 years). **Outcome variable**:	**Attrition:** 35 of 203 families at one year and 55 of 203 families at 2 years. **Weight changes:** Adjusted BMI changes over 2 years: Both parents normal weight: boys –0.305, girls –0.230 Father overweight: boys –0.436, girls 0.400 Mother overweight: boys –0.262, girls –0.532 Both parents overweight: boys 0.670, girls –0.230	Participants not told study was to assess predictors of body fat. **Adjusted for:** BMI adjusted for family risk

family history and demographic predictors of relative weight change in a cohort of children.	evaluation of cardiovascular risk development in young children in Memphis, TN, USA. Children had to be natural biological offspring of parents, no physical condition that could effect relative weight, dietary intake or PA. Parents who were married and had no cardiovascular disease and were staying in the area for the following year. Only one child per family. Obese children were over-sampled **Baseline BMI (kg/m^2), mean (SD):** 16.1 (1.4) boys, 16.1 (1.2) girls; 40% overweight (relative weight greater than 75th percentile);	BMI change. **Self-reported or measured weight:** Measured. **Statistical analysis**: Multiple regression analysis (hierarchical and stepwise-selected variables); final regression model resulted in significant equation *F*(13, 119) = 2.71, *p* > 0.0022). BMI, sex, age, family risk and sex by family risk interactions = 9.8% variance. Baseline percentage energy as fat, baseline aerobic activity, change (year 2–3) in percentage energy as fat, change (year 2–3) in leisure activity = 13.1% variance.	BMI increased in girls with fathers overweight and boys with both parents overweight. **Association of diet with weight change:** Higher baseline percentages of energy as fat were associated with greater increases in BMI (0.168 kg/m^2 per 5%) and recent increases (year 2–3) in percentage of intake as fat (0.201 kg/m^2 per 5% change). Neither baseline total energy nor change in total energy increased variance in change in body mass. **Association of physical activity with weight change:** Higher baseline aerobic activity and increased leisure activity from year 2 to 3 were associated with BMI decreases. **Association of other factors with weight change: parental overweight** Boys with both parents overweight had increases in children's BMI (0.67 kg/m^2) and for girls those with just a father overweight showed BMI gains over 2 years (0.40 kg/m^2).	(number parent overweight) baseline BMI, child sex and age and interaction between child sex and family risk. **Author's conclusions:** Modifiable (dietary intake and PA) and non-modifiable factors (age, family history for overweight) were associated with change in BMI in preschool children with largely modifiable factors appearing to be slightly more important.

	45% families had both parents normal weight, 27% father overweight, 17% mother overweight, 11% both parents overweight.			
Robinson 1993 Prospective cohort 2+ **Aim:** To longitudinally examine the relationships between hours of TV viewing and adiposity in female adolescents.	279 adolescent girls, participating in the no-intervention arm of a study about eating disorders. From four schools in California. Mean age 12.37 (SD 0.73) years. 42.7% White, 23.3% Hispanic/Latino. **Baseline BMI (kg/m^2), mean (SD):** 20.33 (3.89)	**Year of baseline survey:** 1989 **Duration of follow-up**: 2 years. **Self-reported or measured weight:** Measured. **Statistical analysis**: All available follow-up data were used to fit subject-specific least-squares regression lines for changes in Sexual Maturity Index (SMI)-adjusted BMI, and SMI-adjusted triceps skinfold thickness (where height and weight were measured, not self-reported). The outcome variable was the slope of these fitted lines. Univariate relations were tested using Spearman	**Attrition:** Unclear. The sample used in the longitudinal analysis was drawn from a total of 536 students who were initially randomised to the no-intervention control group as part of the overall study – suggests attrition of 48%. **Weight changes:** Not reported. **Association of diet with weight change:** No analysis. **Association of physical activity with weight changes:** No analysis. **Association of other factors with weight changes:** Hours of after-school TV viewing did not longitudinally predict change in SMI-adjusted BMI (univariate Spearman $r = 0.03$, $p = 0.62$; multivariate regression co-efficient estimate = 0.05, $p = 0.82$). Hours of after-school TV viewing did not longitudinally predict change in SMI-adjusted triceps skinfold thickness (univariate Spearman $r = 0.03$, $p = 0.54$; multivariate regression co-efficient estimate = –0.19, $p = 0.67$). Reported hours of after-school TV viewing did correlate negatively with PA levels cross-sectionally (Spearman $r = –0.086$, $p = 0.026$) but explained only <1% of the variance. (Regression coefficient estimate = –1.281, $p = 0.043$.)	**Adjusted for:** In multivariate analyses, adjusted for age, race, parent education and parent fatness. TV viewing was measured by asking subjects how much time they spent in 13 different activities after school. While the validity of this method may be questioned, it had good test-retest reliability – over 24 months, r (Spearman) = 0. 37, $p > 0.0001$. **Author's conclusions:**

		correlation. Multivariate relations tested using multivariate logistic regression.		TV viewing was not associated with changes in adiposity, factors such as the content of and responses to viewing, and the family/peer environment may be more important than total viewing hours.
McConahy 2004 Cross-sectional cohort Aim: To evaluate the relationship of dietary behaviours and total energy intake.	5447 children aged 2-5 years who participated in the Continuing Survey of Food Intakes by Individuals.	Year of baseline survey: 1994-1996 Outcome variable: Body weight Duration of follow-up: 2+ years. Self-reported or measured weight: Parental self-report. Statistical analysis: Multiple linear regression.	Attrition: 0% Weight changes: None reported without reference to behaviours. Association of diet with weight change: Portion sizes (mean gramme quantities consumed at an eating occasion) were determined for the top 10 most commonly consumed foods. Z-scores were calculated for quantities consumed by children so data could be entered into the regression analyses. Diet was assessed using two non-consecutive 24h recalls. Body weight, food portion size, number of eating occasions and number of foods accounted for 38% of the variance in 2-3-year-olds and 39% in 4-5-year-olds. Portion size as a single predictor explained 17% of the variance in 2-3-year-olds and 19% in 4-5-year-olds.	Adjusted for: Body weight. Author's conclusion: Feeding recommendations should highlight age appropriate portion sizes and give guidance on frequency of eating and number of foods consumed.

1

EVIDENCE TABLE 2: MAINTAINING ENERGY BALANCE IN ADULTS

2.1 Summary: evidence from reviews

2.1.1 Dietary factors

With regard to the evidence from reviews, Williamson (1996) found that of the eight studies, two of found that total energy intake was positively associated with weight gain (Rissanen et al. 1991; Klesges et al. 1992). In both of these studies a positive association was found only in women. In Klesges et al. (1992) study a higher energy intake by women was directly related to increased weight gain while in men a higher energy intake was associated with decreased weight gain. In Rissanen et al. (1991) total energy intake had a direct association with subsequent weight gain in women only. The significant associations between weight gain and dietary fat intake were also inconsistent. Kant et al. (1995) found that the percentage of total energy intake from fat was positively related to weight gain in men and the association between percentage of energy intake from fat and weight gain was significantly inverse for women. Total fat intake was positively associated with weight gain in women but not men in one study and vice versa in another study.

2.1.2 Physical activity

With regard to the evidence from reviews, Williamson (1996) found three prospective studies that reported results for prospective analyses. Klesges et al. (1992) and Owens et al. (1992) found that women with higher levels of PA gained less weight. Klesges et al. (1992) found that PA was positively associated with weight gain in men whereas another study found no association between weight gain and PA.

Saris (2003) concluded that from13 cohorts reporting PA level (PAL) and weight change, 11 showed an inverse relation between PAL and increase in BMI, body fat, and weight or percent overweight/obese.

2.1.3 Other behavioural, psychological, social and environmental factors

.

2.2 Summary: evidence from individual studies

2.2.1 Menopause (all women premenopausal at baseline)
Five cohorts examined weight change in relation to the menopause in women from the USA, UK, Chile and Japan. MacDonald (2003) analysed 1064 White women in the UK who were premenopausal at baseline and followed for 6 years and found that mean weight increased and was influenced more by reduced energy expenditure than increased energy intake.

Nagata (2002) analysed a cohort of Japanese women for 6 years and found that nutrient intakes were not significantly associated with difference in weight change between premenopausal and postmenopausal women. Exercise (METs [hours per week]) was not significantly associated with difference in weight change between premenopausal and postmenopausal women. Higher number of births was significantly associated with weight gain in premenopausal women, and early age at menarche was significantly associated with weight gain in postmenopausal women; hormone replacement therapy (HRT) use, smoking status, alcohol consumption were not significantly associated with difference in weight change between premenopausal and postmenopausal women.

Blumel (2001) analysed 271 Chilean women for 5 years and found that weight gain was similar in those who did or did not use HRT (non users 4.3 ± 4.8; users 3.5 ± 3.7 kg; ex-users, 3.4 ± 5.8 kg).

The Healthy Women's Study followed 500 US women for 3–4 years and found there were no significant differences in weight gain of women who remained pre menopausal and those who had a natural menopause (2.07 vs. 1.35 kg). Women who took HRT and women who stopped smoking during the menopause had significantly greater weight gain.

The Massachusetts Women's Health study followed 400 women for 3 years and found that menopause transition was not consistently associated with increased weight, reduced exercise and increased alcohol consumption were more strongly related to weight gain than menopause transition.

2.2.2 Pregnancy
Seven cohorts examined weight change and pregnancy. Williamson (1994) followed-up 2547 white women aged 25-45 years over 12 years, from the first National Health and Nutrition Examination Survey. The SPAWN study examined long-term weight development after pregnancy of 1423 women from Stockholm Sweden and had a 15-year follow-up. Olsen's (2003) study consisted of 622 healthy adult women who gave birth to live singleton infants from New York State, USA. Rosenberg (2003) followed a cohort of 1200 African American women for 4 years and the CARDIA study followed more than 5000 African American and White women for 4 years. More than 10,000 women were followed for 10 years as part of the NHANES I and NHEFS (Wolfe 1997) to examine the effect of parity on weight and a small study of women who breast-fed examined the effect of having more than one child on subsequent weight over an 18-month period (Sowers 1998).

Results of the studies show that those who gained more weight or ate more during pregnancy were more likely to retain weight gain after pregnancy.

Williamson (1994) examined 2547 white women aged 25-45 years from the first National Health and Nutrition Examination Survey. The risk of becoming overweight was increased by 60-110% in women having live births over the 12-year study period. Over 12 years average weight gain whilst having children was modest in US white women, but for some women the risks of major weight gain and becoming overweight are increased in association with childbearing.

The SPAWN study followed for 15 years 1400 women who had given birth and found women that started to eat more irregularly retained more weight at 1-year postpartum and women that started to exercise less frequently after their pregnancies retained more weight 1-year postpartum. Most important risk factor identified for sustained weight gain/retention 1 year after delivery was weight increase during pregnancy. No difference between women who became overweight and those who remained normal weight regarding total number of children, number of pregnancies before and after index pregnancy, age at index pregnancy, age at delivery of first child. Women who became overweight had lower lactation scores ($p > 0.05$) ; relatively more subjects of the group that became overweight stopped smoking during pregnancy ($p > 0.01$).

Olson (2003) followed 600 mainly White women in New York for 2 years and concluded that women who reported eating much more food in pregnancy were 2.35 times more likely than women who ate a little more to gain excessive weight (women were asked how the amount of food they ate had changed compared with when they were not pregnant, response categories were 'a lot less food', 'a little less food', 'a little more food' and 'a lot more food'). Less PA (OR 1.68; 95% CI 1.1, 2.6) was significantly related to excessive gestational weight gain. Family income of less than 185% of the federal poverty line (OR 2.59; 95% CI 1.6, 4.2) was significantly related to excessive gestational weight gain. Income was not as important an influence on gestational weight gain among women who reported that they increased their food intake (OR 0.33).

Rosenberg 2003 followed 1200 African American women for 4 years and found that women who had a child during follow-up gained more weight than women who remained nulliparous, and those who had a first child gained more than those who had a second or later child. Weight gain associated with childbearing increased with increasing baseline BMI and was appreciable among heavier women.

The ongoing CARDIA study in 5000 African American and White women found primiparous within both race groups gained 2 or 3 kg more weight during the 5-year period than did nulliparous women. Multipara did not differ from nulliparous in adiposity change in either race group. At each level of parity, Black women demonstrated greater adverse changes in adiposity than did White women.

Analysis of parity amongst women in the NHANES I and NHEFS (Wolfe 2004) showed weight gain from baseline to 10 year follow-up averaged 4.4 kg for White women and 5.5 kg for African American women.

Among White women, after adjusting for baseline parity and other socio-demographic variables, the weight gain for non-employed married metropolitan women averaged 4.2 kg for those with no change in parity, compared with 4.7 kg for those with a parity increase of one child and 7.4 kg for those with a parity increase of two or more children. Among African American women, adjusted for the same variables, weight gain for those with no change in parity averaged 4.9 kg, compared with 7.2 kg for those with a parity increase of one or more.

The probability of substantial weight gain (more than 11.4 kg) also rose with parity increase. White women with a parity increase of two or more were also twice as likely to experience substantial weight gain as those with no change in parity. However, the probability increased only slightly for those with a parity increase of just one. Among African American women, those with an increase in parity were about five times as likely to experience substantial weight gain as those with no parity increase.

Sowers (2004) evaluated 45 women who breast-fed and at 18-month follow-up the average weight losses in the postpartum period were 4.7 kg for cases and 4.4 kg for controls, which was not significantly different.

There was no statistically significant difference between the weight retention patterns of all the women. The average weight retention curve for the cases and controls (further parity vs. one parity) had similar shapes, initially they declined and then began to plateau at about 8–10 months postpartum.

Among the cases, post pregnancy weight following the baseline pregnancy was compared with post pregnancy weight following the subsequent pregnancy. On average, cases weighed 1.3 kg more after the subsequent pregnancy than they weighed following the baseline pregnancy.

2.2.3 Marriage

Two cohorts (Kahn 1990; Rauschenbach 1995) assessed weight change and change in marital status. Rauschenbach (1995) found that women who entered marriage had greater weight change than women who remained married, for men there were no statistically significant relationships between marital change and weight change. In the model to predict weight change none of the interactions were significant; in the model to predict weight gain none of the interactions were significant for women but for men the interaction of education with becoming unmarried was significant ($p = 0.024$) and associated with greater weight gain in more educated that become unmarried.

Kahn et al. (1990) evaluated the effect of marriage on weight in data from the NHANES I and NHEFS. The mean 10-year change in BMI was similar for the men who were not consistently married and for the men who were married at both baseline and follow-up (0.90 vs. 0.80, respectively).

The non-consistently married men had a significantly wider distribution of this weight-change variable. Men who became married during the 10-year interval showed a trend towards a greater gain in BMI when compared with men who were consistently married. Those men whose marriage ended appeared to experience a relative loss in BMI.

The incidence of major weight gain was generally greater for the men who were not consistently married. The incidence of major weight loss was also generally greater for the men who were not consistently married. The mid-range weight outcome was generally more common among men who were consistently married.

2.2.4 Smoking

Six cohorts assessed smoking cessation and association with weight change.

Williamson (1991) examined data from the NHANES I study and found those who quit smoking for more than 1 year experienced a greater mean weight gain and were more likely to experience major weight gain than continuing smokers. Significant weight gain occurs in a minority of those who quit. By the end of the study (10 years), however, the mean body weight of those who had quit increased only to that of those who had never smoked.

Burke (2000) followed 1930 Mexican American (MA) and non-Hispanic Whites (NHW) for 9 years and found the estimated risk of becoming overweight or obese attributable to smoking cessation was only 7.4% in MA and 3.1% in NHW. The Israeli CORDIS study followed 3816 male factory workers and showed that smoking cessation is associated with weight gain which is still apparent 6-years post-cessation. Burnette (1998) analysed smoking cessation within the Healthy Women's study of 500 US women and found that smoking cessation in perimenopausal to postmenopausal women is associated with greater weight gain for up to 2 years.

Kawachi (1996) analysed women who gave up smoking in the Nurses Health Study of 121,700 women for 2 years and found that weight gain was minimised if smoking cessation was accompanied with moderate increase in levels of PA.

Swan (1995) analysed men over 16 years from the US Twin Registry and found quitters were more likely to experience weight gain of 2.3 kg or more, and less likely to experience weight loss, than continuing smokers and non-smokers. Amongst quitters, super-gainers were younger, of lower SES, and differed on a number of health habits before quitting.

2.2.5 Occupation- and work-based cohorts

Eleven cohorts assessed associations with weight change amongst adults in various occupations and work settings.

Dietary factors:

Bazanno (2005) followed 17,881 US male physicians aged 40 to 82, free from disease for 13 years. Based on self-reported data, they found those men consuming ≥1 serving per day weighed less than those never or rarely consuming cereals. The trends at 8 and at 13 years were both significant (p-value for trend = 0.001). Men who ate ≥1 serving per day were 22% and 12% less likely to become overweight at 8 and 13 years respectively, compared with men who never/rarely ate cereals; relative risk 0.78; (95 CI 0.67, 0.91) and 0.88; (95 CI 0.76,1.00) respectively.

During the 12-year follow-up in the Nurses Health study (He 2004), participants tended to gain weight with age, but those with the largest increase in fruit and vegetables had a 24% lower risk of becoming obese compared with those who had the largest decrease in intake. Similar results were observed for changes of fruit and vegetables and separately.

Schulze (2004) followed 51,603 young nurses in the USA and reported a higher intake of sugar-sweetened beverages was associated with a greater magnitude of weight gain, attributed to excessive energy from the drinks and large amounts of rapidly absorbable sugars found in the drinks.

The Health Professionals Follow-up Study (Koh Banerjee 2003) followed 16,587 health professionals in the USA for 9 years and concluded that waist gain may be modulated by changes in *trans* fat and fibre consumption, smoking cessation and PA.

Gerace (1996) reported that fire fighters who ate faster at the station than else where gained 9.9 lb (4.49 kg) by follow-up (1991) compared with those who said their pace did not differ by location, who increased 6.8 lb (3.12 kg) by 1991, while those who did not nibble increased by 6.9 lb ($p > 0.05$).

Men who reported consuming a good diet in the Whitehall II study (four of total of four healthy aspects of diet) had OR 0.73 (95% CI 0.64, 0.84) and for women OR 0.83 (95% CI 0.68, 1.02) (Martikainen 1999).

Physical activity: Gerace (1996) reported that fire fighters self-reported PA levels at baseline were not associated with change in weight ($p > 0.05$). Likewise, the amount of energy in PA reported at baseline was not associated with weight change ($p > 0.05$). Subjects who reported engaging in at least one recreational PA three or more times per week gained 7.2 lb (3.26 kg) compared with less active fire fighters who gained 9.5 lb (4.30 kg) ($p > 0.05$).

Men in the Whitehall II study (Martikainen 1999) who reported moderate and vigorous PA were less likely to experience an increase in BMI (age-adjusted OR of having a gain in BMI >3 kg/m^2 compared with having a BMI gain of 0–3 kg/m^2).

UK men who became non-employed were significantly more likely to be inactive compared with men who remained employed (39.4 vs. 36.7%; 95% CI of the difference 0.1, 5.7) (Morris 1992).

In the Nurses Health Study II, vigorous PA was protective against weight gain. Women who engaged in ≥5 hours per week of vigorous activity gained approximately 0.5 kg less than their inactive peers between 1989 and 1995. Total hours of activity per week (including walking) was not associated with weight change. Physical inactivity was associated with weight change. For each 10 hours per week a women spent sitting at home or at work, she gained approximately 0.11 kg more than her less inactive peers.

Other behavioural, psychological, social, environmental factors: In a 3-year study of 119 Japanese factory workers, Yamada (2001) found that statistically, no significant changes were found for either the entire 8-hour shift group or the age subgroups during 1996–99. Authors concluded 12-hour shift might be associated with unhealthy weight gain in some clean room workers.

In the Whitehall II study of 5000 UK civil servants over 5–6 years (Martikainen 1999) it was found that employment grade was strongly related to BMI gain from age 25 years to phase 3 (about 25 years), the lower the grade the larger the gain in BMI, and adjustment for health behaviours (smoking, alcohol, etc.) reduced the grade differences in BMI gain by about 20%.

Nakamura (1998) studied non-management White collar Japanese men and found that working overtime was associated with increases in BMI and waist-circumference over 3 years (only explains 5% variance) although the associations were weak; eating habits of those working overtime may reflect an intervening effect on anthropometric changes.

Gerace (1996) reported that fire fighters aged 20–29 years gained the most weight over 7 years (11.3 lb [5.12 kg]). Subjects who were married or living as married gained 7 lb (3.17 kg) compared with those who were never married, divorced, separated, or widowed who gained 11.7 lb (5.30 kg) ($p > 0.001$). Black non-Hispanics gained 15.7 lb (7.12 kg) compared with White Hispanics who gained 8.9 lb (4.03 kg) and White non-Hispanics who gained 6.7 lb (3.03 kg) ($p > 0.001$). Fire fighters who smoked at baseline and reported being ex-smokers in 1991 gained 13.0 lb (5.89 kg) compared with all other fire fighters who gained 7.7 lb (3.49 kg) ($p > 0.004$). Ex-smokers who had smoked >20 cigarettes per day gained 16.4 lb (7.43 kg) compared with those who smoked up to 19 cigarettes per day who gained 8.3 lb (3.76 kg). Self-reported stress at baseline was not associated with weight change over the 7-year period ($p > 0.05$). However, those who worried over financial security gained 11.2 lb (5.08 kg) versus non-worriers who gained 7.4 lb (3.35 kg) ($p > 0.005$).

In the Whitehall II study poor health control and poor decision latitude at work were related to body mass gain.

Male employees ($n = 1980$) from the Danish National Work Environment Cohort Study were observed for 10 years (Hannerz 2004). Among the background variables, age ($p \leq 0.0001$) and baseline BMI ($p \leq 0$ 0003) were statistically significant, and the estimates indicated that the tendency to gain weight decreases with age and BMI.

Among the psychological variables, that only ones that interacted significantly with baseline BMI were psychological demand ($p = 0.0108$) and job insecurity ($p = 0.0027$). Obese employees with job insecurity gained more weight than obese employees without job insecurity, whereas underweight employees with job insecurity gained less weight than underweight employees without job insecurity.

A UK study evaluated the effect of unemployment/retirement on weight in middle-aged men (Morris 1992). At initial screening, the mean BMI of men who remained employed was similar to that of men who experienced some non-employment later (25.52 vs. 25.40 kg/m^2, respectively). However, men who later became non-employed were more likely to be underweight compared with men who remained employed (3.8 vs. 2.7%; 95% CI of the difference 0.1, 2.2)

Five years later the mean BMI had risen slightly in both men who had experienced some non-employment (25.40 to 25.71 kg/m^2) and in men who had not (25.52 to 25.77 kg/m^2). The percentage of men who were underweight had fallen 2.7 to 2.0% in men who were employed and 3.8 to 2.3% in men who had experienced unemployment, and the percentage of men who were overweight had risen (8.1 to 8.4% in employed men and 7.9 to 9.4% in men who had experienced non-employment).

Men who experienced some non-employment were less likely to remain a stable weight than men who remained continuously employed. 2.9% of men who experienced some non-employment lost more than 10% in weight and 7.5% gained more than 10% in weight compared with 2.1% and 5.0% respectively of continuously employed men (95% CI of the differenced 0.1, 1.8 for weight loss and 0.9, 4.0 for gain).

The Nurse Health Study II (Field 2004) evaluated the effect of weight loss in female nurses on subsequent weight. During a 2-year period from 1989 to 1991, 2590 (5.5%) women lost 5–9.9% of their 1989 weight and 1326 (2.8%) women lost at least 10% of their 1989 weight. The proportion of women who lost >5% of their baseline weight increased with category of BMI from 3% (5–9.9% weight loss) among women with a BMI <22 kg/m^2 to 9% among women with a BMI >30 kg/m^2 in 1989.

Between 1991 and 1995, approximately 50% of the women had regained all of the weight they had lost. Among those women who had lost >10% of their 1989 weight, the percentage who regained all of their large weight loss between 1989 and 1991 decreased across baseline categories of BMI from 71% among the women with a BMI <22 to 54% among the women with a BMI >30 kg/m^2 in 1989.

Less than 10% of the women who had large clinically significant weight loss between 1989 and 1991 were able to successfully maintain their weight loss. Women who lost greater than or equal to 10% of their weight between 1989 and 1991 gained more weight between 1991 and 1995 than their peers who did not lose weight.

2.2.6 General population

Dietary factors:

Data from the UK 1958 Birth Cohort (Parsons, 2005) reported that a decrease in chip consumption and an increase in fried food consumption was associated with weight gain over a 9-year period in men and women; a decrease in fruit and salad consumption was also associated with weight gain in women only.

Data from a number of other smaller studies found similar relationships. Samuel (2003) reported that a smaller fruit and vegetable consumption, and a greater consumption of sweets, was associated with weight gain in American women over 4 years.

An interesting study from Sweden (Heitmann 1995) found that a high-fat diet was associated with 6-year weight gain in women predisposed to obesity (had a least one fat parent), but not amongst those with lean parents.

Data from a large cohort in Australia (Ball 2002) found that restrictive eating practices and women who reported eating takeaway occasionally were 15% less likely to have maintained their weight over 4 years compared with those who rarely or never ate takeaways. In addition, data from the CARDIA study found similar results.

There was no independent association of frequency of eating with prospective weight change over the preceding 8–10 years in the NHEFS cohort (Kant 1995).

In the Danish MONICA study of 3000 Danish adults (who were evaluated for 5 years retrospectively) night eating was not associated with weight changes for either sex. Obesity did not modify the association between preceding weight change and night eating. Six-years prospective analysis found that for men, night eating was not associated with subsequent weight change. Analysis revealed that obese women with night eating experienced a greater average 6-year weight gain. The total average 6-year weight gain for obese night eating women was 5.2 kg, whereas obese non-night eating women experienced only a 0.9 kg average weight gain.

Nooyens (2005) found that over five years, weight gain and increase in waist circumference in 288 Dutch men aged 50-65 years were associated with a decrease in fruit consumption (p = 0.01) and fibre density of the diet (p = 0.01), and with an increase in frequency of eating breakfast (p = 0.03).

Quatrimoni (2002) found that in 737 non-overweight women from the Framingham Offspring/Spouse cohort, the likelihood of becoming overweight at 12 years follow-up was approximately 29%. The relative risk of developing overweight was RR 1.4; (95 CI 0.9, 2.2) in women who ate an ‘Empty Calorie’ diet that was rich in sweets and fats with fewer servings of nutrient-dense fruits, vegetables, and lean food choices, compared with women who ate a lower-fat, nutritionally varied ‘Heart Healthy’ diet.

Schulz (2005) looked at food patterns and subsequent weight gain nearly 25,000 subjects from the German cohort in the EPIC study. Those with a food pattern of a high consumption of whole-grain bread, fruits, fruit juices, grain flakes/cereals, and raw vegetables, and of low consumption of processed meat, butter, high-fat cheese, margarine, and meat were less likely to gain weight. Mean annual weight gain gradually decreased with increasing pattern score (higher score indicates healthier diet) (p-value for trend < 0.0001), i.e., subjects scoring high for the pattern maintained their weight or gained significantly less weight over time compared with subjects with an opposite pattern. However the prediction of annual weight change by the food pattern was significant only in non-obese subjects, ie dietary patterns predicted weight gain in normal weight subjects by not in those already obese.

Physical activity: Data from the UK 1958 Birth Cohort (Parsons 2005) reported that neither a decrease or increase in PA was associated with weight gain over a 9-year period in men and women. Data from a number of other smaller studies also found no relationship.

However, data from a large cohort in Australia (Ball 2002) found that women who reported moderate or high sitting time were 17–20% less likely to have maintained their weight over 4 years. In addition, a large cohort in America (DiPietro 1998) found that higher baseline levels of PA and lower levels of TV viewing were associated with a lower risk of becoming overweight over a 24-year period. Similar associations were found in other studies (Sundquist 1998; Bell 2001; Droyvold 2004). The PRIME study (Wagner 2004) provided interesting results showing that weight gain over 5 years in a large cohort of men was inversely associated with the amount of PA expended in getting to work, and the practice of high intensity recreational activities.

Nooyens (2005) investigated the effects of retirement on lifestyle and weight and waist circumference in 288 Dutch men. Over five years increases in weight and waist circumference were associated with a decrease in several physical activities, such as household activities, bicycling (p = 0.03), and walking (p = 0.02). Increase in body weight and waist circumference was higher among men who retired from active jobs (0.42 kg per year and 0.77 cm per year, respectively) than among men who retired from sedentary jobs (0.08 kg per year and 0.23 cm per year, respectively).

A small study (Larew 2003) found that lower rates of weight gain over 1 year were associated with greater levels of strength and fitness. Similar results were found in the CARDIA study.

Of note, a study from Sweden (Lissner 1997) found that women’s fat intake was a predictor of 6-year weight gain only amongst women who were sedentary.

Kahn et al. (1990) evaluated the effect of income, education and marriage on weight in data from the NHANES I and NHEFS. The incidence of major weight gain was lowest among men who reported high levels of PA or whose baseline BMI was between 24.0 and 27.8 kg/m^2.

Other behavioural, psychological, social and environmental factors
Viner (2005) UK conducted an analysis of the 1970 British Birth cohort of over 8000 subjects followed up at 5, 10 and 30 years (30 year follow-up self-reported) examining the relationship between television viewing and BMI change. Weekend but not weekday TV viewing in early childhood independently predicted increased adult BMI.

Mean daily hours of TV viewed at weekends predicted higher BMI z-score at 30 years (coefficient=0.03, 95% CI: 0.01, 0.05, P=.01) when adjusted for TV viewing and activity level at 10 years, sex, socioeconomic status, parental BMIs, and birth weight. Each additional hour of TV watched on weekends at 5 years increased risk of adult obesity (BMI > or =30 kg/m2) by 7% (OR=1.07, 95% CI 1.01, 1.13, P=.02). Weekday viewing, type of program and maternal attitudes to TV at 5 years were not independently associated with adult BMI z-score.

Kahn et al (1990) evaluated the effect of income, education and marriage on weight in data from the NHANES I and NHEFS. There was a significant increase in the mean BMI change for men with lower education levels compare with those who had gone beyond 12th grade.

The incidence of major weight gain was generally greater for the men who were not consistently married, among these men there was a higher incidence of major weight gain for those who had lower incomes or lower educational levels. The mid-range weight outcome was generally more common among men who had higher family incomes, or had higher educational levels.

A 7-year follow-up of young US adults in the CARDIA cohort (Greenlund 1996) showed that father's body size was positively associated with participant's baseline BMI among Black men, White men and White women. Mother's body size was positively associated with baseline BMI among all race–sex groups, and with change in BMI among White women. Father's education was inversely associated with baseline BMI among Black men and White women, and with change among White women.

Data from the UK 1946 Birth Cohort (Hardy 2000; Langenberg 2003) and data from the large NHANES I study in USA (Kahn & Williamson 1991) found that weight gain was greatest in Black women, in low income families, and in those with less education. These results were supported by most other studies identified in this review.

Women, but not men, gain weight at the start of marriage and lose weight at the end of marriage (Rauschenbach 1995).

Data from a large cohort in Australia (Ball 2002) found that smoking was significantly associated with a decreased likelihood of maintaining weight over 4 years in women. Data from a large cohort in Norway (Droyvold 2004) also found that those who did not drink alcohol were less likely to gain weight over a 9-year period.

A study (Samuel, 2003) found weight gain in US women over 4 years was associated with those more likely to have a high anxiety score, and those who had a lower average Quality of Life score. A small study (Tiggerman 2004) found the neither dietary restraint nor self-esteem alone predicted weight change over 4 years, but those who put on the least amount of weight over time were those low in dietary restraint and high in self-esteem.

2.3 Evidence of corroboration in the UK

Five of cohorts of adults were conducted in the UK, with the majority conducted in the USA and generalisable to UK adults. There were also cohorts in Japan, Chile, China, Australia, Norway, Sweden, Denmark and France.

UK studies were:

- MacDonald (2003) study of weight and menopause conducted in UK.
- Fifty-three year follow-up of UK men and women assessed associations between childhood weight and SES and weight change (Hardy 2000).
- Parsons (2005) followed all births 3–9 March 1958 in England, Scotland and Wales (16,000) and studied at age 33 and at age 42 years and assessed associations between diet and PA factors and weight change.
- Maartikainen (1999) assessed employment grade and weight change in the UK civil servants.
- Morris (1992) study of unemployment and retirement in men from one GP practice in UK followed for 5 years.

Evidence of implementation not valid for this review as not intervention studies.

REVIEWS OF COHORT STUDIES				
Williamson 1996 (2++) Review of eight cohort studies (1990–95, all at least 12 months follow-up, measuring dietary intake and/or PA) including:				
Colditz 1990 Nurses Health Study	US female nurses in 11 states 31,940 women aged 30–55 years (excluded women diagnosed with coronary heart disease, cancer, diabetes, smokers, on special diets, >15 g alcohol per day, pregnant, at least ten food items blank, total food score implausibly high or low, missing body weight.	**Year of baseline survey:** 1976 **Duration of follow-up:** 8 years **Outcome variable:** Absolute and percent weight change within 2 time periods: 1978–80 and 1980–84. **Self-reported or measured weight:** Self-reported every 2 years from 1976. **Statistical analysis:** • Pearson correlation • Linear regression	**Weight changes:** • From 1976 to 1984: 74% gained weight, 18% lost weight, 8% stayed at same weight. • Mean weight change (kg): 1976–80 +1.9 kg; 1980–84 +1.6 kg • Inverse correlation between weight change in a 2-year period and contiguous 2-year weight change, mean $r = 0.30$. • Weight change correlations involving non-contiguous periods were nearly 0. **Association of diet with weight change:** **Retrospective** (1978–80) weight change regressed on diet in 1980): • Total energy: ß = 0.00025 ($p > 0.0001$). (For every 1000 kcal [4.2 kJ]/day increase, body weight increased 0.25 kg.) • Total fat: ß = 0.0055 ($p > 0.001$). (For every 100 g/day increase, body weight increased 0.55 kg.) **Prospective** (1980–84 weight change regressed on diet in 1980): • Total energy: ß = 0.000021 ($p = 0.67$). • Total fat: ß = 0.0007 ($p = 0.69$). **Association of physical activity with weight change:** Not assessed.	Age, BMI, total energy and prior weight change in 1978–80.
Rissanen 1991	Twelve communities in Finland, 6165 men, 6504 women, aged 25–64 years	**Year of baseline survey:** 1966–72. **Duration of follow-up:**	**Weight change:** • Mean weight change (kg): +0.6 for men, +0.1 for women. • Range: –36 to +42 for men, –40 to +32 for women. • Prevalence of ≥5 kg gain: 18% for men, 15% for women. **Association of diet with weight change:**	Age, BMI, education, marital status, parity, smoking, alcohol, coffee, PA. Measured.

Statistical analysis:
Stepwise regression.</td>
<td>Attrition:
Approx. 30% (123 of 417)

Weight changes:
Mean weight change (kg): 0.265 (4.55) for men, 1.37 (5.89) for women at 2 years.

Association of diet with weight change:
Women:
Total energy, ß = 0.004 ($p = 0.0407$) (for every 1000 kcal [4.2 MJ]/day increase, body weight increased 4 lb [1.8 kg]).
%Energy (fat), ß = 0.527 ($p = 0.0010$) (for every 5% increase in fat, body weight increased 2.6 lb (1.2 kg).
Change in total energy, ß = 0.005 ($p = 0.0289$) (for every 1000 kcals [4.2 MJ]/day increase body weight increased 5 lb [2.3 kg]).
Men:
Total energy, ß = –0.003 ($p = 0.0235$)
Change in fat intake, ß = 0.383 ($p = 0.0216$)
Change in total kcal, ß = –0.002 ($p = 0.1181$)

Association of physical activity with weight change:

Women:</td>
<td>Age, BMI, smoking, alcohol, 'familial risk for obesity', pregnancy.

Stepwise regression may have lead to important confounders being dropped (some results are not intuitive, i.e. increases in energy intake associated with weight gain in men).

Not clear how authors coded work, sports,</td>
</tr>
</table>

			Work ß = –3.54 (p = 0.0939) Sports ß = +3.02 (p = 0.0582) Leisure ß = –6.18 (p = 0.0003) Change in work ß = –5.87 (p = 0.0221) **Men:** Sports ß = +1.86 (p = 0.0920) **Association of other factors with weight change:** cigarette consumption Change in cigarette consumption in women, ß = –0.707 (p = 0.0001). **Summary of results:** Longitudinal regression model explained 32.45 total variability of weight change in women (p > 0.0001) *and* 12% total variability of weight change for men (p = 0.0035). Higher total energy intake at baseline was directly related to subsequent weight gain in women whereas relationship was inverse in men. %Energy from fat at baseline directly related to weight gain only in women. Increased total energy intake was directly related to weight gain in women (increase in 200 kcal (840 kJ)/day for 2 years resulted in 2.206 kg weight gain) and the inverse for men (not significant for men). In men increases in % energy from fat was related to weight gain (5% increases in fat intake over 2 years resulted in weight gain of 0.86 kg). Higher work and leisure activity in women at baseline was associated with lower weight gain and decrease in work activity during follow-up was associated with higher weight gain. In both men and women higher baseline sports activity was associated with increase in subsequent weight gain and higher baseline weight was associated with less weight gain in men and women. Women who became pregnant gained weight and those initially pregnant (5%) lost weight compared with those with no change in pregnancy status. An increase of five cigarettes per day in women resulted in 1.586 kg decrease in weight over 2 years.	leisure. **Author's conclusions:** Different pattern of predictors for weight change for men and women; for women a high dietary energy and fat intake as well as increases in total energy intake were related to higher weight gain and increases in work activity levels were related to decreased weight gain; for men weight gain was predicted by increases in dietary fat intake.

Owens 1992	Women whose names appeared on motor vehicle license data in Allegheny County, Pennsylvania 500 women participated in the study. Age 42–50 years	**Year of baseline survey:** 1983–84 **Duration of follow-up:** 3 years **Outcome variable:** Absolute weight change **Self-reported or measured weight:** Measured **Statistical analysis:** Linear regression	**Weight change:** Mean weight change: +4.9 lb (2.2 kg) **Association of diet with weight change:** Not reported. **Association of physical activity with weight change:** Baseline activity expressed as 'Log kcal/week' • ß = 1.2*9 lb. Women +6.0, 25–34 years old, in lower quintile of % energy as fat. **Smallest mean weight change (kg):** Men –2.7, 65–74 years old, in lower quintile of % energy as fat. Women –3.8, 65–74 years old, in second quartile of % energy as fat. **Association of diet with weight change:** No association found with total energy. Inconsistent associations found with % energy as fat. **Men** (age >50 years) ß = 0.06 (*p* = 0.10) If % energy as fat increases by 10% then weight increases by 0.6 kg. **Women** (age <50 years) ß = 0.05 (*p* = 0.04) If % energy as fat increases by 10% then weight decreases by 0.5 kg. **Association of physical activity with weight change:** Not reported.	follow-up, total energy, BMI, alcohol, special diet status, parity. Models were also stratified by age and by quartile of total energy, non-recreational PA, BMI, and physician-diagnosed morbidity.

Summary of Williamson's conclusions of review:

Results of associations between dietary and PA variables and weight change were inconsistent.

First author, design, aim	Population	Intervention details, length of follow-up	Results	Confounders adjusted for/comments
Saris 2003 (2++) – review of 13 cohort studies (1990–2001 all at least 4 years, estimating PAL and BMI) including:				
Kahn 1997, 1998 **Aim:** To identify behaviours associated with change in BMI	79,236 White, non-Hispanic healthy adults from 21 selected sites initially recruited for Cancer Prevention	**Year of baseline survey:** 1982 **Duration of follow-up**: 10 years **Outcome variable**:	**Attrition:** Unclear. **Weight changes:** 10-year BMI change for men was 0.6 (1.7) and for women was 1.4 (1.9) kg/m^2. **Association of diet with weight change:**	To obtain original studies and ascertain if reported any other factors associated with weight change.

or with weight gain at the waist. Kahn 1997 included in Saris review and Kahn 1998 identified as individual study but included here as same study	Study II in USA, aged between 50–74 years of age at follow-up; analysis excluded subject who were more than 54 years at baseline, regular diuretic use, cancer history other than non-melanoma skin cancer, diabetes, race/ethnicity other than White non-Hispanic, BMI >32 or <18 kg/m^2, or decrease/increase of greater than 8 kg/m^2 in BMI or 3% over 10 years, or misreported height or weight data. **Baseline BMI:** 25.6 (2.6) kg/m^2 for men, 23.4 (3.0) kg/m^2 for women	Change in BMI. **Self-reported or measured weight:** Self-report **Statistical analysis**: Multivariate linear regression (sex-specific) for change in BMI associated with specific behaviours, multivariate unconditional logistic regression for weight gainers vs. non gainers for weight gain at the waist.	Meat consumption greater than 3 days or servings per week was associated with BMI increase, more strongly for men than women, decrease in BMI for people who consumed greater than 19 days or servings per week of vegetables. **Association of physical activity with weight change:** Jogging/running 1–3 hours per week associated with decrease in BMI (0.2 kg/m^2 for men and 0.5 kg/m^2 for women), for men who performed this activity for ≥4 hours per week there was slightly greater decrease in BMI (0.3 kg/m^2); very few women reported jogging/running for more than 4 hours per week ('impossible to show significant effect'). Aerobics/callisthenics for men at any level was associated with BMI reduction similar to finding for men's jogging/running; for women there was a BMI decrease associated with aerobics/callisthenics performed at least 4 hours per week but not 1–3 hours per week. Tennis/racquetball associated with significant decrease in BMI for women at least 1–3 hours per week but no mean effects on BMI change for lap swimming, bicycling/stationary bike, or dancing. No significant effect on BMI change for heavy housework/vacuuming or heavy home repair/painting, but gardening/mowing/planting was associated with decreases in BMI for men at ≥4 hours per week and for women at ≥1 hours per week (0.1 kg/m^2 both sexes). Walking was highly prevalent activity but no significant effect found on BMI change for persons walking 1–3 hours per week, people who walked ≥4 hours per week experienced small significant decrease in BMI (twice as much for women). Women showed the greatest loss in BMI following PA. In men, those who did gardening or mowing for between 1 and 3 hours per week showed an decrease of –0.03 kg/m^2 while those who did 4 hours showed an decrease of –0.11 kg/m^2 in BMI. Men who walked for between 1 and 3 hours per week showed an increase of +0.01 kg/m^2 and those who did more than 4 hours showed an decrease of –0.8 kg/m^2.	**Adjusted for:** Age, education, BMI at baseline, slope of BMI between 18 years age and baseline, marital status, four regions of the country, estimated total daily energy intake in 1992, smoking, diet, PA and other behavioural characteristics, for women model also adjusted for parity, menopausal status and oestrogen replacement therapy. **Author's conclusions:** Ten-year change in BMI associated positively with meat consumption and smoking cessation and inversely with vegetable consumption, vitamin E

			For women, those who did between 1 and 3 hours of gardening/mowing showed an decrease of –0.09 kg/m^2 and for those who did >4 hours showed an decrease of –0.14 kg/m^2. For those who did between 1 and 3 hours of walking per week showed no change (0.00 kg/m$^{2)}$ and those who did >4 hours showed an decrease of –0.16 kg/m^2 in BMI. **Association of other factors with weight change:** • Vitamin E supplementation ≥100 IU (67 mg α-tocopherol equivalent)/day was associated with BMI decrease of about 0.1 kg/m^2 for men and women; people who continued to smoke experienced modest decrease in BMI (0.2 kg/m^2 for men and 0.3 kg/m^2 for women). The largest mean effect on 10-year BMI was associated with smoking cessation, in comparison with those who did not smoke, quitters experienced an increase of 1.0 kg/m^2. • Men who regularly consumed beer there was a decrease in BMI of 0.1 kg/m^2 but no effect associated with wine or liquor; for women who regularly consumed any form of alcohol experienced a decrease in BMI that was most marked for beer (0.4 kg/m^2) and least marked for wine (0.1 kg/m^2). • Men's likelihood of weight gain at the waist was positively associated with the Household Inequality Index (HII) (*p* = 0.0008), men with a high HII (households above the median receive 81.6 to 82.6% of the income) described weight gain at the waist more often than men from states with a low HII (households above the median receive 77 to 78.5% of the income), OR = 1.12, 95% CI 1.03, 1.22); women's results showed non significant trend in same direction.	supplementation, continued smoking and some vigorous activities. Women's BMI decreased with walking ≥4 hours per week and with regular alcohol intake but these behaviours had smaller effect on men's BMI; also results for waist circumference gain reported in paper. **Conclusion from Saris review:** The main effect of PA had a positive effect of weight gain.
Lee et al. 1993 **Aim:** To investigate body weight and mortality in middle-aged men.	17321 male adults (mean age 46 years) who were Harvard alumni, USA.	**Year of baseline survey:** 1962 **Duration of follow-up:** 12–16 years **Self-reported or measured weight:** BMI	**Association of physical activity with weight change:** No relationship between total or vigorous activity and BMI.	The main effect of PA on weight level of the subjects was non-significant.

</table>

the association between LTPA and 10-year body mass change among working aged men and women.		10 years **Outcome variable**: Body weight (kg). **Self-reported or measured weight:** Not reported. **Statistical analysis**: Not clear.	Men who did weekly light intensity PA had a 2.7 kg weight increase while women showed a 3.0 kg increase. Men who took part in vigorous PA once per week plus light PA showed an increase of 3.0 kg while women showed a 2.8 kg increase. Finally, men who took part in vigorous PA two or more times per week showed a 3.2 kg weight increase while women showed a 3.1 kg increase. NB: All activities including unusual jogging, aerobics and tennis significantly inversely related to weight gain	The main effect of PA had a positive effect of weight gain.
Thune et al. 1998 **Aim:** This was part of the Tromso study, which investigated the effect of PA on metabolic risk profiles in men and women	5220 men and 5869 women from the USA, aged between 20 and 49 years.	**Year of baseline survey:** 1982 **Duration of follow-up:** 7 years. **Outcome variable**: BMI **Self-reported or measured weight:** Self-reported. **Statistical analysis**: Not clear.	**Association of physical activity with weight change:** Sustained high or increased PA was associated with less weight gain during follow up period. Men who were sedentary had a BMI of 25.7 kg/m^2, those who did moderate amounts of PA had a BMI of 25.0 kg/m^2, those who did hard levels of PA had a BMI of 24.5 kg/m^2 and those who did very hard had a BMI of 23.9 kg/m^2. Women who were sedentary had a BMI of 23.6 kg/m^2, those who did moderate PA had a BMI of 23.5 kg/m^2 and women who did hard PA had a BMI of 23.1 kg/m^2.	Statistical adjustments were made for age, smoking, coffee, dietary fat and menopausal status. The main effect of PA had a positive effect of weight gain.
Coakley et al 1998 **Aim:** This was part of the Health professionals follow-up study which looked at predictors of weight change in men.	10,272 males from the USA, aged between 44 and 54 years.	**Year of baseline survey:** 1986 **Duration of follow-up:** 4 years **Outcome variable**: Body weight (kg). **Self-reported or measured weight:**	**Association of physical activity with weight change:** Those who did more vigorous leisure-time PA (LPTA) showed the smallest increases in body weight. **Weight change**: 44–54 years old, mean weight at 4 years follow-up: 82.6 kg (increase of 1.4 kg). 55–64 years old, mean weight at 4 years follow-up: 81.4 kg. >65 years old, mean weight at 4 years follow-up: 78.4 kg (decrease of 0.2 kg). Overall mean weights at 4 years follow-up: 81.5 kg (increase of 0.8 kg). **Association of diet with weight change:**	Statistical adjustments were made for age, diet, smoking, baseline values (including PA and TV use), weight, height, blood pressure and cholesterol. **Authors'**

		Self-reported. **Statistical analysis**: Multivariate regression analyses.	Eating between meals was associated with weight gain. Recently being on diet was more strongly associated with weight loss among older men. **Association of physical activity with weight change:** Those who decreased their vigorous LTPA by 1.5 hours a week showed a 1.7 kg weight increase. Those who maintained less than 1.5 hours of vigorous LPTA per week showed a 1.1 kg increase in body weight while those who maintained over 1.5 hours of vigorous LPTA showed an increase of 0.8 kg of body weight. Finally, those who increased their vigorous LPTA to >1.5 hours showed an increase of only 0.2 kg of body weight. Vigorous activity was associated with weight reduction and TV/video viewing with weight gain. The prevalence of obesity among middle-aged men was lowest among those who maintained a relatively high level of vigorous PA, compared with those who were relatively sedentary. **Association of other factors with weight change (please state factors):** Quitting smoking and a history of voluntary weight loss prior to the study period were consistently related to weight increase. Middle-aged men who increased their exercise decreased their TV viewing and stopped eating between meals, lost an average weight of 1.4 kg, compared with a weight gain of 1.4 kg among the overall population.	**conclusions:** increasing vigorous activity, as well as decreasing TV use and changing eating habits, results in weight maintenance or a modest weight loss over 4 years.
Wier et al. 2001 **Aim:** To determine the amount of PA needed for long-term weight control.	341 males, with a mean age of 42.1 years and 155 females with a mean age of 36.1 years who were all employees from the NASA space centre in the USA.	**Year of baseline survey:** 1990 **Duration of follow-up:** 5.5 years for males and 4.9 years for females. **Outcome variable**: Body weight (kg). **Self-reported or measured weight:** Not stated. **Statistical analysis**:	**Association of physical activity with weight change:** Average weight gain progressively limited for both males and females at levels of PA. Men who were inactive showed a 1.7 kg increase in body weight while women showed an 8.8 kg increase. Moderately active men showed a 1.3 kg increase in body mass while women showed a 1.1 kg increase. Active men showed a 0.5 kg increase in weight while women showed a 0.7 kg increase. Very active men showed a 1.3 kg decrease in body weight while women showed a 3.1 kg body weight decrease.	Statistical adjustments were made for age and initial weight as well as time elapsed. The main effect of PA had a positive effect of weight gain.

		not stated		
Ball et al. 2001 **Aim:** This study looked at the associations of PA with body weight and fat in men and women.	1301 male and females aged 18–78 years from Australia.	**Year of baseline survey:** 1990 **Duration of follow-up:** Not stated. **Outcome variable**: % Overweight. **Self-reported or measured weight:** Self-reported. **Statistical analysis**: Not stated.	**Association of physical activity with weight change:** The percentage of males overweight was higher than the percentage of women overweight regardless if they were sedentary, had low levels of PA or high levels of PA. 50% males who were sedentary were overweight while only 35% of sedentary females were overweight. 42% males who were had low levels of LTPA were overweight while 27 % of women who had low levels of LTPA were overweight. 34% of males who had high activity LTPA levels were overweight while only 20% of women who had high levels of LTPA were overweight.	The main effect of PA had a positive effect of weight gain.
Summary of Saris's conclusions of review: 30 min of exercise is insufficient to prevent weight gain for many individuals. Between 45–60 min or 1.7 PAL per day of moderate intensity exercise is required to prevent the transition of being overweight to obese; this is likely to be more for children.				
INDIVIDUAL COHORT STUDIES: MENOPAUSE				
First author, design, aim	**Population**	**Intervention details, length of follow-up**	**Results**	**Confounders adjusted for/comments**
MacDonald 2003 Prospective cohort 2+ **Aim:** To investigate whether energy intake or energy	1064 initially premenopausal White women aged 45–54 (mean 48 years) years selected from a randomly selected osteoporosis screening programme in	**Year of baseline survey:** 1993 **Duration of follow-up**: 6.2 (0.6) years **Outcome variable**: Mean weight change. **Self-reported or measured weight:**	**Attrition:** 85.2% (*n* = 907) women returned for follow-up of which 898 completed questionnaires **Weight changes:** Difference weight (kg): premenopausal (*n* = 51) 3.08 (4.45), perimenopausal (*n* = 117) 3.68 (5.29), postmenopausal (*n* = 328) 3.02 (5.32), past HRT use (*n* = 115) 4.41 (5.19), present HRT use (*n* = 284) 2.99 (4.63). **Association of diet with weight change:** Alterations in dietary intake had small but significant effect (0.6%,	**Author's conclusions:** Mean weight had increased and was influenced more by reduced energy expenditure than increased energy intake, HRT and dietary

expenditure affects 5–7-year weight gain in perimenopausal and early postmenopausal women and whether HRT use or dietary calcium intake are contributory factors.	Aberdeen, Scotland, not on HRT at baseline or suffering from any condition or taking any medication that would interfere with bone metabolism. **Baseline BMI:** 24.6 (4.0) kg/m^2.	Measured. **Statistical analysis**: Multiple regression analysis.	*p* = 0.013). **Association of physical activity with weight change:** Changes in PAL influenced weight change explaining 4.4% (*p* = 0.001) of the variation. **Association of other factors with weight change: calcium intake** Dietary calcium intake had no effect on weight or weight change; including menopausal status and HRT use as variables in the regression did not add significantly to the model.	calcium intake did not influence weight gain.
Nagata 2002 Prospective cohort 2+ **Aim:** To evaluate the effect of menopause on weight change in Japanese women.	828 Japanese premenopausal women aged 40–54 years randomly selected from women participating in Takayama study; excluded menopause by surgery (*n* = 25), or by radiation/medication (*n* = 9) those who did not report weight (*n* = 16) or menopausal status (*n* = 1), reported history of cancer (*n* = 2). **Baseline BMI:** (adjusted for age at baseline)	**Year of baseline survey:** 1992 **Duration of follow-up**: 6 years. **Outcome variable**: Change in weight (kg). **Self-reported or measured weight:** Self-report (intraclass coefficients between self-report and measured weight of women in another sample form Takayama study) was 0.97. **Statistical analysis**: Regression model.	**Attrition:** 81% response rate. **Weight changes:** Weight gain (kg) (adjusted for age and weight at baseline) premenopausal at follow-up: 0.41 (SE 0.18); postmenopausal at follow-up: –0.18 (SE 0.19); years since menopause at follow-up 1–2 years: –0.26 (SE 0.29); ≥3 years: –0.04 (SE 0.25). Weight gain was significantly higher in women who remained premenopausal at follow-up compared with those who had natural menopause; weight change was less in women who were postmenopausal more than 2 years than those in first or second year of menopause but the difference was not significant. **Association of diet with weight change:** Nutrient intakes were not significantly associated with difference in weight change between premenopausal and postmenopausal women. **Association of** physical activity **with weight change:** Exercise (METs × hours per week) was not significantly associated with difference in weight change between premenopausal and postmenopausal women. **Association of other factors with weight change: number of births, age at menarche** Higher number of births was significantly associated with weight gain in	**Adjusted for:** Age and weight at baseline and menopausal status at follow-up. **Author's conclusions:** Reproductive factors rather than sociodemographic factors and behavioural factors appeared top be associated with weight change during the perimenopausal period; onset of menopause may diminish weight gain whereas early menarche and

	premenopausal at follow-up: 22.4 (SE 0.15); postmenopausal at follow-up: 22.2 (SE 0.15); years since menopause at follow-up 1–2 years: 22.4 (SE 0.23); ≥3 years: 22.0 (SE 0.21).		premenopausal women, and early age at menarche was significantly associated with weight gain in postmenopausal women. HRT use, smoking status, alcohol consumption were not significantly associated with difference in weight change between premenopausal and postmenopausal women.	high parity showed relationships with weight gain.
Blumel 2001 [524] Prospective cohort 2+ **Aim:**To evaluate the influence of menopause on weight and the effect of weight gain on coronary risk factors	271 Chilean premenopausal women (not receiving HRT) aged between 40 and 53 (mean 45.3) years. **Baseline BMI or weight:** Mean weight and BMI for 40–44-year-olds: 60.9 ± 10.1 kg and 25.3 ± 3.5 kg/m^2, 45–49-year-olds: 63.7 ± 8.6 kg and 26.3 ± 3.8 kg/m^2, 50–54-year-olds: 65.1 ± 9.7 kg and 27.3 ± 4.4 kg/m^2.	**Year of baseline survey:** 1991–92 **Duration of follow-up**: 5 years **Outcome variable**: Weight (kg), BMI. **Self-reported or measured weight:** Measured. **Statistical analysis**: Kruskall–Wallis test, Bartlet test and the χ^2 test.	**Attrition:** 57% **Weight changes:** Women showed a weight gain of 4.0 ± 4.6 kg ($p > 0.0001$) and an increase in the BMI of 1.7 ± 2.4 kg/m^2 (from 25.9 ± 3.8 to 27.6 ± 4.1 kg/m^2, $p > 0.0001$). The percentage of overweight and obese women increased from 54.2% observed in 1991–92 to 70.9% ($p > 0.0001$). The risk of obesity (BMI >30 kg/m^2) by the end of the study depended on the initial BMI: only 1.6% of women with BMI <25 kg/m^2 at baseline were obese at follow up, whereas 28.6% of those who were overweight at baseline were obese at follow-up and 91.4% of those who were obese at follow-up. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change: HRT use** Weight gain was similar in those who did or did not use HRT (non users, 4.3 ± 4.8 kg; users 3.5 ± 3.7 kg, ex-users, 3.4 ± 5.8 kg).	**Adjusted for:** Not reported. **Author's conclusions:** During the perimenopausal period there is a weight gain that does not seem to depend on the menopause.

<td>Wing 1991

Prospective cohort
2+

Healthy Women Study. (two papers).

Three main aims:
1) To describe the weight changes that occurs in a sample of healthy women at time of menopause;

2) To determine whether change in weight is related to change in CHD risk factors during the menopausal period;

3) To identify specific variables associated with weight gain to help determine which individuals are</td>
<td>485 women aged between 42 and 50 years old and menstruated within the past 3 months, had no surgical menopause, a diastolic blood pressure less than 100 mmHg, and not to be taking lipid-lowering drugs, insulin, thyroid medication, estrogens, antihypertensive drugs or psychotropic drugs.

Baseline BMI/weight:
See results table.

Burnette 1998
541 menopausal women from Pittsburgh who were non smokers, ex-smokers or smokers

Baseline BMI or weight:</td>
<td>Year of baseline survey:
1983–84

Duration of follow up:
3–4 years (depending on when baseline measurements were taken for Wing, 2 years for Burnette).

Outcome variable:
Weight (kg, lb) and BMI.

Self-reported or measured weight:
Measured.

Statistical analysis:
Regression analyses (Wing) chi square (Burnette).</td>
<td>Wing 1991

Attrition:
11%

Weight changes:
Women gained a mean of 2.25 kg during follow-up. The SD for weight gain was 4.19 kg with a range from a 14.85 kg loss to a 32.4 kg gain. 20% of the women gained ≥4.5 kg, while only 3% lost ≥4.5 kg.

The table below shows changes in weight, BMI and skinfold thicknesses in premenopausal, perimenopausal and postmenopausal women:

<table>
<tr><th>Measurement</th><th>Premenopausal</th><th>Perimenopausal</th><th>Postmenopausal</th></tr>
<tr><td>Baseline weight (kg)</td><td>64.8 ± 11.9</td><td>67.2 ± 12.6</td><td>68.8 ± 13.9</td></tr>
<tr><td>Change in weight (kg)</td><td>2.1 ± 4.1</td><td>2.5 ± 3.3</td><td>1.4 ± 4.9</td></tr>
<tr><td>BMI at baseline (kg/m^2)</td><td>24.34 ± 4.17</td><td>24.85 ± 4.62</td><td>26.01 ± 5.33</td></tr>
<tr><td>Change in BMI (kg/m^2)</td><td>1.09 ± 1.63</td><td>1.29 ± 1.28</td><td>0.98 ± 1.95</td></tr>

</table>

From the table, it is possible to see there were no significant differences in weight gain of women who remained pre menopausal and those who had a natural menopause (2.07 vs. 1.35 kg)

Association of diet with weight change:
No analysis.

Association of physical activity with weight change:
No analysis.

Association of other factors with weight change:
<i>Hormone therapy:</i> Women who took hormone therapy appeared to be greater than that seen in other groups. These women had significant</td>
<td>Adjusted for:
Not reported.

Author's conclusions:

(Wing):
Weight gain is a common occurrence for women at menopause.

Authors' conclusions: (Burnette)
Smoking cessation in perimenopausal to postmenopausal women is associated with greater weight gain but appears to be modestly associated with certain positive changes in cardiovascular risk factors.</td>
</tr>
</table>

at risk of gaining weight at menopause **Burnette 1998** To investigate the relationship between smoking cessation, subsequent weight gain and cardiovascular disease risk factors from premenopause to postmenopause.	Non-smokers mean weight 147.08 ± 27.72 lb (66.7 ± 12.6 kg); all smokers mean weight 143.67 ± 30.51 lb (66.5 ± 13.8 kg). Smokers who continued through second year post menopause mean weight 143.81 ± 30.46 lb (65.2 ± 13.8 kg). Smokers who reported quitting at years 1 and 2 post menopause mean weight 143.09 ± 31.18 lb (64.9 ± 14.1 kg).		increases in weight ($p > 0.0001$), BMI ($p > 0.0001$), triceps skinfold thickness ($p > 0.0001$) and suprailiac skinfold thickness ($p > 0.05$). *Smoking:* In non-smokers ($n = 339$) the mean weight gain during the 3 years of follow up was 2.12 ± 4.05 kg. Weight gain in women who were premenopausal ($n = 202$) averaged 2.21 kg; in those who were perimenopausal ($n = 67$), weight gain averaged 2.30 kg; in postmenopausal women at follow up ($n = 33$), weight gain averaged 0.63 kg. Women who took hormone therapy ($n = 20$) gained 2.30 kg and those who had never had a hysterectomy ($n = 17$) gained 3.11 kg. Changes over time were significant ($p > 0.0001$), although they did not significantly differ among the various menopausal statuses of women. **Burnette 1998** **Attrition:** 8% **Weight changes:** *First-year post menopause:* significant group effects were found for weight; after-baseline quitters gained significantly more weight ($n = 28$, mean 11.36 lb [5.1 kg]) than non-smokers ($n = 297$, mean 5.32 lb [2.4 kg]) and continuing smokers ($n = 91$, mean 5.45 lb [2.5 kg]). *Second-year post menopause:* after baseline quitters experienced significantly greater weight gain ($n = 26$, mean 14.43 lb [6.5 kg]) than non-smokers ($n = 265$, mean = 7.69 lb [3.5 kg]). **Association of other factors with weight change: smoking** NB: Quitters had significantly greater decrease in alcohol consumption than non-smokers and continuing smokers.	
Crawford 2000 Prospective cohort 2+ Massachusetts Women's Health Study **Aim:**	418 women aged between 50–60 years from MA, USA **Exclusion criteria:** Subjects must have had an intact uterus, at	**Year of baseline survey:** 1986 **Duration of follow-up**: 3 years. **Outcome variable**: Weight (kg) and BMI. **Self-reported or**	**Attrition:** 22.4% **Weight changes**: Mean change in weight between annual consecutive interviews was small, ranging from 0.2 kg to 0.04 kg and was not significantly different from zero at any follow up. The percentage of women with stable weight (annual change of no more than 1 kg) rose from 25.9% at year 1 follow-up and 34.9% at year 3 follow-up. 20.4–25.1% of subjects at an interview were over weight and another 18.2–	**Adjusted for:** Baseline weight. **Author's conclusions:** Menopause transition was not consistently associated with increased weight, exercise

To investigate weight gain linked to the menopause.	least one ovary, and at first contact no more than 11 consecutive months of amenorrhoea. **Baseline BMI or weight:** Mean weight of subjects 72.2 kg, mean BMI 27.6 kg/m^2. 22.6% of subjects overweight (BMI 27.3–32 kg/m^2). 20.2% of subjects obese (BMI >32 kg/m^2).	**measured weight:** ***measured*** **Statistical analysis**: Multivariate linear regression.	21.7% were obese. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** Exercise: change in exercise was significantly related to adjusted log weight (p = 0.04), with higher adjusted log weight among women who ceased exercising. **Association of other factors with weight change (please state factors):** *Smoking:* Adjusted weight was higher among women who stopped smoking compared with continuing smokers (p = 0.04), although smoking change as a whole was not significant (p > 0.05). *Alcohol:* Higher alcohol consumption at a previous contact and a larger increase in ethanol consumption between annual contacts also were marginally significantly related to higher adjusted weight (p = 0.07–0.08).	and alcohol were more strongly related to weight than menopause transition.
INDIVIDUAL COHORT STUDIES: PREGNANCY				
First author, design, aim	**Population**	**Intervention details, length of follow-up**	**Results**	**Confounders adjusted for/comments**
Williamson 1994 Prospective cohort Aim: To examine the effect of childbearing on weight change	2547 white women aged 25-45 years who were initially weighed in the First National Health and Nutrition Examination Survey (NHANES) (n = 3699).	Year of baseline survey: 1971-1975 Duration of follow-up: 10+ years Outcome variable: Measured. Self-reported or measured weight: Measured.	Attrition: 31% Weight changes: Estimated weight gain for women who did not have any live births during the study period (n = 2239) was 3.8 kg. Association of diet with weight change: None reported Association of physical activity with weight change: None reported Association of other factors with weight change: pregnancy	Adjusted for: Duration of follow-up, age, BMI, initial parity, education, and other lifestyle behaviours. Author's conclusions: Generally the risk of weight

		Statistical analysis: Linear and logistic regression	Compared to parous women who did not give birth during the study period, the mean excess weight gain was 1.6 kg (95 Confidence Limits, +/- 2.3 kg) for nulliparous women, and was 1.7 kg (+/- 1.1 kg), 1.7 kg (+/- 2.0 kg), and 2.2 kg (+/- 4.3 kg), for women having one, two and three live births, respectively. Among women who were nulliparous at baseline, those that had their live births during the study period gained similar amounts of weight to that of women who began childbearing before the beginning of the study. The risk of gaining more than 13 kg was increased by 60% for women having one live birth and by 40%for women with two live births. The risk of becoming overweight (BMI >27.3) was increased by 60% and risk of becoming severely overweight (BMI>30) was 110% in women having live births during the study.	gain was modest, but for some women the risks of major weight gain and becoming overweight were increased in association with childbearing.
Wolfe 1997 **Design:** Prospective cohort NHANES 1 (1971–75) and NHEFS (1982–84) **Aim:** To examine how the relationship between parity increase and weight gain is modified by socio-demographic and behavioural factors.	2952 adults (2534 White women and 418 African American women) aged 25–45 years residing in the contiguous 48 US states participated in NHANES 1 and were systematically followed up in the NHEFS. Mean baseline weight for White women = 64.3 kg. Mean baseline weight for African American women = 71.3 kg.	**Year of baseline examination and questionnaire:** 1971–75 **Duration of follow-up:** Approximately 10 years. **Outcome variable:** Parity associated weight gain. **Self-reported or measured weight:** Measured within a personal interview and medical examination. **Statistical analysis:** Multiple linear regression analysis Eight socio-demographic covariates and their interactions with parity	**Attrition:** Not mentioned **Weight changes:** Weight gain from baseline to follow-up averaged 4.4 kg for White women and 5.5 kg for African American women. Among White women, after adjusting for baseline parity and other socio-demographic variables, the weight gain for non-employed married metropolitan women averaged 4.2 kg for those with no change in parity, compare with 4.7 kg for those with a parity increase of one child and 7.4 kg for those with a parity increase of two or more children. Among African American women, adjusted for the same variables, weight gain for those with no change in parity averaged 4.9 kg, compared with 7.2 kg for those with a parity increase of one or more. The probability of substantial weight gain (more than 11.4 kg) also rose with parity increase. White women with a parity increase of two or more were also twice as likely to experience substantial weight gain as those with no change in parity. However the probability increased only slightly for those with a parity increase of just one. Among African American women, those with an increase in parity were about five times as likely to experience substantial weight gain as those with no parity increase.	**Adjusted for:** Baseline height, the square of the subject's age to adjust for the curvilinearity of the relationship between body weight and age, and the number of years between the baseline and follow-up measurements as a control for the duration of opportunity for weight change. **Author's conclusions:** The effects of socio-demographic and behavioural factors on

		change in relation to weight gain were examined, these included; baseline weight, baseline parity, baseline age, employment status at baseline, marital status at baseline, rural versus metropolitan residence, family income at baseline and educational level at baseline. Three behavioural variables and their interactions with parity change in relation to weight gain were examined. These included cigarette smoking, recreational exercise and non-recreational PA.	For Whites, a parity increase of two or more was associated with greater weight gain in women with higher baseline weight compare with those with lower baseline weight, in non-employed compare with employed women and in non-married compare with married women. Smoking also interacted with parity increase in its effect on weight gain in White women, but with mixed results. Among women with a parity increase of two or more, smokers gained less additional weight (when compare with women with no parity increase) than non-smokers, but among women with a parity increase of just one, smokers gained much more additional weight. Among African American women, a parity increase of one or more was associated with greater weight gain in women with lower baseline weight, in those with lower incomes and in non-smokers. Smokers in this group not only gained less than non-smokers, but they also gained far less than smokers with non-parity increase. Among White women, being not employed, unmarried, in a rural residence, with lower educational attainment, having fewer children at baseline and having a higher level of non-recreational PA at baseline, all increased the probability of gaining more than 11.4 kg given an increase in parity of two or more. Younger age increased the probability given an increase in parity of one. Among African Americans, the effect of a parity increase of one or more on the probability of gaining >11.4 kg was similar to a parity increase of two or more among Whites. Those with lower educational attainment and fewer children at baseline were more likely to have a substantial weight gain. Older women were more likely to experience substantial weight gain with an increase in parity then were their younger counterparts.	parity-associated weight gain varied by race and parity change, with the most consistent findings being that unmarried and unemployed White women had greater parity associated weight gain, while both White and African American women who smoked, had higher education, or higher parity had lower parity associated weight gain.
Sowers 1998 **Aim:** To compare the weight changes in lactating women within an 18-month inter-	The 25 cases and 20 controls were recruited from a parent population comprised of 115 women, aged 20–40 years and 0–1 parity, who	**Year of baseline examination and survey:** Not stated. **Duration of follow-up:** Evaluation included six measurements in the postpartum period at	**Attrition:** 100% – no dropouts **Weight change:** The average weight loss in the postpartum period was 4.7 kg for cases and 4.4 kg for controls, which was not significantly different. There was no statistically significant difference between the weight retention patterns of all the women. The average weight retention curve for the cases and controls had similar shapes, initially they declined and then	**Adjusted for:** Energy intake, energy expenditure and weight gain during the subsequent gestational period.

pregnancy interval with women who also breastfed but did not have an immediate subsequent pregnancy.	were enrolled in a previous bone mass and lactation study. Cases were women who breastfed an index infant for 6-months and subsequently became pregnant within 18-months. Controls were women who also breastfed an index infant for 6-months but had no ensuing pregnancy within 18 months. Mean age = 29.3 years. Mean BMI prior to pregnancy = 22.2 (range, 16.9 – 33.8) kg/m^2. Mean weight prior to pregnancy = 59.7 (range, 43– 93) kg.	0.5, 2, 4, 6, 12 and 18 months. The 25 cases did not continue with the scheduled measurement intervals; instead these women were measured for the final time within 14 days of their subsequent delivery. **Outcome variables:** 1) Postpartum weight retention – calculated by subtracting weight prior to the pregnancy of the reference infant from weight at each evaluation point during the postpartum period. 2) Across pregnancy weight difference, which was the difference between the weight of the cases 2 weeks after the birth of the reference infant and 2 weeks following the birth of the subsequent infant. **Self-reported or measured:** Measured. **Statistical analysis:** *t* tests were used to assess the comparability of the	began to plateau at about 8–10 months postpartum. Among the cases, post pregnancy weight following the baseline pregnancy was compared with post pregnancy weight following the subsequent pregnancy. On average, cases weighed 1.3 kg more after the subsequent pregnancy than they weighed following the baseline pregnancy. At their final measurement, controls weight 4.59 kg less than their post-pregnancy baseline. **Association of diet and physical activity with weight change:** Not a great deal mentioned other than, estimates of energy intake and/or PA were not important factors in explaining the weight differential between the baseline postpartum weight and the subsequent postpartum weight. **Association of other factors with weight change:** No other factors were considered.	**Author's conclusions:** Data suggest that there is no evidence that women with an inter-pregnancy interval <18 months have a different weight retention pattern than other women who delay a subsequent conception >24 months. **Comments:** Subtle differences in weight retention patterns between cases and controls would have been difficult to observe because of the sample size. Participants in this study were White, non-smokers with high education levels who may have had a different inter pregnancy interval

		controls with the cases. Paired *t* tests were used to assess the change in weight between the baseline post parturition measure and the subsequent postpartum measure among the cases. Simple linear regression analysis was used to describe any factors that might explain the weight changes between the beginning of the initial or baseline postpartum period and subsequent postpartum measure. The comparison of weight retention patterns for the cases and the controls was evaluated by longitudinal analysis using non-parametric mixed models.		experience than women from more diverse populations.
Linne 2003 Prospective cohort 2+ **Aim:** To examine long-term	1423 Women in Stockholm who delivered children in 1984–85. **Pre-pregnant mean weight:** 59.5 (8.1) kg;	**Year of baseline survey:** 1985 **Duration of follow-up**: 15 years. **Outcome variable**: Change in weight and	**Attrition:** 61% (*n* = 1423) of women eligible (*n* = 2342) completed initial questionnaire and 40% (*n* = 563) participated in 15-year follow-up questionnaire. **Weight changes:** Mean weight increase during pregnancy was 14.1 kg (4.1); 1-year after delivery mean weight increase was 1.5 kg, when corrected for underreporting and general phenomenon of weight increase over time the net mean weight increase induced by pregnancy was 0.5 kg, but range was	Women who participated in the 15-year follow-up had higher income and higher educational attainment than non-responders

weight development after pregnancy. The Stockholm Pregnancy and Women's Nutrition Study – SPAWN Also Ohlin 1994, 1996; Rossner 1995; Linne 2002.	pre-pregnant BMI: 21.5 (2.8) kg/m^2.	BMI. **Self-reported or measured weight:** Self-report and retrospective until after birth then prospective and measured (200 of 563 self-reported weight at 15 years). **Statistical analysis**: *t* test and χ^2 test.	very wide and 1.5% women had retained at least 10 kg. Over 15 years the initially normal weight group increased BMI from 20.7 to 22.3 kg/m^2 and the overweight group (BMI >25 kg/m^2 at 15 years) increased from 23.3 to 28.6 kg/m^2 (t = 0.342, df = 548, p > 0.0001); (women who were overweight at both time points [n = 33] and those who lost weight and regained a BMI in the normal range at 15 years [n = 10] were excluded from analysis). Women who became overweight had a higher pre-pregnant BMI (p > 0.001) and gained more weight during pregnancy (p > 0.001). **Association of diet with weight change:** Women that started to eat more irregularly retained more weight at 1-year postpartum. **Association of physical activity with weight change:** Women that started to exercise less frequently after their pregnancies retained more weight 1-year postpartum. **Association of other factors with weight change: pregnancy** Most important risk factor identified for sustained weight gain/retention 1 year after delivery was weight increase during pregnancy (large variances in weight meant any statistically significant relationships were rather weak at 1-year post delivery so other 1-year results not reported here); No difference between women who became overweight and those who remained normal weight regarding total number of children, number of pregnancies before and after index pregnancy, age at index pregnancy, age at delivery of first child. Features of pregnancy that did not differ between the two groups were total gestational duration, type of delivery, sex and birth weight of child, city of residence, breastfeeding and smoking cessation. Women who became overweight had lower lactation scores (p > 0.05); relatively more subjects of the group that became overweight stopped smoking during pregnancy (p > 0.01).	and national average. No control group of women without children. Impossible to determine if 15-year data represent a linear development over time as not seen since 1-year postpartum. **Author's conclusions:** Pregnancy is a vulnerability factor for some women to become overweight, demographic, behavioural, physical and psychological factors only partly explain the weight gain observed at 15-years follow-up
Olsen 2003 Prospective	622 healthy adult women who gave birth	**Year of baseline survey:** Not reported.	**Attrition:** n/a as analysed completer sample **Weight changes:**	Factors related to excessive gestational

cohort 2+ **Aim:** To evaluate whether potentially modifiable psychological and behavioural factors are related to gestational weight gain and whether the same factors relate to both excessive and insufficient weight gain.	to live singleton infants in a 10-county area of upstate New York, 96% White, rural and socio-economically diverse **Baseline BMI: not stated, mean gestational weight gain: 29.7lb**	**Duration of follow-up**: From early pregnancy until 2 years postpartum. **Outcome variable**: Weight change. **Self-reported or measured weight:** Measured. **Statistical analysis**: Multiple linear and logistic regression with adjustment for timing of measurements and length of gestation.	Mean gestational weight gain = 29.7 (11.7) lb (13.5 [5.3 kg]); high-BMI women were five times more likely than normal BMI women to exceed the top of the range of the Institute of Medicine guidelines. **Association of diet with weight change:** Women who reported eating much more food in pregnancy were 2.35 times more likely than women who ate a little more to gain excessive weight. **Association of physical activity with weight change:** Less PA (OR 1.68; 95% CI 1.1, 2.6) was significantly related to excessive gestational weight gain. **Association of other factors with weight change (please state factors):** Family income of less than 185% of the federal poverty line (OR 2.59; 95% CI 1.6, 4.2) was significantly related to excessive gestational weight gain. Income was not as important an influence on gestational weight gain among women who reported that they increased their food intake (OR 0.33).	weight gain only are reported here. **Adjusted for:** Not clear. **Author's conclusions:** Food intake, PA and smoking accounted for 27% variance in gestational weight gain.
Rosenberg 2003 Prospective cohort 2+ **Aim:** To evaluate the effect of childbearing on weight gain in African American women Participants in Black Women's Health Study.	11,196 African American women parous and nulliparous at baseline who had a singleton birth in 1995 to 1997 and none in 1997 to 1999 or nulliparous from 1995–99 and did not report occurrence of cancer; 9966 remained nulliparous, 598 had first child, 387 primiparous women had	**Year of baseline survey:** 1995 **Duration of follow-up**: 4 years. **Outcome variable**: Weight gain (kg). **Self-reported or measured weight:** Self-report. **Statistical analysis**: Multivariate linear regression (women who remained nulliparous served as comparison group).	**Attrition:** unclear **Weight changes:** BMI increased by 1.6, from 26.5 to 28.1 kg/m^2, equivalent to weight gain 4.4kg BMI 23 kg/m^2 in 1995, BMI change: nulliparous = 1.7, parity 1 = 1.9, parity 2 = 1.8, parity 3+ = 1.8 kg/m^2 BMI 36 kg/m^2 in 1995, BMI change: nulliparous = 1.3, parity 1 = 2.4, parity 2 = 2.1, parity 3+ = 2.1 kg/m^2 **Association of other factors with weight change: parity** Women who had a child during follow-up gained more weight than women who remained nulliparous, and those who had a first child gained more than those who had a second or later child, weight gain associated with childbearing increased with increasing baseline BMI and was appreciable among heavier women	**Adjusted for:** Predicted values of BMI change between 1995 and 1999 for parous and nulliparous women with selected characteristics (25–29 years at baseline, age at menarche 12–13 years, 16 years of education, non-smoker, single, BMI 20–24 kg/m^2 at age

	second child, 245 had third or later child **Baseline BMI: 26.5 kg/m^2**			18, 1–4 hours vigorous activity per week, 1–4 hours TV/videos per day, non-use hormonal contraception, no medication-treated depression. **Author's conclusions: childbearing is an important contributor to weight gain among African-American women.**
CARDIA (Coronary Artery Risk Development in Young Adults) Prospective cohort 2+ **Aim:** To estimate the change in BMI over 10 years in a cohort of young US men and women, and assess differences by a range of	CARDIA is a population based prospective study of 5,115 African American and White men and women in USA aged 18–30 year at baseline. Study population was balanced on: Age (45% 18–24 years) Sex (46% men) Ethnicity (52% African	**Year of baseline survey:** 1985–86 **Duration of follow-up**: Ongoing. **Outcome variable**: Measured. **Statistical analysis**: Various, but all used some form of regression analysis. Women who remained nulliparous (*n* = 925) at 5 years were compared with women who had a single pregnancy and who	**Attrition:** Baseline data were collected on 51% of eligible persons contacted. Overall retention rates were 90% at 2 years, 86% at 5 years, 81% at 7 years, 79% at 10 years, and 74% at 15 years. **Association of other factors with weight change: Pregnancy** **Pregnancy (based on 5-year follow-up of 2788 women at baseline):** Primiparous within both race groups gained 2 or 3 kg more weight during the 5-year period than did nulliparous. Primiparous also had greater increases in waist-to-hip ratio that were independent of weight gain. Multipara did not differ from nulliparous in adiposity change in either race group. **Pregnancy – Black and Minority Ethnic Groups:** At each level of parity, Black women demonstrated greater adverse changes in adiposity than did White women. **Conclusion:** Women experience modest but adverse increases in body weight and fat distribution after a first pregnancy and that these changes are persistent.	All analyses were **adjusted for** covariates: Age Education Smoking status Also adjusted for PA in analysis. Overweight was defined as BMI >25.0 kg/m^2.

variables. Smith 1994 (Pregnancy – based on 5-year follow-up.)	American). No data on income presented in this paper. **Baseline weight (kg) as mean (SD) and overweight (%):** African American women: 69.5 (18.3) kg, 44.7% White women: 63.1 (12.8) kg, 22.1% African American men: 77.5 (15.6) kg, 36.9% White men: 77.1 (12.6) kg, 12.6%.	were at least 12 months postpartum at 5 years.

<td>weight and PA.

Author's conclusions:
Major weight gain is strongly related to smoking cessation, but occurs in only a minority of those who stop smoking. (The authors note that weight gain is not likely to negate the health benefits of smoking cessation, but may interfere with attempts to quit for cosmetic reasons.)</td>
</tr>
</table>

			Among sustained quitters, factors significantly related to higher odds of major weight gain were: - Being Black (compared with White); - Being underweight at baseline (compared with normal weight, women only – BMI ranges used not stated); - Having smoked >25 cigarettes per day (compared with <15); - *Lower* recreational PA in men; - Higher recreational PA in women; - Being 25–54 years old at baseline (compared with 55–74 years); - Having had one or more live births (compared with none, women). **Summary of results:** Those who have quit smoking for >1 year experienced a greater mean weight gain and were more likely to experience major weight gain than continuing smokers. By the end of the study, however, the mean body weight of those who had quit increased only to that of those who had never smoked.	
Burke 2000 Prospective cohort 2+ **Aim:** To examine the influence of smoking cessation on weight gain in MA.	1930 MA and 1126 NHW aged between 25–64 years of age from low, middle and high-income neighbourhoods in San Antonio, TX, USA. **Baseline BMI or weight:** MA males never smoked (*n* = 457) BMI = 27.8 kg/m^2, quitters (*n* = 102) BMI = 28.5 kg/m^2, continuous smokers (*n* = 178) BMI =	**Year of baseline survey:** 1979 **Duration of follow-up**: 9 years. **Outcome variable**: Weight (kg), BMI. **Self-reported or measured weight:** Measured. **Statistical analysis**: Linear regression.	**Attrition:** MA 42%, NHW 40% **Weight changes:** As a result of smoking cessation, a total of 342 became overweight during follow up (had a BMI <25 kg/m^2 at baseline and a BMI ≥25 and <30 kg/m^2 at follow-up). Of those, 18 (5.3%) were estimated to be attributed to smoking cessation. For MA, 13 of the 196 (6.6%) were estimated to be attributed to smoking cessation. For NHW, 5 of the 146 (3.4%) were estimated to be attributed to smoking cessation ($p > 0.05$). 331 individuals became obese during follow up (BMI <30 kg/m^2 at follow-up); 18 were attributed to smoking cessation. For MA, 12 of 219 (5.5%) were attributed to smoking cessation; for NHW, 6 of the 112 (5.4%) were estimated to be attributed to smoking cessation ($p > 0.05$). A total of 377 individuals became overweight or obese during follow-up (had a BMI <25 kg/m^2 at baseline and BMI ≥25 kg/m^2 at follow-up). Of the 377 21 (5.6%) were attributed to smoking cessation. For MA, 16 of the 216 (7.4%) were estimated to be attributed to smoking cessation, for NHW 5 of the 161 (3.1%) were estimated to be attributed to smoking cessation. This ethnic difference was borderline statistically significant ($p = 0.072$).	**Adjusted for:** Not reported. **Author's conclusions:** There is an ethnic difference in the influence of smoking cessation on weight gain in MA and NHW. Although, in both ethnic groups this effect is quite small and makes only a slight difference and only makes a slight contribution to

	27.5 kg/m^2. MA females never smoked (*n* = 457) BMI = 27.7 kg/m^2, quitters (*n* = 102) BMI = 27.0 kg/m^2, continuous smokers (*n* = 178) BMI = 27.2 kg/m^2 NHW males never smoked (*n* = 457) BMI = 26.8, quitters (*n* = 102) BMI = 25.5 kg/m^2, continuous smokers (*n* = 178) BMI = 26.4 kg/m^2.		**Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change:** Smoking Overall, the estimated risk of becoming overweight or obese attributable to smoking cessation was only 7.4 % in MA and 3.1% in NHW.	the overall increase in prevalence of obesity in the cohort.
	NHW females never smoked (*n* = 457) BMI = 24.7 kg/m^2, quitters (*n* = 102) BMI = 23.7 kg/m^2, continuous smokers (*n* = 178) BMI = 24.2 kg/m^2.			
The Israeli CORDIS II study	3816 (68.8%) of male employees working in 21 factories in Israel were	**Year of baseline survey:** 1985–87 **Duration of follow-up**: 1988–90. Average	**Attrition:** Difficult to assess. At follow-up in 1988–90 (CORDIS II) only 1338 could be re-examined (many had been made redundant in the interim). Of these, 129 were excluded (missing data), thus *n* = 1209.	Data are presented here only for two groups: QSAE and CS, since

Prospective cohort 2+ **Aim:** To quantify the risk of weight gain after cessation of smoking, the duration of the risk, and the effect of possible moderating variables. **NS**: never smoked **QSBE**: quit smoking before entry to study **QSAE**: quit smoking after entry to study **CS**: current smokers	offered free screening examinations for selected risk factors 1985–87. 68% (*n* = 3816) agreed. These were then subdivided into four groups; NS, QSBE, QSAE, CS. ALL baseline data as mean (SE). QSAE: *n* = 65 CS: *n* = 392 **Age:** QSAE: 40.7 (10.3) years CS: 42.7 (10.9) years **Ethnicity**: (father born in North Africa, Iraq, Iran, Yemen): QSAE: 46.1% CS: 47.4% **Education** (reporting >12 years of education): QSAE: 49.2% CS: 61.0%	follow-up = 2.6 (range 2–4) years. **Outcome variable**: BMI . **Self-reported or measured weight:** Measured. **Statistical analysis**: Multivariate analysis was used to determine the predictive power of a model consisting of all independent variables (smoking status, age, sports activity, education, alcohol consumption, ethnicity, duration of follow-up and BMI at entry) to predict the increase in BMI over the follow-up period.	**Weight changes:** During follow-up, the mean age-adjusted increase in BMI was 0.99 kg/m^2 among QSAE and 0.24 kg/m^2 among CS. QSAE gained weight regardless of age; CS gained less weight with increasing age, and none gained weight after 50 years of age. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** Sports activity was negatively associated with gain in BMI during follow-up. **Association of other factors with weight change:Smoking** No significant interactions were found between **smoking** status and any other variable. Cessation of smoking after entry to study (QSAE) was positively related to an increase in BMI, whereas age, initial BMI, alcohol consumption were negatively associated with gain in BMI during follow-up. Cessation of smoking after entry, age, BMI at entry, and sports activity explained 8.7% of the variance in increase in BMI during follow-up. Further analysis of the QSBE group suggested that the increased rate of weight gain after smoking cessation is transient. However, the weight gained is retained for at least 6 years.	this is most meaningful comparison for this review, i.e. 'what happens when people give up smoking compared with those who do not quit'. **Adjusted for**: All variables included in the model. **Authors' conclusions:** The increased gain of weight gain after smoking cessation is transient. However, the weight gained is retained for at least 6 years.

Healthy Women Study. (two papers).

Three main aims:
1) To describe the weight changes that occurs in a sample of healthy women at time of menopause;

2) To determine whether change in weight is related to change in coronary heart disease risk factors during</td>
<td>Wing 1991
485 women aged between 42 and 50 years old and menstruated within the past 3 months, had no surgical menopause, a diastolic blood pressure less than 100 mmHg, and not to be taking lipid-lowering drugs, insulin, thyroid medication, estrogens, antihypertensive drugs or psychotropic drugs.

Baseline BMI/weight:
See results table.

Burnette 1998</td>
<td>Year of baseline survey:
1983–84

Duration of follow up:
3–4 years (depending on when baseline measurements were taken for Wing, 2 years for Burnette).

Outcome variable:
Weight (kg, lb) and BMI.

Self-reported or measured weight:
Measured.

Statistical analysis:
Regression analyses (Wing) chi square (Burnette).</td>
<td>Wing 1991
Attrition:
11%

Weight changes:
Women gained a mean of 2.25 kg during follow up. The SD for weight gain was 4.19 kg with a range from a 14.85 kg loss to a 32.4 kg gain. 20% of the women gained ≥4.5 kg, while only 3% lost ≥4.5 kg.

The table below shows changes in weight, BMI and skinfold thicknesses in premenopausal, perimenopausal and postmenopausal women:

<table>
<tr><th>Measurement</th><th>Premenopausal</th><th>Perimenopausal</th><th>Postmenopausal</th></tr>
<tr><td>Baseline weight (kg)</td><td>64.8 ± 11.9</td><td>67.2 ± 12.6</td><td>68.8 ± 13.9</td></tr>
<tr><td>Change in weight (kg)</td><td>2.1 ± 4.1</td><td>2.5 ± 3.3</td><td>1.4 ± 4.9</td></tr>
<tr><td>BMI at baseline (kg/m^2)</td><td>24.34 ± 4.17</td><td>24.85 ± 4.62</td><td>26.01 ± 5.33</td></tr>
<tr><td>Change in BMI (kg/m^2)</td><td>1.09 ± 1.63</td><td>1.29 ± 1.28</td><td>0.98 ± 1.95</td></tr>
<tr><td>Triceps skinfold thickness at entry (mm)</td><td>24.8 ± 7.3</td><td>25.1 ± 7.1</td><td>26.0 ± 7.7</td></tr>
<tr><td>Change in triceps skinfold thickness (mm)</td><td>2.9 ± 8.0</td><td>2.6 ± 7.1</td><td>3.2 ± 8.3</td></tr>
</table>

From the table, it is possible to see there were no significant differences in weight gain of women who remained pre menopausal and those who had a natural menopause (2.07 vs. 1.35 kg).

Association of diet with weight change:
No analysis.</td>
<td>Adjusted for:
Not reported.

Author's conclusions (Wing):
Weight gain is a common occurrence for women at menopause.

Author's conclusions: (Burnette)
Smoking cessation in perimenopausal to postmenopausal women is associated with greater weight gain but appears to be modestly associated with certain positive changes in cardiovascular risk factors.</td>
</tr>
</table>

the menopausal period; 3) To identify specific variables associated with weight gain to help determine which individuals are at risk of gaining weight at menopause. **Burnette 1998** **Aim:** To investigate the relationship between smoking cessation, subsequent weight gain and cardiovascular disease risk factors from pre-menopause to post-menopause.	541 menopausal women from Pittsburgh who were non smokers, ex-smokers or smokers. **Baseline BMI or weight:** Non-smokers mean weight 147.08 ± 27.72 lb (66.7 ± 12.6 kg); all smokers mean weight 143.67 ± 30.51 lb (65.1 ± 13.8 kg); smokers who continued through second year post-menopause mean weight 143.81 ± 30.46 lb (65.2 ± 13.8 kg); smokers who reported quitting at years 1 and 2 post-menopause mean weight 143.09 ± 31.18 lb (65.3 ± 14.1 kg).		**Association of physical activity with weight change:** No analysis. **Association of other factors with weight change:** *Hormone therapy:* Women who took hormone therapy appeared to be greater than that seen in other groups. These women had significant increases in weight (*p* > 0.0001), BMI (*p* > 0.0001), triceps skinfold thickness (*p* > 0.0001) and suprailiac skinfold thickness (*p* > 0.05). *Smoking:* In non-smokers (*n* = 339) the mean weight gain during the 3 years of follow up was 2.12 ± 4.05 kg. Weight gain in women who were premenopausal (*n* = 202) averaged 2.21 kg; in those who were perimenopausal (*n* = 67), weight gain averaged 2.30 kg; in postmenopausal women at follow-up (*n* = 33), weight gain averaged 0.63 kg. Women who took hormone therapy (*n* = 20) gained 2.30 kg and those who had never had a hysterectomy (*n* = 17) gained 3.11 kg. Changes over time were significant (*p* > 0.0001), although they did not significantly differ among the various menopausal statuses of women. **Burnette 1998** **Attrition:** 8% **Weight changes:** *First year post-menopause:* Significant group effects were found for weight; after-baseline quitters gained significantly more weight (*n* = 28, mean 11.36 lb [5.2 kg]) than non-smokers (*n* = 297, mean 5.32 lb [2.4 kg]) and continuing smokers (*n* = 91, mean 5.45 lb [2.5 kg]). *Second-year post-menopause*: After baseline quitters experienced significantly greater weight gain (*n* = 26, mean 14.43 lb [6.5 kg]) than non-smokers (*n* = 265, mean = 7.69 lb [3.5 kg]). **Association of other factors with weight change: Smoking** NB: Quitters had significantly greater decrease in alcohol consumption than non-smokers and continuing smokers.

2) Analysis of quitters: comparison of super-gainers and stable weight group

a) at baseline

Super-gainers:
• Were slightly younger (45.9 vs. 46.5 years);
• Were of lower SES (rank 66.2 vs. 71.2);
• Started smoking at a younger age (17.6 vs. 18.7 years);
• Were heavier smokers (26.6 vs. 23.0 cigarettes per day);
• Were slightly less physically active (rank 3.3 vs. 3.7);
• Drank more coffee (4.3 vs. 3.8 cups per day);
• And ate slightly fewer pastries (1.5 vs. 1.6 per day).
At baseline than those in the stable weight category (<i>p</i> > 0.05).

No significant effects for:
• BMI at age 25 years;
• BMI at baseline;
• alcohol consumption;</td>
<td>did not change with adjustment for age, SES and baseline weight.

Author’s conclusions:
Super-gainers differ in important ways from those who do not gain weight after smoking cessation. These weight changes may be partly influenced by genetic factors.</td>
</tr>
</table>

			• frequency of candy per day; • dieting. **b) at follow-up** Super-gainers were more likely: • to be single (15 vs. 10%) • to report having to diet to keep weight low (53 vs. 28%) at follow-up than those in the stable weight category ($p > 0.05$). No significant effects for retirement status or presence of cardiovascular disease. **c) changes in behaviours from baseline** Super-gainers: • reported a smaller increase in wine consumption (3.3 vs. 6.2 drinks per month) but a larger increase in liquor consumption (15.2 vs. 7.9 drinks per month) • reported a larger increase in candy consumption (0.1 vs. 0.0 pieces per day) from baseline to follow-up than those in the stable weight category ($p > 0.05$). No significant effects for change in beer, coffee or pastry consumption. **3) Twin concordance for weight change amongst quitters** Concordance rates for weight gain were 53% for monozygote twins and 38% for dizygote twins (p for difference <0.05). Concordance rates for weight loss were 46% (monozygote) and 27% (dizygote) (p for difference <0.05). **Summary of results:** • Quitters were more likely to experience weight gain of 2.3 kg or more, and less likely to experience weight loss, than continuing smokers and non-smokers. • Amongst quitters, super-gainers were younger, of SES, and differed on a number of health habits before quitting. At follow-up, super-gainers reported changes in health habits significantly different from those with stable weight.	

			- Pairwise concordance for weight change amongst quitters was significantly higher for monozygotes than for dizygote twins.

INDIVIDUAL STUDIES: MARITAL STATUS

First author, design, aim	Population	Intervention details, length of follow-up	Results	Confounders adjusted for/comments
Rauschenbach 1995 Prospective cohort 2+ **Aim:** To evaluate the influence of change in marital status on weight change over 1 year. The National Survey of Personal Health Practices and Consequences – telephone survey.	2436 adults within the US, mean age 39, modal income group US$15,000 to $24,000. **Baseline BMI: not reported**	**Year of baseline survey:** 1979–80 **Duration of follow-up**: 1 year. **Outcome variable**: Weight change. **Self-reported or measured weight:** Self-report. **Statistical analysis:** Regression analysis of weight change and regression analysis of weight at follow-up controlling for baseline weight (not reported as similar to initial analysis) three models – weight change, weight gain and weight loss.	**Attrition:** 81% participated at 1-year follow-up (excluded those with inconsistent height data at follow-up). **Weight changes:** Mean weight change in men was 1.38 (9.94) lb (0.6 [4.5 kg] and 1.26 (10.52) lb (0.8 [4.8] kg), 44% of both men and women gained weight. **Association of other factors with weight change: Marital status** Nineteen men became unmarried and 46 became married; 37 women became unmarried and 33 became married. Women who entered marriage had greater weight change than women who remained married, for men there were no statistically significant relationships between marital change and weight change. In the model to predict weight change none of the interactions were significant; in the model to predict weight gain none of the interactions were significant for women but for men the interaction of education with becoming unmarried was significant (*p* = 0.024) and associated with greater weight gain in more educated that become unmarried.	**Adjusted for:** Age, race, education, family income, children, metropolitan residence; and in model to predict weight change also adjusted for interaction of education, family income and age with change in marital status. **Author's conclusions:** Results suggest gender differences in rate of body weight change after marriage.

1

INDIVIDUAL STUDIES: OCCUPATION- AND WORK-BASED COHORTS

First author, design, aim	Population	Intervention details, length of follow-up	Results	Confounders adjusted for/comments
Bazzano 2005 Prospective cohort	17,881 US male physicians aged 40 to 82, and free from cardiovascular disease,	Year of baseline survey: 1982 Duration of follow-up: 8 and 13 years	Attrition: 17% Association of diet with weight change: Dietary data were from the Semi-quantitative Food Frequency Questionnaire (SFFQ) and breakfast cereals were classified as either whole	Adjusted for: Age, baseline BMI, alcohol, PA, smoking, histories of hypertension

Aim: To examine the association between whole and refined grain cereals with risk of overweight and weight gain.	diabetes and cancer. Subjects were from the Physicians Health Study which s a completed randomised control trial of aspirin and β-carotene in the prevention of cardiovascular disease and cancer (n = 21,431).	Outcome variable: BMI Self-reported or measured weight: Self-report. Statistical analysis: Various, but all used some form of regression analysis.	or refined grain. Men consuming ≥1 serving per day weighed less than those never or rarely consuming cereals. The trends at 8 and at 13 years were both significant (p-value for trend = 0.001). Men who ate ≥1 serving per day were 22% and 12% less likely to become overweight at 8 and 13 years respectively, compared with men who never/rarely ate cereals; relative risk 0.78; (95 CI 0.67, 0.91) and 0.88; (95 CI 0.76,1.00) respectively.	and high cholesterol and vitamin use. Author's conclusions: **BMI and weight gain were inversely associated with intake of breakfast cereals independently of other risk factors.**
Field 2001 NHS II **Design:** Prospective cohort. **Aim:** To assess the prevalence of clinically significant weight loss among women and whether this is associated with smaller long term weight gains. Secondary to this, the study	A total of 47,515 women from the Nurses Health Study II.	**Year of baseline examination and questionnaire:** 1989 **Duration of follow-up:** 6 years 1989–95 **Outcome variable:** Weight gain (kg) **Self-reported or measured:** Self-reported weights in 1989, 1991, 1993 and 1995, dietary intake, PA, inactivity, history of weight cycling and smoking. **Statistical analysis:** Focused on two main	**Attrition:** Not mentioned. **Weight changes:** During a 2 year period from 1989 to 1991, 2590 (5.5%) women lost 5–9.9% of their 1989 weight and 1326 (2.8%) women lost at least 10% of their 1989 weight. The proportion of women who lost >5% of their baseline weight increased with category of BMI from 3% (5–9.9% weight loss) among women with a BMI <22 to 9% among women with a BMI >30 kg/m^2 in 1989. Between 1991 and 1995, approximately 50% of the women had regained all of the weight they had lost. Among those women who had lost >10% of their 1989 weight, the percentage who regained all of their large weight loss between 1989 and 1991 decreased across baseline categories of BMI from 71% among the women with a BMI <22 kg/m^2 to 54% among the women with a BMI >30 kg/m^2 in 1989. Less than 10% of the women who had large clinically significant weight loss between 1989 and 1991 were able to successfully maintain their weight loss.	**Adjusted for:** Age, smoking, BMI at age 18, weight gain from age 18 to 1989, dietary intake, hours per week of vigorous activity, inactivity and history of weight cycling. **Author's conclusions:** Although few women can completely maintain weight losses, women should not be discouraged

aimed to assess factors associated with weight change over time.		outcomes, weight change and weight loss maintenance. – Linear regression analysis was used to assess whether women who had clinically significant weight loss between 1989 and 1991 had different weight change patterns to their peers. Logistic regression was used to determine whether other factors measured, or the amount of weight lost between 1989 and 1991, predicted successful weight maintenance from 1991 to 1995.	Regardless of the definition of weight maintenance, baseline category of BMI was inversely associated with successful weight loss maintenance. Women who lost greater than or equal to 10% of their weight between 1989 and 1991 gained more weight between 1991 and 1995 than their peers who did not lose weight. **Weight maintenance:** In further analysis limited to a subset of women who had clinically significant weight loss between 1989 and 1991, results showed that the more weight a women lost between 1989 and 1991, the more likely she was to maintain that loss between 1991 and 1995. Each 10 lb (4.5 kg) weight loss approximately doubled the probability that women would maintain her weight loss. History of weight cycling between the ages of 18 and 30 years reduced this likelihood. Severe weight cyclers were approximately 40% less likely to maintain their weight loss and mild weight cyclers 20% less likely. There was no association between inactivity or intake of total energy from dietary fat; however, hours engaged in vigorous activity was a significant predictor of weight loss maintenance between 1991 and 1995. Each hour of vigorous activity increased the likelihood of maintaining the weight over 4 years by 7%. **Association of diet with weight change:** Dietary intake during the years 1990–91 was modestly associated with subsequent weight change from 1991 to 1995. Energy intake had a modest positive association with weight gain, whereas, alcohol intake was associated with less weight gain **Association of physical activity with weight change:** Vigorous PA was protective against weight gain. Women who engaged in ≥5 hours per week of vigorous activity gained approximately 0.5 kg less than their inactive peers between 1989 and 1995. Total hours of activity per week (including walking) was not associated with weight change.	from attempting to lose weight since it was observed that women who had a clinically significant weight loss gained less weight than their peers over the 6-year period of the study. Data support the importance of PA as an effective means to prevent weight gain. Data also suggest that weight maintenance and weight gain prevention efforts should be targeted at young adults since BMI at age 18, weight gain from age 18 to 1989 and history of weight cycling between the ages of 18 and 30 years were all independently

			Physical inactivity was associated with weight change. For each 10 hours per week a women spent sitting at home or at work, she gained approximately 0.11 kg more than her less inactive peers. **Association of other factors with weight change:** BMI at age 18 years and weight change during early adult life were predictive of weight gain. Each one unit difference in BMI at age 18 years was associated with gaining an additional 0.32 kg between 1989 and 1995. This association was slightly attenuated when a history of weight cycling between the ages of 18 and 30 years was entered into the statistical model.	predictive of adult weight gain.
Hannerz 2004 Prospective cohort **Aim:** To explore whether factors related to the work environment could predict changes in BMI and whether the effects of psychosocial factors was dependent on baseline BMI.	Of the 2603 potential study participants, 1980 male employees from the Danish National Work Environment Cohort Study were observed during analysis. **Baseline BMI (kg/m^2):** <20 *n* = 59 20–24 *n* = 1,111 25–29 *n* = 692 >30 *n* = 118	**Year of baseline examination and questionnaire:** 1990 **Duration of follow-up:** 10 years, 1990–2000. **Outcome variable:** The change in BMI between the calendar years 1995–2000. **Self-reported or measured weight:** Self-reported over during a telephone interview, i.e. 'what is your weight? **Statistical analysis:** The change in BMI, as a function of a series of background variables and a series of occupational variables, were analysed by multiple linear	**Attrition:** Not mentioned. **Weight changes:** Among the background variables, age ($p \leq 0.0001$) and baseline BMI ($p \leq 0$ 0003) were statistically significant, and the estimates indicated that the tendency to gain weight decreases with age and BMI. Job security was the only significant occupational variable ($p = 0.157$). Among the psychological variables, that only ones that interacted significantly with baseline BMI were psychological demand ($p = 0.0108$) and job insecurity ($p = 0.0027$). Obese employees with job insecurity gained more weight than obese employees without job insecurity, whereas underweight employees with job insecurity gained less weight than underweight employees without job insecurity. The background variables explained 4.8% of the variation in BMI changes. The model, which incorporated all main effects, explained 5.8%, whereas the model that also included significant interaction effects between psychological factors and baseline BMI explained 7.3%. **Association of diet with weight change:** No such relationships were included. **Association of physical activity with weight change:** PA at work was included in the analysis yet it wasn't statistically significant for predicting changes in BMI ($p = 0.0674$). **Association of other factors with weight change**:	**Adjusted for:** Not stated. **Author's conclusions:** Age, baseline BMI, job insecurity, and psychological demands predict changes in BMI. Job insecurity and high or low psychological demands increase the likelihood of weight gain among obese employees, whereas they increase the likelihood of weight loss among employees with a low BMI.

		regression. In the first model, all of the selected variables were jointly analysed for main effects. In a second model, significant two-way interactions between baseline BMI and psychosocial variables were included. **Background variables:** Age, cohabitation, smoking status and baseline BMI. **Occupational variables:** Long working hours, irregular working hours, PA at work, cold work environment, hot work environment, decision authority, psychological demands, possibilities to communicate with colleagues, conflicts at work and job insecurity.	No other mentioned.	**Comments:** All measures were self-reported and so when it comes to the work-environment variables it is possible that different individuals might have perceived the same objective exposure differently.
Morris 1992 Prospective cohort study (British Regional heart Study). **Aim:**	**Setting:** One general practice in 24 towns in Britain. 6057 men aged 40–59 years who had been continuously	**Year of baseline examination and questionnaire:** 1978–80. **Duration of follow-up:** 5 years (1983–85).	**Attrition:** 7112 men were screened for participation yet 6057 were eligible for inclusion based upon the fact that they had experienced no unemployment in the previous 5 years. **Weight changes:** At initial screening, the mean BMI of men who remained employed was similar to that of men who experienced some non-employment later (25.52 vs. 25.40 kg/m^2, respectively) However, men who later became non-	**Adjusted for:** Age, social class and town of residence **Author's conclusions:** In this group of British middle-

To assess the effect of unemployment and early retirement on cigarette smoking, alcohol consumption, and body weight in middle aged British men.	employed for five years before the initial screening. The men were placed into employment groups based on their employment experience over the five years after screening. 4412 men had been continuously employed (mean BMI = 25.52 kg/ m^2) and 1645 had experienced some unemployment or retired (mean BMI = 25.40 kg/ m^2).	**Outcome variable:** BMI, number of cigarettes smoked and units of alcohol consumed per week. **Self-reported or measured weight:** Self-reported via a standard questionnaire, which included questions on occupational history, employment status, smoking habits, alcohol intake and usual patterns of PA. **Statistical analysis:** The adjusted proportions were calculated by fitting logistic regression models and by using the marginal prediction method described by Wilcosky and Chambless Changes in weight were analysed by fitting a nominal polytomous regression model on the six separate weight change categories.	employed were more likely to be underweight compared with men who remained employed (3.8 vs. 2.7%; 95% CI of the difference 0.1, 2.2). Five years later the mean BMI had risen slightly in both men who had experienced some non-employment (25.40 to 25.71 kg/m^2) and in men who had not (25.52 to 25.77 kg/m^2). The percentage of men who were underweight had fallen 2.7 to 2.0% in men who were employed and 3.8 to 2.3% in men who had experienced unemployment) and the percentage of men who were overweight had risen (8.1 to 8.4% in employed men and 7.9 to 9.4% in men who had experienced non-employment). Men who experienced some non-employment were less likely to remain a stable weight than men who remained continuously employed. 2.9% of men who experienced some non-employment lost more than 10% in weight and 7.5% gained more than 10% in weight compared with 2.1% and 5.0% respectively of continuously employed men (95% CI of the difference 0.1, 1.8 for weight loss and 0.9, 4.0 for gain). There was a strong association between cigarette smoking and BMI, with an increase in BMI occurring on stopping smoking. Excluding men who stopped smoking from the analysis reduced the percentage of men who gained more than 10% in weight. However, non-employed men were still significantly more likely to gain more than 10% in weight than men who remained continuously employed. **Association of diet with weight change:** No dietary analysis as such took place. **Association of physical activity with weight change:** Men who later became non-employed were significantly more likely to be inactive compared with men who remained employed (39.4 vs. 36.7%; 95% CI of the difference 0.1, 5.7). Only men retired for reasons other than illness were significantly less likely to be inactive than continuously employed men (31.6% were inactive; 95% CI 0.4, 0.8). **Association of other factors with weight change:** *Smoking:* At initial screening, compared with men who remained employed men who later became non employed were more likely to be current smokers (43% vs. 37%, respectively; 95% CI of the difference 3.2, 9.0) and	aged men the only evidence of those who experienced non-employment adopting behaviour detrimental to their future health was the increased propensity to gain a large amount of weight (>10%) This was not detected if only mean weight change was analysed. The high levels of smoking and alcohol consumption observed in non-employed men was due to these men being more likely to be heavy smokers and drinkers before the non-employment occurred. There was a strong association

			to be heavy smokers (15.5% vs. 13.1%; 95% CI 0.4, 4.7) They were also more likely to have smoked at some time (22.1 vs. 26.3% who remained employed never smoked; 95% CI 1.5, 6.7). Five years later the level of smoking had fallen: 26.8% of smokers had stopped smoking and only 44.6% of heavy smokers still smoked heavily. Overall men who had experienced some unemployment were still more likely to be current smokers than men who had remained continuously employed (33.0% vs. 29.3% respectively; 95% CI 1, 6.5), but they were no longer more likely to be heavy smokers (7.5 vs. 8.1%; 95% CI 2.1, 1.0). The main changes occurred in men who stated their non-employment was due to illness, with the percentage of heavy smokers falling from 23.6% to 5.8% for men unemployed through illness and from 16.0% to 3.1% for those retired through ill health. *Alcohol:* At initial screening, men who later became non-employed were more likely to be heavy drinkers (12.1%) compared with men who remained employed (9%; 95% CI of the difference 1.3, 5.1). Overall, the percentage of non-drinkers was similar among men who later became non-employed and those who remained employed (5.4 and 5.6%, respectively; 95% CI 1.25, 1.5). Five years later, the percentage of heavy drinkers had fallen (9.0 to 3.0% for men who were continuously employed and 12.1 to 4.1% of men who were non-continuously employed) and the percentage of non-drinkers had risen (5.6 to 8.4% in the employed group and 5.4 to 10.8% in the unemployed group). Overall, only 10.7% of men reported increasing their alcohol consumption compared with 36.9% who reported reducing their consumption.	between illness, unemployment, and changes in body weight, alcohol consumption, and cigarette smoking. The men who stated that their non-employment was due to illness were much more likely to lose weight and to reduce their levels of smoking and drinking than both non-employed men and men remaining continuously employed. **Comments:** The study did not comment on financial pressure that may have lead to the reductions in alcohol consumption.
He 2004 Prospective cohort	In 1976, 121,700 female registered nurses aged	**Year of baseline survey:** 1984 (In this paper, 1984 was considered	**Attrition:** 61% of those who took part in the study in 1976 were included in this analysis.	**Adjusted for:** Covariates stated in statistical

2+ Nurses Health Study: this paper focuses on fruit and vegetable consumption. **Aim:** To estimate the change in BMI over 12 years in a cohort of female nurses, dependent on change (not baseline) in fruit and vegetable consumption over the same time period.	30–55 years from 11 US states responded to a mailed questionnaire. 12-year follow-up. Questionnaire was mailed every other year. Analysis for this paper *n* = 74,063 female nurses aged 38–63 at baseline in 1984. This represented approx 61 % of those who were included in the study at 1976, but unclear how many nurses were originally invited to take part in 1976. **Exclusion criteria:** Cardiovascular disease, cancer, diabetes, incomplete information on questionnaire	as baseline since the expanded food frequency questionnaire [FFQ] was used that year.) **Duration of follow-up**: 12 years. **Outcome variable**: BMI. **Self-reported or measured weight:** Self-report. **Statistical analysis**: Change in intake of fruits and vegetables was ranked from largest decrease to largest increase during the 12-year follow-up period and quintiles of this variable were used in the analysis. ORs were computed using logistic regression models. Multivariate ORs were estimated by simultaneously adjusting for age, year of follow-up, change in PA, change in smoking status, baseline BMI, change in alcohol consumption and caffeine intake, change in hormone replacement therapy, and changes in energy	**Weight changes**: Not reported separately **Association of diet with weight change:** During the 12-year follow-up, participants tended to gain weight with age, but those with the largest increase in fruits and vegetables had a 24% lower risk of becoming obese compared with those who had the largest decrease in intake. OR 0.76 (95% CI 0.69, 0.86), *p* for trend <0.0001. Similar results were observed for changes of fruits and vegetables separately.	analysis. **Author's conclusions:** Increasing intake of fruits and vegetables may reduce long-term risk of obesity and weight gain among middle-aged women.

	(e.g. no data on body weight) or implausible information (e.g. total daily energy intake (TDEI) <600 or >3500 kcal [<2.51 MJ or >14.6 MJ]) **Baseline BMI, mean (SD):** 24.9 (5) kg/m^2	adjusted intakes of saturated fat, polyunsaturated fat, monounsaturated fat, trans-unsaturated fatty acid, protein, and TDEI. The median values of quintiles of changes in fruit and vegetable intake were used as a continuous variable for the tests for linear trend. To estimate the mean difference of changes in BMI by category of fruits and vegetables, general linear models with least-square means was used.		
Schulze 2004 Prospective cohort 2+ **Aim:** To examine the relationships between sugar-sweetened beverage consumption and weight and its links to type 2 diabetes in a cohort of young and middle-	51,603 female nurses from the USA, aged 24 to 44 years were used as subjects. Women were excluded if they did not complete a dietary questionnaire or if subjects reported dietary intake was implausible with regard to total	**Year of baseline survey:** 1991 **Duration of follow up:** 8 years. **Outcome variable:** Weight (kg) and BMI (kg/m^2). **Self-reported or measured weight:** Self-reported. **Statistical analysis:** Difficult to assess. Means calculated for	**Attrition:** 44 % (116,671 recruited at initiation, 51,603 left for analysis). **Weight changes:** Mean change in BMI was 0.49 kg/m^2 for 1991–95 and 0.05 kg/m^2 between 1995–99). **Association of diet with weight change:** From 1991–95 and 1995–99, women who increased their intake of sugar sweetened soft drinks from low to high had significantly larger increases in weight (4.69 kg during 1991–95 and 4.20 kg during 1995–99) and BMI (1.72 kg/m^2 during 1991–95 and 1.53 kg/m^2 during 1995–99) than women who maintained a low or a high intake or significantly reduced their intake ($p > 0.01$). The lowest weight gain and increase in BMI were observed among the women who reduced intake from high to low (1.34 kg in 1991–95 and 0.15 kg during 1995–99.	**Adjusted for:** Age, alcohol, PA, smoking, BMI, other lifestyle and dietary confounders at baseline **Author's conclusions**: A higher intake of sugar-sweetened beverages is associated with a greater magnitude of weight gain and

aged women.	energy intake (i.e. <500 kcal/d or >3500 kcal/d [<2.09 MJ or >14.64 MJ]); if they had history of diabetes, cancer, cardiovascular disease at baseline or if they had not provided data on PA in 1991.	the mean weight changes in groups. Cox proportional hazards analysis was used.	Those who increased consumption of fruit punch from one drink or less per week in 1991 to 1 drink or more per day in 1995 gained more weight (3.69 kg) compared with women who reduced their intake (2.43 kg, $p > 0.001$). Increased fruit juice consumption was associated with larger weight gain (4.03 kg) compared with decreased fruit juice consumption (2.32 kg, $p > 0.001$). Oppositely, weight gain in participants who increased their diet soft drink consumption from one drink or less per week in 1991 to one drink or more per day in 1995 (1.59 kg) was significantly lower compared with women who decreased their diet soft drink consumption from one drink or more per day in 1991 to 1 drink or less per week in 1995 (4.25 kg, $p > 0.001$). Subjects who increased soft drink consumption between 1991 and 1995 and continued with this high level of intake during 1995–99, on average gained 8.0 kg between 1991 and 1999. Women who reduced their consumption between 1991 and 1995 and maintained a low level of intake on average gained 2.8 kg between 1991 and 1999. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change:** No analysis.	an increased risk for development of type 2 diabetes. This was attributed to excessive energy from the drinks and large amounts of rapidly absorbable sugars found in the drinks.
Koh-Banerjee 2003 Prospective cohort 2+ The Health Professionals Follow-Up Study. **Aim:** To determine the associations of	16,587 US male health professionals (dentists, veterinarians, pharmacists, optometrists, osteopathic physicians and podiatrists) aged 40–75 years. **Baseline BMI:** 40–49 years (n = 7577) 24.9	**Year of baseline survey:** 1986 **Duration of follow-up:** 9 years (1986–94 for dietary exposures and 1986–96 for all other exposures) **Outcome variable:** Change in waist circumference. **Self-reported or**	**Attrition:** 1751 excluded due to death, 15,833 excluded due to disease, 17,358 excluded due to incomplete data. **Weight changes:** Mean (SD) waist circumference increased by 3.3 (6.2) cm from 1987 to 1996. **Association of diet with weight change:** 2% increment in energy intake from *trans* fats that were isoenergetically substituted for either polyunsaturated fats or carbohydrates was significantly associated with a 0.77 cm waist circumference gain over 9-years ($p > 0.001$ for each comparison). An increase of 12 g total fibre/day was associated with 0.63 cm decrease in waist circumference ($p > 0.001$).	Adjusted for baseline age, baseline waist circumference, baseline BMI, baseline and changes in total energy, baseline and changes in alcohol consumption, baseline and changes in total PA and changes in

changes in diet, PA, alcohol consumption and smoking with 9-year waist gain in US men.	(2.8) kg/m^2. 50–59 years (*n* = 5314) 25.2 (2.8) kg/m^2. 60–75 years (*n* = 3696) 24.9 (2.6) kg/m^2.	**measured weight:** Self-report waist circumference. **Statistical analysis:** Multivariate linear regression.	Change in total fat intake was significantly related to waist gain of 0.27 cm ($p > 0.001$) but was not significant when further adjusted for concurrent change in BMI; alcohol consumption was not significantly related to waist gain. **Association of physical activity with weight change:** Increases of 25 METs hours per week in vigorous PA and at 0.5 hours per week or more in weight training were associated with 0.38 cm and 0.91 cm decreases in waist circumference respectively ($p > 0.001$ for each comparison). Increases of 25 METs hours per week in vigorous PA remained significant ($p > 0.05$) after control for concurrent change in BMI (–0.19 cm); 0.5 hours per week or more in weight training were associated with 0.74 decreases in waist circumference ($p > 0.001$) after controlling for change in BMI; (also significant decreases in waist circumference with 12–24 MET hours per week and ≥25 MET hours per week. Change in walking volume was not significantly related to waist gain, an increase in walking pace of at least 1 mph (0.45 m/s) was related to loss in waist circumference of 0.50 cm ($p = 0.002$) (–0.27 cm, $p = 0.05$) when BMI held constant); a decrease in walking pace of at least 1 mph was related to a gain in waist circumference of 0.60 cm ($p > 0.001$) (0.26, $p = 0.03$ when BMI held constant). **Association of other factors with weight change: Smoking and TV** Smoking cessation and a 20-hours per week increase in TV watching were associated with a 1.98 cm and 0.59 cm waist circumference gain respectively ($p > 0.001$). Those who quit smoking gained waist circumference 1.98 cm ($p > 0.001$) but this was not significant when change in BMI was controlled for.	smoking. To identify lifestyle factors that predicted increase in waist circumference independent of weight gain changes in BMI were adjusted. **Author's conclusions:** Waist gain may be modulated by changes in *trans* fat and fibre consumption, smoking cessation and PA.
Yamada 2001 Prospective cohort 2+ **Aim:** To clarify the health effects	189 Japanese men, aged 21 to 47 years (mean 31.1 years on the 1 April 1996) who worked in a electronic parts producing factory.	**Year of baseline survey:** 1996 **Duration of follow up:** 3 years **Outcome variable:** Weight (kg) and BMI.	**Attrition:** 1.5% **Weight changes:** For the 12-hour shift workers, mean body weight was 66.6 kg in 1996, 66.6 kg in 1997, 67.6 kg in 1998 that shows a weight gain of 1.0 kg between 1997 and 1998. The BMI of workers on 12-hour shifts increased significantly from 22.8 to	**Adjusted for: not stated** **Author's conclusions:** Implementing a 12-hour shift caused unhealthy

of implementing a 12-hour shift in place of a traditional 8-hour shift in a clean room in an electronic parts-producing factory.	All participants had been working 8-hour shifts for >2 years. Seventeen men aged between 27 and 38 years who had been working 8-hour shifts for >2 years, continued working 8-hour shifts. These were used as a reference group. **Baseline BMI/weight:** Mean baseline BMI of subjects: 22.9 kg/m^2. Subgroup of 20-year-olds: 22.1 kg/m^2. Subgroup of 30-year-olds: 23.4 kg/m^2. Subgroup of 40-year-olds: 23.7 kg/m^2.	**Self-reported or measured weight:** Measured. **Statistical analysis:** StatView 5.0 for windows.	23.2 kg/m^2 for all the workers. The 8-hour shift workers showed a large variation in mean body weight, particularly 67.0 kg in 1996, 66.5 kg in 1997, 67.1 kg in 1998 and 66.3 kg in 1999. 20-year-olds showed a weight gain of 0.8 kg between 1997 and 1998; however, there were only four of them. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change:** *Age:* 12-hour shift workers – weight gain in the year between 1997 and 1998 was 1.2 kg for the 20-year-olds and 0.9 kg for the 30-year-olds. 40-year-olds showed a weight gain of 0.7 kg in the year between 1997 and 1998 but showed a loss of 1.3 kg between 1998 and 1999. This is a 0.2 kg of body weight over the 3 years. A paired *t* test showed a significant increase in the 12-hour shift workers as well as for the 20-year-olds and 30-year-olds between 1997 and 1998 ($p > 0.05$). For 20-year-olds BMI was 22.0 to 22.4 kg/m^2 and 23.4 to 23.7 kg/m^2 for the 30 year olds between 1997 and 1998. The increase for the 40-year-olds was from 23.8 to 24.0 kg/m^2 with a decrease to 23.6 kg/m^2 in 1999. Eight-hour shift workers – 20-year-olds showed a weight gain of 0.8 kg between 1997–98; however, there were only four of them. Thirty-year-olds showed a weight gain of 0.2 kg between 1997 and 1998 but showed a loss of 1.1 kg between 1998 and 1999. Statistically, no significant changes were found for either the entire 8-hour shift group or the age subgroups during 1996–99. The changes in BMI among the subjects were not found to be significant either ($p > 0.05$). Thirty-year-olds showed a weight gain of 0.2 kg between 1997 and 1998 but showed a loss of 1.1 kg between 1998 and 1999. Statistically, no significant changes were found for either the entire 8-hour shift group or the age subgroups during 1996–99. The changes in BMI among the subjects were not found to be significant either ($p > 0.05$).	weight gain among some clean room workers.

Martikainen 1999 Prospective cohort 2+ **Aim:** To describe socio-economic differences in change in BMI from age 25 years, assess possible factors behind these differences, and study whether socio-economic differences in a variety of coronary risk factors can be accounted for by change in BMI.	5507 men and 2466 women who participated in London-based civil servant Whitehall II study who were 35–55 years old in phase 1 (1985–88) and participated in third phase (1991–1993). **Baseline BMI:** 22.60 (22.53–22.67) kg/m^2 for men, 21.97 (21.84–22.10) kg/m^2 for women.	**Year of baseline survey:** 1985–88 **Duration of follow-up:** 5–6 years **Outcome variable**: BMI gain **Self-reported or measured weight:** Measured but self-reported recall at baseline of weight at age 25 years. **Statistical analysis:** Logistic regression, multinomial logistic regression, linear regression.	**Attrition:** 2335/10308 **Weight changes:** BMI change (mean, 95% CI) from 25 years of age to phase 3: all men 2.52 (2.46, 2.59) (7.8 kg), all women 3.74 (3.59, 3.88) (9.3 kg). **Association of diet with weight change:** Age-adjusted OR of having a gain in BMI >3 kg/m^2 compared with having a BMI gain of 0–3 kg/m^2: Men who reported consuming a good diet (three or four of total of four healthy aspects of diet) had OR 0.73 (95% CI 0.64, 0.84) and for women OR 0.83 (95% CI 0.68, 1.02). **Association of physical activity with weight change:** Age-adjusted OR of having a gain in BMI >3 kg/m^2 compared with having a BMI gain of 0–3 kg/m^2: Moderate and vigorous PA were less likely to experience an increase in BMI, OR for men who took part in vigorous activity was 0.61 (95% CI 0.49, 0.76) and 0.67 (95% CI 0.51, 0.89) for women. **Association of other factors with weight change: employment grade, alchol and smoking** With adjustments for age, duration of follow-up, BMI at age 25 years, the change in BMI was 0.37 kg/m^2 more in grade II than in grade I men and 1.19 for women. The largest grade differences in men and women were observed in those with the largest increases in body mass; men in grade III were 2.5 times more likely to have had a gain in BMI of 6 kg/m^2 or more and for women the OR was 2.8. Age-adjusted OR of having a gain in BMI >3 kg/m^2 compared with having a BMI gain of 0–3 kg/m^2: Grade II men had OR of 1.80 of experiencing a BMI gain of >3 kg/m^2 as compared with grade I men, corresponding OR for women was 2.18. Alcohol consumption was negatively related to BMI gain in women (>10 units per week OR 0.63 (95% CI 0.46, 0.86), consumed 1–2 times per week OR 0.71 (95% CI 0.57, 0.89), consumed daily OR 0.64 (95% CI 0.49, 0.83); in men the relationship was much weaker, with regular and heavy drinkers tending to have a larger gain in BMI.	Grade **I** = administrative, grade **II** = professional and executive, grade **III** = clerical and office support (grade **I** is the reference group for analyses) Mean change in BMI adjusted for age, duration of follow-up, BMI at age 25 years; OR of having a gain in BMI of >3 kg/m^2 compared with having a BMI gain of 0–3 kg/m^2 was adjusted for age. **Author's conclusions:** Employment grade was strongly related to BMI gain from age 25 years to phase 3 (about 25 years), the lower the grade the larger the gain in BMI, adjustment for

			Male smokers and ex-smokers were more likely to gain BMI (OR 1.49, 95% CI 1.22, 1.82 and OR 1.40, 95% CI 1.22, 1.61, respectively); whereas women were more likely to experience a decline in BMI (OR 0.79, 95% CI 0.61, 1.03 and OR 0.88, 95% CI 0.69, 1.12). Poor health control and poor decision latitude at work were related to body mass gain. **Summary of results:** In men separate adjustment for PA and diet accounted for approximately 15 to 20% of the grade difference of having a BMI gain >3 kg/m^2, adjustment for other explanatory values did not make a major contribution; in women the grade differences in OR of BMI gain could only be accounted for by including alcohol consumption in the logistic regression analysis, but grade differences could be partly accounted for by PA and alcohol consumption (about 20% each) and the model that accounted for all explanatory variables accounted for about one-third of the grade differences.	health behaviours reduced the grade differences in BMI gain by about 20%.
Nakamura 1998 Cohort 2+ **Aim:** To determine whether working overtime is associated with anthropometric indices and serum lipids, risks for obesity in White-collar workers.	Non-management White-collar (programmers, designers, clerical) male workers in printing and personal computer manufacturing company in Fukushima, Japan **Baseline BMI:** 22.6 (3.3), range 15.7–34.2 kg/m^2	**Year of baseline survey:** 1990 **Duration of follow-up**: 3 years (analysed retrospectively). **Outcome variable**: BMI change. **Self-reported or measured weight:** Measured. **Statistical analysis:** Multiple linear regression (stepwise).	**Attrition:** 1990 data for 230 of 248 workers present in 1993. **Weight changes:** Change in BMI over 3 years: 0.55 (1.12), range –2.87–5.98 kg/m^2 **Association of diet with weight change:** Overtime hours were inter-correlated with dinnertime ($r = 0.436$, $p > 0.0001$). **Association of other factors with weight change: Overtime** Overtime hours correlated significantly with 3 year **change** in BMI ($r = 0.206$, $p > 0.0017$) and waist circumference ($r = 0.218$, $p = 0.0091$) but not with either the most recent anthropometric indices. Working overtime explains less than 5% variability in change in BMI.	Difficult to ascertain which data is cross-sectional and which is longitudinal. Average monthly overtime worked = 45.5 (SD15.6,)range 0–86.1) hours. **Adjusted for:** Not clear. **Author's conclusions:** Working overtime is associated with increases in

				BMI and waist-circumference over 3 years although the associations were weak; eating habits of those working overtime may reflect an intervening effect on anthropometric changes.
Gerace 1996 Prospective cohort 2+ **Aim:** To assess predictors of weight gain that might be used to prevent increases in weight.	438 male paramedics and fire fighters from Dade Country, Florida, USA. Subjects were aged between 20–58 (mean 35.4) years. The subject sample comprised of Black non-Hispanics, White Hispanics and White non-Hispanic. **Baseline BMI/weight:** Mean BMI for those attended in 1984 and 1991: 25.8 kg/m^2.	**Year of baseline survey:** 1984 **Duration of follow-up:** 7 years **Outcome variable:** Weight (lb). **Self-reported or measured weight:** Measured. **Statistical analysis:** Pearson correlation coefficients were calculated for continuous variables. Analysis of variance and covariance programs were run to examine differences in weight change by group.	**Attrition:** Not reported. **Weight changes:** At follow-up mean body weight increased 8.3 lb (3.8 kg) with 65.2% of fire fighters gained 5 lb (2.3 kg) or more, 42.1% gained 10 lb (4.6 kg) or more; 26.1% gained 15 lb (6.8 kg) or more. In 1991 24% were within 4 lb (1.8 kg) of their weight at baseline measurement. 11% of subjects lost ≥5 lb (≥2.3 kg). 41% of the year-to-year changes were actually increases from the previous year, while in the top quartile, 30% of the year-to-year changes were actually decreases in weight. Weight, % of an individual's ideal weight, BMI and triceps skinfold thickness at follow up were inversely related to weight change ($p > 0.01$). Subjects with the smallest anthropometric values in 1984 tended to have the biggest increases in body weight over the 7 years. **Association of diet with weight change:** Fire fighters who ate faster at the station than else where gained 9.9 lb (4.5 kg) by follow up (1991) compared with those who said their pace did not differ by location, who increased 6.8 lb by 1991, while those who did not nibble increased by 6.9 lb (3.1 kg) ($p > 0.05$) **Association of physical activity with weight change:** Self-reported PA levels at baseline were not associated with change in	Outcomes not adjusted. **Author's conclusions:** Prevention programmes will reach fire fighters likely to gain the most weight if aimed at those who are unmarried, younger, Black, recent ex-smokers, fast eaters and experiencing certain stressful life events.

			weight ($p > 0.05$). Likewise, the amount of energy in PA reported at baseline was not associated with weight change ($p > 0.05$). Subjects who reported engaging in at least one recreational PA three or more times per week gained 7.2 lb (3.3 kg) compared with less active fire fighters who gained 9.5 lb (4.3 kg) ($p > 0.05$). **Association of other factors with weight change:** *Demographic variables:* Fire fighters aged 20–29 years, gained the most weight over 7 years (11.3 lb [5.1 kg]). The Pearson correlation coefficient between age and weight change was –0.17 ($p > 0.01$). Subjects who were married or living as married gained 7 lb (3.2 kg) compared with those who were never married, divorced, separated, or widowed who gained 11.7 lb (5.3 kg) ($p > 0.001$). Black non-Hispanics gained 15.7 lb (7.1 kg) compared with White Hispanics who gained 8.9 lb (4.0 kg) and White non-Hispanics who gained 6.7 lb (3.0 kg) ($p > 0.001$). *Behavioural variables:* Fire fighters who smoked at baseline and reported being ex-smokers in 1991 gained 13.0 lb (5.9 kg) compared with all other fire fighters who gained 7.7 lb (3.5 kg) ($p > 0.004$). Ex-smokers who had smoked >20 cigarettes per day gained 16.4 lb (7.4 kg) compared with those who smoked up to 19 cigarettes per day who gained 8.3 lb (3.8 kg). *Psychological variables:* Self-reported stress at baseline was not associated with weight change over the 7-year period ($p > 0.05$). However, those who worried over financial security gained 11.2 lb (5.1 kg) versus non worriers who gained 7.4 lb (3.4 kg) ($p > 0.005$).	

INDIVIDUAL STUDIES: GENERAL POPULATONS				
First author, design, aim	**Population**	**Intervention details, length of follow-up**	**Results**	**Confounders adjusted for/comments**
Nooyens 2005 Prospective cohort Aim: To study changes in	288 healthy men aged 50-65 years who remained employed or retired over follow-up. Men were from the Doetinchem	Year of baseline survey: 1985–86 Duration of follow-up: 5+ years Outcome variable:	Attrition: 0% Association of diet with weight change: Weight gain and increase in waist circumference were associated with a decrease in fruit consumption (p = 0.01) and fibre density of the diet (p = 0.01), and with an increase in frequency of eating breakfast (p = 0.03). Association of physical activity with weight change:	Adjusted for: Age and behaviour changes at baseline. Author's conclusions:

body weight and waist circumference in men.	Cohort Study (rural Netherlands)	Weight change and waist circumference. Self-reported or measured weight: Measured. Statistical analysis: Linear regression.	Weight gain and increase in waist circumference were associated with a decrease in several physical activities, such as household activities, bicycling (p = 0.03), walking and doing odd jobs (p = 0.02). Association of other factors with weight change: Increase in body weight and waist circumference was higher among men who retired from active jobs (0.42 kg per year and 0.77 cm per year, respectively) than among men who retired from sedentary jobs (0.08 kg per year and 0.23 cm per year, respectively).	Retirement was associated with increases in weight and waist circumference among those with former active jobs, but not among those with former sedentary jobs.
Schulz 2005 Prospective cohort Aim: To identify a dietary pattern predictive of subsequent annual weight change by using dietary composition information.	24,958 middle-aged men and women of the European Prospective Investigation into Cancer and Nutrition-(EPIC) Potsdam cohort, Germany. Men were aged between 24-69 and women 19-70 years.	Year of baseline survey: 1994–1998 Duration of follow-up: 4+ years Outcome variable: Weight change. Self-reported or measured weight: Measured and self-report. Statistical analysis: Linear regression.	Association of diet with weight change: Reduced rank regression method was used to derive dietary patterns with 3 response variables presumed to affect weight change: fat density, carbohydrate density, and fibre density. A scoring system was devised with high scores indicating healthier diet. A food pattern of high consumption of whole-grain bread, fruits, fruit juices, grain flakes/cereals, and raw vegetables, and of low consumption of processed meat, butter, high-fat cheese, margarine, and meat to be predictive of subsequent weight change. Subjects with these food patterns were less likely to gain weight. Mean annual weight gain gradually decreased with increasing pattern score (p-value for trend < 0.0001), i.e., subjects scoring high for the pattern maintained their weight or gained significantly less weight over time compared with subjects with an opposite pattern. The prediction of annual weight change by the food pattern was significant only in non-obese subjects; eg normal weight women (p< 0.0001) vs obese women ((p = 0.184).	Adjusted for: Age, total energy intake, PA, smoking, and other dietary behaviour changes. Author's conclusions: Identified a food pattern characterized by high-fibre and low-fat food choices which helped to maintain body weight or at least prevent excess body weight gain.
Quatromoni 2002 Prospective cohort	1828 non-overweight women from the Framingham Offspring/Spouse	Year of baseline survey: Exam 3, year not given Duration of follow-up:	Attrition: 60% 737 having complete data sets Association of diet with weight change: Five dietary patterns were identified among the cohort at baseline via cluster analysis: 'Heart Healthy', 'Light Eating', 'Wine and Moderate Eating',	Adjusted for: Age, total energy intake, PA, cigarette usage, and

Aim: To investigate relationships between dietary patterns and the development of overweight	(FOS) Cohort. Mean age 45 years, with a range of 30-89 years.	12+ years Outcome variable: BMI >25. Self-reported or measured weight: Measured. Statistical analysis: Various, but all used some form of regression analysis.	'High Fat', and 'Empty Calorie'. Over 12 years, the crude risk of becoming overweight was 29% overall, ranging from 22% of women in the 'Wine and Moderate Eating' cluster to 41% of women in the 'Empty Calorie'. Compared with women who ate a lower-fat, nutritionally varied 'Heart Healthy' diet, women who ate an 'Empty Calorie' diet that was rich in sweets and fats with fewer servings of nutrient-dense fruits, vegetables, and lean food choices were at higher risk for developing overweight; RR 1.4; (95 CI 0.9, 2.2). Women who ate an 'Empty Calorie' dietary pattern were also younger and were more likely to smoke.	other dietary behaviour changes. Author's conclusions: Behavioural interventions may be enhanced by targeting differences in eating patterns, dietary quality, and other lifestyle behaviours of distinct subgroups.
Kahn (1990) Prospective cohort **Aim:** To explore the effects of family income, education and changing marital status on change in BMI over 10 years.	1552 White and Black US men were included in this study of 10-year weight change, therefore representing 77% of the Black and White men who initially entered the Health and Nutrition Examination Survey-I (in 1971–75) at ages 25–44 years.	**Year of baseline examination and interview:** 1971–75 **Duration of follow-up:** 10 years. **Outcome variable:** BMI . **Self-reported or measured:** Measured. **Statistical analysis:** Considering BMI change as a	**Attrition:** Not mentioned **Weight changes: Mean 10-year change:** The mean 10-year change in BMI was similar for the men who were not consistently married and for the men who were married at both baseline and follow-up (0.90 vs. 0.80 kg/m^2, respectively). The non-consistently married men had a significantly wider distribution of this weight-change variable. Multivariate models showed a significant increase in the mean BMI change for men with lower education levels compare with those who had gone beyond 12th grade. Men who became married during the 10-year interval showed a trend towards a greater gain in BMI when compared with men who were consistently married. Those men whose marriage ended appeared to experience a relative loss in BMI.	**Author's conclusions:** Study demonstrated that among US men an education to less than college level was a risk factor for increased mean weight gain and that low family income was a risk factor for major weight gain.

		continuous variable, multiple linear regression was used to estimate the effects of each independent variable of interest. Considering BMI change as a categorical variable, logistic regression analysis was used to estimate the OR of either major weight gain (MWG) or major weight loss (MWL) for subgroups defined by the various categories of family income, educational attainment and marital change.	**Incidence of major weight gain/loss:** The incidence of MWG was generally greater for the men who were not consistently married, among these men there was a higher incidence of MWG for those who had lower incomes or lower educational levels The incidence of MWL was also generally greater for the men who were not consistently married The mid-range weight outcome was generally more common among men who were consistently married, had higher family incomes, or had higher educational levels. **Risk factors for major weight change:** Low family income and either becoming married or remaining unmarried during the 10-year follow-up interval were independently associated with an increased risk of MWG. Education to grade 11 or less was only marginally associated with an increased risk of MWG. Neither low family income nor low education had any effect on the risk of MWL. However, ending a marriage or remaining unmarried was associated with an increased risk of MWL. **Association of diet with weight change:** Not measured. **Association of physical activity with weight change:** The incidence of MWG was lowest among men who reported high levels of PA or whose baseline BMI was between 24.0 and 27.8 kg/m^2. **Association of other factors with weight change:** The incidence of MWG was highest among ex-smokers and those reporting low levels of PA. The incidence of major weight loss was highest for men with the highest BMI at baseline or men who continued to smoke. Black race had no consistent effect on MWG or MWL.	Compared with men who were consistently married, men who become married between baseline and follow-up had an increased risk of MWG while men ending a marriage had an increased risk of MWL. Men unmarried at both baseline and follow-up had an increased risk for both MWG and MWL. Findings indicate that US men in greatest need of help in preventing weight gain are those with low family incomes, those with low educational levels and those who are unmarried. **Comments:** Fluctuations in weight that may

				have occurred during the 10-year follow-up were not recorded in this data; therefore, it failed to include everyone who had a major weight change between baseline and follow-up examinations. The definitions of MWG and MWL cannot identify how much of the weight changes were due to changes in the amount of lean or fat tissue. **Adjusted for:** Race (White, non-White), education, smoking status, age and BMI at baseline, length of follow-up, PA, level of morbidity, energy intake, alcohol intake, special diet

				status and parity.
Andersen 2004 (MONICA) **Aim:** To investigate whether night eating per se predicts weight gain, or weight gain predicts night eating. **Design:** Prospective study with initial examination of the cohort in 1982–83 (M-82), re-examination in 1987–88 (M-87) and a third examination in 1993–94 (M-93).	In 1982 to 83 a total of 3608 Danish citizens born in either 1922, 1932, 1942 or 1952 participated. This group invited for re-examination 5 years later in 1987–88, a total of 2987 subjects participated. Finally, in 1993–94 the cohort was invited for a third examination, and 2436 of the initial 3608 individuals participated in all three examinations. In total, 95/1050 (9.1%) women and 76/1061 (7.4%) men reported night eating. Based on data from the 1987–88 examination 14% of male	**Year of baseline examination and questionnaire:** 1982–83 **Duration of follow-up:** 6 years from 1987–88 to 1992–93 **Outcome variable:** 5-year preceding and 6-year subsequent weight change (kg) **Self-reported or measured weight:** Measured. **Statistical analysis:** Association the between night eating and the preceding weight change, multiple logistic regression models were used. To estimate the effect of night eating on subsequent weight change, multiple linear regression analysis was used.	**Attrition:** 67.5% for all three examinations. **Weight changes:** (M-82 to M-87) Night eating was not associated with weight changes for either sex in the crude and adjusted analyses. Obesity in M-82 did not modify the association between preceding weight change and night eating. (M-87 to M-93) For men, night eating was not associated with subsequent weight change. Analysis revealed that obese women with night eating experienced a greater average 6-year weight gain. The total average 6-year weight gain for obese night eating women was 5.2 kg, whereas obese non-night eating women experienced only a 0.9 kg average weight gain. **Association of diet with weight change:** No specific analysis of food types but reference was made to eating patterns, i.e. restraint when eating meals and data were adjusted for this variable. No significant associations with weight change were observed. **Association of physical activity with weight change:** No specific analysis; however, LTPA was recorded on a four point scale ranging from almost completely inactive, some PA, regular PA and regular hard physical training for competition. Data were adjusted for this variable and no significant associations with weight change were observed. **Association of other factors with weight change:** Other factors considered were present smoking habits and education as recorded by the number of years in school. No significant relationships with weight change were noted for either variable.	Adjusted for Age, smoking, years in school, LTPA, restrained eating and baseline BMI. **Author's conclusions:** Findings indicate that when using a simple yes/no question to assess the night eating phenomenon, obesity and night eating have a joint effect on 6-year weight change for women but not for men, suggesting that night eating maybe a significant contributor to further weight gain among already obsess women but not for others. **Comments:**

	and 13% of female night eaters were obese (BMI > 30) and 11% of male and 9% of female non-night eaters were classed as obese.			A simple yes/no question to identify night eaters with no specific time frame may have reduced the sensitivity of the analyses.
Kant (1995) (NHANES I and NHEFS) Prospective cohort **Aim:** To examine the association of frequency of eating occasions with prospective and retrospective weight change.	In total 7147, 2580 men and 4567 women. All respondents were 25–74 years of age at the time of the initial survey. Mean ages of men and women in the analytic cohort were 44.5 and 45.9 years, respectively.	**Year of baseline examination and survey:** 1971–75 **Duration of follow-up:** 8–10 years . **Outcome variable:** Weight change (kg). **Self-reported or measured:** Measured. **Statistical analysis:** The association of weight change with frequency of eating occasions at baseline and at follow-up were examined using sex-specific multivariate regression analyses. All regression analyses were run with and without adjustment for variables that may potentially affect body	**Attrition:** At follow-up in 1982–84, 46 respondents did not answer the two questions regarding the number of meals and number of snacks consumed daily, leaving 7101 respondents in the follow-up eating occasion cohort. Two or fewer eating occasions were reported by only 2% of the cohort at baseline 24-hour recall. At follow-up, from a summary of two questions on snack and meal frequency, nearly 15% of the cohort reported eating frequency of less than two occasions. Nearly 30% of the cohort reported more than six eating occasions at baseline using 24-hour recall relative to only 5% at follow-up based on answers to two questions on meal and snack frequency. In absolute terms, men and women reported a mean frequency of 5.3 and 4.9 eating occasions at baseline, respectively; at follow-up the mean frequency was 3.6 eating occasions for both men and women. No clear relation between frequency of eating and weight change was evident. **Weight change:** At baseline, weight changes and frequency of eating occasions were positively related in unadjusted models for both men and women. For every unit increase in frequency of eating, men and women gained 0.22 and 0.34 kg of body weight, respectively, over the period of the follow-up. After adjustment for age, and other confounders, the relationship was no longer significant. At follow-up, there was no association of weight change with eating frequency in men or women. **Association of diet with weight change:** At baseline, relative to all other categories, the eating occasion category of	**Author's conclusions:** There was no independent association of frequency of food ingestion estimated from 24-hour dietary recall with prospective weight change or frequency of eating estimated from answers to questions on number of meals and snacks consumed daily with weight change over the preceding 8–10 years in the NHEFS cohort. **Comments:** Twenty-four-hour dietary recall may not

		weight.	<2 was associated with the smallest mean weight change in men, but the largest mean weight change in women. In women, mean baseline BMI, triceps skinfold thickness, subscapular skinfold thickness and plasma cholesterol decreased with increasing baseline frequency of eating occasions. In men, the mean baseline BMI and subscapular skinfold decreased with increasing frequency of eating occasions. Trends in triceps skinfold and plasma cholesterol were not consistent. Mean dietary energy and alcohol intake increased with increasing baseline-eating frequency in both men and women. At follow-up, the highest frequency category (>6) was associated with the largest mean weight change and baseline BMI in women but not men. Mean plasma cholesterol measured at baseline was inversely associated with frequency of eating at follow-up in women but not in men. Mean alcohol intake decreased with increasing frequency of eating at follow-up in both men and women. **Association of physical activity with weight change:** Self-reported level of usual PA at baseline or at follow-up were not related with frequency of eating at baseline or follow-up (data not shown). **Association of other factors with weight change:** Whites, respondents with >12 years educations, and >1 poverty income ratio reported higher mean frequency of eating occasions both at baseline and at follow-up. Current smokers, and alcohol drinkers reported a higher frequency of eating occasions at baseline, but lower frequency at follow-up.	represent respondents 'usual' eating patterns. Different measures of dietary intake were used at baseline and follow-up. The extents of changes in frequency of food ingestion were unable to be measured.
Parsons 2005 Prospective cohort 2+ **Aim:**	All births 3–9 March 1958 in England, Scotland and Wales studied at age 33 and at age 42 years.	**Year of baseline survey:** 1991 **Duration of follow-up**: 9 years	**Attrition:** 860 out of 16460 **Weight changes: not stated** **Association of diet with weight change:** Among women the proportion who decreased chip consumption also	Outcomes not adjusted. **Author's conclusions:** Associations between BMI

To investigate whether adults studies in 1991 and 1999 improved their diet and PA level in the direction of recommendations.	**Baseline BMI:** Not reported.	**Outcome variable**: BMI quartile. **Self-reported or measured weight:** Self-report? **Statistical analysis**: Trends in % subjects increasing/decreasing activity, consumption of chips, fried food or fruit and salad, compared with remaining stable across the BMI quartile were assessed.	increased slightly with higher BMI ($p > 0.0001$); among women proportion who increased fried food consumption increased with lower BMI ($p = 0.001$); among women the proportion who decreased fruit and salad consumption increased with higher BMI ($p = 0.03$); among men significant difference between proportion who decreased chip consumption and between proportion who decreased fired food consumption fried food consumption ($p = 0.04$ and 0.01, respectively). **Association of physical activity with weight change:** No significant differences by BMI group among men and women who increased or decreased PA, or who increased chip consumption, or who increased fruit/salad/raw vegetable consumption.	and change in activity or diet were inconsistent.
Larew 2003 Prospective cohort 2+ **Aim:** To determine the relationship of muscle metabolism to exercise performance (results not relevant to this review) and of exercise performance to rate of weight gain	83 Black and White premenopausal women aged 23–47 years (mean age 34 [6.1] years with normal body weight (BMI 21–25 kg/m^2); some had previously been overweight; normal glucose tolerance, not smoked in previous year, not taking medication known to affect metabolism. **Baseline BMI:** 23.6	**Year of baseline survey:** Not reported. **Duration of follow-up**: 1 year. **Outcome variable**: Change in weight. **Self-reported or measured weight:** Measured. **Statistical analysis**: Multiple regression analysis.	**Attrition:** 61 of 83 subjects returned at 1 year. **Weight changes:** Mean rate of weight gain 3.8 (4.7) kg/year/to the power minus 1 (range –5.6kg/year/to the power minus 1 to 12.8 kg/year to the power minus 1). **Association of physical activity with weight change:** Greater muscle metabolic economy ($r = -0.25$, $p = 0.04$); greater quadriceps muscle strength ($r = -0.34$, $p > 0.01$); greater VO_{2max} ($r = -0.22$, $p = 0.04$) and longer treadmill endurance time ($r = -0.21$, $p = 0.04$) were significantly correlated with lower rates of weight gain over 1 year. Muscle metabolic economy, VO_{2max} and quadriceps muscle strength all independently and significantly contributed to the estimate of rate of weight gain model and the model explained 23% of weight gain variability ($r = 0.48$, $p > 0.01$). **Association of other factors with weight change (please state factors):** None.	**Adjusted for:** Not reported. **Author's conclusions:** Greater exercise endurance reduces weight gain.

Association of other factors with weight changes:

Other variables:</td>
<td>**Adjusted for:**
Independent variables – all at baseline.

The lack of association between significant weight gain and dietary and PA variables may reflect the relatively crude methods used to measure them. Diet measured with FFQ. PA variables were also self-reported and depended on recall. Recall bias may have been a factor.

Sample was unrepresentative – high attrition could have created bias; only urban women and two ethnic groups represented.

Author's conclusions:</td>
</tr>
</table>

Significant:
Those with significant weight gain:

- Were more likely to be younger ($p = 0.039$);
- Were more likely to have a high anxiety score ($p = 0.037$);
- Had a lower average Quality of Life score ($p = 0.041$).

Marginally significant:
Those with significant weight gain:

- Were more likely to have a high depression score ($p = 0.053$);
- Had a greater number of pregnancies ($p = 0.086$);
- Were more likely to be on a diet ($p = 0.082$).

Non-significant:

- BMI category; waist-to-hip ratio;
- Perceived stress;
- Current cigarette smoking status; alcohol consumption (average. no of drinks per week);
- Race; education; whether employed outside the home;
- Reproductive hormone values.

2. Final model (with significant results in **bold**):

Summary of results:

Race
• No significant effects by race for men.
• Black women had a greater mean BMI change than White women, even when adjusting for confounding variables (independent effect of race was 0.6 kg/m^2, $p > 0.05$). This is, however, probably due to differences in odds of major weight *loss* (Black vs. White women: adjusted OR 0.6, $p > 0.05$). Although the crude incidence of major weight gain was nearly 50% higher in Black than White women, race did not independently alter odds of major weight gain in women.

Family income
No effect for mean BMI changes but low income was associated with significantly greater odds of major weight gain in both men and women and greater chance of major weight loss only amongst women.

Education
Less education was independently associated with greater mean BMI change in both men and women. No effects by education for major weight change.

Marital variables
Women's but not men's mean BMI change showed effects for marital change (increase with start of marriage, decrease with end of marriage). Women were more likely to experience major weight gain if they became married than if they were consistently married. Men were more likely to experience major weight gain if they became married or if they stayed unmarried than if they were consistently married. Men were more likely to experience major weight loss if they stayed unmarried or if their marriage ended than if they were consistently married.

<table>
<tr>
<td>cohort
2+

Aim:
To test the hypothesis that a high-fat diet has a different predictive value for long-term weight change at varying levels of PA.</td>
<td>participating in **The Population Study of Women** in Gothenburg, Sweden. 38–60 years old at baseline.

Baseline BMI (kg/m^2):
Lower fat consumers: 24.6 (4.1); higher fat consumers: 24.1 (4.1) (no significant difference).</td>
<td>**Duration of follow-up**: 6 years.

Outcome variable: Mean weight change (kg).

Self-reported or measured weight: Measured.

Statistical analysis: Multivariate regression analysis. Where interactions were significant, did stratified analysis - effect of dietary fat on weight change in each separate PA group. Leisure time and occupational PA analysed separately. Computation of activity categories reported elsewhere. Low fat intake defined as <38.5% energy from fat; high as 38.5%+.</td>
<td>follow-up examination (for follow-up weight measurement). Twelve excluded because of cancer, myocardial infarction, stroke or diabetes at baseline. Suggests attrition of 17%.

Weight changes:
Lower fat consumers (*n* = 180): +0.64 (1.8) kg
Higher fat consumers (*n* = 181): +0.79 (1.8) kg

Association of diet with weight change:
No analysis.

Association of physical activity with weight changes:
Leisure time physical activity: In the prediction of weight change, there was a significant interaction (*p* = 0.03) between PA level and dietary fat.

1) Unadjusted analysis. Dietary fat consumption predicted weight gain in the physically inactive women (*p* = 0.03) but not in the two groups reporting higher activity levels.

Weight change in kg, mean (SD):

</table>
</td>
<td>Initial body weight, current smoking status and age.

No adjustment for socio-economic factors.

Author's conclusions:
Sedentary recreational activity *plus* a low-fat diet may have a combined contribution to weight change that is not equivalent to the sum of the separate effects.</td>
</tr>
</table>

			Same pattern of results for overall energy intake. The high-fat association with weight gain in the sedentary group became marginally significant after controlling for overall energy intake and vice versa – i.e. the two dietary measures explained the same variance. *Occupational physical activity:* No interactions, data not shown in paper. **Association of other factors with weight changes:** No analysis. **Summary of results:** Women's fat intake was a predictor of 6-year weight gain *only* amongst women sedentary in leisure time.	
Ball 2002 Prospective cohort 2+ **Aim:** To investigate patterns of weight change, the incidences of major weight gain, overweight and obesity and how weight varied by sex, age, education, and initial body mass.	12,125 men and 17,674 women aged 35–69 years from Melbourne, Australia. **Baseline BMI or weight:** 1.1% of men and 4.1% of women were underweight; 28.2% of men and 41.0% of women were in healthy weight range; 53.2% of men and 35.7% of women were overweight; and 17.5% of men and 19.2% of women were obese.	**Year of baseline survey:** 1994 **Duration of follow-up:** 5 years **Outcome variable:** Weight change **Self-reported or measured weight:** Measured at baseline and self report throughout the rest of the study **Statistical analysis:** Linear regression.	**Attrition:** Not reported. **Weight changes:** Women gained (2.42 kg) significantly more ($p > 0.01$) weight than men (1.58 kg). Within each ethnic group, women gained significantly more weight than men ($p > 0.01$). Mean weight changes were 1.54 kg and 2.35 kg, respectively, for Anglo-Celtic men and women; 1.82 kg and 1.68 kg, respectively for Greek men and women; and 1.64 kg and 2.69 kg, respectively, for Italian/Maltese men and women. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change: Age, education, baseline weight** *Age:* Those in younger age groups gained significantly more weight than older groups, with those aged 35–44 years gaining the most weight within every sex or ethnic group. In all three ethnic groups, younger men were more likely to report larger weight gains ($p > 0.01$ for all groups), with men aged 35–44 years more likely than any other age group to have gained 2–4.99 kg, 5–9.99 kg or 10 kg or more. Younger women ($p > 0.01$ for all ethnic groups) were more likely to	**Adjusted for:** Not reported. **Author's conclusions:** Findings of widespread weight gain and obesity across the entire population sample, particularly among younger women and women who were already overweight, are a cause for alarm.

			experience moderate to large weight gains. *Education:* Education level was not significantly associated with weight gain, except among Anglo-Celtic men, with those who were tertiary educated gaining most weight. Education level was not associated with weight change for Greek (p = 0.23) or Italian/Maltese (p = 0.13) men. Anglo-Celtic men who were primary educated were the most likely to have maintained their weight, and those who were tertiary educated were most likely to report small to moderate gains (2–9.99 kg) (p > 0.05). However, education level was not associated with weight gain among women in any ethnic group. *Baseline weight:* Obese Anglo-Celtic women were likely to gain 10 kg or more than were all other women. Across all three ethnic groups, overweight and obese women also tended to be more likely than other women to report major weight loss (>10 kg).	
Ball 2002 Prospective cohort 2+ **Aim:** To investigate the prevalence and predictors of weight maintenance over time in Young Australian Women. More specifically relationships between weight maintenance and behavioural factors like PA, diet, and	8726 young women, who are residents of Australia, aged 18–23 years at baseline. **Baseline BMI or weight:** 47% of women were categorised as having a healthy weight (BMI 20–25 kg/m^2), 23.3% as overweight or obese (BMI 25–30 kg/m^2) and 11% who had height or weight missing and could not be classified.	**Year of baseline survey:** 1996 **Duration of follow-up**: 4 years. **Outcome variable**: BMI/ weight. **Self-reported or measured weight:** Self-reported. **Statistical analysis**: Logistic regression.	**Attrition:** 0% **Weight changes:** Only 44% of the women reported their BMI at follow up to be within 5% of their baseline BMI; 41% had gained weight and 15% had lost weight. **Association of diet with weight change:** Restrictive eating practices (p > 0.05) and women who reported eating takeaway occasionally were 15% less likely to be weight maintainers than those who rarely or never ate takeaway. **Association of physical activity with weight change:** Women who reported moderate or high sitting time were 17–20% less likely to have maintained their weight **Association of other factors with weight change: Smoking** **Smoking** was significantly associated with decreased likelihood of weight maintenance. Low **alcohol** intake was associated with increased likelihood of maintaining weight. Weight maintainers were more likely to be in managerial or professional occupations; to have never married; to be currently studying and not to be	**Adjusted for:** Not reported. **Author's conclusions:** Early adulthood may be an important time for implementing strategies to promote maintenance of healthy weight.

alcohol consumption.			mothers.	
Bell 2001 Prospective cohort 2+ **Aim:** To describe and analyse 8-year weight change in Chinese adults and to determine the baseline characteristics of those who gained weight in the time period.	2488 Chinese adults aged between 20–45 years from seven provinces of China. **Baseline BMI or weight:** Mean weight of males 58 kg and BMI 21.2 kg/m^2. Mean weight of females 52 kg and BMI 21.7 kg/m^2.	**Year of baseline survey:** 1989 **Duration of follow-up**: 8 years. **Outcome variable**: Weight (kg), BMI. **Self-reported or measured weight:** Measured. **Statistical analysis**: Multiple logistic regression.	**Attrition:** 41% **Weight changes:** Mean BMI increased from 21.5 to 22.4 kg/m^2. From 1989 to 1997 the proportion of underweight men and women dropped by 2.3% and 4.4%, respectively. There was a 9% increase in the proportion of men and women who were overweight. The prevalence of obesity in women increased 7-fold from 0.2 to 1.5% over 8 years. By 1997 14.1% of men and 20.7% of women were overweight or obese compare with 5.0 and 10.5% in 1989. Overweight (BMI > 25 kg/m^2) doubled in females (10.4–20.8%) and almost tripled in males (5.0–14.1%). **Association of diet with weight change:** Energy intake did not affect the risk of weight gain. **Association of physical activity with weight change:** Men who experienced large weight gain (>5 kg) were three more times likely to have engaged in light rather than heavy work related activity, two and a half times more likely to have engaged in moderate rather than heavy PA. For men, having light to moderate activity levels at work (vs. heavy) was predictive of subsequent weight gain. Only PA played a role in weight gain for women. Women who gained >5 kg were 83% and 69% more likely to have done light and moderate rather than heavy PA compared with those who remained stable weight. **Association of other factors with weight change: Height, education, alcohol, smoking** For men, being **tall** at baseline and having a college **education** (vs. primary school education) were predictive of subsequent weight gain. For women having a college education at baseline was predictive of subsequent weight loss. Men who experienced large weight gain (>5 kg) were 55% more likely to have consumed **alcohol**. **Smoking** did not affect the risk of weight gain.	**Adjusted for:** Anthropometric and socio-economic variables were included as control variables. **Author's conclusions:** The prevalence of overweight increased dramatically in this particular cohort. Light work-related PA was the strongest predictor of the weight gain.
DiPietro 1998 Prospective cohort 2+	4599 men and 724 women with an age range of 20–82 years (mean	**Year of baseline survey:** 1970 **Duration of follow-up**:	**Attrition:** Not stated. **Weight changes**: Small weight gain over the follow up (0.61 ± 5.29 kg for men and	**Adjusted for**: Age, height, baseline weight, baseline treadmill time,

Aim: To determine the longitudinal relationship of change in cardiopulmonary fitness to subsequent change in body weight in a cohort of healthy middle-aged adults.	43 ± 9 years) from Dallas, TX, USA (no personal history of heart attack, hypertension, stroke or diabetes and no resting electrocardiogram (ECG) or exercise ECG abnormalities). **Baseline BMI or weight:** Mean weight of men: 81.2 ± 10.7 kg. Mean weight of women: 43.1 ± 8.7 kg.	24 years. **Outcome variable**: Weight (kg). **Self-reported or measured weight:** Measured. **Statistical analysis**: Multivariate linear regression.	1.51 ± 4.67 kg for women; $p > 0.001$), which is consistent with population trends for middle-aged adults. NB: These summary statistics, however, may mask heterogeneous patterns of change, as some participants lost substantial amounts of weight over the follow-up, while others gained weight. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** *Physical activity and television viewing:* Each 1 min improvement in treadmill time, significantly attenuated weight gain in both men ($p > 0.001$) and women ($p > 0.001$), respectively. Each 1 minute improvement in treadmill time, reduced the odds of a >5 kg gain by 14% in men and by 9% in women; and the odds of a >10 kg gain by 21% in both men and women. Higher baseline levels of PA and lower levels of TV/video viewing remained independently related to a lower risk of becoming overweight. The association between the 2-year change in PA or TV/video viewing and the 2-year change in BMI was also examined in the same male cohort. This suggests a small significant correlation between changes in activity or sedentary behaviour and BMI. Each 10 METs per week increase in PA (1 extra hour of running per week) was associated with a 0.03 BMI (0.44 kg) attenuation in weight gain and each 10 hour per week increase in TV/video viewing correlated with an excess weight gain of 0.05 BMI units (0.73 kg) over 2 years. .	smoking status, number of clinic visits and follow up time were all adjusted for. **Author's conclusions:** Improvements in fitness, appear important in attenuating age-related weight gain in healthy middle-aged adults. Thus, an active lifestyle should be promoted early and maintained through adulthood to prevent substantial weight gain and obesity with age.
Droyvold 2004 Prospective cohort 2+ **Aim:** To study the association between PA at baseline and change in BMI	9357 healthy women aged 20–49 years who had a normal body weight (a BMI of 18.5 – 24.9 kg/m^2) at baseline from Nord-Trondelag County, Norway (not >50 years	**Year of baseline survey:** 1984–86 **Duration of follow-up**: 9 years. **Outcome variable**: BMI. **Self-reported or measured weight:**	**Attrition:** Not reported. **Weight changes:** Mean BMI gain was 2.5 (range 5.6 –18.5) kg/m^2. The mean BMI increased in all age cohorts and in all categories of LTPA, smoking, education, baseline BMI, marital status and alcohol consumption. By follow-up 60.3% were in the normal weight category and the proportion of those in the overweight category (BMI of 25.5–29.9 kg/m2) was 36.4%. 3.1% were classified as obese (BMI >30 kg/m2). 1.3% of subjects gained >5 kg during the 11th year of follow-up time and	**Adjusted for:** Age, education and BMI at baseline to investigate association between LTPA and BMI 11 years later. **Author's conclusions:**

during follow up (11 years).	old and no reports of diabetes, stroke, angina, myocardial infarction, or long term illness impairing their function in daily life). **Baseline BMI or weight:** Average BMI of 22.0 kg/m^2.	Measured. **Statistical analysis**: Linear regression.	only 1.4 % lost >5 kg. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** Those with moderate and high levels of leisure PA at baseline gained less weight than those with low levels. However, the observed difference in mean weight change between low and moderate levels of LTPA did not reach statistical significance. Those with high level of activity gained 0.18 kg/m^2 (95% CI 0.05, 0.32) less than those with low level of PA over 11 years. **Association of other factors with weight change: BMI, age, PA, education, alcohol** Characteristics associated with highest BMI gain were high baseline BMI level, younger age, low or moderate LTPA level, low level of education and not drinking alcohol in the last 14 days.	LTPA has a moderate effect on BMI. However, not even a high level of LTPA was sufficient to prevent weight gain and BMI increase in all subgroups of the study population.
Hardy 2000; Langenberg 2003 Prospective cohort 2+ **Aim:** To investigate the effect of childhood weight and childhood socio-economic status on the pattern of change in BMI between 20 – 53 years.	2547 women and 2815 men born in the first week of March in 1946 from **England, Scotland and Wales.** **Baseline BMI/weight:** Number of men overweight (BMI >25 kg/m^2): 134 Number of men obese (BMI >30 kg/m^2): 8 Percentage of men overweight: 11.5% Percentage of men obese:	**Year of baseline survey:** 1946. **Duration of follow-up:** 53 years. **Outcome variable:** BMI. **Self-reported or measured weight:** Ages 7–14, 36, 43 and 53 years measured . Other ages self-reported. **Statistical analysis:** Repeated measures.	**Attrition:** At 43 years 6.8 % had died, 12.1 % had withdrawn from the study, 11.5% were living abroad and 8.8% had temporarily refused to participate or could not be traced. **Weight changes:** In general, the rate of increase in BMI with age was non-linear, with the rate of increase in mean BMI accelerating with increasing age at differing rates for both sexes**.** Mean BMI, which was calculated separately for each measurement, increased with age for both sexes and at every age the mean BMI was lower among women than men. Birth weight was positively associated with adult BMI (0.53 kg/m^2 for every kg increase in birth weight). **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change:** *Age:* There was a greater percentage of men overweight (>25 kg/m^2) at	**Adjusted for:** Assessment of influence of father's social class at 4 years of age was adjusted for offspring's own social class in young adulthood and middle-age (Langenberg). Final childhood risk factor model was adjusted for adult social class and educational attainment to assess whether the influence of

	0.7% Number of women overweight: 113 Number of women obese: 16 Percentage of women overweight: 10.1% Percentage of women obese: 1.4%		each age but a lower percentage obese (>30 kg/m^2). At all ages those from a manual **social class** had a greater proportion classified as overweight and obese compared with those from non-manual social classes. Of those overweight at 20 years and by 43 years, 80% were overweight. The increase in obesity was also very high in this particular group increasing from 6% at 20 years to 35% at 43 years. For men at age 20 years the estimated mean BMI was 23.33 kg/m^2 while for women it was 21.72 kg/m^2. The estimated mean linear increase in BMI was greater among men at 0.12 kg/m^2 per year than women for whom it was 0.03 kg/m^2. Women had a mean BMI of 0.61 kg/m^2 less than men at 20 years, which is 1 kg/m^2 less at both 26 and 36 years with the difference decreasing again to 0.6 kg/m^2 less at 43 years. *Social class:* Father's social class at 4 years was inversely associated with adult central and total obesity at age 53 years in both men and women. The mean difference of waist-to-hip ratio between fathers professional social class I and unskilled manual social class V was 2.6 (range 0.7–4.6)% for men and 2.5 (range 0.5–4.4)% for women. The effect of fathers social class remained after adjustment for participants own social class in young adulthood and middle age. Both adult social classes were inversely related to obesity among women, but not men. Active men and women were less obese than participants remaining in their fathers' social class and their levels of obesity tended to be between the class they left and the class they joined. At 14 years, mean BMI and faster rate of increase than others and those from a manual social class background had a higher mean BMI and a faster rate of increase than those from a non-manual background.	childhood factors was independent of adult social factors (Hardy). **Authors' conclusions:** Childhood relative weight and childhood social class were shown to have an effect on BMI in adult life and change in BMI from ages 20 to 43 years, even after adjustment for adult SES and education. The effect of social class on adult obesity differed according to the stage in the life course at which social class was measured, and gender. Childhood circumstances had enduring influences on adult obesity.
CARDIA (Coronary Artery Risk	CARDIA is a population based	**Year of baseline survey:** 1985–86	**Attrition:** Baseline data were collected on 51% of eligible persons contacted. Overall retention rates were 90% at 2 years, 86% at 5 years, 81% at 7 years, 79%	All analyses were **adjusted for**:

Development in Young Adults) Prospective cohort 2+ **Aim:** To estimate the change in BMI over 10 years in a cohort of young US men and women, and assess differences by a range of variables. Lewis 2000 Black and minority ethnic group [BMEG]-based on 10-year follow-up data) Pereira 2005 Fast Food – based on 15 year follow-up data. Sternfeld 1998 PA – based on 7-year follow-up data of selected individuals who completed a treadmill test at	prospective study of 5,115 African American and White men and women in the USA aged 18–30 years at baseline. Study population was balanced on: Age (45% 18–24 years) Sex (46% men) Ethnicity (52% African American) **Baseline weight (kg) as mean (SD) and overweight (%):** AAW: 69.5 (18.3) kg, 44.7% WW: 63.1 (12.8) kg, 22.1% AAM: 77.5 (15.6) kg, 36.9% WM: 77.1 (12.6) kg, 12.6%	**Duration of follow-up**: Ongoing. **Outcome variable**: measured height and weight (and % overweight) at baseline and again at 2, 5, 7, 10 and 15 years), and waist-to-hip ratio. Self-reported or measured variables: • Age • Education • Smoking status • CARDIA PA history questionnaire • Physical fitness (treadmill test, only assessed in selected subsample) • CARDIA dietary assessment = a structured interview (was not done at year 2 follow up) and CARDIA diet history. • Parental fatness and education were derived from self and interviewer-administered questions	at 10 years, and 74% at 15 years. **Association of diet with weight change** (based on 15 year follow-up data)**:** Fast foods were quantified based on eating out occasions at restaurants 'such as McDonalds, Burger King, Wendy's. Arby's. Pizza Hut or Kentucky Fried Chicken'. **Fast food intake** was lowest for WW (about 1.3 times per week) compared with the other race-sex groups. Baseline **fast food frequency** was directly associated with changes in weight in both black (p = 0.0050) and white people (p = 0.0013). Change in fast-food frequency over 15 years was directly associated with changes in bodyweight in white individuals (p<0.0001), with a weaker association recorded in black people (p=0.1004). By comparison with average 15-year weight gain in participants with infrequent (less than once a week) fast food restaurant use at baseline and follow up (*n* = 203), those with frequent (more than twice a week) visits to fast food restaurants at baseline and follow up (*n* = 87) gained an extra 4.5 kg weight (p = 0.0054) . **Association of physical activity with weight change:** *Note:* analysis based on a selected subgroup (*n* = 1777) who completed a symptom-limited graded treadmill exercise test at baseline and year 7. Decreased fitness during young adulthood is strongly associated with increased weight (correlations ranged from –0.34 in WM to –0.49 in WW). Decreased PA was moderately associated with increased weight in WM and BW (correlations –0.13 and –0.15, respectively). Analysis by baseline physical fitness and PA was not presented. **Association of other factors with weight change:** *BMEG (based on 10-year follow-up):* Weight gain 0.96 kg/year (95% CI 0.79, 1.13) in AAW; 0.55 kg/year (95% CI 0.41, 0.69) in WW. *Pregnancy (based on 5 year follow-up of 2788 women at baseline):* Primiparous within both race groups gained 2 or 3 kg more weight during the 5-year period than did nulliparous. Primiparous also had greater increases in waist-to-hip ratio that were independent of weight gain.	Age; Education; Smoking status. Also **adjusted for** PA in analysis. AAW: African American Women WW: White Women AAM: African American Men WM: White Men Overweight was defined as BMI >25.0 kg/m^2.

baseline and 7 years. Smith 1994 Pregnancy – based on 5-year follow-up. Greenlund 1996**;** To assess whether parental educational attainment, parental body shape, and offspring's education were associated with BMI and change in BMI over 7 years		**Statistical analysis**: Various, but all used some form of regression analysis. Women who remained nulliparous (*n* = 925) at 5 years were compared with women who had a single pregnancy and who were at least 12 months postpartum at 5 years.	Multipara did not differ from nulliparous in adiposity change in either race group. *Pregnancy – Black and ethnic minority groups:* At each level of parity, Black women demonstrated greater adverse changes in adiposity than did White women. In conclusion: women experience modest but adverse increases in body weight and fat distribution after a first pregnancy and that these changes are persistent. **Association of other factors with weight change:** (education/body size) **Parental education:** With adjustments for major independent variables, significant associations between fathers educational level and participants baseline BMI were observed among Black men and White women. Father's educational level was associated with a 7-year difference in BMI for White women only. Further adjustment for smoking, alcohol consumption, and PA yielded similar results. In analysis adjusted for age only, father's educational level was also associated with baseline BMI among Black women. In similar models in which father's educational level was replaced by mother's education, only the association with a 7-year change in BMI was significant among White women. **Parental body size:** Father's body size was positively associated with BMI among Black men, White men and White women. Trends were similar in analyses adjusted for age only and analyses adjusted for other lifestyle factors. Mother's body size was positively associated with BMI among all four race-sex groups, and with a change in BMI among White women. When adjusted for age only, a positive association with change in BMI among Black men and Black women was also observed. When adjusted for smoking, alcohol consumption and PA level, results were similar.	

			Participant education: Those participants with the highest education had the lowest BMI and change in BMI over 7 years.	
Wagner 2004 Prospective cohort 2+ PRIME Study **Aim:** To examine the influence of PA on change in BMI (and waist) in middle-aged men over a 5-year period, with special regard to moderate-intensity activities.	Data for this study were collected as part of the PRIME Study (arisen out of the MONICA study). Total *n* = 8069. A cohort of 8865 men aged 50–59 years from centres in France and Northern Ireland. Weight data were missing for 796 of these men at 5 years. No data on ethnicity presented in this paper. **Exclusion criteria:** History of coronary heart disease, diagnosis of cancer during follow-up. **Baseline BMI, mean (SD):**	**Year of baseline survey:** 1991–93. **Duration of follow-up**: 5 years. **Outcome variable**: BMI. **Self-reported or measured weight:** Measured at baseline, but self-reported at yearly follow-ups. **Statistical analysis**: Multiple linear regression.	**Attrition:** 90% of those who took part in the study in 1991–93 were included in the analysis at 5 years. **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** Change in BMI was inversely associated with PA expenditure spent in getting to work, and the practice of high-intensity (> 6 METs) recreational activities. Men who regularly spent more than 10 MET hours per week on walking or cycling to work had a mean change in BMI 0.06 kg/m^2 lower than those who expended less than 10 MET hours per week on walking or cycling to work. In the subgroup of men who did not perform high intensity activities, the level of recreational PA expended was *not* associated with weight gain. **Association of other factors with weight change:** No analysis. **Summary:** In middle-aged men, PA of moderate intensity, which are probably easier to promote than more vigorous activities and, in particular, a more current daily activity, walking or cycling to work, may have a more favourable effect on weight gain.	**Adjusted for**: Covariates: Educational level; Smoking status; Alcohol consumption; Centre; Age; Marital status; Pursuit of weight-control diet; SES. *Note*: Lengthy details about how PA was categorised and calculated are in the paper. PA – the MOSPA-Q was used to assess the amount of PA performed during the previous year, according to the category of PA (occupational activity, walking or cycling to and from work, and leisure-time activities)

	26.6 (3.4) kg/m^2			
Heitmann 1995 Prospective cohort 2+ **Aim:** To examine the influence of dietary fat on changes in BMI in adult women at 6 years while taking into account their predisposition to obesity, total daily energy intake, leisure PA, smoking status, and menopausal status. **Ow/Op:** Overweight women (BMI > 25 kg/m^2) with at least one obese parent; *n* = 56. **Ow/Np:** Overweight women (BMI > 25 kg/m^2) with non-obese parents; *n* = 53. **Nw/Op:** Ideal weight women	*n* for this analysis = 308. Data for this study were collected on a subset of 437 women, selected randomly at baseline from a larger population sample of 1462 women aged 38, 40, 50, 54 or 60 years living in Gothenburg, Sweden. At baseline in 1968–69, 418 of these women participated in a diet history interview, a 24-hour dietary recall, and a health examination. Six and 12 years later, in 1974–75 and 1980–81, all participants were invited to follow-up health examinations. The second examination (at 6 years) was attended by 373	**Year of baseline survey:** 1968–69 **Duration of follow-up**: 6 years. **Outcome variable**: BMI (measured height and weight). **Self-reported or measured weight**: Measured **Statistical analysis**: The relation between change in BMI over 6 years and fat intake at baseline within the four groups of women was assessed by regression. In the regression analysis, a number of covariates at baseline were included; age, BMI, total daily energy intake, LTPA, smoking habits. Menopausal changes between baseline and 6 years were included as covariates.	**Attrition:** 70% **Association of diet with weight change:** *Summary:* High dietary fat (>40% total daily energy intake) was significantly associated with a 6-year gain in BMI only among women predisposed to obesity (*p* = 0.003), but not among obese women with lean parents, or lean women with or without obese parents. *Note*: Only six Ow/Op women had fat intakes >40% total daily energy intake. **Association of physical activity with BMI change:** No analysis. **Association of other factors with weight change**: No analysis.	**Adjusted for:** Covariates stated in statistical analysis.

(BMI <25 kg/m^2) with at least one obese parent; *n* = 87. **Nw/Np:** Ideal weight women (BMI <25 kg/m^2) with non-obese parents; *n* = 112.	(89%) of the 418 women, and the third examination (at 12 years) was attended by 324 (78%) of the 418 women. At the12-year follow up, 316 of the 324 women answered questions about the fatness of their mother and father. For this paper, only women who provided baseline data, data on height and weight at 6 years, and answered questions about the fatness of their mother and father at 12 years were included. Of the potential 316 women who could be included in this analysis, eight were excluded (had cancer at baseline).			

	Women already overweight with one or more obese parent(s) were considered to be predisposed to obesity. No data on ethnicity, education or income presented in this paper. **Exclusion criteria:** Pre-existing major chronic diseases at baseline (stroke, myocardial infarction, diabetes, cancer) **Baseline BMI (kg/m^2), mean (SD):** Ow/Op (*n* = 56) 29.6 (4.0) Ow/Np (*n* = 53) 28.0 (2.7) Nw/Op (*n* = 87) 22.4 (1.7) Nw/Np (*n* = 112) 21.9 (1.9)			
Sundquist 1998 Prospective	1972 women and 1871 men (*n* = 3843) aged	**Year of baseline survey:** 1980/81	**Attrition:** 17%	None stated **Author's**

cohort 2+ **Aim:** To assess the influence of ethnicity (country of birth) and SES on BMI.	between 25–74 years, from Sweden. The subjects were all Swedish residents either born in Sweden, Finalnd, Western Europe and Western Europe. **Baseline BMI:** Baseline mean BMI for male subjects: 25–34 years: 23.5 kg/m^2 35–44 years: 24.4 kg/m^2 45–54 years: 25.2 kg/m^2 55–64 years: 25.3 kg/m^2 65–74 years: 25.4 kg/m^2 Baseline mean BMI for female subjects: 25–34 years: 21.7 kg/m^2 35–44 years: 22.7 kg/m^2 45–54 years: 24.1 kg/m^2 55–64 years: 24.9 kg/m^2 65–74 years:	**Duration of follow-up**: 8 years. **Outcome variable**: BMI. **Self-reported or measured weight**: Not stated. **Statistical analysis**: Pearsons correlation coefficient was used to calculate the correlation between BMI in 1980–81 and 1988–89.	**Weight changes:** The mean BMI increased significantly between 1980–81 and 1988–89 in both men and women in all age groups, apart from the age group 65–74 years where BMI decreased. **Association of other factors with weight change:** *Socioeconomic status:* People of a low level of education had the highest BMI. All educational groups increased their BMI over 8 years with the exception of poorly educated men. Less educated individuals increased their mean BMI by 0.25 kg/m^2 less than highly educated people (reference group), based on educational level 1988–89. Men and women who were single in 1980–81 and married in 1988–89 increased their BMI by 0.37 and 0.65 kg/m^2 more than those who were married at both times. Poor health status was related to a decreased BMI among men but not among women. Males who reported good health status in 1980–81 and bad health status at follow up decreased their BMI by 0.28 kg/m^2 less than males who were in good health status at baseline and follow-up. *Ethnicity:* The different ethnic groups had similar changes in BMI changes in BMI from 1980–81 to 1988–89. The BMI of men and women born in Sweden and other western countries and of women born in Finland increased significantly through the 1980s. The BMI of southern European Men increased from 25.5 to 27.0 kg/m^2 during the same period. Southern European men had a higher BMI compared with the reference group; this was the same for southern European women, but no significantly so. Finnish women had an increased BMI on adjusting for the age, smoking, exercise, education, marital status, health status and time. *Smoking:* Male smokers had an increased BMI compared with those who had never smoked. Female smokers had a much lower BMI compared with those who have never smoked. *Physical activity:* Not taking exercise was associated with an increased BMI for men and women.	**conclusions:** SES and ethnicity are two separate independent factors that influence BMI in males and females. Former smokers had a larger increase in BMI than those who have never smoked. Males who quit doing exercise had a larger increase in BMI than regular exercisers.

	25.1 kg/m^2		Males taking exercise in 1980–81 but not at follow up increased their BMI by 0.28 kg/m^2 more than the reference group (people taking exercise at baseline and follow-up). Females who did not take exercise on both occasions decreased their BMI by 0.37 kg/m^2.	
Tiggemann 2004 Prospective cohort 2+ **Aim:** To assess dietary restraint and self-esteem as predictors of weight change over 8 years.	*n* = 77 young adults (19 men, 58 women), mean age 25 years, all undergraduate first-year students at University in Australia. No data on ethnicity, education or income is presented in this paper. **Exclusion criteria:** Pregnancy, medical condition that significantly affected weight **Baseline weight (kg), mean (SD):** Men: 75.2 (6.2) Women: 58.0 (7.0)	**Year of baseline survey:** Not reported. **Duration of follow-up**: 8 years. **Outcome variable**: BMI. **Self-reported or measured weight**: Self-reported. **Statistical analysis**: Hierarchical multiple regression.	**Attrition:** 60% of those who took part in the study at baseline (*n* = 166). **Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change:** Neither dietary restraint nor self-esteem predicted weight change on its own in men or women, but their interaction did in women. The women who put on the most weight were those low or high in both dietary restraint and self-esteem. The group who put on the least weight were those low in dietary restraint and high in self-esteem.	None stated.
van Lenthe 2000	*n* = 767 young Dutch adults (362 men, 405	**Year of baseline survey:** 1991	**Attrition:** Difficult to assess.	None stated.

Prospective cohort 2+ GLOBE study **Aim:** To assess socio-demographic variables as predictors of weight change over 6 years in a group of young Dutch adults.	women), age 20–49 years at baseline. **Exclusion criteria:** Missing information, serious heart problem, cancer, and diabetes. **Baseline BMI (kg/m^2), mean (SD):** Men: 24.3 (2.9) Women: 23.0 (3.3)	**Duration of follow-up**: 6 years. **Outcome variable**: BMI. **Self-reported or measured weight:** Self-reported. **Statistical analysis:** Multivariate linear regression.	**Association of diet with weight change:** No analysis. **Association of physical activity with weight change:** No analysis. **Association of other factors with weight change:** Despite significant associations between BMI and SES at baseline, no statistically significant associations were found between SES variables and the 6-year change in BMI.	Author's conclusions: SES was not associated with the 6-year change in BMI.

Appendix 5

Raising awareness of what constitutes a healthy weight range and the need to stay within such a range

EVIDENCE SUMMARY TABLES

EVIDENCE TABLE 1: **RAISING AWARENESS OF WHAT CONSTITUTES A HEALTHY WEIGHT RANGE AND THE NEED TO STAY WITHIN SUCH A RANGE**

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for weight maintenance/reduction								
O'Loughlin et al. 1998	RCT	1	+	Intervention *n* = 94 Control *n* = 94 Data based on completers (intervention = 82, control = 75) **Age:** Intervention group: Female: 67.1% Age: 39.2 years ± 14.5 Control group: Female: 72.0% Age: 37.0 ± 12.6 years **Education attainment (%):** Intervention group:	This RCT investigated the impact of a low intensity, healthy weight intervention in low-income adult volunteers from inner city St Henri, Canada. Pamphlets (18 four-page, two-colour, glossy and pre-punched, two or three per week) were distributed to the	**Intervention:** 8 weeks. **Follow-up:** 10 weeks (2 weeks after end of intervention).	816 people were contacted but 188 (23%) volunteered to receive the pamphlets. Seventy-three participants were recruited from the Awareness and Participation Survey (13.6%); 115 participants were recruited from the 279 households contacted in the supplemental survey (41.2%). Eighty-two of 94 intervention participants (87.2%) and 75 of 94 control participants (79.8%) completed both interviews. The intervention had no effect on body mass index (BMI).	Short follow -up period. Data were self-reported. Use of telephone interviews (minimal face to face contact) possibility of bias related to social desirability. **Generalisability:** Unclear, low-income low-literacy inner city population of

				Less than secondary: 17.1 Completed secondary: 39.0 Completed university: 43.9 Control group: Less than secondary: 17.8 Completed secondary: 38.4 Completed university: 43.8 **Main activity in past 12 months (%):** Intervention group: Work: 54.9 Looking for work: 3.7 Student: 15.9 Retired: 13.4 Homemaker: 7.3 Other: 4.9 Control group: Work: 63.5 Looking for work: 2.7 Student: 17.6 Retired: 5.4 Homemaker: 6.8 Other: 4.1 **Marital status:** Intervention group: Married: 41.5% Single (never married): 37.8% Separated/widowed/Divorced: 20.7***%*** Control group: Married 38.7%	participants' homes for an 8-week period. The pamphlets focussed on increasing awareness of healthy weight ranges, increasing self-acceptance and satisfaction with weight, and improving eating habits, while not putting much emphasis on dieting and weight loss. Pamphlets designed to be highly accessible to persons of low literacy and based on Canadian recommendations 1988 for healthy weight, pamphlets were piloted. Recruited during October 1995 Awareness and Participation		**Awareness:** Intervention participants remembered receiving 13.1 (± 4) of 18 pamphlets, 89.6% had read one or more and 90.4% found the information useful. Participants in the intervention group were 3.7 times more likely than participants in the control group to report they knew how to control their weight. Participants in the intervention group were also less likely to report they were too heavy (odds ratio [OR] 0.3).	French/English-speaking Canadians.

				Single (never married) 48.0% Separated/widowed/Divorced: 13.3% **Income sufficiency (%):** Intervention: Insufficient: 12.2 Sufficient: 22.0 High: 45.1 Missing: 20.7 Control group: Insufficient: 17.3 Sufficient: 22.7 High: 46.7 Missing: 13.3 Volunteers more likely than non-volunteers to be female, younger and obese and less likely to be in pre-contemplation stage of readiness to improve eating habits. Adults were randomly selected from households which were randomly selected from residential telephone subscriber lists for the main survey; additional survey households also randomly selected but individual who answered the phone was asked to identify one adult member who might want to participate in the trial. All participants then 'randomly	telephone survey of adults in St Henri (plus a supplemental sample from telephone subscriber list) one of three annual surveys to monitor community penetration of Coeur en sante St Henri activities (multifactorial community heart health promotion programme in Montreal). **Providers of intervention:** Research staff.			

				allocated' to intervention or control group.				
Wardle et al. 2001; Miles et al. 2001	Before and after study design with one cross-sectional survey by the Office of National Statistics (ONS) and pre-post survey of random sample of respondents.	2	+	ONS survey: Total sample *n* = 1894 Men *n* = 938 Women *n* = 956; All adults but targeted more to overweight and obese adults. Age (years) **Women (%) Men (%)** 16–24 11.2 16.5 25–34 18.1 16.3 35–44 20.3 18.8 45–54 16.8 18.4 55–64 13.5 11.3 65 +0.1 18.7 Ethnicity **Women (%) Men (%)** White 95.1 94.7 Non-White 4.9 5.3 Maritial status % **Women(%) Men (%)** Single 15.9 24.4 Married/ cohabiting 63 66.7 Separated/ divorced/ widowed 21.1 8.9 Occupational social class	The study's primary objective was to evaluate the BBC's national 'Fighting Fat, Fighting Fit' (FFFF) campaign's success in achieving public awareness of the need for obesity prevention and putting over its message of healthy eating and increased physical activity (PA). The campaign aimed to stimulate behaviour change and was based on behaviour change theories such as Social Learning Theory and the Health Belief Model. Main message of campaign was that weight problems are	Campaign was for 7 weeks. General population survey by ONS: 3 months after the campaign finished. (March 1999). Registrants survey (random sample of 6000) where pre-campaign baseline behaviour assessed retrospectively 5 weeks into the 7-week campaign and again 5 months later.	70% (*n* = 1894 interviews) of random sample of ONS survey participated in telephone interview; 0.9% sent for registration pack; 0.2% registered with scheme. **Registrants survey:** 14% of those who requested an information pack returned their registration card, 61% returned the baseline questionnaire, 58% of people who completed baseline questionnaire also completed 5-month follow-up questionnaire (35% of original random sample of 6000). Non-completion rate of activity measure was 12% so results here should be treated with caution. Adults from higher socio-economic groups not only more likely to complete baseline questionnaire but complete follow-up questionnaire (suggesting more active participation in campaign). **Office of National Statistics survey:** 56.6% (*n* = 1072) had heard of the campaign, 29% recalled watching one of the television	Self-reported data. Generalisation of the results is limited due to the 70% response rate for ONS survey and less than 1% registered and of these 6000 surveyed in registrants survey.

					for £2 including self-help guide and three registration cards to return over 5 months to chart progress also money-off vouchers for FFFF book and exercise video up to total of £3, other incentives/prizes such as years free supply of fruit and vegetables. The FFFF campaign aimed to target specifically groups with higher prevalence of obesity (those in socio-economic groups 3M and 4). The crossover between those most likely to be obese and BBCs typical audience was considered to be those in		not in target audience (67% vs. 54%, $p > 0.001$). **Registrants survey:** Average post-campaign weight was 2.3 kg lower for full sample (baseline scores carried forward to follow-up for those who did not complete follow-up questionnaire, $n = 3661$) and 4.2 kg for completers ($n = 2122$, $p > 0.001$) with 44% full sample and 78% completers losing weight. Average BMI remained in the obese category. Predictors of change (completers only): men were more likely to report changes in weight, exercise and fried food intake, deprivation level was associated only with decreases in fried food intake, baseline weight predicted weight loss and positive changes in diet with obese reporting greater changes. Predictors of change (all participants): groups with higher levels of deprivation were less likely to report weight loss or exercise increase, obese did not report greater changes in diet and weight loss and changed less in terms of exercise than normal weight groups.	

					social classes 3NM and 3M aged between 21–45 years (skilled non-manual and manual groups). The generic campaign trail was broadcast on TV and radio late in December 1998 and in early January 1999. Principal TV programmes (with different target audiences) were ‘Weight of the Nation’, ‘Fat Free’, ‘Fat Files’ (Horizon trilogy), and ‘Body Spies’. BBC radio had 3-day launch with celebrities, TV chef, health minister and phone-in. FFFF campaign mentioned in 60 magazines, 9 national newspapers and 120 regional		Men, people aged <25 years, low SES and Black and Minority Ethnic Groups (BMEGs) may require specifically targeted campaigns – significantly fewer participants in these groups failed to complete the follow-up (registrants survey).

Tudor-Smith et al. 1998	Before and after design but samples are independent (cross-sectional) population surveys with an intervention community and a	2	–	**Geographical area:** Wales, UK and north-east England (reference area). Wales: 1985: *n* = 18538 1990: *n* = 13045 North-east England: 1985: *n* = 1483 1990: *n* = 4534 All participants were aged between 18–64 years No further details	To assess the 5-year effect of an intervention of a community-based demonstration project called 'Heartbeat Wales'. The main aim of Heartbeat Wales was to help prevent cardiovascular disease in adults (aged 18–64 years) by focussing on modifiable behaviour risks	Cross-sectional survey took place before and after the end of the 5-year intervention in intervention and control community.	In Wales, the response rate for the household interview was 88% in 1985 and 79% in 1990 and the self-completion response to questionnaire was 67% and 61 % respectively. In the reference area the household interview response was 84% in 1985 and 77% in 1990 and the self-completion response was 64% and 61 % respectively. Altogether 31,583 questionnaires (18,538 in 1985 and 13,045 in 1990) were returned over the surveys in Wales, with 6017 (1483 and 4534, respectively) returned in the north-east of	Self-reported data. The sample size at the baseline measurement at baseline in the North East was too small to give sufficient statistical power to detect a net intervention effect. There is evidence of increases in funding for heart health promotion in the reference area and

	matched reference area.				such as smoking, diet and exercise. Two population surveys (multistage cluster sampling) were conducted in the summer and autumn of 1985 and 1990 in nine different districts of Wales and a matched reference area in the North East of England. Sample size in 1985 survey was determined to detect a 5% change in smoking prevalence within each of the 10 strata (two-tailed). In 1990 sample size was increased in reference area. Heart health promotion used public education campaigns alongside policy		England. Positive changes (for health) in behavioural outcomes were observed among the population in Wales, including a reduction in reported smoking prevalence and improvements in dietary choice. There was no net intervention effect for the programme over and above observed change in the reference area. **Percentage point changes 1985–90 (95% confidence intervals [CI]) aged 18–64 years:** BMI at least 24 kg/m^2 for women and 25 kg/m^2 for men, Wales 2.5 (1.0, 4.0) kg/m^2, control 1.1 (–2.9, 5.1) kg/m^2. Positive change in all behaviour indicators except for overweight, 14 of 15 behaviour-change indicators significant in Wales and 9 of 15 significant in control (13 positive changes).	diffusion of other health promotion campaigns (contamination).

					and infrastructure change. TV programmes were especially developed by BBC Wales and HTV. such as ‘Don’t Break Your Heart’, ‘Fit for Life’ and the BBC Diet programme, ‘Quit and Win’, a smoking cessation programme, food labelling and nutrition education with a major grocery retailer, ‘Heartbeat Awards’, a restaurant and canteen scheme to increase the availability of healthy food choices and smoke free areas and ‘Make Health Your Business’, which was a worksite health promotion programme.			

					In the north-east of England (reference area), no additional community heart health promotion was planned though considerable activity did take place, in order to influence people health behaviours in the north-east. **Providers of intervention:** Health promotion Wales and Research Staff.			

EVIDENCE TABLE 2: RAISING AWARENESS OF WHAT CONSTITUTES A HEALTHY DIET

First author	**Study design**	**Research type**	**ResEarch quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for dietary outcomes								
O'Loughlin et al. 1998	RCT	1	+	Intervention group *n* = 94 Control group *n* = 94 Data below are based on completers (intervention *n* = 82, control *n* = 75). Intervention group: Female: 67.1% Age: 39.2 ± 14.5 years Control group: Female: 72.0% Age: 37.0 ± 12.6 years See weight outcomes table (Table 1) for more detail .	See weight outcomes table (Table 1) for more detail.	**Intervention:** 8 weeks. **Follow-up:** 10 weeks (2 weeks after end of intervention).	The frequency of consumption of junk food/high-fat food remained stable in control and decreased in the intervention group (*p* = 0.019). Intervention participants reported more improvements in their eating habits than control (*p* = 0.021).	
Departm	CBA	2	+	National evaluation of five-a-day	**Aim:**	One-year	Response rate information not	

ent of Health 2003			/ – * [?]	pilot projects in five areas of the UK. No details provided in the executive summary and none available from project despite two approaches (fiveaday@sh.gsi.gov.uk) by Cardiff.	To assess the feasibility of implementing an area-wide approach to increasing fruit and vegetable consumption by improving access, increasing awareness and consumption. The intervention included action to improve access to fruit and vegetables by retailers, food co-operatives and targeted promotional activities in the community and by primary health care professionals. Interventions provided by community based cross-sectoral teams in each area. **Delivered by:**	intervention with pre- and post-questionnaires.	available. The community initiatives stemmed a fall in fruit and vegetable intake against the national trend. There was a fall in intake in the control group by almost half a portion (although baseline data suggested control group had a higher intake by 1.5 portions compared with intervention sites). Overall the intervention had a positive affect on people with the lowest intakes. Those who ate less than five-a day at baseline increased their intake by one portion over the course of the study. In contrast, those who ate five or more a day at baseline decreased intakes by about one portion per day. **Awareness:** 17% increase in proportion of intervention group who correctly reported that five-a-day was the optimal fruit and vegetable intake compare with 8% in the control group.

Wardle et al. 2001; Miles et al. 2001	Before and after study design with one cross-sectional survey by ONS and pre-post survey of random sample of respondents.	2	+	ONS survey: Total sample $n = 1894$ Men $n = 938$ Women $n = 956$; Age (years) **Women (%) Men (%)** 16–24 11.2 16.5 25–34 18.1 16.3 35–44 20.3 18.8 45–54 16.8 18.4 55–64 13.5 11.3 65 +0.1 18.7 See weight outcomes table (Table 1) for more detail.	The study's primary objective was to evaluate the BBC's national FFFF campaign. See weight outcomes table (Table 1) for more detail.	Campaign was for 7 weeks.	**Registrants survey: values are for full sample, all values in parenthesis are for completers only** Fruit and vegetable intake increased by 0.8 (1.3) portions per day, $p > 0.001$. Percentage eating recommended five portions per day increased by 13% (23%), $p > 0.001$. Number of participants eating fried food less than once per week increased by 16% (28%), $p > 0.001$. Proportion consuming whole milk decreased from 10 to 7% (9 to 4%), $p > 0.001$. Cutting visible fat off meat increased, $p > 0.001$. Snack intake decreased by 3 (5) snacks per week, $p > 0.001$. Number of starch-based meals increased slightly with 4% (6%) changing from eating one or fewer to two or more a day.	

							Number of pats of butter/margarine used decreased by 0.6 (1.3), *p* > 0.001); number of pats of low-fat spread decreased by 0.4 (0.7), *p* > 0.001. **Predictors of change (all participants):** Groups with higher levels of deprivation were less likely to report weight loss or exercise increase, obese did not report greater changes in diet and weight loss and changed less in terms of exercise than normal weight groups.	
Tudor-Smith et al. 1998	Before and after design, but samples are independent (cross-sectional) population surveys with an intervention community and a matched reference	2	–	**Geographical area:** Wales, UK and north-east England (reference area). Wales: 1985: *n* = 18538 1990 *n* = 13045 North-east England: 1985 *n* = 1483 1990 *n* = 4534 All participants were aged between 18–64 years. No further details.	The main objective of the study was to assess the 5-year effect of an intervention of a community-based demonstration project called 'Heartbeat Wales'. See weight outcomes table (Table 1) for more detail.	Cross-sectional survey took place before and after the end of the 5-year intervention in intervention and control community.	Positive changes (for health) in behavioural outcomes were observed among the population in Wales, including a reduction in reported smoking prevalence and improvements in dietary choice. There was no net intervention effect for the programme over and above observed change in the reference area. Percentage point changes 1985–1990 (95% CI) aged 18–64 years: Consume fresh fruit at least 4 days a week: Wales 8.4 (6.7, 10.1), control: 8.6 (3.0, 14.2). Consume green vegetables or	

	area.						salad at least 4 days per week: Wales 7.2 (5.1, 9.3), control 9.4 (2.7, 16.1). Consume fried food cooked in lard or other solid fat at least 2 days per week at home: Wales –18.7 (–16.8, –20.6), control –21.5 (–14.6, –28.4); note that consumption of fried food was significantly lower in Wales than reference area at baseline. Positive change in all behaviour indicators except for overweight, 14 of 15 behaviour change indicators significant in Wales and 9 of 15 significant in control (13 positive changes).	
Van Wechem et al. (1997)	Before and after design but samples are independent (cross-sectional) with an intervention community and a control communi	2	–	*n* = 1000 Control community group *n* = 500 Experimental community group *n* = 500 All participants were from Alkamaar in the Netherlands (intervention) and Gouda in the Netherlands (control). Participants were selected by random sampling from local telephone books. Every subject that was selected were contacted a maximum of five times during weekdays at different times of the day. Household members who	Community-based campaign ‘Fat Watch’ 1992, primary aim was to reduce fat intake by 10% among the general Dutch population. Within framework of nationwide fat watch campaign (1991–1994). This intervention was used as a pilot study, which looked at the	Not clear but telephone questionnaires were used before (February 1992) and after (December 1992) the campaign so approximately 8 months.	In Alkamaar, 56% of all respondents reported to be aware of a campaign about dietary fat in their community. A significant lower proportion of all respondents in the control community (17%), with exposure to the nationwide Fat Watch campaign only, were aware of the campaign about dietary fat in their community ($p > 0.001$). 43% of respondents in Alkamaar aware of national campaign and in control this was significantly lower at 34% ($p > 0.01$). In Alkamaar of those who were	

	ty.			would be the first ones celebrating their birthday were selected to be interviewed.	effectiveness of strategies and activities, with the hope of applying the campaign to other cities. The intervention conveyed a positive message about a low-fat diet (i.e. a healthy diet) and was put over in a motivating and informing way, which highlighted the positive consequences of low-fat diets and the consequences of a high-fat diet. During the campaign a total of eighty-one activities took place and attempted to communicate the messages of 'Fat Watch'. These activities were aimed mainly at intermediaries		aware of local campaign, 80% had noticed mass media written information, campaign activities which required more active participation by target groups were less noticed; mean appreciation rating of 7 (out of 1–10, with 10 positive) to local campaign among those who were aware. In the post-test no significant difference in actual fat consumption was found between Alkamaar and the control community. In the experimental community, a small but significant decrease (3%) in fat consumption was found in Alkamaar ($p > 0.04$) when pre test results were compared with post-test results, in control community there was no decrease in fat consumption pre- to post-test (28.3 to 28.4). A significant difference at post-test between Alkamaar and the control community was found for self rated dietary fat consumption. In Alkamaar 65% of all respondents rated their fat intake as ' fat' or 'relatively fat', whereas this was 56% in the control community ($p > 0.02$) (i.e. after the campaign self-rated fat consumption was significantly	

					and partly at the local population. The project group, who ran the project, organised 24 activities, which were aimed at various intermediary organisations, such as supermarkets, hotel and catering industry, health units, common welfare workers, educational organisations and several media. The majority of the activities were based on transfer of diverse, mostly written, mass mediated information and interpersonal communication. Research staff provided intervention and assisted intermediaries (e.g.		higher in intervention community) Additionally in the post-test, more respondents in Alkamaar (32%) than in the control community than in the control community (24%) reported that they had tried to lower their dietary fat intake in the past 6 months (*p* > 0.01). There was no significant difference (*p* > 0.05) between the experimental and control group community in the proportion of these respondents that referred to the Fat Watch campaign as a reason for their behavioural change. No significant post-test differences were found between the experimental and the control group with respect to attitude, perceived social support and self-efficacy expectations towards a reduction in fat consumption and intention to buy lower-fat food products. In the post-test, more participants in Alkamaar (20%) than in the control group (12%) showed the intention to eat lower fat food products in the following 6-month period (*p* > 0.01). Of those respondents who intended to eat lower-fat food products,	

					supermarkets, educational organisations, media) to organise local intervention activities.		significantly more respondents in Alkamaar (29%) than in the control group (11%) referred to the Fat Watch campaign as a motive for this intention ($p > 0.01$). This difference was not found among respondents who intended to buy lower-fat food products.	

EVIDENCE TABLE 3: RAISING AWARENESS OF THE NEED TO BE PHYSICALLY ACTIVE

First author	Study design	Research type	Research quality	Study population	Research question and design (include power calculation if available)	Length of follow-up	Main results (include effect size(s)/confidence intervals for each outcome if available)	Confounders (potential sources of bias)/comments
Evidence of efficacy (internal validity) for physical activity outcomes								
Cavill & Bauman 2004	Systematic review, eight studies were before and after studies, seven were controlled CBAs, most studies used repeat cross-	2	++	**Inclusion criteria:** 1) Campaign had to have at least one media element with mass reach. 2) Campaign needed to use the media in a purposive and organised manner to influence awareness/knowledge/saliency/attitudes, beliefs/self-efficacy/intention/behaviour. 3) Campaign had to employ at least a pre-post design using population samples to measure changes brought about as a result of the campaign. 4) There has to be clear PA mass media component to the	Review of 15 mass media campaigns with an explicit focus on PA to explore impact.	Twelve campaigns used random probability samples with the other three using some form of quota sample; response rates varied from 45 to 96%. **Length of intervention/follow-up:** Varied from	Campaigns achieved high recall with a median 70% (range 38% to 97%) of target group aware of the campaign. Important to note that baseline awareness can be as high as 15–20% if no campaign or message exists. Levels of awareness are likely to vary according to type of media used and scale of the campaign – number of campaigns is too limited for conclusions on minimum dose of media needed. Increases in knowledge or attitudes to PA were found among half the campaigns that reported	Authors unable to determine reliably the extent to which many of the studies represented true ‘community-wide’ campaigns and as a result it is difficult to separate out the effect of the mass media component in addition to any community activity. Important to measure the dose of the intervention as there

	sectional surveys to assess effects, eight used a cohort and four combined both cross-sectional and cohort.			intervention. Sample sizes ranged from 204 to 7097, with a median sample size of 1800 adults surveyed at baseline.		pre-post surveys only a few weeks apart to follow-up of a cohort after 7 years.	this measure (6 of the 15 studies). Impact on behavioural intention is equivocal. All 15 campaigns measured PA levels. Thirteen of the studies evaluated total population identified as the target group at the start of the campaign and among these only five showed significant increase in PA at the population level. Five studies reported an increase in PA levels and ten reported no significant increases in measures of PA. Four studies reported change in PA in motivated subgroups of volunteers and all four studies showed increases in PA. Campaigns increase awareness of the issue of PA but may not have a population level effect on behaviour.	is a strong relationship between amount of media exposure of a campaign message and the resulting level of awareness – the scale of expenditure, media exposure or outputs from the campaigns was unclear in 10 of 15 campaigns studied. Malmgrem 1986 and Miles 2001 were organised by media providers themselves rather than media space purchased at commercial rates. Difficult to ascertain how much attention was paid to the PA component in the five studies that covered factors other than PA (exposure to PA element likely to be lower in multiple-risk factor media campaigns). Many of the included campaigns were

								single events, others were integrated parts of community-wide cardiovascular education, few were sustained and focused PA initiatives over a number of years. Most campaigns measured distal variables (behaviour), which are least likely to change in the short-term, more measurement need of proximal variables (knowledge, etc.).
RESULTS OF INDIVIDUAL STUDIES INCLUDED IN SYSTEMATIC REVIEW								
Meyer (1980) Part of Stanford Heart Disease Prevention Programme	Quasi-experimental, compared two intervention groups vs. control with baseline and three annual follow-			Adults aged 35–59 years at high risk of cardiovascular disease in three Californian communities (each approx. n = 15,000)	Compared media plus face-to-face (Watsonville) with media only (Watsonville and Gilroy) and control (Tracy). 	ups.							
Malmgren & Andersson 1986 'Get fit with *Corren*' (name of newspaper)	Analysis of all registrants reports; follow-up survey of registrants (12 months) and single survey of random sample.			Adult (≥17 years) readers of the *Corrren* newspaper in Linkoping, Sweden.	Newspaper-initiated health information campaign. Fitness tests offered to participants. Analysis of registrant's reports, follow-up survey of registrants (12 months). Single survey of random sample of inhabitants in Linkoping.	Unclear.	All registrants *n* = 2887. 56% sent in one report, 7% sent in all 12. Survey of registrants *n* = 935 (60% response). Random sample of residents in Linkoping *n* = 204 (82% response). 97% inhabitants aware of the campaign (prompted recall), 75% had read about programme. 6% aware of the campaign and follow it fully. Increase in exercise and fitness among those who registered for the campaign and completed fitness test.	
Aaro 1991a	Quasi-experimental, two experimental and one control group, using cohort surveys.			Residents of Oppland County aged 40–54 years. *n* = 1440 per area, (two experimental and one control group).	Cardiovascular disease intervention programme in Oppland County, Norway 1982–84. Described as mass media and community approach, but details not clear. Two experimental and one control group, using cohort surveys.	Unclear.	Response rate 63.1% Average increase of one training session every third week.	
Aaro	Cohort			Adults aged 16–	One-week campaign	Unclear.	Response rate 60%.	

1991b Sogn og Fjordane County campaign 1983	survey			68 years in Sogn og Fjordane County Western Norway. *n* = 1000	combining community action with mass media. Cohort survey.		64.3% had heard about campaign. Increase in proportion having tried a new activity.	
Booth et al. 1992 'Exercise: make it part of your day'	Pre and post repeat random cross-sectional surveys.			Australian residents aged >15 years.	Cinema commercials, radio and newspaper, linked to community activities such as publicity and events, PA days, competition during heart week. Population samples.	Few weeks.	Response rates vary between 45% and 60% of households = 2426 pre and 2474 post. Unprompted campaign recall 46% pre, 77% post ($p > 0.001$). Non-significant increase in proportion believing that exercise helped a lot in the prevention of heart disease. Significant association between stage of change and pre-post surveys ($p > 0.01$). 3.9% increase in proportion reporting any walking for exercise in the previous 2 weeks.	
Osler & Jespersen 1993 Slangerup – a heart healthy town	Quasi experimental design comparing intervention and control			Adults aged 20–65 years in Slangerup, Denmark. Baseline *n* = 1072 (51% response).	Cinema commercials, radio and newspaper linked to community activities. Strong links to activities such as fitness tests, lectures, heart day.	One-year follow-up.	One-year follow-up *n* = 1196 (59% response). 82% aware of the programme compare with 67% in control area ($p > 0.001$). Health beliefs measured but not specific to PA.	

	areas with two repeat cross-sectional surveys.				Random samples of central person register.		20% considered doing more exercise (17% control). 'Advice from social network and mass media' was related to trying to be more active (*p* > 0.001). 9% participated in local projects. No significant difference in exercise participation between intervention and control.	
Owen et al. 1995 'Exercise: take another step'	Pre- and post-repeat random cross-sectional surveys.			Australian residents aged ≥15 years.	TV adverts, radio public service announcements (PSAs), campaign materials, scripts in national soaps, unpaid media, associated community activity. Community and health agency activities, physician education, serial heart week campaign. Built on previous campaign 1991 (Booth 1992).	Few weeks	Response rates vary between 45% and 60% of households, *n* = 2584 pre and 2517 post. Unprompted recall 62.5% pre and 73.5% post (*p* > 0.001). No change in intention to exercise. No significant change in walking or inactivity.	
Blake et al. 1987; Luepker et al.	Quasi experimental with three			Sampled from 4,000,000 persons aged 25–74 years resident in six	High-intensity campaign via the mass media linked to community activity	7 years. Half of the sample	Average total survey response rate = 78.7%. *n* = 6039 at baseline, 67.1%	

1994 Minnesota Heart Health Program	intervention communities and three controls. (i) Repeat cross-sectional surveys. (ii) Cohort surveys. Random samples of 300–500 adults from each of the six communities.			communities in the Upper Midwest, USA. *n* = 6039 at baseline.	and training and education programmes. PA covered in annual 1–3-month concentrated campaigns. Strong community component including health professional education, screening, counselling. Random sample from within cross-sectional sample taken.	followed-up after 2 years, other half after 4 years, and all cohort after 6–7 years.	completed all waves. During one concentrated PA campaign 93% heard of at least one campaign event. Awareness of media not reported for complete programme but 60% of all adults were recruited to the training and education programmes. Single question 'Are you active in your leisure time?' showed small increase in proportion physically active at 2 years but most of this was light PA. The longer Minnesota Leisure Time Physical Activity (MLTPA) questionnaire showed decline in PA.	
Young et al. 1996 Stanford five-city community-wide cardiovascular risk reduction project.	Quasi-experimental residents of two intervention communities compare with two			All residents of Monterey and Salinas Counties, California aged 12–74 years.	Print materials, weekly news column, talks, seminars, workshops, segments in TV news and PSAs. Associated worksite and school programmes. Average of nine messages per person per year.	Unclear	(i) Each random sample approx. *n* = 1800 to 2500 response rates for each wave: 65, 70, 65 and 56% (ii) Cohort *n* = 408 men and 499 women. 39% completed all waves. No evidence of significant impact on knowledge attitudes or self-efficacy. No significant differences were	

	control communities and an additional control community for cardiovascular disease morbidity and mortality data. (i) Repeat cross-sectional surveys. (ii) Cohort surveys.				Strong community-based components including talks, seminars, workshops, walking groups, worksite programmes, competitions.		found for the global estimates of PA for women or men between treatment and controls. Increase in number of 'usual activities' compare with control ($p = 0.014$) for independent and 0.001 for cohort samples).	
Wimbush 1998 HEBS [Health Education Board for Scotland] walking campaig	Before and after design. (i) Awareness: 3 × pre-post tracking survey.	2	+	'Fitline' callers $n = 4036$. Adults of target age (30–55 years) in October 1995: $n = 335$ Adults of target age in February 1996: 370	National campaign in Scotland, to increase the number of individuals, aged between 30–55 years of age, who are not regular exercisers to take up walking. 2 × 1 month bursts of	**Length of intervention:** TV advertising: September and October 1995 and March and April 1996. **Length of follow-up:** June 1995–	(i) Men and women 16–74 $n = 693$ (October 1995), 768 (February 1996) 733 (June 1996). Multistage cluster random probability sample, response rates reported between 62–86%. (ii) Adults $n = 1066$ (June 1995), 1085 (June 1996), response rates not given.	Three stages of developmental and pre-testing research reported. At a population level, the campaign had a notable positive impact on knowledge about walking as a form of exercise but

n 'Walking: take exercise in your stride'	(ii) Impact: 2 × pre-post cross-sectional surveys. (iii) Baseline survey of Fitline callers and follow-up at 10 weeks and 1 year			Adults of target age in June 1996: *n* = 345. All participants were from Scotland. Bias towards lower SES. Female 'Fitline' callers: 59% Male 'Fitline' callers: 41% *n* = 4036 <16 years: 8% 16–29 years: 26% 30–55 years: 46% >55 years: 20% *n* = 3476 **Housing tenure:** Owner occupied: 61% Rented: 29% Other: 10% *n* = 2828 **Social class:** Manual: 40% Non-manual: 60% *n* = 2042	40 second TV advert. Telephone direct response (Fitline) and information pack, little community activity reported. To assess the actual impact of the campaign on those who actively responded to the walking campaign a baseline survey occurred with all those who telephoned 'Fitline' between the 13 September and 25 of October 1995; this accounted for 4036 callers. Two follow-up surveys were carried out with a sub-sample of responders. The baseline had a response rate of between 62–86% and it involved asking questions to participants about their current walking/exercise patterns.	October 1996 (Tracking survey of awareness, October 1995, February 1996 and June 1996; Omnibus survey of knowledge June 1995 and June 1996; Fitline callers survey September/October 1995, January 1996 and September/October 1996).	(iii) Baseline – all Fitline callers, *n* = 4036; 10 weeks *n* = 490, 1 year *n* = 283 (58%). % Agree 'Walking a mile uses up the same energy as running a mile': 20% June 1995, 56% June 1996. % Strongly agree, 'walking is a good form of exercise': 38% June 1995, 57% June 1996. No change for other statements. Intend to walk more: 55% June 1995, 57% June 1996 (not significant). Population change: days spent walking for 30 min: 4.26 June 1995, 4.13 June 1996 (not significant). Fitline callers 0.5 stage increase in average stage of change, overall shift from the contemplation stage of change (Transtheoretical Model) at baseline towards the 'action' stage at the 10-week and 1-year follow-up. In Fitline callers; 48% reported being more physically active, 46% said about the same as before and 7% less physically active at 1 year follow-up. Prompted awareness of HEBS walking campaign – general	had very little impact on walking behaviour. Campaign was efficacious in supporting the exercise behaviour change process among non-regular exercisers in the ' contemplation stage' (of the Transtheoretical Model) through advertising of a free direct response telephone service but response was higher among non-manual, owner-occupier groups and those who were already regular exercisers. Fitline had less appeal to lower SES groups despite higher awareness levels.

					Providers of intervention: Health Education Board for Scotland. Staff from the Centre for Leisure Research at Heriott Watt University, Edinburgh Staff from the Centre for Social Marketing at Strathclyde University, Glasgow		population adults. Awareness of the “Gavin TV advertisement”: October 95 = 70%, February 96 = 54%, June 96 = 69% Awarenes of Local radio features 8%, 13%, 21% Awareness of Fitline October 95 = 5%, February 96 = 16% but only 5% of these respondents used the service. This level of use indicates 0.1% coverage at the beginning of the campaign rising to 1% 4 months later.*n* = 693 in October 1995, 768 in February 1996 and 733 in June 1996 Prompted awareness of HEBs walking campaign – Target group (aged 30–55 years). Miles et al. 2001; Wardle et	Before and after study	2	+	**Office of National Statistics survey:** Total sample	The study’s primary objective was to evaluate the BBC’s	Campaign was for 7 weeks.	0.9% sent for registration pack; 0.2% registered with scheme.	Self-reported data. Generalisation of the

al. 2001 BBC 'Fighting fat fighting fit' campaign	design with one cross-sectional survey by ONS and pre-post survey of random sample of respondents.			$n = 1894$ Men $n = 938$ Women $n = 956$ All adults but targeted more to overweight and obese adults See weight outcomes table (Table 1) for more detail.	national FFFF campaign. Seven weeks of peak and daytime programming across BBC TV and radio.		Significant increases in brisk walking, moderate activity and vigorous activity, overall 39% (74%) increased their activity levels. Total number of min per week spent in activity increased by 94 (181) min per week, $p > 0.001$. % Classified as sedentary reduced from 34 to 25% (35 to 17%). % Doing irregular moderate exercise decreased from 36% to 29% (36% to 22%). % Regular moderate exercise increased from 29 to 45% (29 to 60%). % Vigorous exercise increased from 3 to 6% (2 to 9%). All $p > 0.001$. **Predictors of change (completers only):** Men were more likely to report changes in weight, exercise and fried food intake, deprivation level was associated only with decreases in fried food intake, baseline weight predicted weight loss and positive changes in diet with obese reporting greater changes. Predictors of change (all	results is limited due to the 70% response rate for ONS survey and less than 1% registered and of these 6000 surveyed in registrants survey Men, people <25 years, lower SES and BMEGs may require specifically targeted campaigns (registrants survey).

							participants): groups with higher levels of deprivation were less likely to report weight loss or exercise increase, obese did not report greater changes in diet and weight loss and changed less in terms of exercise than normal weight groups.	
Hillsdon et al. 2001	Before and after study	2	+	*n* = 6711 Completers *n* = 3189 Non-completers *n* = 3522 All participants were from England, aimed at young women 16–24 years, men 45–55 years, adults ≥50 years. 42.5% of completers were males. 44.7% of non completers were male. 43.6% of the total sample were male. **Social grade %** AB 20.3	Based on concept of social marketing using advertising, public relations and publicity. ACTIVE FOR LIFE campaign was a 3-year health promotion mass-media campaign run in England and commissioned by Department of Health and run by Health Education Authority, aimed to increase knowledge and acceptability of 5 sessions, 30 min each of moderate intensity PA per week (walking, cycling, swimming, dancing, heavy gardening and housework); integrated with professional education and support.	2 years (1995–97).	12,907 addresses were identified and 6711 baseline interviews were conducted (52% response rate). In phase 2 in 1996, 4268 interviews were conducted (64% of baseline) and 3189 in 1997 (48% baseline). 38% of all the participants were aware of the campaign (unprompted and prompted awareness combined), assessed six to eight months after the main period of advertising. 5.5% could recall key images of the TV campaign unprompted with a further 32% recognising still photographs taken from the TV advertisement. Greatest awareness was in those aged 16–24 years (65%) and lowest awareness in those aged 65–74 years (25%). Men were more aware than women as were those with children living at home and those in lower social grades. Participants who were more ready to adopt regular PA and who were already active at a vigorous level were more aware of the campaign than those who were less ready and less active. Those aware of the	Media budget £2 million. Linked to professional education programme. Developmental research and pre-testing. 52% response rate may have lead to an under represented sample. No published reliability and reliability studies exist for the PA questionnaire used in the study. Results of the study may have been confounded by secular trends, e.g. between 1994 and

				C1 30.1 C2 20.8 DE 28.7 Car use 72.1% Non-White 5.4% Home ownership (%) 73 Children (% yes) 30.3 Non-completers were younger; fewer were in social grade AB, owned their own home or car. Fewer had children or perceived that PA would lead to physiological benefits. More were non-White.	Campaign resources, which included posters, leaflets, postcards, two websites and other promotional items were all implemented and developed to promote the main campaign message to specific priority groups. These groups included young women aged between 16–24 years, middle-aged men aged 45–55 years, men and women aged 50 years. All these groups were targeted in three different phases of the campaign. The first phase of the campaign was a 40 second TV advertisement – 'The thirty minute games'. This emphasised the importance of activities such as walking, gardening and cycling for health and that activity		campaign, when asked at year 1 were already more active at baseline than those not aware of the campaign (suggest active people more likely to recall advertising). The proportion of participants' knowledge about moderate PA recommendations increased by 3.0%. (95% CI 1.4, 4.5) between baseline and year 2 and 3.7% (95% CI 2.1, 5.3) between baseline and year 3. No significant difference in knowledge by awareness of the campaign advertising suggesting if campaign did produce these increases in knowledge it was through element other than TV advertisements. (Assessed as knowledgeable if could recall all three elements of a complicated message.) Changes in proportion of participants who knew about recommendations were higher in women, older age group and social grades C2/DE. No significant differences in PA levels at baseline and 1-year follow-up, but at year 2 there were 8.8% fewer people active at a vigorous level and 6.8% more people classified as sedentary. The change in proportion of active people between baseline and year 1 was –0.02% (95% CI 2.0, 1.7) and	1998 the number of sedentary men increased by 5% and the number of women by 6%, while those categorised as physically active remained virtually unchanged.

					should be done for 30 min. It was aired over a 6-week period in the spring of 1996 and it targeted abroad range of people aged 16–74 years. The second phase of the campaign began in 1997 and was aimed specifically at men and women aged >50 years. The TV advertisement was repeated in July 1997 but this phase also included campaigns in tabloid newspapers aimed at middle-aged men. The third and final phase of the campaign took place in 1998 and was aimed at young women aged 16–24 years and used advertisements placed in women's magazines. In addition, two sub-campaigns communicated campaign messages to groups that were		between baseline and year 2 was –9.8% (95% CI –7.9, –11.7). 21% increase in number of people active at recommended levels at year 1, in those not active at baseline, along with 46% of people who ceased being active at this level between baseline and year 1 suggest there was a regression to the mean (demonstrates importance of control group). 1.3% decrease in 'readiness to change' score, participants who were aware of campaign were more ready to take up PA than those not aware ($p > 0.05$).	

					defined as having particular access or communication needs: people from BMEGs and people with disabilities. These were highly targeted by advertising in specialised media or through joint promotions with ethnic minority and disability organisations. A national sample of 3189 adults, aged between 16–74 years was used to assess the impact of the campaign. Multi-stage cluster random probability design used with Postcode Address File for England to get representative sample of adults aged >16 years. Thirty-minute interview conducted in the home, baseline data in September and November 1995 and follow-up data in			

					same months in 1996 and 1997. **Providers of intervention:** The Health Education Authority and the research unit at the London school of Hygiene and Tropical Medicine			
Bauman et al. 2001 Exercise; you only have to take it regularly not seriously.	Quasi-experimental design using: (i) cohort; (ii) independent cross-sectional samples, representative population surveys, before and after the campaign; (iii) control survey in			Adults aged 25–60 years in New South Wales Australia who were ‘motivated but insufficiently active’.	Two × 15 second TV advertisements, print media advertisements and inserts, phone line, campaign materials. Community level support offered including toll-free phone line; local level and regional initiatives and events, physician education. Extensive formative qualitative focus group research.	Unclear.	(i) Cohort, n = 1185 (response rate = 87%), baseline n = 2009 (response rate 83%), follow-up, n = 1700 (response rate 80.6%). (ii) Control baseline n = 3006 (response rate 81.5%), follow-up n = 2253 (response rate 80.3%), random probability samples of population. Unprompted recall increased from 2.1 to 20.9% (p > 0.001), prompted recall increased from 12.9 to 50.7% (p > 0.0001); no change in comparison region (rest of country; prompted recall 14% pre to 16% post). Knowledge of appropriate PA increased significantly in the campaign state (four items used). Intention to be more active showed no change in any group.	Media budget AUD$7,000,000.

	non-campaign states.						26.7% of target group (motivated but insufficiently active) increased their activity to above the recommended thresholds (five times per week for 30 min) ($p > 0.01$).	
Reger et al. 2002 'Wheeling Walks'	CBA Quasi experimental; compared intervention in Wheeling with control town, cohort design using surveys and observational measures (trail use)	2	++	Intervention community *n* = 719. Control community *n* = 753 Intervention group: Female: 67.5% Age (mean): 57.4 years Control group: Female: 68.5% Age (mean): 57.2 years Intervention group: Income >US$30,000: 40.6% College graduates: 29.5% Married: 60.2% Estimated BMI: 28.0 kg/m^2 Control group: Income >US$30,000: 44.6%	The pilot study, which was called 'Wheeling Walks' had two main aims: 1) effect a 10% increase in the proportion that meet the Centers for Disease Control (CDC)/American College of Sports Medicine (ACSM)/Surgeon General standard for regular moderate intensity walking; and 2) effect a 15% forward movement one or more stages in Transtheoretical Model stage of change for regular moderate intensity walking. The intervention took place in the city of Wheeling, West Virginia, USA, and was primarily aimed	Length of intervention: 8 weeks (April 2001 – June 2001). Length of follow-up: post-tests occurred immediately after the end of the 8-week intervention period.	517 of the 719 (72%) of the respondents in the intervention group and 571 of the 753 (76%) in the control group completed the baseline and follow-up survey. Post-test surveys were successfully completed with 69 and 74% of the sedentary adults in the intervention community and 252 in the comparison community. Behaviour observation showed a 23% increase in the number of walkers in the intervention community versus no change in the comparison community (OR 1.31; 95% CI 1.14, 1.50). Thirty-two percent of the baseline sedentary population in the intervention community reported meeting the CDC/ACSM/Surgeon General recommendation for moderate-intensity PA by walking at least 30 min at least five times per week vs. 18.0% in the comparison community (OR 2.12; 95% CI 1.41, 2.24).	Messages were pretested. Poor generalisability because income per capita and educational attainment is lower than in the rest of the USA and heart disease death rates and prevalence of obesity are both 18% higher than the national average in the USA. Short intervention period.

				College graduates: 20.2% Married: 63.5% Estimated BMI: 28.5 kg/m^2	at sedentary and irregularly active adults aged between 50 and 65 years of age. Comparison community was Parkersburg, West Virginia (similar demographics but no overlapping media). The intervention was an 8-week paid media-based community PA campaign using paid advertising, public relations and public health education activities to promote 30 min of moderate intensity walking as a daily activity to people. Applied Theory of Planned Behaviour and social marketing techniques. A Public Relations firm developed two newspaper advertisements, two 30-second TV advertisements and two 60-second radio advertisements.		The intervention community also realised a pre to post increase in positive stage change ($p > 0.001$). **Awareness:** In the intervention community 90% reported hearing about the campaign, 76% saw some or a lot of TV advertisements, 81% saw some or a lot of TV news stories, 32% reported hearing radio advertisements and 5% reported seeing or participating in any of the public health education programmes.	

					Average households exposed to TV campaign 50 times, radio message 70 times and 14 newspaper advertisements were placed in local newspapers over the 8 weeks. Other public relations activities, work-site programmes, website exposure, physicians prescriptions for walking and other public health education programmes were carried out. Telephone survey questionnaire (random digit dialling) at baseline of adults aged 50–65 years and followed up immediately after the 8-week campaign. Telephone survey questionnaire and observation. **Providers of intervention:** Research staff from			

					West Virginia University (college-level research technicians were recruited to observe, count and intercept adult walkers at five predetermined popular walking sites for 2 hours per day for 1 week before and after the intervention). Wheeling-Ohio County Health Department and the local media.			
Renger et al. 2002 Yuma on the move. Tagline 'Think about it. Its your choice to be active'	Before and after design with cross-sectional surveys. Sub-group analysis of 33 who completed pre and post surveys. Separate detailed	2	–	Targeted adults in Yuma, Arizona 1997–99, especially those aged 30–64 years and in pre-contemplation/contemplation stages of change. *n* = 1203 (*n* = 500 for telephone survey, *n* = 703 for written survey). No SES data available, but Yuma county is a rapidly growing area with	The main aim of the study was to develop, implement and evaluate a community-based effort to increase PA. Community members from the Yuma Regional Medical centre and the University of Arizona developed television and worksite media messages, which focussed on the benefits and barriers of PA and on increasing self-	**Telephone interview:** 3 years (1996–1999). **Written survey:** 1 year (1998–99).	Of the 703 respondents to the written survey 84 at baseline and 75 at follow-up were evaluated as respondents who completed survey at both time points were removed and limited to target population – 30–64 years in first two stages of change. Random digit dialling pre-post surveys (*n* = 500 in 1996 and 500 in 1999) response rate not stated. Written surveys to volunteers (created cohort *n* = 33) and cross-sectional samples (*n* = 75) pre *n* = 84 post) of volunteers (convenience sample). 'The media campaign was effective	Formative research with community regarding PA barriers, taskforce developed message a\and used Centers for Disease Control (CDC) resources, other media/poster. Very small sample analysed from written survey. Independent samples at pre- and post-evaluation but a within-participants analysis was done of

	written survey administers at events and health fairs to volunteer completers. Process evaluation of number of campaign posters displayed.			55% of its population <35 years of age and an ethnic distribution that is predominantly Hispanic (48.5%) and White (46.8%).	efficacy. These media messages were developed using and based upon Prochaska's Transtheoretical model and consciousness raising strategy. The task force, which produced the media messages, chose three different methods to deliver the media messages: public service announcements, comic strips and worksite posters. The first comic strip was released in December 1998 in 17 worksite newsletters. The second comic strip was released in October 1999 and was published in five worksite newsletters by 1 December 1999. The first poster was used in January 1999 and 135 posters were displayed at 74 worksites and community buildings.		in changing perceived barriers, perceived benefits and self-efficacy surrounding PA and 'unexpectedly' had a positive effect on changing behaviour (i.e. main purpose was to get people to think about it but some actually changed behaviour).' Mean recall of PA messages on television score increased significantly (only from 30 volunteer responders). Many cited campaign as the message they heard (numbers not further stated). In volunteer samples, knowledge and beliefs assessed, no significant change in ten-item knowledge score, no change in decisional balance score (benefits/barriers to PA). In volunteer samples, increases in self-efficacy reported. The evaluation of the written survey found no significant change in level of activity. Within-subject analysis of 33 participants (took part in baseline and follow-up survey) showed significant change in level of PA from baseline to follow-up *p* > 0.002. Telephone survey showed that 29.8% respondents reported they did not engage in leisure time	33 participants (took part in baseline and follow-up survey) showed significant change in level of PA from baseline to follow-up, *p* > 0.002.

					The second was released in November 1999 with seventy-one posters were on display by 1 December 1999. Posters were put in areas of high traffic as well as other areas where employees may gather. To evaluate the impact of the intervention a telephone interview and a written survey was used. 500 households in Yuma County were contacted by telephone in 1996; the questionnaire consisted of 111 questions, many of which were the same as those used in the Behavioral Risk Factor Surveillance Survey (BRFSS). The telephone interview was repeated in the fall of 1999. The written survey consisted of 11		physical activity (LTPA) in 1997 and in 1999 this was reduced to 25.6%. Corresponding values in Arizona were 33.8% in 1997 and 51.5% in 1999. Analysis of the telephone survey found only one statistically significant change among age categories, with self-reported no LTPA decreasing from 35.6 to 23.1% ($p > 0.05$) amongst women aged 40–64 years.	

					questions was administered to local schools, businesses and at the county fair prior to the media campaign and again administered year later at the same locations.			
INDIVIDUAL STUDIES								
Merom 2005	Before and after study (not controlled)	2	+	Primary school-age children and their parents in New South Wales, Australia.	To describe the reach, participation and support of the New South Wales Walk Safely to School Day (WSTSD). Paid media advertising before the event promoted WSTSD.	One day every year for 4 years	School register: 2001: 496 schools 2002: 717 schools 2003: 708 schools 2004: 751 schools participated in the New South Wales WSTSD (repeat participation over 3 years was low). 53% of all NSW schools registered to participate in one WSTSD and 15% participated for 3 years. Significantly more schools from urban regions participated ($p > 0.05$). School evaluation forms: Only 37% of participating schools returned evaluation – smaller schools had a higher participation rate. 7% schools organised walking related activities, and 28% indicated that promotion of healthy lifestyle was a reason for participating.	Only 37% of participating schools returned evaluation – potential for bias.

							Parent survey: (89% response rate to randomly selected eligible telephone numbers). 53% were aware of WSTSD with main source of information being the school then the media. Relative increase of 31% of children walking attributed to the event. On a population level this equates to an increase prevalence of walking to school of 6.8%. **Author's conclusion:** Stronger interventions required but campaign did result in moderate short-term change.	
O'Loughlin et al. 1998	RCT	1	+	Intervention group *n* = 94 Control group *n* = 94 See weight outcomes table (Table 1) for more detail.	This RCT investigated the impact of a low intensity, healthy weight intervention in low-income adult volunteers from inner city St Henri, Canada.	**Intervention:** 8 weeks. **Follow-up:** 10 weeks (2 weeks after end of intervention).	Intervention participants were 2.7 times more likely than control to change from reporting no exercise at baseline to exercising once or more a week at follow-up.	Short follow-up period. Data were self-reported. Use of telephone interviews (minimal face to face contact) possibility of bias related to social desirability Generalisability unclear, low-income low-literacy inner city

								population of French/English-speaking Canadians.
Huhman et al. 2005	Before and after study (not controlled)	2	+	**Geographical area:** USA *n*= 3120 parent–child dyads All participants were aged between 9 – 13 years of age. Participants were of either Black, Hispanic/Latino, Asian or Native American. No further details.	The intervention aim was to determine the effects of a mass media campaign on PA levels among multi-ethnic children aged 9 to 13 years of age from the USA. Primary aim was to achieve high levels of awareness among the target audience. The VERB campaign combined paid advertisements with school and community promotions and internet activities to encourage children 9–13 years to be physically active every day. Launched in 2002 by CDC, VERB used child-focused commercial marketing methods to advertise being physically active as cool, fun and a	1 year. For the baseline survey, persons in 60.5% of sampled households completed the screening interview. Among eligible adult respondents, 3084 (87.0%) completed the parent interview; 3120 eligible child respondents (81.3%) completed the child interview. As determined with standard American Association of Public Opinion Research response rate formulas, the overall baseline	The overall campaign produced high levels of awareness. 26% of the participants had no recall of the VERB campaign, 7% had recall but no understanding, 50% had aided recall with understanding and 17% of the participants had unaided recall with understanding. Therefore, the overall awareness (all three categories that had recall) achieved by the VERB campaign was 74% among the nation's 9- to 13-year-old youths. Ninety percent of children who were aware of VERB also demonstrated understanding of the messages. Overall awareness for White children and Hispanic/Latino children was 78% and 70%, respectively, significantly higher than that for Black children at 63% ($p > 0.05$). A significant positive relationship was detected between the level of awareness of VERB and weekly median sessions of free-time PA among the total population of 9- to 13-year-old youths ($p <0 .05$), meaning that, as VERB awareness increased, levels of PA increased. Within subgroups, this relationship between increasing levels of awareness and more free-time	Self-report. Reverse causation is a possibility – physically active children becoming more aware of the campaign. Overall awareness for White children and Hispanic/Latino children was 78% and 70%, respectively, significantly higher than that for Black children at 63% ($p > 0.05$).

					chance to have good time with friends. Paid advertising ran nationally from June 2002 to June 2003 targeting youths 9–13 years. A baseline survey was conducted between April and June 2002, before the campaign started, (random digit dialling method). Same cohort of parent–child dyads followed-up after 1 year. **Providers of intervention:** Research staff, advertising agencies, the National Centre for Chronic Disease Prevention and Health promotion and Centres for Disease Control and Prevention in Atlanta.	response rate was 43% (the product of the completion rates for the screening, parent, and child interviews). At the follow-up assessment in 2003, data were collected from 2732 of the same dyads (87.6%).	sessions of PA was also observed at the *p* > 0.05 level for 9- to 10-year-old children, White children, children whose parents had less than a high school education, children from households with incomes of US$25,000 or less, and incomes between $50,000 and $75,000, children living in urban areas of high density, children from rural areas, children who reported engaging in less than three free-time PA sessions at baseline and children who reported engaging in at least three free-time sessions at baseline. The average 9–10-year-old engaged in 34% more free-time PA sessions per week than did 9–10 years olds who were unaware of the campaign. When free-time PA sessions of all US children were compared with those of the children who were unaware of the campaign no overall effect on free-time PA sessions was detected at the population level. However, within subgroups, significant overall effects were observed for 9–10 year old children, girls, children with parental education of less than high school, children from households with income US$25,001 to $50,000, children living in urban areas of high density, and children who were low	

							active at baseline (*p* > 0.05). At the total population level no relationship was found between awareness of VERB and organized activity (*p* > 0.05). Within the subgroup classified as low active at baseline, 39.1% of children were engaged in an organised PA, compared with 31.9% of the comparison group, a significant difference of 7.2 percentage points (*p* > 0.05). The other subgroup effect for organised activity was for children with parents with a college degree or higher education level.	
Tudor-Smith et al. 1998	Before and after design but samples are independent (cross-sectional) population surveys with an intervention community and a matched reference area.	2	–	**Geographical area:** Wales, UK and north-east England (reference area). Wales: 1985: *n* = 18538 1990 *n* = 13045 North-east England: 1985 *n* = 1483 1990 *n* = 4534 All participants were aged between 18–64 years No further details.	To assess the 5-year effect of an intervention of a community-based demonstration project called 'Heartbeat Wales'. See weight outcomes table (Table 1) for more detail.	Cross-sectional survey took place before and after the end of the 5-year intervention in intervention and control community. See weight outcomes table (Table 1) for more detail.	Engage in moderate or strenuous activity at least two times per week for over 20 min each time: Wales 2.1 (95% CI 0.8–3.4), control 3.2 (95% CI –0.7–7.1) percentage point changes.	The sample size at the baseline measurement at baseline in the North East was too small to give sufficient statistical power to detect a net intervention effect. There is evidence of increases in funding for heart health promotion in the reference area and diffusion of other health promotion campaigns (contamination).

Jeffery 2005	Survey of Earlybird cohort.	N/A		UK parents and their children.	Explored parent's awareness of overweight in themselves and their children.	N/A	19% of children, 52% of mothers and 72% of fathers were overweight (including obese). Among overweight parents, 40% of mothers and 45% of fathers judged their own weight 'about right' and 27% of mothers and 61% of fathers were unconcerned about their weight. Only one-quarter of parents recognised overweight in their child. Parents were less likely to identify overweight in sons than in daughters. More mothers than fathers correctly assessed their child's weight. Maternal weight status did not affect mothers awareness of children's weight but only 74% overweight fathers compared with 85% normal weight fathers were correct. 86% of parents who were unaware their child was overweight were also unconcerned. Prevalence of overweight in parents did not differ by SES, neither was there a difference in correct perception of child's weight between SES groups.	
Hastings et al. 2003	Systematic review	N/A		Literature search 1970–2003. Studies used for this particular research	Does food promotion influence children's nutritional knowledge? Five studies were RCTs	No details provided.	The eight studies provide modest evidence of an effect on children's nutritional knowledge. Four studies found that exposure to food promotion had a significant impact	Four of the studies did not take a baseline measure of knowledge and therefore it is very

				question covered an age range of 3–16 years and all but one of the studies was conducted with North American samples in the 1970s and 1980s.	and three were cross-sectional surveys. The control condition in one of the experiments (Ross et al, 1980, 1981) comprised exposure to non-food adverts; in the other four studies the control condition involved no exposure to any adverts. The food promoted in the adverts of the experimental studies were adverts for cereals and soft drinks (Ross et al. 1980, 1981), branded sugar snacks and breakfast cereals (Goldberg et al. 1978a, 1978b), sugared foods (Goldberg et al. 1978a,1978b; Galst 1980) measured whether the effect of a pro-nutritional television programme' was modified by being shown alongside advertisements.		on or was associated with differences in nutritional knowledge. Three studies found that exposure to food promotion had no impact on or was not associated with changes in children's perceptions of the healthiness of different foods or what constitutes a healthy diet.	difficult to ascertain whether experimental and control groups differed in nutritional knowledge before the experiment.
Hastings et al. 2003	Systematic review	N/A		Literature search 1970–2003. Participants were all	Does food promotion influence children's food preference?	No details provided.	Fourteen studies provide reasonably strong evidence of food promotion on children's preferences.	One study (Ritchey & Olson 1983) did not describe the TV viewing measure

				North American and ranged in age from 2 to 18 years. The majority of the studies were conducted in the 1980s.	Fourteen studies were used, with 13 of them being experiments and one being a cross-sectional study (Ritchey & Olson 1983). Twelve of the studies used a similar study design, which involved exposing one or more experimental groups to one or more food promotion stimuli, and 11 of them compared children's subsequent food preferences or attitudes to those of a control group exposed to a different or no stimuli. The food promotion stimuli in the experimental studies were all advertisements for various products (branded sugared snacks, breakfast cereals, non-specific 'sugared foods', salty snacks, sweets, soft drinks, ice cream and 'pronutrition foods'. Six studies measured if different modifications to the experimental stimuli		Of the four higher scoring studies, three found that promotion had significant effects on children's product and brand preferences. Three of these studies (Goldberg et al. 1978a, 1978b; Stoneman & Brody, 1981; Kaufman & Sandman 1983) found that children were more likely to choose high fat, salt or sugar foods than alternative 'healthy' products after viewing food advertisements. Of the five medium scoring experimental studies, three found that food promotion had effects on children's products and brand preferences (Gorn & Goldberg 1980a; Heslop & Ryans 1980; Borzekowski & Robinson 2001). Borzeowski & Robinson (2001) found that children were more likely to choose the advertised brand than a non-advertised brand of the same product type after exposure to food advertisements. Gorn & Goldberg (1980a) found that food promotion had an effect on children's brand and to a lesser extent product preferences. Of the two lower scoring experimental studies, Clarke (1984) found no significant effects ($p > 0.05$) while Norton et al. (2000) found that television advertising was reported to be a significant influence only on degree of liking for three products	used so it was not possible for the author to judge what level of potential exposure was measured. There were inconsistencies in parental and child reporting of child food preferences within the study, and the authors themselves suggested that the preferences measure used was possibly not sensitive enough to detect difference between children. All the studies used for answering the research question were graded for quality. Four studies were high scoring in terms of quality, five experimental studies were medium scoring and two of the studies were lower scoring.

					weakened or strengthened children's effect on food preferences. Five of the studies asked children to pick between products in different categories (lower fat, sugar or salt vs. higher fat, sugar or salt). Five studies also asked children to choose between different brands of the same product, one or more of which had been advertised on the experimental tape and one or more of which had not. Two of the studies (Gorn & Goldberg, 1980; Gorn & Florsheim 1985) measured product preferences but between alternatives that were necessarily designated healthier and less healthy.		which are generally not excessively advertised on television: chicken, apples, beans and low-fat milk. Two studies did not report results.	
Hastings et al 2003	Systematic review	N/A		Literature search 1970–2003. The participants in the studies were 475 9–12-year-old English speaking	Does food promotion influence children's food purchasing and purchase related behaviour?	No data provided.	All seven studies reviewed found that exposure to food promotion had an influence on, or was significantly associated with the specific purchase related behaviour measured in each study. The findings were reported according to the type of behaviour	The two cross-sectional studies would have been stronger had they used multiple regression analysis to examine the

				and French speaking children in Montreal (Goldberg 1990), 36 3–5-year-old children in Georgia and their mothers (Stoneman & Brody 1982), 775 4th–7th grade children in Michigan (Atkin 1975b), 66 mothers of children aged 3–8 years in Californian public ‘preschools’ and elementary schools (Taras et al. 1989), 41 3–11-year-old children (mean age range 4–7 years) in New York and their mothers (Galst & White 1976), 100 children aged 3–13 years in Michigan (Reeves & Atkin 1979) and vending machine users in 12 secondary schools and 12 workplaces in Minnesota (French et al. 2001). The samples achieved a reasonably			measured in each study. **Sales:** Sales of low-fat snacks increased significantly and proportionately with increasing price reductions and promotional labels and signage also had a small, independent effect on low fat-snack sales. Promotion (labelling and signage) was significantly and independently associated with increased low-fat snack sales ($p > 0.04$). Overall sales volume was unrelated to promotion, but was related to price reduction. **Observed purchase influence behaviour:** No significant difference was found between experimental group and control group children in numbers of hours of television reportedly viewed per week, and the two groups of children did not differ in the amount of attention they paid to the experimental tape, which increased the likelihood of the observed differences in behaviour being attributable to the experimental tape. A study by Galst & White (1976) who focused on children’s supermarket behaviour after being exposed to food advertising found the more effort a child exerted to keep the overall videotape playing and the more effort they exerted to watch advertisements the more ‘purchase influence attempts’	relationship between food promotion and other factors on purchase related behaviour.

				representative range of income levels.			they made per minute in the supermarket. **Household purchase:** A study by Goldberg (1990) which examined the degree to which children are affected by television advertising found that children who had the highest level of US TV viewing reported more household purchase of children’s cereals (mean 2.67) than children with a low level of US TV viewing (mean 1.62). There was also a significant effect for income ($p > 0.01$), with low-income children reporting more household purchase of children’s cereals (mean 2.42) than upper-middle income children (mean 2.03). No significant effects were found for language nor were any significant interactions found, although the interaction of level of US TV viewing by income approached significance ($p > 0.007$). **Reported purchase influence behaviour:** A study by Atkin (1975b) who measured exposure using a ‘cereal advertising exposure index’ found that children who reported watching more Saturday morning television more often asked for cereals. More than twice as many ‘heavy viewers’ of Saturday morning television as ‘light viewers’ reported making cereal purchase	

							requests ‘a lot’ of the time. A study by Taras et al. (1989), which investigated the relationship between children’s television viewing and their food purchase requests, found significant correlations were found between hours of TV viewing and the number of food items which mothers perceived had been requested because of television’s influence (*p* = 0.006) and the number of food items subsequently purchased (*p* = 0.01). Snacking while watching television was also significantly positively correlated with number of food items requested and purchased and with energy intake.	
Hastings et al. 2003	Systematic review	N/A		Literature search 1970–2003. Participants in all the 11 studies were all North American and the age range was 2–11 years. Some involved relatively small sample sizes (e.g. Cantor 1981, *n* = 37), while other studies involved samples of several hundred, such as Atkin (1975b) *n* = 775 and Bolton (1983) *n* = 262.	Does food promotion influence children’s food consumption behaviour? Eleven studies investigated the effects of exposure to food promotion on children’s food consumption behaviour (defined as encompassing three types of behaviour: one - off consumption, short-term consumption and self-reported regular patterns of consumption behaviour.	No details provided.	Two experimental studies (Gorn & Goldberg 1980b, 1982) found that exposure to food promotion had an effect on children’s consumption. It reduced likelihood of selecting fruit or orange juice, compare with a sweet for a daily snack. Three cross-sectional studies (Atkin 1975b; Bolton 1983; Ritchey & Olson 1983) found small but significant associations between exposure to television food advertising and frequency of snacking or consumption of foods (*p* > 0.05). Two studies (Jeffrey et al. 1982; Dawson et al. 1988) found variations in consumption behaviour, according to exposure to food promotion, but the results were not statistically significant	

				Several studies involved using participants who were mainly middle class (Galst 1980; Gorn & Goldberg 1980a; Bolton 1983; Dawson et al. 1988).	Eight of the studies were RCTs and three were cross-sectional studies.		($p > 0.05$) and no effect could be concluded. Four studies produced results, which were inconclusive. Galst (1980) appeared to indicate that exposure to food promotion had a positive effect on consumption behaviour (i.e. it reduced children's selection of sugared snacks), whereas Peterson et al. (1984) found that exposure to food promotion had no effect on children's consumption behaviour, but it was not possible in wither study to disentangle the effects of food promotion from other experimental stimuli examined at the same time. Cantor (1981) and Gorn & Goldberg (1980a) reported that exposure to food promotion had an effect on consumption behaviour but that under certain conditions it did not. Cantor (1981) reported the effect was to increase consumption of sweet foods while in Gorn & Goldberg (1980a) the effect was to reduce consumption of ice-cream. Overall, the studies used provide evidence of an effect of food promotion on consumption behaviour. Effects were sometimes inconsistent and were not found in all the studies, but were found in sufficient studies to suggest that food promotion influence children's food consumption.	

Hastings et al 2003	Systematic review	N/A		Literature search 1970–2003. The age range of the participants was 2–20 years. Five of the studies were North American and one was Australian. Dietz & Gortmaker (1985) had a very large sample of nearly 11,500 and Wong et al. (1992), Gracey et al. (1996) and Bolton (1983) also had large sample sizes of 1081, 391 and 262 respectively. Bolton's (1983) sample was predominantly White and of higher SES, whereas in Coon et al. (2001), the sample was non-randomly selected and of above average educational level; the other samples appeared to reflect a range of SES groups.	Does food promotion influence children's diet and health-related variables? Six cross-sectional studies were used to investigate the research question, four of which investigated the relationship between television and children's diet. The other studies examined health related variables and one examining the relationship between TV viewing and obesity.	No details provided.	There were small but significant ($p > 0.05$) associations between TV viewing and diet, television and obesity and television viewing and cholesterol. In five of the studies, the possible effect of food advertising on this relationship could not be distinguished from the general effect of the TV viewing. One study by Bolton (1983) which attempted to measure the specific contribution of food advertising found that the greater a child's food advertising exposure, the more frequent a child's snacking and the lower his or her nutrient efficiency.	Coon et al. (2001) and Gracey et al. (1996) studies had a number of limitations. Gracey et al. (1996) study used a long questionnaire administered under school staff supervision, but with only a one-item question on TV viewing. The validity of this could well be questionable compare with other diary recall types of question. Also the generalisability of the findings to all Australian children maybe questioned. In the Coon et al. (2001) study the way TV viewing was measured was poor and the sample appears to have been unrepresentative of the general population in the study's geographical area.
Hastings et al.	Systematic review	N/A		School children.	If food promotion is shown to have an effect	No details provided.	Seven cross-sectional studies and one experimental study (French 2001).	

2003					on children’s food knowledge preferences and behaviour what is the extent of this influence relative to other factors?		There is evidence from studies of various methodological quality that food promotion or TV viewing significantly influences children’s food behaviour and diet independently of other factors known to influence children’s food behaviour and diet. However there is little evidence to show whether the influence of food promotion on children’s food behaviour and diet is greater or lesser than that of other factors. One study found that 25–50% price changes appeared to have a stronger influence than promotional signage on low-fat snack sales from vending machines in secondary school. However, promotion significantly increased low-fat snack sales independently of pricing strategies (French 2001). Another study showed that food advertising exposure had a small but significant and independent impact on diet but explained less of the variance in snacking frequency than parents snacking frequency (Bolton 1983).	
Conclusion: Food promotion can have and is having an effect on children, particularly in the areas of food preferences, purchase behaviour and consumption. Most studies uncover an effect that will be harmful however there is evidence that promotion can have a beneficial effect. Food promotion has the potential to influence children in a positive way. There is evidence that food promotion has an effect on children’s nutritional knowledge. The evidence presented supports the ideal that food promotion may have little influence on children’s general perceptions of what constitutes a healthy diet, but that it can have an effect on more specific types of nutrition. There is good evidence that food promotion has an effect on children’s food preferences. In particular there is strong evidence that food promotion influences children’s food purchase-related								

behaviour. In the majority of studies the effect was in the direction of increasing purchase requests for foods high in fat, sugar or salt.

There were also significant effects between TV viewing and diet, and between TV viewing and health related variables; food promotion or TV viewing significantly influences children's food behaviour and diet independently of other factors known to influence children's food behaviour and diet. Although there is minimal evidence demonstrating the influence of, food promotion on children's food behaviour and diet is greater or lesser than that of other factors.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design**	**Length of follow-up**	**Main results**	**Confounders/ comments**
Family Food Survey 2003 Prepared by the www.raisingkids.co.uk (Dr P Spungin).	Survey	N/A		Parents and within the UK (all areas). The survey was open to parents with children under the age of 18 years living in the UK. *n* = 1521 parents 29.7% of respondents were one-child families. 44.0% were two-child families. 16.3% were three-child families 10% were four-child families.	A large-scale survey was undertaken on the 'raisingkids.co.uk' website to investigate the influence of food advertising alongside numerous other factors, including knowledge of nutrition and parenting values. The survey and paper covered three main topics: • food knowledge; • food purchasing; • attitudes to advertising to children.	N/a	85% of survey respondents were correct in thinking that children should only be given semi skimmed milk when they are >2 years of age. 56% of respondents knew that beef was the best source of iron from a particular selection of foods. Only 13% of respondents knew that that an 8-year-old boy should consume 1750 kcal (7.3 MJ)/day. When asked about the main source of information about their children's diet and	

				Amongst the sample, in total the families had 2547 children (1718 boys and 1829 girls).			nutrition, 43% said that their main source was from books and magazines and 15% relied on family and friends. Out of 1521 parents, only 13 (0.9%) said their main source of information was the Food Standards Agency. **Food purchasing:** 98% of respondents deemed nutritional value ‘important’ or ‘very important’. Parents may not have flawless food knowledge, but is still a big issue when selecting food. ‘What children prefer’ and ‘value for money’ were next in the rankings with 91% and 86% of people surveyed rating them ‘important’ or ‘very important’ respectively. Regionally and socio-economically, there was very little difference in opinions, although ‘price’ is rated less important by the higher earners.	

							63% stated that advertising was the biggest influence if a child asks for a new product. Other influences included' linked to a TV programme' and 'on the box promotion' receiving 37% and 36% respectively. The peer group is also a significant influence, with 50% of mothers saying 'They've seen it at school or friends have said it's good'. 14% of mothers let their children try a product after being asked to buy the product that a child has seen advertised. The survey reports that most parents make a decision depending on the food values of the product or the price. **Attitudes to advertising to children:** Of the people surveyed only 190 (12.9%) stated that they would like	

							advertising for children to be banned. 45% of respondents agreed with the statement 'I accept advertising is a commercial reality'. Although parents have certain reservations about advertising and the effects it has on children, they accept it. Parents recognise that in educating children to realistic expectations, with by far the largest response (96%) being 'It's up to parents to explain they can't have everything they see advertised'.	
Goode 1996	Survey and in-depth interviews	N/A		420 adults living in Leicester and Leicestershire, 58% female, 53% employed full-time, 95% White.	Examined how respondents made dietary choices.	N/A	High levels of awareness of healthy eating initiatives (72% aware of dietary recommendations aimed at improving the health of the nation), of nutritional knowledge, and of accuracy when asked to apply such knowledge. Despite knowledge there were those who failed to make dietary changes.	

							64% reported having made dietary changes due to increased awareness of healthy eating messages.	
Maddock 1999	Interview-administered survey and group discussions.	N/A		311 people representative of UK in terms of age, socio-economic class, employment status and region.	To investigate the nations current degree of interest in healthy eating and to find out whether people are taking note of guidelines.		High level of awareness of need to reduce sugar/salt and fat intake, some confusion regarding types of fat and their health effects and very few knew recommended intake is five portions of fruit and vegetables per day. No statistically significant difference in involvement in healthy eating according to demographic variables; within the groups respondents indicated that excessive information on healthy eating could have the opposite effect to the one intended.	
McCullough 2004	Questionnaire as part of a case study.	N/A		171 primary school children and 124 parents in one primary school in Manchester UK compares with	To compare awareness towards nutrition education between primary schools in UK and Korea and nutritional knowledge.	N/A	Children and parents are aware of importance of limiting fat, sodium and sugar intakes and requiring non-starch polysaccharide. In the case of some foods they	Data not extracted for Korean children and their parents.

				school in Korea (10–11 years old).			did not have satisfactory knowledge of which foods were high in salt, fat, sugar and non-starch polysaccharide. British **children** had less knowledge of salt levels in cornflakes, ketchup and chips and did not realise that chocolate and cake are high-fat foods. Children identified parents as main source of nutritional information. Children perceived health/nutrition as most important factor in choosing food followed by taste and parental influence (however their preferences suggested taste is most important). 16% British children selected fruit as their favourite snack yet 33% said they would buy fruit if they had an extra £2 for food. British children preferred to learn about nutrition through cookery classes then information packs then computer packages.	

							British **parents** said taste was most important factor for choosing food then health/nutrition, appearance and price. Least important factor was TV and friends. British parents said main source of information on nutrition was from doctor/health professional. 32% British parents said extra £10 per week available for food would be spent on fruit.	

Evidence for implementation – will it work in the UK?

Appendix 6

The effectiveness of interventions, including family interventions, to prevent weight gain or maintain a healthy weight in children aged 2–5 years

EVIDENCE SUMMARY TABLES

1. INTERVENTIONS TO PREVENT WEIGHT GAIN, OR IMPROVE BEHAVIOURS ASSOCIATED WITH THE MAINTENANCE OF A HEALTHY WEIGHT (DIET AND ACTIVITY), IN CHILDREN AGED 2–5 YEARS

SUMMARY

Evidence of efficacy for weight management/reduction

Of the five included studies (four randomised controlled trials [RCTs] and one controlled non-randomised trials [CCT]) that have published outcome data, three RCTs found some evidence that the intervention prevented unhealthy weight gain leading to obesity, compared with controls. Ethnic minority children from Head Start programmes in Chicago that received a 14-week diet and physical activity (PA) intervention (Hip-Hop to Health Jr) had significantly smaller increases in body mass index (BMI) compared with control children at 1-year follow-up (0.06 vs. 0.59 kg/m^2; difference –0.53 kg/m^2 (95% confidence interval [CI] –0.91, –0.14), $p = 0.01$; and at 2-year follow-up, 0.54 vs. 1.08 kg/m2; difference –0.54 kg/m^2 (95% CI –0.98, –0.10), $p = 0.02$, with adjustment for baseline age and BMI.

Girls (but not boys) that received the intervention in the STRIP study gained slightly less weight between the ages of 2 and 3 years compared with controls. The already overweight children that received the intervention in the study conducted in China gained much less weight over time compared with controls – but this study was very intensive, costly, and demanded a substantial amount of effort from the parents of the 2–5-year-olds.

There were two studies that reported that interventions were not effective in preventing unhealthy weight gain (Dennison 2004; Healthy Start 2004). For example, Dennison (2004), who investigated if seven educational sessions would encourage reduction in television (TV) viewing, found that although the intervention produced a significant reduction in TV viewing it did not significantly alter anthropometric measurements of the subjects, i.e. did not improve weight loss.

Evidence of efficacy for diet/physical activity outcomes

Eight of the nine completed studies (five RCTs and three CCTs) reported improved diet and/or PA outcomes compared with the controls. These included interventions as part of the Healthy Start (USA), STRIP and the MAGIC (pilot) studies. The MAGIC pilot study, which focussed on a programme of structured PA, reported that there was a significant improvement in PA (based on accelerometry output) of children. Mean fat intake at age 5 years was significantly lower in the intervention group of the STRIP study. The Hip-Hop to Health Jr. study demonstrated only one significant difference between intervention and control children regarding diet/activity outcomes and this was a difference in percent of energy from saturated fat at 1-year follow-up (11.6 vs. 12.8%, $p = 0.002$). Improved outcomes from primary studies included He et al. (2004), McGarvey et al. (2004) and Koblinksky (1992). McGarvey et al. (2004) reported that attending educational sessions significantly improved the frequency of engaging active play with their child and increased frequency of offering the child water. Koblinksky (1992) reported that a parent education programme focusing on nutrition-related behaviour in Maryland, USA, resulted in the intervention group consuming significantly more fruits, vitamin C rich fruits, green vegetables, breads, rice/pasta and orange vegetables than the control group. The only study that reported no effectiveness was an intervention (Horodynski, 2004; controlled before and after [CBA]) that focused solely on nutrition education – a change in knowledge and attitudes was insufficient to change behaviour.

Evidence of corroboration in the UK

Many of the interventions cited within the included studies could be implemented in the UK. It seems reasonable to assume that such interventions could be implemented within the existing programmes and services, e.g. Healthy Start (UK), Sure Start, Child Centres and other existing services (e.g. Healthy Living Centres), and also into nursery and day care provision.

EVIDENCE TABLE 1: INTERVENTIONS TO PREVENT WEIGHT GAIN IN CHILDREN 2 TO 5 YEARS AND THEIR FAMILIES/CARERS

First author, study design, research type, quality	Study population	Research aim/question	Intervention details and length of follow-up	Results	Confounders/comments
Evidence of efficacy (internal validity) for weight maintenance/reduction					
Dennison 2004 Cluster RCT 1+	Sixteen preschool and day care centres in rural upstate New York enrolling children between 3 and 5 years of age. Intervention group *n* = 93, mean age 3.9 years, 47% male, 93% white. Control group *n* = 83, mean age 4.0 years, 53% male, 100% white. The parents were well educated with half having a college degree or higher.	To evaluate an intervention to reduce TV viewing.	**Intervention group:** Seven educational sessions (over 10 weeks) that included a party to celebrate not watching TV for a week Information sent home for parents, children encouraged to read rather than watch TV. **Control group:** Safety and injury prevention programme. This was part of larger 'Brocodile the Crocodile' health promotion programme, which lasted for 39 weeks (no published papers identified on further search).	Sixteen centres entered and completed TV intervention element, 3 of 93 children in intervention group lost to follow-up and 10 of 83 in control group. **Difference in mean changes:** Mean change in intervention group – mean change in control group (95% CI): BMI (kg/m^2) per year: –0.36 (–1.22, 0.50), *p* = 0.38 Standardised BMI/year: –0.19 (–0.83, 0.46), *p* = 0.54 Triceps skinfold thickness (mm/year): –0.41 (–3.52, 2.70), *p* = 0.78 Weight (kg): –0.73 (–1.84, 0.39), *p* = 0.18 Although intervention produced significant reduction in TV viewing it did not significantly alter anthropometric measurements.	Parent-reported child's TV viewing. Only published study on TV viewing intervention in preschool children identified. Generalisability limited as conducted in small centres in rural community with relatively small sample size lasting only 10 weeks.
He 2004 Individual RCT 1+	Two kindergartens of 'average living standard' in Qingdao, China, children aged 4 to 6 years. Intervention group, *n* = 24, 17 male, weight 27.2 (4.1) kg, BMI 19.6 (1.4) kg/m^2.	To explore an effective intervention programme to control obesity in preschool children, to reduce obesity and related diseases at school age.	A 1-year family-based educational programme with joint participation of parents, childcare workers and head of the kindergarten, aimed at changing improper attitude and behaviour of weight control, provided in various forms, such as parent meetings, training of the childcare workers and lessons on children's health. Behaviour	No reported loss to follow-up. Mean change in weight (kg, 95% CI), intervention vs. control: +1.3 (–2.5–+5.2) vs. +5.4 (+3.0–+9.0) kg. Mean change in BMI (95% CI), intervention vs. control; –1.4 (–0.6 to +2.2) vs. +1.5 (–0.3 to +3.8) kg/m^2.	Mean age not reported. All children in intervention and control are obese at baseline – but meets inclusion criteria otherwise.

First author, study design, research type, quality	Study population	Research aim/question	Intervention details and length of follow-up	Results	Confounders/comments
	Control $n = 19$, 15 male, weight 27.5 kg (4.0), BMI 19.3 (2.8) kg/m^2.		correction and dietary adjustment (reducing speed of eating, intake of snacks, sugary drinks and fast food), right amount of exercise (active role play and more outdoor activity) emphasised in educational activities and the daily life of the children. No further details reported regarding 'non-intervention control' group. Measurements were taken before and immediately after 1-year intervention.	Author concluded the programme was safe and effective, alleviated obesity levels without restricting normal height growth.	No details of randomisation process. Two groups of obese children were randomised and one group of normal weight children were not randomised but included in study for comparison (data not extracted for normal weight non-randomised group). Reviewers assumed CI for intervention change in BMI was –0.6 to –2.2. Author not contactable by email.
HEALTHY START (USA) 2004 Williams 1998a, 1998b, 2004; Bollella 1999a, 1999b; Spark 1998; D'Agostino 1999 CCT (quasi-randomised cluster trial) 2++	Nine Head Start preschools in upstate New York that served minority children (2 to 5 years old) from families with annual incomes below national poverty line (less than US\$15,000 for family of four). Mean age (months) A = 48.3 (6.9), B = 47.9 (6.4), C = 49.3 (6.1) Boys (%) A = 51.4, B = 51.3,	To evaluate the impact of a multi-component cardiovascular health intervention 'Healthy Start' to promote heart healthy behaviours and decrease cardiovascular disease risk factors.	Modification of preschool food service to reduce saturated fat content 30% or less total energy from fat and 10% or less total saturated fatty acid intake. **Group A:** Food service and supplementary nutrition education (skills based, lessons on healthy eating) – in school and family based. **Group B:** Food service only (education component focused on safety and accident prevention) – in school and	787 enrolled, 88–93% children in all three groups followed up for anthropometric testing. Since no significant difference found between food service and food service plus nutrition education group on outcomes, these groups were combined for analysis. Neither intervention had a significant effect on gain in weight-to-height ratio). The impact of the intervention varied by ethnicity ($p = 0.04$) but not	Quasi-randomised, six centres able to modify food service were randomly assigned by centre, three centres unable to modify food service served as controls. Many baseline differences between groups, the most significant/relevant of which are: differences in

First author, study design, research type, quality	Study population	Research aim/question	Intervention details and length of follow-up	Results	Confounders/comments
	C = 50.4 African-Caribbean (%); A = 54.2, B = 44.9, C = 39.8 Hispanic (%); A = 14.2, B = 1.9, C = 57.4 White (%); A = 31.6, B = 53.2, C = 2.8		family based. **Group C:** Control (no food modification and education component focused on safety and accident prevention) – in school and family based – this group was not randomised. Parent meetings on health themes held 2–3 times year for all groups. Three-year intervention, baseline measures in fall 1995 and measures planned semi-annually. Only reports outcomes at follow-up between 4.8 to 6.6 months post-baseline. Study ongoing.	gender ($p > 0.05$). There was a significant difference in weight to height ratio for white participants but not African American or Hispanic. Mean difference (95% CI) change in weight-to-height ratio from baseline to follow-up between groups A + B vs. C: African American = 0.004 (–0.007, 0.014) White = 0.034 (0.023, 0.045), Hispanic = –0.006 (–0.020, 0.009).	ethnicity (only 2.8% white in control vs. 31.6 and 53.2% in other two groups). Time to follow-up significantly different between groups: A = 5.8 (0.6) months B = 6.6 (0.5) months C = 4.8 (1.0) months from baseline to follow-up.
Hip-Hop Fitzgibbon et al. 2002; Stolley et al. 2003 Cluster RCT 1+	3–5-year-old African American and Latino minority children in 24 Head Start sites in Chicago. **Mean age (months):** Intervention: 48.6 months(7.6) Control: 50.8 months(6.4) % Female: Intervention: 49.7% Control: 50.5% % Black: Intervention: 99% Control: 80.7%	Weight change in low-income ethnic minority children. Didn't recruit or retain enough children for original power calculations, power recalculated to detect a difference of 0.35 standard deviations.	Reduction in fat, increase in fibre, increase in PA and inclusion of family are main elements of intervention. Theoretical base is combination of social learning theory and transtheoretical model of stages of change. Children had 45 min, three times per week for 14 weeks, hands-on learning about go and grow foods ('foods that will help you go and grow') vs. slow foods ('will make you slow'), using puppets of characters from each of the food groups.	Fourteen-week active intervention plus 2 years follow-up. Intervention $n = 179$ Control $n = 183$ Intervention children had significantly smaller increases in BMI compared with control children at 1-year follow-up (0.06 vs. 0.59 kg/m^2; difference –0.53 kg/m^2 (95% CI –0.91, –0.14), $p = 0.01$; and at 2-year follow-up, 0.54 vs. 1.08 kg/m^2; difference –0.54 kg/m^2 (95% CI –0.98, –0.10), $p = 0.02$, with adjustment for baseline age and BMI.	Trial was piloted for 3 weeks where elements were changed. Curriculum materials translated and taught in both English and Spanish. Twelve of the sites were randomly assigned to receive the intensive intervention and 12 were assigned to the general health intervention.

First author, study design, research type, quality	Study population	Research aim/question	Intervention details and length of follow-up	Results	Confounders/comments
	Baseline BMI: Intervention: 16.5 (1.5) kg/m^2 Control: 16.7 (2.0) kg/m^2 Intervention *n* = 197 Control, *n* = 212		Parents had weekly newsletter, homework (compensated US$5 if completed), and twice weekly 30-minute low impact aerobic classes at children's Head Start sites. Control had 20-min class once per week for 14 weeks spent on general health activity. Parents had weekly newsletter.		Assessors not blinded at baseline but blinded at follow-up.
STRIP Lagstrom 1997; Niinikoski 1997; Rask-Nissila 2000; Talvia 2004 RCT 1+	Babies from well-infant clinics, Turku (Finland), randomised at 7 months of age. Clinics visited regularly by over 98% of Finnish families so sample probably represented range of socio-economic classes (but no details reported).	To evaluate euenergetic, low-saturated fat, low-cholesterol diet to reduce children's exposure to high serum cholesterol values.	Families received individualised counselling at 1–3 month intervals from child aged 7 months to 2 years then twice per year to age 7 years, letters sent home to children between visit to increase interest in food and nutrition. When child aged 7 years separate counselling sessions given to child and parents. Counselling based on constructivist theory of learning. Optimal diet = energy without any restriction, protein 10–15% energy; carbohydrates 50–60% energy; up to 2 years fat 30–35% energy and after 2 years fat 30% energy (unsaturated to saturated fat ratio 2:1). Encouraged to use vegetables, fruit, berries, whole-grain products. Up to 2 years recommended daily supplement of Vitamin A and D_2,	1062 randomised (56.5% eligible age cohort) at age 7 months. 289 of 540 assessed at child age 10 years in intervention group and 268 of 522 in control. Dropout nearly 50%. Infants in both groups were breastfed for mean of 5 (SD 4) months. Relative mean weight gain (SD) (kg) at 2 years in boys: 1.3 (7.6) *n* = 235 vs. 0.7 (7.3) *n* = 221 Relative mean weight gain (SD) at 3 years in boys 1.5 (7.1) *n* = 225 vs. 0.5 (7.3), *n* = 215, *p* = 0.86 Relative mean weight gain (SD) (kg) at 2 years in girls 2.2 (8.6) *n* = 212 vs. 0.9 (9.3), *n* = 219 Relative mean weight gain (SD) (kg) at 3 years in girls 0.8 (8.4) *n* = 200 vs. –0.1 (9.8), *n* = 202 *p* = 0.17 Low fat intake in very young	Important long-term evidence to address restricting dietary intake in the very young. Nordic Nutrition Recommendations propose fat should comprise 30–35% of energy intake and daily energy intake should average 1300 kcal (5.4 MJ) in 1–3-year-olds; previous study in Finnish children with 3-day food records showed mean daily energy intake in 1–2-year-olds was 1167 kcal (4.9 MJ) of which 33% came from fat and 16% came from protein.

First author, study design, research type, quality	Study population	Research aim/question	Intervention details and length of follow-up	Results	Confounders/comments
			breast or formula milk encouraged until at least 12 months (control 1.9% fat cow's milk after 12 months, intervention group advised to replace missing fat milk with vegetable oil). Control families seen twice per year until aged 7 years then once yearly, did not receive any detailed counselling on risk factors of atherosclerosis. Follow-up from age 8 months to 10 years.	children did not adversely affect vitamin and mineral intake and normal physical and neurological growth and lessened age-associated increases in serum cholesterol.	
Evidence of efficacy (internal validity) for diet/physical activity outcomes					
Worsley 2004 Systematic review – five studies: four of which were RCT s and one CCT 1+	Hammond et al. 1998 Kindergarten study in Canada. Mean age: 5 years. Intervention group *n* = 67; 57% male 43% female; control group *n* = 56, 45% male 55% female.	To evaluate whether familiarity with 16 various foods and willingness to eat them would be affected by a nutrition education programme.	The intervention groups were introduced to eight of the test foods. The early childhood nutrition education programme reinforced recent childhood acquisitions of gross and fine motor controls, cognitive skills, language abilities and social competencies at the same time as associating healthy eating habits with social fun and learning. **Intervention:** 7–12 months (throughout school year). **Follow-up:** 7 months.	Education programme had no direct impact on children's willingness to eat specific foods. More parents of the intervention group ($p < 0.001$) than control group children reported their child had stated exposure to a food at school when requesting it at home. Children in the study consistently stated that they were willing to eat a greater number of foods than their parents perceived.	Consumption of food was not measured directly. Instead, stated willingness to eat the foods was assessed using food models. Designation of foods into either food category (introduced or non-introduced) was restricted by the foods available as food models and by the design of the study that included equal representation of the four food groups in each food category.

					Active involvement in a situation of interest to preschoolers will more likely result in accurate memory later on.
	Lagstrom et al. (1997). Finnish study (part of STRIP). Intervention group *n* = 540; control group *n* = 522.	To examine whether counselling to parents would reduce a child's intake of saturated fat and cholesterol as well as ensuring adequate energy intake.	The intervention included a nutrition education programme, which included individualised dietary counselling focused on the amount and type of fat in the children's diet. Part of STRIP – see above for intervention details **Follow-up:** 38 months from beginning of intervention (when child aged 8 months).	Children's intake of fat (saturated and polyunsaturated) and cholesterol were significantly improved/lowered with intervention compared with control ($p < 0.01$). After the age of 13 months, the cholesterol intake of the children in the control group exceeded that of the children in the intervention group by 20 mg ($p < 0.01$). The intervention group consumed 3% less (of their energy intake) saturated ($p < 0.01$) and 1% more (of the energy intake) more polyunsaturated fats ($p < 0.01$) than the control group at 13 months and older.	Families knew which group they belonged to (intervention or control).

	Sangster et al. (1999). Long Day Care Centres (LDCCs) in South Sydney Australia Intervention group *n* = 40 day care centres; Control group *n* = 20 day care centres. Of the 40 intervention centres 23 centres were privately run and 17 centres were community or council based- reflecting the mix of community/council and private centres in the area.	To evaluate the Good Food for Children (GFFC), which was a multi-strategic intervention aimed at improving the nutritional adequacy of food provided in childcare centres.	Assessment of centres' menus with feedback, advice on development of policies and development of workshops for childcare staff. The time between pre and post-test data collections was 14 months.	Generally, the GFFC intervention improved LDCC menus and consequently the nutritional quality of food available to children attending these centres. At post-test 97% of intervention centres had a planned cycle menu for at least 1 week as opposed to 87% in pre-test. There was a 45% increase in the number of centres with adequate served of dairy food on their menu ($p < 0.05$), a 21% increase in the number of centres with adequate servings of bread and cereal ($p < 0.05$) and a 36% increase in the number of centres that diluted fruit juice before serving ($p < 0.05$). Control centres showed no significant improvements.	—

	Heino et al. (2000). Finnish study (part of STRIP). Intervention group *n* = 100; Control group *n* = 100. All children were aged between 3 and 5 years.	To examine sodium intake and dietary sodium sources of preschool-age children.	The intervention included a nutrition education programme, which included individualised dietary counselling focused on the amount and type of fat in the children's diet. Salt reduction in the children's diet was not included in the counselling before children were aged 5 years. Part of STRIP – see above for intervention details **Intervention:** 24 months **Follow-up:** 24 months	Nutrition counselling had minimal influence on children's sodium intake. Children's mean daily sodium (NaCl) consumption (intervention and control combined) was 1600 ± 527 mg (4.0 ± 1.3 g), 1900 ± 504 mg (4.8 ± 1.3 g) and 2200 ± 531 mg (5.5 ± 1.3 g) at the ages of 13 months and 3 and 5 years of age respectively. Intervention children consumed as much or slightly more sodium than the control children at all ages studied. Half the sodium consumption was derived from added salt in the commercially prepared or homemade foods.	The assessment of children's sodium intake is unreliable. It has been suggested that 3-day food records may underestimate sodium intake by as much as 11%.
	Dixon et al. (2000) Children (*n* = 303) aged 4–10 years with elevated LDL-cholesterol, recruited from paediatric practices in suburbs north of Philadelphia, USA. Intervention group *n* = 148; Control group *n* = 155. Majority were white children from middle	To evaluate the impact of nutrition education promoting lower dietary fat on the overall diet quality in children.	The intervention children were either assigned to the parent–child autotutorial (PCAT) programme, a 1-week home based self-instruction nutrition education programme, or nutrition counselling from a registered dietitian. **Intervention:** 10 weeks **Follow-up:** 3 months	Nutrition education that promoted lower dietary fat improved children's overall diet quality. However, numerous dietary behaviours important for long-term health remained unchanged. Children who received PCAT or counselling significantly improved their overall diet quality (–0.6 and –0.4 change in diet quality index (DQI) scores) compared with at risk control children. Children who received either nutrition education were more likely to meet the recommendations for three components of the DQI (total fat,	Results may not be generalisable to all children.

First author, study design, research type, quality	Study population	Research aim/question	Intervention details and length of follow-up	Results	Confounders/comments
	to upper income households.			saturated fat, sodium), but did not improve their intakes of three components of the DQI (vegetables and fruits, complex carbohydrates, calcium) at 3 months.	
Overall conclusions from Worsley 2004 Two out of the five studies published were effective. The authors concluded that the few studies highlight the lack of evaluation in this area, but do suggest that intervention *may* be worthwhile. Although there is little evidence, this age is a key time to establish good nutritional habits especially when involved with parents.					
Dennison 2004 Cluster RCT 1+	As above.	As above.	As above.	Difference in mean change from baseline between intervention and control (95% CI): TV/video-viewing hours per week: –4.7 (–8.4, –1.0). Alternate activities as a result of reduced TV viewing were not stated/measured. No significant changes or differences between intervention and control groups in the frequency of snacking whilst watching TV or the number of days family ate dinner together or watched TV during dinner (actual data not reported).	As above.
He 2004 Individual RCT 1+	As above.	As above.	As above.	'Through intervention, improper behaviours toward obesity out of misunderstanding were changed remarkably, which is beneficial to weight control of obese children. At home their overeating, consumption of double breakfast, eating speed and food intake ($p < 0.01$) but not amount of exercise. At kindergarten eating speed, dietary intake and

McGarvey 2004 (Special supplemental nutrition programme for WIC) CBA 2+	Two WIC (Women, Infants and Children) clinics in Northern Virginia, USA. Low-income mothers of 2–4–year-old children. Intervention *n* = 185 parents; Control *n* = 151 parents. **Baseline for completers:** Mean age in intervention group = 3.06 (1.93) years; in control = 3.15 (0.9) years. % Male in intervention group = 46% and in control = 49% BMI (kg/m^2) in intervention = 17.2 (1.93), control = 17.38 (1.688).	To assess the benefits of a programme to promote parental behaviours and prevent obesity in preschool children.	Intervention (modified educational content of sessions) vs. normal educational classes provided by the WIC. Intervention group participants attended educational sessions once every 2 months and had an individual session with a WIC nutritionist every 6 months. Follow-up 1 year.	65% intervention group completed 12 months (*n* = 121) and 43% control group completed (*n* = 65). Pre-test and post-test differences by site were significant for 'frequency of engaging in active play with child' ($p < 0.01$) and frequency of offering the child water' ($p < 0.01$). Intervention demonstrated significant improvement in offering child water and frequency of engaging in active play with child.	Outcomes were Parental self-report which is susceptible to bias. Differential rates of follow-up between intervention and control sites. Groups were not balanced at baseline: Spanish-speaking participants had significantly lower baseline scores for frequency of watching TV whilst eating and frequency of offering child water through the day compared with English-speaking participants.

2. FAMILY-BASED INTERVENTIONS TO PREVENT UNHEALTHY WEIGHT GAIN IN CHILDREN AGED 5–16 YEARS

SUMMARY

Evidence of efficacy for weight management/reduction
Evidence was identified from one systematic review that included eight relevant interventions (all RCTs in children who were at least 15% above ideal body weight (IBW) at baseline, with weight outcomes at 1 year or more, with four of these eight interventions published pre 1990) plus one RCT of two school-based interventions (Hopper 1996). Six of the studies included in the systematic review assessed different amounts and types of behaviour change therapy taught to both parent and child and all studies included in the review aimed to produce weight loss rather than prevent weight gain. Only two studies assessed behaviour change therapy given to the child alone compared with behaviour change therapy provided to both parent and child together. One of these two studies (in adolescents) showed that treating the mother and child separately appeared to be significantly more effective than treating them together, or treating the child alone. In the other study (10–11-year-old children) there was no significant difference in effect on weight outcomes between treating the parent and child together or separately.

The two school-based studies reported in the RCT (Hopper 1996) showed no significant differences between groups in post-intervention weight or skinfold thicknesses at 6 and 8 weeks follow-up. In younger children (5–12 years), five of the seven interventions reported no significant difference in weight outcomes at follow-up ranging from 1 to 5 years. One three-armed family-based RCT achieved a significant effect at 10-year follow-up. At 10-year follow-up the proportion overweight in the parent/child target group was 11.7% lower than in the child target group and 20.6% lower than in the non-specific target group. Authors also concluded that no significant differences in percent overweight changes were shown for children with one vs. two obese parents at 10-years follow-up. Another study (by the same primary author) concluded that although no significant treatment effect was observed, children with obese parents regained weight faster. One family-based intervention showed that mastery and contingency reinforcement of mastery significantly improved weight loss in obese children up to 1 year but these effects were not maintained at 2 years. There was no evidence to assess variation in effect with age or gender of children. Authors of the systematic review conclude that the studies suggest that parental involvement is associated with weight loss in children and the use of a greater range of behaviour change techniques improves weight outcomes for both parents and children. Although five of the studies showed no significant effect of intervention on weight outcomes only one of the studies did not use any parental involvement in the control group.

Evidence of efficacy for diet/physical activity outcomes
In two school-based RCTs (both reported in Hopper 1996) both treatment groups in ‘Study 1’ scored significantly higher than the control grou*p* on exercise knowledge and obtained a lower proportion of their energy from fat. In ‘Study 2’, the treatment group scored higher than the control group on post intervention fitness and nutrition knowledge as well as consuming more servings of fruit and vegetables. Within the treatment grou*p* a measure of the degree of family involvement significantly correlated with reduction in intake of fat and cholesterol.

Evidence of corroboration in the UK
No studies conducted in the UK were identified. Family based interventions are relatively labour-intensive for both providers and participants. Treating small groups of families at the same time, and using a distant component, can facilitate implementation. Generalisability from the systematic review is limited as two authors conducted five of the studies and the majority were conducted in North America.

Cost-effectiveness data
No evidence.

EVIDENCE TABLE 2: FAMILY-BASED INTERVENTIONS TO PREVENT UNHEALTHY WEIGHT GAIN IN CHILDREN AGED 5–16 YEARS

Evidence of efficacy for weight maintenance/reduction					
McLean 2003 Systematic review 1 ++ Sixteen studies included, seven in school-age children and one in adolescents – only these results are relevant to this review and reported. Of the 8 relevant studies only 3 were published since 1990 plus a 10-year follow-*up* of a study begun in 1979 (Epstein 1990).	Age range 6–13 years (seven studies) and 12–16 years (one study) at baseline; 70% female All children/adolescents overweight by at least 20% IBW at baseline (seven studies) and at least 15% IBW (one study). Studies sizes were small (mean *n* = 52), majority conducted in North America and concerned with weight loss; approximately 15% loss to follow-up.	To evaluate the nature and effectiveness of family-based interventions targeting food intake and/or PA, in terms of weight control, weight maintenance or weight loss. (In comparison to another type of family based intervention or non-family based component.) The aim of seven of the eight interventions considered here was weight loss, and the other's aim was weight control (Israel 1985).	Only RCTs published in English language, with at least 1-year follow-up and incorporating and family-based component were included. All eight interventions included PA plus diet. One study compared an active intervention to a waiting list control only (Israel 1985) and seven compared active interventions. The study in adolescents (Brownell 1983) and one other study (Kirschenbaum 1984) assessed behaviour change therapy given to child alone compared with behaviour change therapy provided to both parent and child together. Six studies assessed different amounts and types of behaviour change therapy taught to both parent and child. Duration of intervention ranged from 9 weeks (Kirschenbaum 1984, Israel 1985) to 2 years (Flodmark 1993) and follow-up from 1 year to 10 years (Epstein	Five of the seven interventions in school-age children found no significant difference between intervention and control at follow-up, ranging from 1 to 5 years. One three-armed family-based RCT achieved a significant effect at 10-year follow-up. At 10-year follow-up the proportion overweight in the parent/child target group was 11.7% lower than in the child target group and 20.6% lower than in the non-specific target group. One family-based intervention showed that mastery and contingency reinforcement of mastery significantly improved weight loss in obese children up to 1 year but these effects were not maintained at 2 years (Epstein 1994). Authors conclude that greater weight loss for parents and children tended to be associated with: the use of a greater range of behaviour change techniques; parent training in behaviour change techniques; and targeting parent and child together. In the study of adolescents (Brownell 1983), focusing the intervention on the mother and child separately was more effective than treating them together and treating the child alone (adolescents lost significantly more weight when treated alone).	No studies of children under age 6 years, no studies found from 1994–2000, no studies found assessing prevention of weight gain, three studies were by the same author and conducted at the same institution, another two studies were conducted by the same author and at the same institution (therefore limiting generalisability). Weight outcomes were heterogeneous

			1990). Majority studies included face-to-face sessions. Four studies included monetary deposits.	No evidence to assess variation in effect with age or gender of children.	within and between studies. The authors conclude that ‘parental involvement is associated with weight loss in children’ even though five of the seven interventions in school-age children found no significant differences in weight outcomes between intervention and control. However, in only one of these studies was the family-based intervention being compared with an intervention that did not involve parents at all, and, as the authors note, the subtlety of differences between

					interventions may have reduced power to detect differences in outcomes between treatment groups.
Flodmark 1993 (included in McLean 2003 systematic review) RCT with non-randomised untreated control group.	Children aged 10–11 years of age screened for obesity at school and then referred to University Hospital, Sweden if obese (BMI of at least 23 kg/m^2). Conventional treatment *n* = 19 (nine girls, ten boys); baseline BMI 25.5 (SE 0.53) kg/m^2. Family therapy *n* = 25 (14 girls, 11 boys); baseline BMI 24.7 (SE 0.36) kg/m^2. Untreated (non-randomised) control group *n* = 50.	To evaluate the effect of family therapy on childhood obesity.	Conventional treatment consisted of dietary counselling by dietitian (ten families saw dietitian once, nine families satisfied with only seeing paediatrician) and regular visits to paediatrician with interest in weight problems (seen twice during initial 6 months then every 6 months, total five visits), 1500–1700 kcal (6.28–7.11 MJ)/day, 30% from fat and encouraged to exercise. Family therapy group received same as above plus six sessions with paediatrician and psychologist spread over 1 year, family therapy focussed on family structure and how to create change through constructing solutions (de Shazer model). Control group received no treatment. Mean duration treatment 14–18 months with follow-up after another year (when children were 14 years).	At end of treatment family therapy group had significantly smaller increase in BMI compared with conventional group when expressed in percent of initial value: 0.66 vs. 2.31%, *p* = 0.042, and reduction in subscapular skinfold thickness: –16.8 vs. 6.8%, *p* = 0.034. At follow-up 1 year after end of treatment there was no significant difference between family therapy and conventional treatment groups for BMI but was significant differences between groups for skinfold thickness. Mean BMI (kg/m^2) (SE) family vs. conventional: End of treatment: 25.0 (0.53) *n* = 22 vs. 26.1 (0.72) *n* = 19, *p* = 0.22. 1 year follow-up: 25.8 (0.73) *n* = 20 vs. 27.1 (0.88) *n* = 19, *p* = 0.15 (non-random control 27.9 [0.61] *n* = 48). Median % change (range) skinfold thickness, family vs. conventional, *n* = 15 in each group. 1 year follow-up: Triceps: –7.2 (55) vs. 8.1 (133), *p* = 0.027 Subscapular: –13.2 (113) vs. 19.6 (167), *p* = 0.005 Suprailiac: –15.1 (113) vs. 30.1 (178), *p* = 0.002 ‘Gender and puberty status did not contribute to variation of BMI.’ Four of 19 children dropped out of conventional	Authors conclude family therapy seems to be effective in preventing progression to severe obesity during adolescence if treatment starts at 10–11 years. Intention to treat (ITT) – school nurses obtained measurements in children who dropped out.

	Baseline BMI 25.1 (SE 0.35) kg/m^2. Twenty children had one obese parent and 13 had two; 17 children had no siblings and 11 had at least one sibling – no significant differences between groups.			treatment. Nine of 24 children (one pilot case excluded from analysis) dropped out of family therapy group.	
Epstein 1981, 1987, 1987, 1990 (included in McLean 2003 systematic review) RCT	Seventy-six families with obese 6–12–year-olds with at least one obese parent, selected from population who applied to enter study (obese defined as >20% IBW). Socio-economic status (SES) of parents equal to medium-sized business owners, minor professionals and technical workers; 53 of 55 families	To test the hypothesis that treatments that target and reinforce habit change and weight loss in obese parents and children together will be superior over 10 years to treatments that focus on child habit and weight change independent of parent success or to a control treatment that targets and reinforces the family members for attendance only.	All three groups received similar diet, exercise and behaviour management training and differed only in the reinforcement for behaviour change and weight loss. Traffic-light diet limiting sweets and sugared beverages, 1200–1500 kcal (5.02–6.27 MJ)/day limit, daily minimum of two servings high protein foods, two servings dairy foods, four servings grains, four servings fruit and vegetables; instructed to begin an exercise programme (Cooper aerobic point system); parent + child and child target groups received self-monitoring and social reinforcement training, money deposited was returned only if parent and child lost weight in parent + child target group and if child only lost weight in child	Change in % overweight at 5 years in parent + child vs. child vs. non-specific groups (SD or SE not reported): –12.7% (*n* = 24) vs. 4.3% (*n* = 21) vs. 8.2% (*n* = 16). Change in % overweight at 10 years in parent + child vs. child vs. non-specific groups: –7.0% (*n* = 20) vs. 4.7% (*n* = 16) vs. 13.6% (*n* = 19). 'No significant differences in percent overweight changes were shown for children with one vs. two obese parents.' Change in weight gain at 10 years in parent + child vs. child vs. non-specific groups: 34.0 kg (*n* = 20) vs. 43.1 kg (*n* = 16) vs. 46.6 kg (*n* = 19); children in child and non-specific groups were significantly heavier than children in parent + child group ($p < 0.05$). No significant difference in percent overweight in *parents* at 10 years in parent + child vs. child vs. non-specific groups: 9.1% (13.9) vs. 4.6% (10.1) vs. 10.6% (13.4).	First long-term study to show that behavioural family-based treatment began between ages 6 to 12 years can have persistent and positive effect on weight through into young adulthood; the importance of targeting and reinforcing only the child vs. the child + parent or only the child vs. non-specific

	were white. Child and parent target group mean age 9.4 (1.8) years, male/female 14/6, weight 47.2 (12.7) kg. Child target mean age 10.4 (1.2) years, male/female 9/7, weight 54.9 (12.6) kg. Non-specific control mean age 9.9 (2.3) years, male/female 13/6, weight 53.2 (13.7) kg.		target group; non-specific target group had money returned on attendance regardless of weight lost and received education on diet through standard lecture-style format. All groups received eight × weekly meetings then six additional meetings in next 6 months, then at 21, 60 and 120-month follow-up meetings.	Effect of study also assessed on non-treated parents and siblings (Epstein 1987) – overweight non-participating siblings of children in the parent + child target group had significantly greater percent overweight change at 5 years than overweight siblings in the child alone target and non-specific target groups (–7.0 [14.6] vs. 4.1% [10.4]). No significant group differences were observed for obese non-participating parents or non-obese non-participating siblings or parents (based on participating parent report).	target cannot be inferred. Study also showed that weight regulation had no effect on height. Outcome results differ in abstract compared with text of study paper (Epstein 1990).
Brownell 1983; (included in McLean 2003 systematic review) RCT	12–16 years, 79% female, at least 20% above IBW, attended with mothers, *n* = 42 in total.	To evaluate any difference in effectiveness between treating adolescents alone, separately from mothers and together with mothers on weight.	Mother and child seen together vs. mother and child seen separately vs. child alone; aim of all three interventions were change in target behaviour of child, mother gave active support in mother and child seen together and mother and child seen separately groups; mother gave passive support in child alone group. Intervention included target setting, monitoring, contingencies, increasing skills, prompts/triggers/cues, social	At 1-year follow-up change in weight, mother-child separately vs. mother-child together vs. child alone: –7.7 (14.2) vs. 2.9 (7.3) vs. 3.2 (5.9) kg. *n* = 42 in total. At 1-year follow-up change in % overweight, mother–child separately vs. mother–child together vs. child alone: –20.5% (22.5) vs. –5.5% (12.1) vs. –6.0% (13.2). *n* = 42 in total. ‘Adolescents targeted separately from their mothers lost significantly more weight than when	

			support, information regarding behaviour and outcome. 16-week intervention with follow-up at 1 year.	targeted with their mothers.'	
Epstein 1986, 1987 (included in McLean 2003 systematic review) RCT	Forty-one families with 8–12-year-old children between 20–80% over IBW (24 children had at least one obese parent)	To investigate the role of parent weight (obese/non-obese) and parent control vs. child self-control on eight loss in obese preadolescent children >3 years old.	Parent control group and child self-control group, US$85 deposit returned on attendance; children and overweight parents given 1200 kcal (5.01 MJ) diet and lifestyle exercise programme, non-obese parents given weight maintenance diet and same exercise programme; children in both groups earned points backed up by privilege and activity reinforcers that were sued to regulate child eating and exercise habits; initially determination of when goals were met were made by therapist this then changed to parents (parent control group) or children (child self-control group). Eight × weekly meetings and ten × monthly meetings in which parent and child seen separately over 1-year period, 3-year data available for 38 families, 5-year follow-up for 33 families.	Parent or child self-control had no significant effect on weight change: change in % overweight, parent control vs. child self-control: 6 months: –17.4 vs. –14.7% (*n* = 38 families in total) 1 year: –12.4 vs. –11.7% (*n* = 38 families in total) 3 years: –5.7 vs. 0.1% (*n* = 38 families in total) 5 years: –3.6 vs. 3.3% (*n* = 33 families in total) Change in % overweight between children of non-obese parents vs. children of obese parents: 6 months: –17.2 vs. –14.3% (*n* = 38 families in total) 1 year: –16.3 vs. –7.7%, $p < 0.01$ (*n* = 38 families in total) 3 years: –5.6 vs. –0.9% (*n* = 38 families in total) 5 years: 10.7% lower in children of non-obese parents vs. children of obese parents ($p = 0.044$, *n* = 33 families in total). Children with non-obese parents were more compliant for energy limit and had better eating behaviour. 'No significant treatment effect was observed but children with obese parents regained weight faster and so parent weight may influence long-term outcome of child weight.'	Authors evaluated effect of parent weight on weight outcomes but parent weight was crossed with treatment condition. Change in percentage overweight between children with obese/non-obese parents differs in two papers but pattern is same (one paper adjusted results for difference in baseline initial percent overweight between parent weight groups).
Epstein 1994 (included in McLean 2003 systematic review)	Forty-four families with obese (20–80% above IBW) 8–12-year-old	To evaluate the effects of mastery criteria and contingent reinforcement for	All subjects had same information regarding self-monitoring, diet (traffic light diet with energy intake goals ranging from 900–1800 kcal (3.77–7.53 MJ) on level 1 to 900–	Changes in % overweight experimental group (*n* = 17 children) vs. control (*n* = 22 children): 6 months: –30.1 vs. –20.0%, $p < 0.05$ 1 year: –26.5 vs. –16.7%, $p < 0.05$ 2 years: –15.4 vs. –10.6%, $p = 0.29$	

RCT	children, mean age 10.2 (1.1) years, 59.6 (22.0)% over 50th percentile for BMI, 74% female; 82% parents were mothers, 54% participating parents were obese and 30.1 (20.9)% participating parents were over 50th percentile for BMI, majority middle class SES status.	family-based behavioural treatment of childhood obesity.	1200 kcal (3.77–5.02 MJ) by level 4 and individually adjusted energy intake control on level 5 based on maintenance requirements) and exercise (lifestyle exercise programme) and both treatments included behaviour management (focussing on praise and stimulus control, also included quizzes, contracting and lottery tickets) and parenting education. In experimental group families progressed through treatment at own rate based on mastery of information and skills and were reinforced on individual basis; control group were 'yoked' to progress in treatment group and did not have to demonstrate mastery of behaviour change skills. Twenty-six × weekly meetings and 6 monthly meetings up to 2 years.	Mastery and contingency reinforcement of mastery can significantly improve weight loss in obese children up to 1 year but these effects were not maintained at 2 years.	
Israel 1985 (included in McLean 2003 systematic review) RCT	Thirty-three families, children aged between 8–12 years and at least 20% over IBW; mean age 11 years and 4 months. Behavioural weight reduction only group, *n* = 12 (nine girls,	To evaluate the effect of explicit and additional training in general child management skills in the context of a behavioural treatment programme for overweight children.	Behavioural weight reduction only group and behavioural weight reduction plus parent training group received identical treatment consisting of stimulus control cues, exercise, food intake and rewards; responsibility for monitoring was divided between parent and child, also included homework. Behavioural weight reduction plus parent training group also received 2-hour-long sessions of instruction in behavioural child	Changes in weight at 1-year behavioural weight reduction plus parent training vs. behavioural weight reduction only: 5.2 (*n* = 11) vs. 4.8 kg (*n* = 9). Change in % overweight at 1 year behavioural weight reduction plus parent training vs. behavioural weight reduction only: –10.2 (*n* = 11) % vs. –1.3% (*n* = 9). No significant difference between two active treatment groups.	

	three boys, range 9–12 years). Behavioural weight reduction plus parent training group, *n* = 12 (eight girls, four boys, range 8–13 years). Wait list control group, *n* = 9 (six girls, three boys, range 9–12 years).		management skills prior to start of programme, understanding was tested in three quizzes and concepts were referred to in treatment programme. Nine × 90 min sessions then brief problem-solving discussions at 1, 2, 4, 6, 9 and 12 months including telephone calls.		
Israel 1994 (included in McLean 2003 systematic review) RCT	Thirty-four children aged 8–13 years and at least 20% over IBW; mean age 10 years 11 months (SD 1 year 2 months).	To evaluate the effect of enhanced self-regulation in the treatment of childhood obesity.	Both treatment groups consisted of stimulus control cues, exercise, food intake and rewards; instruction in general child management principles, families monitored children's food intake and parents rewarded appropriate behaviours. Enhanced child involvement group placed less emphasis on parental control and children trained in self-goal setting, formulating and implementing behaviour change, self-evaluation, self-reward and training for high-risk situations, parents also rewarded children for engaging in self-management skills. Groups of five to seven families, eight × weekly 90-min parent and child sessions held separately followed by 9 × biweekly sessions	26/34 families completed 26 weeks, 20/34 families completed 1- and 3-year follow-up (no difference between groups). Change in % overweight standard treatment vs. enhanced child involvement: 1 year: –0.7 (*n* = 11) vs. –5.8% (*n* = 9) 3 years: 6.4 (*n* = 11) vs. –4.8% (*n* = 9) No significant difference between treatment groups.	

			for 26 weeks, follow-up at 1-year and 3-years post-treatment.		
Kirschenbaum 1984 (included in McLean 2003 systematic review) RCT	Forty parent–child dyads where child aged 9–13 years and at least 20% above IBW and parent at least 10% above IBW. Parent + child group *n* = 16 (mean age 10.4, *n* = 13). Child only group, *n* = 15 (mean age 11.2, *n* = 9). Non-randomised control group, *n* = 9.	To evaluate the effects of parental involvement and family environment on weight loss on obese preadolescents.	Both treatment groups received cognitive-behavioural treatment including self-monitoring, increasing exercise, nutrition education, stimulus control, meal and exercise planning, self-reward, decelerated eating, coping techniques. Parent + child group attended all sessions together. Child only group children only attended sessions and had to bring in parent's homework and emphasis on child becoming the expert. Waiting list control dyads attended assessments only. Nine × weekly sessions plus 3-month and 1-year follow-up sessions; US $30 fee plus $50 deposit refunded contingent on attendances.	Change in % overweight at 1 year, parent + child vs. child only: –7.6% (*n* = 13) vs. –6.2% (*n* = 9). Change in weight at 1 year, parent + child vs. child only: –3.2 kg (*n* = 13) vs. –2.8 kg (*n* = 9). Children in both active treatment groups lost and sustained weight loss over 1 year with no significant difference in effect between the two groups.	Significant difference in treatment dropout between two active interventions groups (voluntary dropout 33% in child only group*p* vs. % in parent +child group, *p* < 0.03, with three of five cases stating parent dissatisfaction at being assigned child only group).
Hopper 1996 RCT (cluster, by class) 1+	**Study 1:** 132 school children, mean age 11.6 (SD 0.7) years plus a participating parent for 42 of the 45 children in the school-and-home treatment condition.	**Study 1:** To assess the effectiveness of including a family participation component in a 6-week school-based programme to develop children's heart-healthy exercise and nutrition habits.	**Study 1:** School-and-home and school-only groups received nutrition education two × half-hour in school sessions per week for 6 weeks; emphasising different meals and targets for behaviour change, focus on reducing saturated fat and heart-healthy foods. Three × 40 min in-school sessions per week for 6-weeks	**Studies 1 and 2:** No significant differences between groups in post-intervention weight or skinfold thickness.	Lack of follow-up is a major weakness of the study. Family was defined as at least one adult and one child sharing usual household activities.

	Study 2: ninety-seven school children, mean age 8.9 (SD 1.18) years, plus a participating parent of each child in the treatment condition.	(School-and-home treatment condition *n* = 45 vs. school-only treatment condition *n* = 43 vs. control condition *n* = 44.) **Study 2:** To assess the effectiveness of a 10-week school-based fitness and nutrition programme with parent involvement. (School-based treatment with parent participation treatment condition *n* = 48 vs. control condition *n* = 49.) Outcomes in the same classes as above.	instruction in physical fitness particularly aerobic exercise. In addition the school-and-home group received weekly homework packs and received points for completing nutrition and exercise activities. Control group received no additional instruction in nutrition and exercise from school curriculum. Length of intervention was 6 weeks. **Study 2:** School-and-home and school-only groups received nutrition education two × half-hour in school sessions per week for 10 weeks; emphasising different meals and targets for behaviour change, focus on reducing saturated fat and heart-healthy foods. In addition the school-and-home group received weekly homework packs and received points for completing nutrition and exercise activities. Four × 30 min in-school sessions per week for 10 weeks instruction in physical fitness particularly aerobic exercise. Control group received no additional instruction in nutrition		

			and exercise from school curriculum. Length of intervention was 10 weeks.		
Evidence of efficacy (internal validity) for diet/physical activity outcomes					
McLean 2003	As above.	As above.	As above.	Not reported	As above.
Hopper 1996	As above.	As above.	As above.	**Study 1:** The school-and-home group scored significantly higher than the control group on post-intervention nutrition knowledge and sit-and-reach flexibility. There was no significant difference between the school-only and control groups. Both treatment groups scored significantly higher than the control group on exercise knowledge and both obtained a smaller proportion of their energy from fat. There were no significant between-group differences in any other measures of dietary intake (grams of protein, carbohydrates or fat, and % energy from protein or carbohydrates) or other performance measures (number of sit-ups in a minute, time to run one mile). **Study 2:** The treatment group scored higher than the control group on post-intervention measures of fitness/nutrition knowledge, and consumption of servings of fruit and vegetables. There were no significant between-group differences in any other post-intervention scores, i.e. any other measures of dietary intake and time to run a mile. Within the treatment group, a measure of the degree of family involvement significantly correlated with reduction in intake of fat and cholesterol but no other change scores.	As above.

School-based interventions to prevent obesity

EVIDENCE SUMMARY TABLES

EVIDENCE TABLE 1: SCHOOL-BASED INTERVENTIONS TO MAINTAIN A HEALTHY WEIGHT/PREVENT OVERWEIGHT OR OBESITY

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for weight maintenance/reduction								
DIET ONLY STUDIES								
James 2004	RCT Cluster, by class	1	++	**Setting:** Schools in Christchurch, Dorset, UK. **Participants**: Twenty-nine classes in six junior schools in children aged 7–11 years. 320 females, 324 males, mean age 8.7 (range 7–10.9) years. *n* (randomised to intervention) 325 (15 classes). *n* (randomised to control) 319 (14 classes). Baseline mean BMI (SD): Intervention: 17.4 (0.6) kg/m^2	**Aim:** To reduce consumption of carbonated drinks. One investigator delivered programme to all classes and teachers assisted. One-hour session each class each term (four sessions) encouraging children not to drink carbonated drinks but to switch to water or fruit juice diluted 1:3 with water. Study had 90% power.	12-month intervention.	Assessed at 12 months: Intervention *n* = 295 Control *n* = 279 10.9% not assessed Change in body mass index (BMI) over 12 months not significantly different between intervention and control 0.7 (0.2) vs. 0.8 (0.3) kg/m^2. Percentage of overweight and obese children increased in the control group by 7.5% at 12-months compared with a decrease in the intervention group of 0.2% (mean difference 7.7%, 95% confidence interval [CI] 2.2, 13.1).	

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				Control: 17.6 (0.7) kg/m^2				
PHYSICAL EDUCATION ONLY STUDIES								
Flores 1995	RCT Cluster, by class	1	+	**Setting:** Four physical education (PE) classes at one school in Palo Alto, CA, USA. **Participants**: 10–13-year-olds, boys and girls, mean age 12.6 years. 54% female. *n* (intervention baseline) = 43; *n* (control baseline) = 38. **Baseline BMI:** Intervention girls: 22.9 (SD 6.1) kg/m^2 Control girls: 22.9 (SD 4.4) kg/m^2 African American (44%) and Hispanic	**Aim:** To evaluate an aerobic dance programme to help maintain or decrease weight. **Intervention:** Culturally sensitive health education curriculum twice a week plus dance orientated aerobic physical education class three times a week (50 min each) for 12 weeks. **Control:** Usual PA (playground activities) Delivered by teachers and trained personnel from the research team.	12 weeks.	*n* (intervention follow-up) = 26 girls, number of boys not reported *n* (control follow-up) = 23 girls, number of boys not reported. Statistically significant reductions in BMI (kg/m^2) between intervention and control girls at 12-weeks: Intervention girls: 22.1 (SD 6.0) Control girls 22.5 (SD 4.4) This represents a change of –0.8 kg/m^2 in the intervention grou*p* and +0.3 kg/m^2 in the control grou*p* ($p<0.05$). No statistically significant change between intervention and control boys re BMI (BMI –0.2 kg/m^2 intervention boys vs. –0.6 kg/m^2 control boys).	Only results for girls were presented in the paper. Programme piloted. Attendance at intervention was mandatory as it took place in usual PE class. Rewards given (juice, stickers, t-shirts) for participation.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				(43%)	Power not stated.			
Jamner 2004	CCT Cluster by school	2	+	**Setting:** Two public high schools in Orange County, CA, USA **Participants:** 58 female adolescents, 25 intervention and 22 control. Mean age = 14.94 (SD 0.79) years. Mean baseline BMI percentile = 67.28 for intervention completers) mean baseline BMI percentile = 60.47 for control completers. 53% non-Hispanic white, 29% Hispanic, 8% Asian and 3% 'other'.	**Aim:** To evaluate the effect of a school-based intervention designed to increase PA among sedentary adolescent females. **Intervention**: Special PE class. The class met five days per week for 60 min each day (approximately 40 min of activity time). Types of activity included aerobic dance, basketball, swimming and tae bo. One day per week of class time was devoted to a lecture or discussion focusing on the health benefits of physical activity (PA) and strategies for	4 months	At follow-up, data were available for 25 intervention participants and 22 control participants. The intervention had no significant effect on BMI percentile, 67.28 at baseline and 66.74 at 4 months; % body fat 32.64 at baseline and 31.85 at 4 months.	Study participants overall reported more moderate and less light activity at baseline, as these measures were obtained during summer vacation, whereas follow-u*p* assessments were conducted during the school year which may have confounded results.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					becoming more physically active. Not stated who delivered intervention. Power not stated – small study.			
Mo-suwan 1998	RCT Cluster, by class	1	+	**Setting**: Two kindergartens in privately owned schools Southern Thailand (Hat Yai municipality, Songkla province). **Participants**: Second year kindergarten pupils, boys and girls, aged 4.5 (SD 0.4) years. *n* (intervention baseline) = 158; *n* (control baseline) = 152. **Baseline BMI (kg/m^2):** Intervention: 16.25	To evaluate the effect of a school-based aerobic exercise programme on obesity indexes of preschool children. 15-min walk before morning class, 20-min aerobic dance session after afternoon nap, three times per week for 29.6 weeks. Delivered by teachers and Aerobic session led by trained personnel. Power not stated.	30 weeks	*n* (intervention follow-up) = 147 *n* (control follow-up) = 145. Both intervention and control groups experienced reduction in BMI (kg/m^2) and not significantly different between groups at 30-weeks: Intervention: 15.76 (2.46) Control: 15.94 (2.26) Not significant No significant difference between groups in skinfold thickness at 30-weeks. Intervention girls had significantly lower mean BMI at 30-weeks than intervention boys ($p < 0.01$). Intervention girls had lower likelihood of having an increased	Statistically accounted for the potential unit of analysis errors. Both schools had 1 hour physical education per week and one school had swim class for 1-hour per week (adjustments made for these children). Triceps skinfold thickness (TSF) also available. Appears to be informed by an environmental change model.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				(2.35) Control: 16.36 (2.22)			BMI slope than the control girls (Odds ratio [OR] 0.32; 95% CI 0.18, 0.56).	
Pangrazi 2003	CCT Control schools were not randomly selected	2	+	**Setting:** Thirty-five schools in Arizona, USA **Participants**: Fourth grade, mean age for boys and girls was 9.8 years (SD 0.6). PLAY + PE: *n* = 183 PE only *n* = 175 PLAY only *n* = 150 No treatment control *n* = 91	**Aim:** To evaluate the effects of the PLAY intervention Promotes 30–60 min moderate to vigorous PA daily, 15-min activity break each day to teach variety of physical activities, promotes attitudes and behaviours to sustain active habits for life; includes self-monitoring and self-awareness. Teachers received training from county health co-ordinators. PLAY is not intended to replace comprehensive PE programme but act as important supplement.	12 weeks	However, no significant differences between groups were found for BMI.	Previously adopted in Arizona elementary schools and 24,000 children have received the intervention. No treatment control not randomly assigned.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					The intervention comprised three stages: Step 1: promote play behaviour (first week) teachers and students participated, more walking, less standing, sitting, children were informed about the importance of PA and identified appropriate adult role models. Step 2: teacher-directed activities (3 weeks) games and activities that were enjoyable and could be played outside school. Step 3: encourage self-directed activity (8 weeks) with students aiming to achieve 30 min of			

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					activity per day independently of teacher outside school. Treatment and PE schools, children received log sheets similar to the PLAY ones but were asked to record their after school activities (active and sedentary). Teachers trained by county co-ordinators, with programme implemented across Arizona with more than 24,000 children receiving PLAY. Power not stated.			
Pate 2005	RCT Cluster by school	1	+	**Setting**: Twenty-four high schools in 14 South Carolina counties, USA. **Participants**: 2744 girls, 48.7% African American	**Aim:** To evaluate school-based PA intervention among high school girls. **Intervention:** LEAP, based on social ecological	Start of 9th grade through until Spring? Approx. 6 months?	Intervention: 863 Control: 741 Completers only Slightly higher % African American girls lost to follow-up. % Girls classified as overweight or at risk for overweight (at least	

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				and 46.7% white, mean age 13.6 years, mean BMI 23.1 kg/m^2.	model drawn mainly from social cognitive theory; LEAP project staff supported the LEAP teams within the schools which included a LEAP champion; girl friendly PA of moderate to vigorous PA for 50% or more of PE class time (aerobics, dance, walking, self-defence, martial arts, weight training plus competitive sport and traditional PE). Environmental change included role modelling by school staff, family and community-based activities. School personnel headed by a champion implemented programme with training from		85th percentile BMI 34% both groups) or overweight (at least 95th percentile BMI 17% both groups) did not differ between intervention and control.

					research staff. Power not stated.			
Robinson 1999	RCT Cluster, by school	1	++	**Setting**: Two public elementary schools in San Jose**,** CA, USA. **Participants**: Third and fourth grade students, mean age 8.9 years, boys and girls. *n* (intervention baseline) = 95; *n* (control baseline) = 103. BMI (kg/m^2) at baseline: Intervention: 18.38 (3.67) Control: 18.10 (3.77)	**Aim:** To evaluate a school-based intervention to reduce TV, videotape and video game use on adiposity. Designed to have 80% power to detect an effect size of 0.20 or greater. Based on Bandura's social cognitive theory; 18 × lessons of 30 to 50 min, included self-monitoring of TV, videotape and video game use, then 10-day turn-off, then 7-hour budget, children taught to become selective viewers and advocators of reducing media use.	6 months	*n* (intervention follow-up) = 92; *n* (control follow-up) = 100. Three children lost to follow-up in each group. Compared with controls, children in the intervention group had statistically significant relative decreases in BMI –0.45 kg/m^2 with 95% CI –0.73, –0.17, *p* = 0.002; TSF –1.47 mm with 95% CI –2.41, –0.54, *p* = 0.002; and waist-to-hip ratio –0.02 with 95% CI –0.03, –0.01, *p* <0.001.	Each household received electronic television time manager (control power to TV and VCR). Schools were matched. Assessors blinded.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					Parental involvement. Programme built into standard curriculum and taught by classroom teachers trained by research staff. Study 80% power to detect effect size at least 0.20.			
Sallis 1993, 1997	RCT Cluster, by school	1	+	**Setting**: Seven suburban elementary schools in Southern California, USA. **Participants**: Elementary school children, mean age 9.25 years. Seven schools involved, six schools randomly assigned to the three experimental conditions and one further school added to the	To evaluate a school-based intervention involving physical education and self-management (delivered either by specialists or teachers) on weight and adiposity, Three × 30-min classes per week including warm-up, fitness activities such as walk/run/jog/aerobic dance and sports	2 years	Total 549 children assessed at follow-up (305 boys and 244 girls); 26% attrition. Boys (after intervention) *n* control = 101, *n* specialist-led = 91, *n* teacher-led = 113. Girls (after intervention) *n* control = 97, *n* specialist-led = 60, *n* teacher-led = 87. Specialist PA promotion programme did not produce significant reductions in children's BMI or adiposity. No differences observed between teacher-led and specialist-led programme.	Interim results only (2 year data from 3-year study). Actual data for BMI and skinfold thicknesses is only presented in graphical form.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				control group. 85% non-Hispanic white. *n* total (intervention and control at baseline) = 745.	skills such as soccer/basketball/softball; plus weekly 30-min self-management training, also incentives and parental involvement through newsletters and signature on weekly goal sheets. Two intervention groups receiving same programme but provided by either certified PE specialist or teachers trained for total 38 hours in-house over 2 years with substitute teachers provided and provided with detailed daily lesson plans to implement programme. Power not stated.		All boys in all three groups increased their BMI over 2 years. Control girls had significantly lower BMI than girls in either teacher-led or specialist-led intervention group ($p < 0.01$). Changes in skinfold thicknesses not significant between groups in girls or boys.	
Schofield 2005	CCT	2	+	**Setting:** Three high schools	To pilot efficacy of using pedometer as	12 weeks	Pedometer: *n* = 23 Minutes: *n* = 21	

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
	Cluster by school			in central Queensland, Australia. **Participants**: Low active girls (defined from previous study as those girls who took least amount of recorded steps). Mean age 15.8 years. **BMI:** Pedometer intervention: 22.3 (SD 4.1) kg/m^2 Minutes intervention: 23.7 (SD 6.6) kg/m^2 Control 24.5 (SD 5.5) kg/m^2 Pedometer intervention: *n* = 27 Minutes intervention: *n* = 28 Control: *n* = 30	basis of time efficient yet effective non-curriculum school-based programme Intervention; group meetings once a week for 6 weeks for 30 min each in groups of eight either before or after school or in lunch break. Intervention groups received log book to record min in PA or amount of step counts; actual activity intervention was 12 weeks with weeks 7–12 maintenance phase (no group meetings). **Pedometer intervention:** 1000–2000 step increase daily each week until reached 10,000 steps per day.		Control: *n* = 24 No significant difference between groups for BMI or from baseline to follow-up.	

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					Minutes intervention: Increase by 10–15 min daily each week until reached daily average of 30–60 min/day. Power not stated.			
Stephens 1998	CCT Cluster, by school	2	+	**Setting:** Two urban elementary public schools in Cleveland, OH, USA. **Participants:** 56% boys, 8.4 years, 98% African American in intervention group; 43% boys, 8.4 years, 78% African American in control. 'Predominantly from low income families' – no other details reported.	To evaluate a school-based supplementary programme of PA on weight in addition to usual PE (45 min once per week). Control children received usual PE (45 min once per week). Delivered by medical student volunteers who received a 2-day orientation session. Power not stated.	15 weeks	Control group gained significantly more weight (*p* <0.001). Weight (kg) intervention vs. control at 15 weeks = 25.8 vs. 27.0. Significant decrease in skinfold thickness intervention vs. control, *p* < 0.01. Baseline: 25 vs. 26 mm 15 weeks: 23.5 vs. 28.5 mm	Significantly more black children in intervention compared with control group (*p* < 0.01).

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				n (intervention – baseline and follow-up) = 45; *n* (control – baseline and follow-up) = 44. Weight in kg at baseline intervention vs. control = 25.4 vs. 26.1.				
Trudeau 2000, 2001	Unclear, controlled, CCT	2	–	**Setting**: Primary schools in Trois-Rivieres, Quebec, Canada. **Participants**: Primary school boys and girls aged 6 years at baseline, all children French descent. Intervention: *n* = 272 Control: *n* = 275	To evaluate whether a programme of PA and fitness in school children over 6 years would result in enhanced cardiovascular fitness in adulthood. The Trois-Riveries Growth and Development study was a 6-year intervention involving 1 hour per day (5 hours per week) of physical education to increase aerobic and muscular capacity, in	Twenty-two-years follow-up of 6-year intervention study	Random selected sample (22% of original group) contacted by telephone for follow-up: Intervention: *n* = 68 Control: *n* = 65 Mean age 33–34 years No significant difference between intervention and control with respect to BMI, body fat, skinfold thickness, waist-to-hip ratio (Trudeau 2000). Baseline values not reported. Comparisons of tracking suggested intervention and control developed similar gains in BMI and skinfold thicknesses over 22-year interval (Trudeau 2001).	Small sample followed-up, with control women significantly older and intervention and control women earning significantly less income per annum despite similar education levels (14 years of schooling). Author contacted regarding BMI status of intervention and control groups during original study.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					comparison to a control group that received single 40-min PE per week. Delivered by research team for follow-up. Professional physical educators provided original intervention. Power not stated, subgroup analysis unlikely to be powered.		Change in BMI (kg/m^2) over 22 years intervention vs. control: 5.7 (0.4) females (*n* = 57), 8.6 (0.4) males (*n* = 56) vs. 5.8 (0.3) females (*n* = 38), 8.0 (0.2) males (*n* = 40). BMI was not significantly different between intervention and control groups at age 10, 11, 12 and 34 years. Skinfold thickness change also available (not significant between groups).	
DIET AND PHYSICAL EDUCATION STUDIES TO PREVENT OBESITY								
Caballero 2003	RCT Cluster, by school	1	+	**Setting**: Forty-one elementary schools in seven American Indian communities in Arizona, New Mexico, South Dakota, USA. **Participants**: Mean age 7.6 ± 0.6 years. Sex not reported.	**Aim:** To evaluate a school-based multi-component intervention to reduce percentage body fat in American-Indian children. **Intervention:** Four components: 1) Change in dietary	3 years	*n* (intervention at follow-up) = 727 *n* (control at follow-up) = 682 17% attrition. Completer analyses only. No significant difference in weight, BMI, % body fat or skinfold thickness between intervention and control groups. BMI in the intervention group at baseline was 19.0, at follow-up 22.0. In the control group BMI was 19.1 kg/m^2 at baseline and	Intervention piloted. Compared with Centers for Disease Control (CDC) reference values, distribution of BMI in study children was shifter towards higher values.

First author	**Study design**	**Rese arch type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				American Indian school children. Six schools randomly assigned to the three experimental conditions and one further school added to the control group. *n* (intervention) = 879 *n* (control) = 825	intake (Pathways guidelines for food-service personnel and regular visit by Pathways nutritionist to support and monitor school lunches). 2) Increase in PA (3 × 30-minute moderate to vigorous PA based on SPARK programme (see Sallis 1993) per week during term-time, exercise break during classroom time and guided play during recess). 3) A classroom curriculum focused on healthy eating and lifestyle (12 weeks per year, 8 weeks in 5th grade, twice weekly 45-min classroom lessons integrating social learning theory with		22.2 kg/m^2 at follow-up. Mean difference in BMI = –0.2 (95% CI –0.50, 0.15) kg/m^2. % Body fat increased by approximately 7% in both groups at 3 years.	

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					American Indian traditions and indigenous learning modes such as story telling). 4) A family-involvement programme (family fun nights, workshops, events at school and fun packs linked to classroom curriculum). Almost the entire intervention was delivered by school personnel, teachers and food service staff; the Pathways staff focused on research measurements and training and support of school staff. Teachers, food service staff and PE teachers trained annually by SPARK or PATHWAYS instructors and

					supported within schools. Power not stated.			
Donnelly 1996	CCT By school	2	+	**Setting:** Elementary schools in rural Nebraska, USA. **Participants:** Age 9.2 years. Boys and girls (no values given). 94% White, 42–44% received free and reduced school lunches. Mean BMI (kg/m^2): Intervention: 18.3 (SD 3.9) Control: 18.5 (SD 3.4) Intervention *n* = 102; Control *n* = 236	**Aim:** To evaluate a school-based PA and nutrition programme to attenuate obesity and promote fitness. Components included a nutrition intervention (changes to school lunches using Lunchpower! which is a reduced energy, fat and sodium lunch, and nutrition education in curriculum) and PA intervention of 30–40 min per day 3 days per week of aerobic activities. Utilised school curriculum and existing staff resources.	2-years	Completer analysis only for BMI (kg/m^2) at 2 years Intervention Baseline: 17.9 (SD 3.8) *n* = 44 2-years: 18.9 (SD 4.3) *n* = 44 Control Baseline: 18.1 (SD 2.6) *n* = 64 2-years: 19.3 (SD 3.2) *n* = 64 Significant increase in both groups from baseline to follow-up but no significant difference between groups. Authors suggest children compensate in energy intake and PA outside school.	Small rewards for volunteers.

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					Research nutrition staff consisted of PhD student in nutrition, registered dietitian, and several graduate students. PA research staff comprised an exercise physiologist and graduate students. Power not stated.			
Gortmaker 1999; Austin 2005	RCT By school	1	+	**Setting**: Ten secondary schools in Boston, USA. **Participants**: Girls and boys, grades 6 and 7, mean age 11.7 (SD 0.7) years for both intervention and control. 48% female BMI (kg/m^2): Baseline 20.6 (SD 4.5)	**Aim:** To evaluate impact of school-based health behaviour intervention known as PLANET HEALTH on obesity amongst boys and girls in grades 6 to 8. Implemented programme via existing school staff and curricula. Underpinned by behavioural change and social cognitive	Two school years.	Intervention *n* = 641, control *n* = 654, 17% loss to follow-up. At 2 years: prevalence of obesity among girls in the intervention schools was reduced compared with controls, controlling for baseline obesity (OR 0.47; 95% CI 0.24, 0.93; *p* = 0.03). Among boys obesity declined among both control and intervention students however, after controlling for co-variates, there was no significant difference in outcome (OR 0.85; 95% CI 0.52, 1.39, *p* = 0.48).	Obesity definition based on BMI and TSF measure greater than or equal to 85th percentile of age and sex-specific reference data statistically accounted for the potential unit of analysis errors. Blinded outcome assessment was reported. Also reported on the issue of the promotion of unintended side

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				Intervention, 20.7 (SD 4.0) Control (based on completers only) Higher % African American girls in control schools (17 vs. 10%) and Hispanic boys in control schools (18 vs. 12%). Intervention *n* = 1560 on total at baseline	theory. Promotion of PA, modification of dietary intake (decreasing consumption of high-fat foods, increasing fruit and vegetable consumption) and reduction of sedentary behaviours (with a strong emphasis on reducing television viewing). 32 classroom lessons of 45-min each over 2 school years. Utilised school curriculum and existing staff resources. Only 33 incident cases of obesity 'limited the statistical power of the study to detect differences'.		There was greater remission of obesity among intervention girls vs. control girls (OR 2.16; 95% CI 1.07, 4.35, $p = 0.04$). Intervention reduced television hours among both girls (–0.58 hours; 95% CI –0.85 to –0.31, $p = 0.001$) and boys (–0.4 hours, 95% CI –0.56, –0.24; $p < 0.001$). Author concludes that reductions in TV viewing predicted obesity change and mediated the intervention effect (in girls but not boys). Among girls, each hour of reduction in television viewing predicted reduced obesity prevalence (OR 0.85; 95% CI 0.75, 0.97; $p = 0.02$). Measures of extreme dieting behavior remained unchanged (and low) throughout the intervention and were not different between intervention and control schools. Analysis of girls only using self-report, showed a reduced risk of using self-induced vomiting,	effects (extreme dieting behaviours). Schools experienced with interdisciplinary curricula found it easier to implement Planet Health material.

							laxatives or diet pills to control weight within the previous 30 days.	
Graf 2005	CCT Cluster by school	2	+	**Setting:** Seven primary schools in Cologne, Germany. Three schools were chosen to participate in a prospective programme of intervention, the step TWO programme, for prevention of obesity. Four schools served as controls. **Participants:** In total, 830 boys and 848 girls took part. Mean age = 8.2 ± 1.3 years; mean BMI = 17.1 ± 2.9 kg/m^2. Of all children 7.3% were obese, 10.4%	**Aim:** To present the baseline and final data from the step TWO programme. The step TWO programme, which is designed for overweight and obese children, consisted of health education and PA delivered by a team of nutritionists, gymnasts, psychologists and medical doctors. Power not stated.	8–9 months	Forty controls and 145 in the intervention group The increase in BMI tended to be lower in those undergoing intervention mean difference in BMI for the intervention and control groups were 0.27kg/m^2 and 0.66 kg/m^2 respectively (p = 0.069) After intervention, the increase in waist circumference with time was lower than the controls (3.11cm and 4.56cm respectively)	Intervention group had higher BMI, waist circumference and blood pressure at baseline than control. Body weight showed high correlations with the result of bioelectric analyses (r = 0.770, $p \le 0.001$) and waist circumference (r = 0.857, $p \le 0.001$), and low correlation with the waist-to-hip ratio (r = 0.180, p = 0.001) adjusted for gender and age. BMI showed high correlation with the results of bioelectric analyses (r = 0.839, $p \le 0.001$) and waist circumference (r = 0.861, $p \le 0.001$), and low correlation with the waist-to-hip ratio

					Delivered by research team, PE teachers and school counsellors. Power not stated.			
Sahota 2001	RCT Cluster, by school	1	+	**Setting:** Ten primary schools in Leeds, UK. **Participants:** 7–11-year-olds, boys and girls, mean age 8 years. *n* (intervention) = 314 *n* (control) = 322	Assessed the impact of a primary school-based intervention, which included teacher training, modification of school meals, the development of school action plans targeting the curriculum, physical education, tuck shops, and playground activities. Sahota used a population approach underpinned by the Health-Promoting Schools philosophy and the intervention involved the whole school community including parents, teachers and catering	1 year	*n* (intervention) = 292 *n* (control follow-up) = 303 (at 1-year follow-up for weight) At 1 year, there was no difference in change in BMI between the children in the two groups (BMI SD score, weighted mean difference 0 (95% CI –0.1, 0.1), nor was there any difference in dieting behaviour.	Statistically accounted for the potential unit of analysis errors 89% of the actions points were implemented in the ten schools and changes were made to the food provision. Both parents and teachers were supportive of the dietary education and promotion of PA. Parental questionnaires (64% returned) detailed suggestions for improvements such as promotion of healthier break-time snacks with enforcement by school, material on healthy eating for children and fun PA ideas. Of the 20 teachers invited, 19

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
					staff. 80% power to detect difference in means of a normally distributed outcome measure of at least 1.8 standard deviations at 5% significance level.			attended and were satisfied training, resources and materials offered. Children had higher scores for knowledge, attitudes and were positive about the intervention in focus groups. APPLES intervention was successful in producing changes at the school level, in terms of changing the ethos of the schools and the attitudes of the children, but had little effect on children's behaviour other than a modest increase in the consumption of vegetables.
Sallis 2003	RCT Cluster, schools randomised by district	1	+	**Setting:** Twenty-four public middle schools (grades 6 to 8) in San Diego County, California. **Participants:**	**Aim:** To evaluate the effects of environmental, policy and social marketing interventions on PA and fat intake of middle school	Two school years	Number assessed in each group at follow-up not reported There was a significant reduction in BMI among intervention boys, compared with control boys, but there was no effect for girls.	All 24 schools received an incentive to participate (US$1000 for PE equipment), and intervention schools received an additional US$500 for kitchen equipment and

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
				Mean enrolment across 24 schools was 1109 (SD 356) students per school, of whom 49% were female, 44.5%, were non-white, 39.5% received free or reduced school meals and 36.4% were bussed to school. Mean age and mean baseline BMI not reported.	students. The primary aims of the intervention were: 1) Increase the total energy expenditure from PA by the student population at school. 2) Decrease the grams of total saturated dietary fat purchased or brought to school by students. One intervention component was designed to increase PA in PE classes through changing lesson context, lesson structure, and teacher behaviour. Another intervention component was intended to increase PA on campus during leisure periods throughout the school day.		Boys BMI (kg/m^2) at baseline for the intervention and control groups, 20.12 (0.98) and 19.68 (0.63), respectively. BMI for the controls and the boys in the intervention group after 2 years 20.04 (0.85) and 19.84 (0.61). Girls BMI (kg/m^2) at baseline for the intervention and control groups, 19.76 (0.77) and 19.52 (0.89), respectively. BMI for the girls in the intervention group and the controls after 2 years 19.88 (1.16) and 19.73 (1.16), respectively. Gender-specific analyses revealed the time by condition interaction was significant for boys (F = 12.16, p = 0.00) with a large effect size of d = 1.10. The intervention was not significant for girls (F = 0.73, p = 0.396), and the effect size was small.	US$2000 for PA programmes or equipment.

DIET ONLY STUDIES								
French 2004	Review, five controlled studies and one CBA	2	+	Review methods not reported as this was a paper from a workshop. School-based, four studies targeted 4th and 5th grade students and one targeted secondary schools (Nicklas 1998) – all US based	Review of five multi-component school-based intervention studies to promote food and vegetable consumption. One CBA to examine effect of price reduction and promotional signage on sales of lower fat vending machine snacks in 12 secondary schools. Power of individual studies not reported.	All five controlled studies were 2–3 years in duration; the CBA was 1 year All five studies included classroom curriculum focusing on increasing students knowledge, developing behavioural skills, increasing motivation to choose fruit and vegetables	Three studies reported significant increases in fruit and vegetable servings per day among students in intervention vs. control schools (Baranowski 2000; Foerster 1998; Reynolds 2000). Across the five studies increases in fruit intake ranged from 0.2 to 0.6 servings per day and vegetable intake from 0 to an increase of 0.3 servings per day; total changes in fruit and vegetable intake across five studies ranged from 0 to 0.6 servings per day. Four studies reported fruit and vegetables intakes separately and effects were most often attributable to fruit intake; only one study reported significant increases in vegetable intake (Reynolds 2000); two studies reported significant	Most of these studies were funded as part of National Cancer Institute's five-a-day research programme.

						Three studies included food service component to increase fruit and vegetable availability by training food service staff to include more fruit and vegetables in meals and promote fruit and vegetables. At least two of the studies included a parent–home component usually consisting of newsletters to increase home consumption of fruit and vegetables. Two studies included a community component involving	increases in fruit intake (Reynolds 2000, Perry 1998). The one study in secondary schools (Nicklas 1998) did not observe significant effects on fruit and vegetable intake. Cannot assess which independent elements of the interventions affected behaviour change. **CBA:** Price reductions of 10, 25 and 50% on low-fat snacks were associated with significant increases in low-fat snack sales; percentages of low-fat snack sales increased by 9, 39 and 93%, respectively. Promotional signage was independently but weakly associated with increases in low-fat snack sales. Average profits per machine were not affected by the vending interventions.	

						community groups in developing and implementing activities to promote fruit and vegetable intake such as grocery taste tests or cookery demonstrations (Foerster 1998; Baranowski 2000). **CBA:** Low-fat snacks were added to 55 vending machines in a convenience sample of 12 secondary schools. Four pricing levels (equal price, 10% reduction, 25% reduction, 50% reduction) and three promotional conditions (none, low-fat label, low-fat label plus		

						promotional sign) were crossed in a Latin square design. Sales of low-fat vending snacks were measured continuously for the 12-month intervention.		
Woolfe 2005	Review	2	+	Overview of five school-based dietary interventions funded by the Food Standards Agency. Primary and secondary schools throughout UK.	To evaluate feasibility and effectiveness of dietary change interventions in UK school-based settings.	Short-term to 14 months	Overview of five school-based dietary interventions funded by the Food Standards Agency. All five studies focused on different approaches and topics but all have potential to be incorporated into the type of health promoting school approach, which systematic reviews (Lister–Sharp) have indicated is the most effective way of changing behaviour.	Non-systematic review. Supersedes Lister–Sharp systematic reviews of health promoting schools as relatively few included studies were UK-based. In terms of engaging schools: importance of listing support of school gate keepers (secretaries), a hindrance to engaging schools is selection to control, if schools are asked to 'buy-into' future initiatives this may lead to increased commitment compared with a

								research scenario; commitment of schools effects success of the project (tuck shops).
Warren 2003 within review by Woolfe 2005	RCT Individual	1	+	**Setting:** Three primary schools in Oxford, UK. **Participants**: Children aged 5 – 7 years (children in Year 1 and Year 2). Sex not reported.	Be Smart was a school and family-based intervention to prevent obesity in children aged 5–7 years. (See above.)	Twenty-week intervention over 14 months.	Nutrition intervention at follow-up $n = 42$ PA intervention at follow-up $n = 42$. Combined nutrition and PA intervention $n = 42$. Control $n = 46$. Dropout $n = 46$ for weight Only those who completed were included in analysis (not ITT). Significant increase in vegetable consumption ($p < 0.05$) and fruit ($p < 0.01$) in all groups; in males there was a significant increase in fresh fruit consumption $p < 0.01$ regardless of group assignment. Significant increase in fruit consumption in control ($p < 0.05$) and nutrition groups ($p < 0.05$). No significant difference between groups in sweet or crisps consumption. Strong association between parents and children's diets both before and after intervention for crisps, vegetables, salads, and fruit other than fresh ($p < 0.001$). Parental food frequency	See above.

							questionnaires showed little change as they reported low fat and medium to high fibre intakes initially.	
Moore 2001 within review by Woolfe 2005	RCT	1	+	Forty-three primary schools in South Wales and south-west England. 1902 pupils in years 5 and 6 (aged 9–11 years). At baseline, differences were detected in fruit and snack consumption between schools, which were statistically significantly associated with schools' policy on snacks brought into school.	To evaluate fruit tuck shops to increase fruit and vegetable consumption **Intervention:** Each school set up a fruit tuck shop in the autumn term, 1999. Tuck shops sold fruit at 15p per item, and were operated by the schools with no additional funding, and with limited support from the research team. Fruit was supplied to schools by wholesale greengrocers, fruit retailers, or by teachers buying fruit from supermarkets. **Control:** The other 20 schools agreed not to set up a fruit tuck shop in the academic year 1999/2000.	12 months	All 23 intervention schools successfully set up fruit tuck shops, and many schools were very positive about them. In particular, schools identified numerous positive spin-offs from the tuck shops, including benefits for the curriculum, social benefits, community links and litter reduction. In all schools, fruit sales were high in the first few weeks of operation, but then declined at varying rates over the intervention year. At 12 months there was no significant difference between intervention and control for fruit intakes. It is estimated that 70,000 fruits were sold in the 23 intervention schools over the year, but this equates to only 0.06 fruits per pupil per day. Four schools had ceased to operate their tuck shops by the end of the intervention year.	Authors concluded that fruit tuck shops on their own would not have a substantial impact on the fruit intake of pupils. However, they are likely to be a valuable component of any comprehensive plan to increase children's fruit consumption. Within schools, a comprehensive school policy on snacks brought to school supplemented by a school fruit tuck sho*p* (and, in England, by National School Fruit Scheme fruit provided to younger infants) may achieve a more substantial impact.
Livingstone 2002	Controlled study	?	?	Twenty-seven secondary schools	To evaluate interactive CD-ROM	Unclear, 4–5 weeks?	Preliminary evaluation in ten schools with 305 pupils divided equally	Questionnaires not validated.

within review by Woolfe 2005				in UK participated in one or more of the five phases of the study; representative of urban and rural environments and different social and ethnic backgrounds and academic abilities.	to promote nutrition education in 12-year old children. CD 'Dish it up!' was a virtual school day in life of a 12-year old and involved self-monitoring, analysis and food intake and goal setting; positive and entertaining activities aimed at promoting autonomy, decision-making skills and self-esteem with regard to healthy eating; based on social learning theory.		between intervention and control. Significant positive shifts in reported frequency of consumption of fruit, pasta, yoghurt, breakfast cereals (more than usual) and sweets (less than usual) but no other indications of changed eating behaviour. Children particularly liked the intervention.	Authors concluded that interactive multimedia tools have potential to be a sustainable and valuable resource.
Barker 2002 within review by Woolfe 2005	Controlled study	?	?	UK primary schools, main pilot carried out in school in Derbyshire, children aged 4–10 years old.	To test the effectiveness of a 9-month art/play therapy intervention on fruit and vegetable intake. Art/play therapist responsible for management of intervention that was built into the curriculum; aimed to change attitudes to healthy eating	Nine-month intervention, post-intervention delayed due to management reasons for 9 months.	Intervention increased amount of vegetables and salad and fruit juice consumed with an increase in the variety eaten; those children who ate no fruit at baseline appeared to respond more positively. No gender or age differences.	Small-scale pilot.

					through emotion and creativity rather than having a knowledge focus.			
Anderson 2002 within review by Woolfe 2005	CCT	?	?	Two primary schools with 2 matched control schools in Dundee, Scotland 'Five a day the Bash Street Way'. 128 children from year 2 (6–7 years) and year 6 (10–11 years).	To evaluate whole school approach with multiple strategies to increase fruit and vegetable intake. Included food preparation and food testing, increased provision of fruit and vegetables in tuck shops (had to complete with non-healthy foods) and school lunches, point of purchase marketing, teacher information sessions and parent newsletters.	Nine months (October to June of school year).	Fruit consumption increased significantly by average 0.5 portions per child per day in intervention schools compared with control ($p < 0.05$).	Relatively labour and time intensive intervention.
Bere 2005	CCT	2	+	**Setting:** Secondary schools from two Norwegian countries, Hedmark and Telemark. **Participants:** A total of 795, 7th graders (11 or 12 years old at	**Aim:** To investigate the effect of the Norwegian School Fruit Programme on the intake of fruit and vegetables and on the consumption of 'unhealthy' snacks both at standard conditions and when	8/9 months September, 2001 – May/June 2002	Free fruit $n = 222$ Paid fruit $n = 157$ Opted not to participate $n = 416$ The free fruit group reported a significantly higher intake of fruit and vegetables at school than pupils in the two other groups. No actual servings data ($p = 0.001$ for both comparisons).	Schools taking part in the programme at standard conditions and the control group were self-selected, that is, it was the schools that decided whether to take part in the programme or not.

				baseline) participated at both baseline and at follow-up. Free fruit *n* = 222 (nine schools) Paid fruit *n* = 157 (nine schools) Opted not to participate, *n* = 416 (20 schools) % Female and baseline BMI not reported.	provided for free. No more intervention details provided. Power not stated.		Furthermore, the pupils in the Paid fruit group reported a significantly higher intake than did pupils in the no fruit group. No actual servings data, $p = 0.003$. The free fruit group reported a significantly higher fruit and vegetable all day intake than both the paid fruit and the no fruit groups. No actual servings data, $p = 0.03$ and $p = 0.003$, respectively No significant differences were seen between the paid fruit group and the no fruit group regarding fruit and vegetable all day intake. The free fruit group reported a significantly lower intake of soda/candy/chips than the no fruit group. A significant positive effect of the Fruit Subscription Programme was seen for fruit and vegetables at school (with stronger effect for pupils with low baseline habitual fruit and vegetable intake), for fruits and vegetables all day, and for soda/candy/chips (for pupils with low baseline habitual fruit and vegetable intake only).	72% of children and 64% of the parents in the free fruit group rated the programme as 'very good' The pupils without two valid 24-hour recalls (baseline and follow-up *n* = 97) differed from the pupils with valid 24-hour recalls in that they were less physically active (mean values were 3.0 vs. 3.4 times per week, respectively) and a higher proportion of their parents participating in this study had education from college or university (52 vs. 40%).

Horne 2004	CBA	2	–	**Setting:** Two inner-city London schools, UK **Participants:** Children aged 5–11 years. **Intervention school:** Brixton, 364 pupils, 67% free meal entitlement, 85% ethnic minorities. **Control school:** Stockwell, 385 pupils, 46% free meal entitlement, 80% ethnic minorities.	To evaluate 'Food dudes' programme to increase consumption of fruit and vegetables. All children in all schools were presented with fruit and vegetables at lunchtime and 5–7 years received fruit at snack time. Intervention school also watched 'Food Dudes' video over 16 days featuring heroic peers and children received small rewards for eating those food themselves; two home packs also sent to parents to encourage fruit and vegetable consumption at home. Power not stated.	16-days and 4-month follow-up	At 4-month follow up there was a decline in intervention schools from immediate post-intervention but intervention school still consuming substantially more fruit and vegetables compared with baseline. **Baseline mean consumption:** Intervention 5–7 years: 20% fruit, 35% vegetables 7–11 years: 47% fruit, 51% vegetables Control 5–7 years: fruit 11%, 16% vegetables 7–11 years: 20% fruit, 36% vegetables **Four-month mean consumption:** Intervention 5–7 years: 56% fruit, 53% vegetables 7–11 years: 65% fruit, 63% vegetables Control 5–7 years: fruit 9%, 10% vegetables 7–11 years: 9% fruit, 23% vegetables In intervention school the largest increases were found in children who consumed least at baseline In control schools the largest	Was this the study that the 5-a-day data was based on (used as corroborative evidence for another review). Significant differences in fruit consumption at baseline.

							declines were seen in those who consumed most at baseline.	
James 2004	RCT Cluster, by class	1	++	**Setting:** Schools in Christchurch, Dorset, UK **Participants:** Twenty-nine classes in six junior schools in children aged 7–11 years. 320 females, 324 males, mean age 8.7 (range 7–10.9) years. *n* (randomised to intervention) 325 (15 classes) *n* (randomised to control) 319 (14 classes). Baseline mean BMI (kg/m^2) (SD): Intervention: 17.4 (0.6) Control: 17.6 (0.7)	**Aim:** To reduce consumption of carbonated drinks. One investigator delivered programme to all classes and teachers assisted. One-hour session each class each term (four sessions) encouraging children not to drink carbonated drinks but to switch to water or fruit juice diluted 1:3 with water. Study 90% power.	12-month intervention.	Assessed at 12 months: Intervention *n* = 295 Control *n* = 279 10.9% not assessed Both control and intervention groups significantly increased consumption of water (intervention from 3.1 [1.1] glasses over 3 days at baseline to 4.3 [2.0] glasses at 12-months; control from 2.9 [0.3] glasses over 3 days to 5.1 [2.0] at 12 months).	
Loughridge & Barratt 2005	CCT	2	+	**Setting:** Three secondary schools in disadvantaged	**Aim:** To measure the effect of health promotion and the	3 months	The average volume of water drunk by students in the W+P school was greater (p = 0.05) than that drunk in the W and C schools.	Data presented are poor. The children enjoyed

				areas of North Tyneside. **Participants:** All children within the three schools were exposed to the study. Water (W) + active health promotion (P) *n* = 903 W *n* = 1190 Control (C) *n* = 872	free provision of cooled filtered water in school cafeterias, at both morning break and lunch time, on the consumption of water (free cooled filtered water, free jug and cup water, and bottled water on sale) and soft drinks during the school day. **Intervention**: Over a 3-month period one school was given cooled filtered water and active health promotion (W+P) – note that the active health promotion intervention took place over the first month only, one school had water only (W). The control school (C) received neither W or P. Power not stated.		Note: assume this is all sources of water drunk, but unclear from paper. The volume of soft drinks purchased at school by students before and during the intervention remained static in all three schools. Note: all assessments relate to consumption or purchase of drinks at school, not over the whole day.	the cooled filtered water and this is a relatively cheap and sustainable intervention to provide.
Lytle 2004 TEENS study	RCT By school	1	+	**Setting:** Middle schools in Twin cities, Minnesota, USA.	To evaluate school-based intervention to increase fruit and vegetable intake and lower fat food	2 years	Intervention *n* = 1425, control *n* = 1431. No significant difference between groups for total fruit and vegetable	Race and parents education significantly different between groups at baseline and so this

				Participants: 16 schools, *n* = 3, 878 (96% of those eligible). 51% male in intervention and in control; 70.1% white in intervention, 75.7% white in control; 22.2% of intervention and 17.3% control received free school lunch across groups; both parents having high school education all less 14.5% intervention, 10.8% control.	80% power to detect differences of 1.1 servings of fruit and vegetables and 1.9% difference in energy from total fat intake between treatment groups. Included random selection for 24-hour recall and student survey of all students. Ten nutrition education lessons in 7th and 8th grade, based on social cognitive theory. Family component with newsletters, behaviour coupons and prizes School-wide component included school food modification with school nutritional advisory councils made up of school administrators, school staff, parents, students, and TEENS staff.		intake, mean difference –0.492 (95% CI –1.032, 0.049). Or energy from fat, mean difference +0.635 (95% CI –0.866, 2.137). These difference not significant when analysed by high or low dose exposure to intervention. Students in intervention had slightly higher scores for food choice indicative of making lower fat choices (non-validated measure).	was adjusted for in analysis. Significant positive interim results not maintained at 2-year follow-up.

					Due to potential variability in dose of intervention that each school received – secondary data analysis performed by dose of intervention received by students. Regular classroom teachers and food service staff implemented the intervention. Power not stated.			
Perry 2004	RCT Cluster by school	1	+	**Setting:** Twenty-six elementary schools, from one large school district in the Twin Cities metropolitan area of Minnesota. **Participants:** 1,668 total students (49% female), 1st and 3rd grade. Mean age and Baseline BMI not reported.	**Aim:** To determine if a cafeteria-based intervention would increase the fruit and vegetable consumption of elementary school children. **Intervention activities included:** Increasing the availability, attractiveness and encouragement of fruit and vegetables. Special events were	24 months	At follow-up 1,168 (70%) students were observed (numbers in each group not reported). The number of fruits and vegetables on the snack cart was associated with increased fruit and vegetable consumption from baseline to follow-up (although there were no intervention vs. control differences). Significant impact on children's total fruit and vegetable intake (when potatoes were excluded). The impact however, comes from increases in fruit consumption (0.17 vs. 0.14 servings, respectively), as there were no significant differences between conditions for juices and	Intervention dose was limited to the kinds and amounts of fruits and vegetables served, the attitudes and behaviours of the food service staff, and to the specific activities that could be physically done in the lunch-room environment.

					held, such as sampling sessions and challenge weeks. Food service staff delivered the intervention. Power not stated.		vegetables. **Lunch observations:** Verbal encouragement by food service staff in the lunch line was significantly associated with consumption of fruits and vegetables (no potatoes, no juice), fruits and vegetables (no potatoes), fruit (no juice), and increased consumption in fruits and vegetables (no potatoes, no juice) from baseline to follow-up.	
Wells & Nelson 2005	CCT	2	+	**Setting:** Seventeen primary schools on the outskirts of London in south-east England. **Participants**: All children within the 17 schools that were 4–6 years of age (age over which the intervention occurs), and also 7–8 years (to assess the impact of having had the intervention when aged 4–6 years old). Response rate was 51%. Children included in	**Aim**: To measure the short-term and long-term effect of the National School Fruit Scheme (NSFS) on daily fruit consumption. **Intervention:** Eight schools in the NSFS and nine not in the NSFS. Study and control schools were selected in areas of similar deprivation. Power not stated	2 years	Daily fruit consumption was assessed using a questionnaire that was given to each pupil to take home for their parents to complete and return. Median total fruit consumption (excluding fruit juice) in infants receiving free fruit was 117 g/d compared with 67 g/d in infants not receiving free fruit ($p < 0.001$). Median total fruit consumption in juniors who had received free fruit at school as infants was similar to that consumed by those who had not received free fruit (83 vs. 86 g/d).	

				the study were ‘selected’ samples from each year group. Unclear how samples were selected. Total *n* = 1492. Unclear how many in each group.				
PHYSICAL ACTIVITY INTERVENTION								
Robinson 1999	RCT Cluster, by school	1	++	**Setting:** Two public elementary schools in San Jose**,** CA, USA. **Participants:** 3rd and 4th grade students, mean age 8.9 years, boys and girls. *n* (intervention baseline) = 95; *n* (control baseline) = 103. **BMI (kg/m^2) at baseline:** Intervention: 18.38 (3.67) Control: 18.10 (3.77)	To evaluate a school-based intervention to reduce TV, videotape and video game use on adiposity. Designed to have 80% power to detect an effect size of 0.20 or greater/ Based on Bandura’s social cognitive theory; 18 × lessons of 30 to 50 min, included self-monitoring of television (TV), video and video-game use, then 10-day turn-off, then 7-hour budget, children taught to become selective	6 months	*n* (intervention follow-up) = 92 *n* (control follow-up) = 100 Three children lost to follow-up in each group. Daily servings of high-fat foods: (adjusted for baseline value, age and sex) adjusted change: –0.82 (95% CI –1.87, +0.23), not significant.	Each household received electronic television time manager (control power to TV and video). Schools were matched.

					viewers and advocators of reducing media use. Parental involvement. Programme built into standard curriculum and taught by classroom teachers trained by research staff. 80% power to detect effect size of at least 0.20.			
DIET AND PHYSICAL EDUCATION STUDIES TO PREVENT OBESITY								
Caballero 2003	RCT Cluster, by school	1	+	**Setting**: Forty-one elementary schools in seven American Indian communities in Arizona, New Mexico, South Dakota, USA. See above.	**Aim:** To evaluate a school-based multi-component intervention to reduce percentage body fat in American Indian children. Power not stated. See above.	3 years	*n* (intervention at follow-up) = 727 *n* (control at follow-up) = 682 17% attrition Completer analyses only. **24-hour recall:** Total daily energy intake significantly lower in intervention compared with control (1892 kcal [7.92 MJ]/day vs. 2157 kcal [9.02 MJ]/day) and % energy from total fat was significantly lower in intervention vs. control (31.1 vs. 33.56%). Actual school-lunch observation confirmed lower fat intake in intervention group but no difference in energy intake between the two groups.	Intervention piloted. Compared with CDC reference values, distribution of BMI in study children was shifter towards higher values. Included family component. School food modification.

Donnelly 1996	CCT By school	2	+	**Setting:** Elementary schools in rural Nebraska, USA. **Participants:** Age 9.2 years. Boys and girls (no values given). See above.	**Aim:** To evaluate a school-based PA and nutrition programme to attenuate obesity and promote fitness. Power not stated. See above.	2 years	At year 2 intervention lunches had significantly less fat and sodium and more fibre but 24-hour recall showed significant differences in intake between groups for sodium only. Authors suggest children compensate in energy intake and PA outside school.	Small rewards for volunteers. School food modification.
Gortmaker 1999	RCT By school	1	+	**Setting:** Ten secondary schools in Boston, USA. **Participants:** Girls and boys, grades 6 and 7, mean age 11.7 (SD 0.7) for both intervention and control; 48% female. See above.	**Aim:** To evaluate impact of school-based health behaviour intervention known as PLANET HEALTH on obesity amongst boys and girls in grades 6 to 8. Implemented programme via school curriculum and existing staff resources. Underpinned by behavioural change and social cognitive theory. Promotion of PA, modification of dietary intake	Two school years	Intervention *n* = 641 Control *n* = 654 17% loss to follow-up Intervention increased fruit and vegetable consumption in girls (0.32 servings/day; 95% CI 0.14, 0.5; *p* = 0.003). Intervention resulted in a smaller daily increment in total energy intake among girls (–575 kJ; 95% CI 1155, 0; *p* = 0.05). Measures of extreme dieting behavior remained unchanged (and low) throughout the intervention and were not different between intervention and control schools. Analysis of girls only using self-	See above.

					(decreasing consumption of high-fat foods, increasing fruit and vegetable consumption) and reduction of sedentary behaviours (with a strong emphasis on reducing TV viewing). Thirty-two classroom lessons of 45-min each over 2 school years. Power limited.		report, showed a reduced risk of using self-induced vomiting, laxatives or diet pills to control weight within the previous 30 days.	
Sahota 2001	RCT Cluster, by school	1	+	**Setting:** Ten primary schools in Leeds, UK. **Participants**: 7–11-year-olds, boys and girls, mean age 8 years. *n* (intervention) = 314 *n* (control) = 322	Assessed the impact of a primary school based intervention which included teacher training, modification of school meals, the development of school action plans targeting the curriculum, physical education, tuck shops, and playground activities. Study powered. See above.		*n* (intervention) = 292 *n* (control follow-up) = 303 (at 1-year follow-up for weight) Children in the intervention group reported higher consumption of vegetables (weighted mean difference 0.3 portions/day, 95% CI 0.2, 0.4), but fruit consumption was lower in obese children in the intervention group (–1.0 portions/day, 95% CI 1.8, –0.2).	See above.

Sallis 2003	RCT Cluster, schools randomised by district	1	+	**Setting:** Twenty-four public middle schools (grades 6 to 8) in San Diego County, California. **Participants:** Mean enrolment across 24 schools was 1109 (SD 356) students per school, of whom 49% were female, 44.5%, were non-white, 39.5% received free or reduced school meals and 36.4% were bussed to school. Mean age and mean baseline BMI not reported.	**Aim:** To evaluate the effects of environmental, policy and social marketing interventions on PA and fat intake of middle school students. The primary aims of the intervention were: 1) increase the total energy expenditure from PA by the student population at school; 2) decrease the grams of total saturated dietary fat purchased or brought to school by students. Power not stated. See above.	Two school years.	Number assessed in each group at follow-up not reported. **Fat intake:** The time by condition interaction term was not statistically significant for total ($F = 0.01$, $p = 0.903$) or saturated ($F = 0.08$, $p = 0.781$) fat, indicating no differences in change over time by condition in fat measures at the school level. Effect sizes indicated a near null effect for total ($d = 0.03$) and saturated ($d = 0.13$) fat. There was no intervention effect on fatty foods consumed.	All 24 schools received an incentive to participate (US$1000 for PE equipment), and intervention schools received an additional US$500 for kitchen equipment and US$2000 for PA programmes or equipment.
Story 2003 GEMS-Minnesota	RCT	1	+	**Setting:** Lunchtime clubs in schools in low income areas, Minnesota, USA. **Participants:** 8–10-year-old	**Aim:** To assess feasibility of obesity prevention programme in African American girls. **Intervention:** Lunchtime clubs in	12 weeks	Intervention $n = 26$ Control $n = 28$ Intention to treat analysis No significant difference between groups for dietary intake at 12 weeks.	This study was a pilot study to assess feasibility and was not intended to be sufficiently powered to detect a significant intervention effect. Fully powered studies

				African American girls, at least 25th percentile for age and gender BMI, with a parent willing to be involved. **Mean age (years):** Intervention: 9.3 (SD 0.9) Control: 9.4 (SD 0.9) **Sex:** Girls only Intervention *n* = 26 Control *n* = 28	school designed to improve nutrition, PA and self-esteem through a range of activities. The intervention which was conducted twice per week, focused on increasing healthy eating and PA. Intervention meetings, designed in a ‘club meeting’ format, were held twice per week for one hour after school at each of the schools used in the study. The intervention was based on social cognitive theory (Bandura) and targeted key points from three domains: 1) environmental factors such as peer support; 2) personal factors such as knowledge and values; 3) behavioural factors such as goal setting and social reinforcement.		% Energy from fat (parental reported) and low-fat food practices (parental reported) were significantly better in intervention group compared with control.	of two of the GEMS pilots are currently underway.

					Control: The control group served as an 'active placebo', non-nutrition/PA condition and focused on promoting positive self-esteem and cultural enrichment. Participants attended monthly Saturday morning meetings (three meetings over 12 weeks). This included arts and crafts; self esteem activities, creating memory books and a workshop on African percussion instruments. Providers of the intervention included University Staff, Trained African American GEMS staff and school staff. Study not powered (pilot).			
DIET AND PHYSICAL EDUCATION STUDIES TO IMPROVE CARDIOVASCULAR HEALTH								
Luepker	RCT	1	+	**Setting:**	Sample size	3 years	Total *n* = 4109 at 3 years (21%	See above.

1996 (CATCH)	Cluster, by school			Ninety-six public state schools in 12 school districts in California, Louisiana, Minnesota and Texas. **Participants:** Mean age 8.76 years. 2461 of 5106 were girls. Total cohort *n* = 5106 at baseline. Ethnically diverse (white, African American and Hispanic).	determined. See above.		dropout for serum cholesterol measurement at 3 years). % Energy intake from fat fell significantly more in intervention school lunches than control (38.7 to 31.9% in intervention vs. 38.9 to 36.2% in control); self reported % daily energy intake from total fat was significantly reduced in intervention (32.7 to 30.3%) compared with control (32.6 to 32.2%, $p < 0.001$) and total energy intake also significantly reduced in intervention schools ($p < 0.01$).	
Manios 1998, 1999, 2002	CCT (by school)	2	+	**Setting**: Schools in Iraklio and Rethimno (intervention) and Chania (control) Crete, Greece. **Participants**: First-grade primary school children aged 5.5 to 6.5 years; 509 boys and 453 girls.	To evaluate a school-based intervention involving a health and nutrition element and a physical fitness and activity element, on chronic disease risk factors. Power not stated. See above.	6 years	Total 831 available at 6 years, 787 assessed (those who did not change schools and completed). Total energy intake change intervention vs. control: +179 kcal (749 kJ) (*n* = 90) vs. +367 kcal [1535 kJ] (*n* = 86), $p < 0.05$. Total fat intake change intervention vs. control: +5.9 g (*n* = 90) vs. +18.8 g (*n* = 86), $p < 0.05$. Saturated fatty acids change	See above.

				See above.			intervention vs. control: +0.8 g ($n = 90$) vs. +5.1 g ($n = 86$), $p < 0.05$.	
Vandongen 1995	RCT Cluster, by school	1	+	**Setting:** Thirty schools in Western Australia. **Participants:** Age range 10–12 years. 1,147 boys and girls See above.	To evaluate programme of fitness and nutrition alone and combined and school and home-based nutrition programmes to improve cardiovascular health. Delivered by teachers and PE teachers who received in-service training sessions. Study powered See above.	Nine months	971 of 1147 assessed at 9 months for blood pressure, anthropometric and fitness tests. Significant decrease in total fat intake in girls compared with boys in school and home nutrition group (2.9, 95% CI 1.5–4.3) and home nutrition group (3.6, 95% CI 2.1–5.1). When adjusted for baseline values only significant decrease in home nutrition group compared with control. Also significant decrease (unadjusted) in saturated fat intake in girls in school and home nutrition group, home nutrition group, fitness and school nutrition group.	All follow-up measures adjusted for baseline values.
Evidence of efficacy (internal validity) for physical activity outcomes								
PHYSICAL ACTIVITY INTERVENTIONS								
Jamner 2004	CCT Cluster by school	2	+	**Setting:** Two public high schools in Orange County, CA, USA. **Participants:** Fifty-eight female adolescents 25 intervention and	**Aim:** To evaluate the effect of a school-based intervention designed to increase PA among sedentary adolescent females. **Intervention:**	Four months	At follow-up, data were available for 25 intervention participants and 22 control participants The intervention had no significant effect on BMI percentile, 67.28 at baseline and 66.74 at 4 months; % body fat 32.64 at baseline and 31.85 at 4 months.	Study participants overall reported more moderate and less light activity at baseline, as these measures were obtained during summer vacation, whereas follow-up assessments were

				22 control Mean age = 14.94 (SD 0.79) years Mean baseline BMI percentile = 67.28 for intervention completers) mean baseline BMI percentile = 60.47 for control completers. 53% non-Hispanic white, 29% Hispanic, 8% Asian and 3% ‘other’.	Special PE class. The class met five days per week for 60 min each day (approximately 40 min of activity time). Types of activity included aerobic dance, basketball, swimming and tae bo. One day per week of class time was devoted to a lecture or discussion focusing on the health benefits of PA and strategies for becoming more physically active. Not stated who delivered intervention. Power not stated.		Two-day PA recall data: significant effect of the intervention on light ($F = 5.53$, $p = 0.023$), moderate ($F = 7.946$, $p = 0.007$) and total ($F = 4.155$, $p = 0 .043$) activity. The intervention had a significant effect on lifestyle activity, with the intervention group increasing their mean self-reported lifestyle activity from 2.33 (using the sum of affirmative responses to the Stanford Usual Physical Activity Scale) at baseline to 3.19 at 4 months, whereas the control group showed little change (2.58 at baseline and 2.26 at 4 months).	conducted during the school year which may have confounded results.
Pangrazi 2003	CCT By school Control schools were not	2	+	**Setting:** Thirty-five schools in Arizona, USA. **Participants:** 4th grade, mean age for boys and girls was 9.8 (SD	**Aim:** To evaluate the effects of the PLAY intervention. Promotes 30–60 min moderate to vigorous PA daily, 15-min	12 weeks	At 12-weeks the treatment was effective at increasing the PA level of children, especially girls $p < 0.001$. All students: PLAY + PE, and PLAY only groups were significantly more active than C.	Previously adopted in Arizona elementary schools and 24,000 children have received the intervention.

	randomly selected			0.6) years. PLAY + PE: *n* = 183 PE only *n* = 175 PLAY only *n* = 150 No treatment control (C) *n* = 91	activity break each day to teach variety of physical activities, promotes attitudes and behaviours to sustain active habits for life; includes self-monitoring and self-awareness. Teachers received training from county health co-ordinators PLAY is not intended to replace comprehensive PE programme but act as important supplement. The intervention comprised three stages: Step 1: promote play behaviour (first week) teachers and students participated, more walking, less standing, sitting, children were informed about the importance of PA and identified appropriate adult role models.		Girls: PLAY + PE, and PE only groups were significantly more active than C. Boys showed no significant differences in steps across treatment groups as the control boys were already more active than average 10-year-old boys in the area (data from previous study).	

					Step 2: teacher directed activities (3 weeks) games and activities that were enjoyable and could be played outside school. Step 3: encourage self-directed activity (8 weeks) with students aiming to achieve 30 min of activity per day independently of teacher outside school. Treatment and PE schools, children received log sheets similar to the PLAY ones but were asked to record their after school activities (active and sedentary). Teachers trained by county co-ordinators, with programme implemented across Arizona with more than 24,000 children receiving PLAY. Power not stated.			

Pate 2005	RCT Cluster by school	1	+	**Setting**: Twenty-four high schools in 14 South Carolina counties, USA. **Participants**: 2744 girls, 48.7% African American and 46.7% white, mean age 13.6 years, mean BMI 23.1 kg/m^2.	To evaluate school-based PA intervention among high school girls. School personnel headed by a champion implemented programme with training from research staff. Power not stated.	Start of 9th Grade through until Spring? Approx. 6 months?	Intervention: *n* = 863 Control: *n* = 741 Completers only Slightly higher % African American girls lost to follow-up. 45% intervention girls vs. 36% control girls reported vigorous PA during an average of one or more 30 min time blocks per day over a 3-day period. However, most girls in both groups reported daily average of at least two 30-min blocks of moderate to vigorous PA at both baseline and follow-up.	
Robinson 1999	RCT Cluster, by school	1	++	**Setting:** Two public elementary schools in San Jose**,** CA, USA. **Participants:** 3rd and 4th grade students, mean age 8.9 years, 192 boys and girls, 45%-49% girls See above.	To evaluate a school-based intervention to reduce television, videotape and video game use on adiposity. Designed to have 80% power to detect an effect size of 0.20 or greater. See above.	6 months	*n* (intervention follow-up) = 92 *n* (control follow-up) = 100 Three children lost to follow-up in each group. Statistically significant decreases in children's reported television viewing and meals eaten in front of the television in intervention group compared with control. PA metabolic equivalent-weighted, min/week (adjusted for baseline value, age and sex) adjusted change: –16.7 (95% CI –78.6, 45.3), not significant.	Each household received electronic television time manager (control power to TV and video). Schools were matched.
Sallis	RCT	1	+	**Setting:**	To evaluate a school-	2 years	Total 549 children assessed at	Interim results only (2

1993, 1997	Cluster, by school			Seven suburban elementary schools in Southern California, USA. **Participants:** Elementary school children, mean age 9.25 years. No significant groups differences on weekday or weekend PA outside school using accelerometer (no baseline scores available so results unconditional).	year data from 3-year study). Actual data for BMI and skinfold thicknesses is only presented in graphical form.
Schofield 2005	CCT Cluster by school	2	+	**Setting:** Three high schools in central Queensland, Australia. **Participants:** Low active girls (defined from previous study as those girls who	To pilot efficacy of using pedometer as basis of time efficient yet effective non-curriculum school-based programme Intervention; group meetings once a week for 6 weeks for 30 min each in	12 weeks	Pedometer: *n* = 23 Minutes: *n* = 21 Control: *n* = 24 Mean blinded 4-day step count was significantly different only between pedometer vs. control *p* = 0.03, group with participants in both intervention groups significantly increasing step count across 12 weeks (despite pedometer group	

				took least amount of recorded steps); mean age 15.8 years. **BMI (kg/m^2):** Pedometer intervention: 22.3 (SD 4.1) Minutes intervention: 23.7 (SD 6.6) Control 24.5 (SD 5.5)	groups of 8 either before or after school or in lunch break. Intervention groups received log book to record min in PA or amount of step counts. Actual activity intervention was 12-weeks with weeks 7–12 maintenance phase (no group meetings). **Pedometer intervention:** 1000–2000 step increase daily each week until reached 10,000 steps per day. **Minutes intervention:** Increase by 10–15 min daily each week until reached daily average of 30–60 min/day. Power not stated.		showing significant improvement at 6 weeks). No significant changes in moderate or vigorous PA between any groups. Mean increase 2747 steps per day in pedometer group.	
Simon et al. 2004	RCT	1	+	Children in first-level of middle-	**Aim:** To evaluate the	Ongoing trial entitled	The proportion of intervention adolescents not engaged in	Ongoing.

				school (initially aged 11–12 years) in eight schools in Eastern France were recruited, and were randomised to Intervention (I) or Control (C). 954 adolescents were recruited to the study (92% of eligible); 475 in I schools, 479 in C schools.	impact of a PA intervention in adolescents. **Intervention:** The intervention was directed at changing knowledge and attitudes and at providing social support and environmental conditions that encourage PA of adolescents inside and outside school. It is classified here as a school based intervention, it is not strictly school-based but requires numerous partnerships intervening at different levels (school boards, teachers and medical staff, club educators, families, territorial and community agencies in charge of recreational areas and transportation infrastructure, etc).	'Intervention Centred on Adolescents PA and Sedentary Behaviour' (ICAPS) – this paper reports results from first 6 monthsof trial.	organised PA was reduced by 50% after 6 months, whereas it was unchanged among control students. Participation in leisure-organised PA significantly increased among intervention girls (OR 3.38, 95% CI 1.42, 8.05) and boys (OR 1.73, 95% CI 1.12, 2.66), compared with the control group. In addition, high sedentary behaviour (defined as >3 hours/day TV viewing and computer/video games) was reduced in intervention girls (OR 0.54, 95% CI 0.38, 0.77) and boys (OR 0.52, 95% CI 0.35, 0.76) compared with control group.	PA was assessed with a questionnaire adapted from the 'Modifiable Activity Questionnaire for Adolescents'.

					A mean of 10–12 different weekly activities was provided on I sites. About 50% of adolescents participated in at least one weekly activity. The authors reported that implementation increased progressively throughout the school year, thanks to regular individual contacts and more formal meetings (at least one every 2 weeks). Sample size determined.			
DIET AND PHYSICAL ACTIVITY INTERVENTIONS TO PREVENT OBESITY								
Caballero 2003	RCT Cluster, by school	1	+	**Setting**: Forty-one elementary schools in seven American Indian communities in Arizona, New Mexico, South Dakota, USA. **Participants**: Mean age	**Aim:** To evaluate a school-based multi-component intervention to reduce percentage body fat in American Indian children. Almost the entire intervention was	3 years	*n* (intervention at follow-up) = 727 *n* (control at follow-up) = 682 17% attrition Completer analyses only. Self-reported PA levels were higher among intervention compared with control at end of 3 years (both lower than at baseline though).	Intervention piloted. Compared with CDC reference values, distribution of BMI in study children was shifter towards higher values.

				7.6 ± 0.6 years. Sex not reported. See above.	delivered by school personnel, teachers and food service staff; the Pathways staff focused on research measurements and training and support of school staff. Teachers, food service staff and PE teachers trained annually by SPARK or PATHWAYS instructors and supported within schools. Power not stated.			
Donnelly 1996	CCT By school	2	+	**Setting**: Elementary schools in rural Nebraska, USA. **Participants:** Age 9.2 years. Boys and girls (no figures given). 94% White, 42–44% received free and reduced school lunches. **Mean BMI (kg/m^2):** Intervention: 18.3	**Aim**: To evaluate a school-based PA and nutrition programme to attenuate obesity and promote fitness. Utilised school curriculum and existing staff resources. Research nutrition staff consisted of PhD student in nutrition, registered	2 years	PA in the classroom was significantly greater for intervention than control by 6% but PA outside school was significantly less for intervention than control by 16%. Authors suggest children compensate in energy intake and PA outside school.	Small rewards for volunteers.

				(SD 3.9) Control: 18.5 (SD 3.4) Intervention *n* = 102 Control *n* = 236	dietitian, and several graduate students. PA research staff comprised an exercise physiologist and graduate students. Power not stated. See above.			
Gortmaker 1999	RCT By school	1	+	**Setting:** Ten secondary schools in Boston, MA, USA. **Participants:** Girls and boys, grades 6 and 7, mean age 11.7 (SD 0.7) for both intervention and control. See above.	**Aim:** To evaluate impact of school-based health behaviour intervention known as PLANET HEALTH on obesity amongst boys and girls in grades 6 to 8. Power limited. See above.	Two school years	Intervention *n* = 641 Control *n* = 654 17% loss to follow-up Intervention reduced TV hours among both girls (–0.58 hours; 95% CI –0.85, –0.31; *p* = 0.001) and boys (–0.4 hours; 95% CI –0.56, –0.24, *p* < 0.001). Author concludes that reductions in television viewing predicted obesity change and mediated the intervention effect (in girls but not boys). Among girls, each hour of reduction in television viewing predicted reduced obesity prevalence (OR 0.85; 95% CI 0.75, 0.97; *p* = 0.02). Hours per day spent in moderate to	Obesity definition based on BMI and TSF measure greater than or equal to 85th percentile of age and sex-specific reference data statistically accounted for the potential unit of analysis errors. Blinded outcome assessment was reported. Also reported on the issue of the promotion of unintended side effects (extreme dieting behaviours). Schools experienced

							vigorous PA was not significantly different between intervention and control school.	with interdisciplinary curricula found it easier to implement Planet Health material.
Neumark -Sztainer 2003	CCT Cluster, by school	2	+	**Setting:** Six secondary Schools in twin Cities area, school districts Minnesota, USA. **Participants:** 201 females. Mean age 14.9 (SD 0.9) years in intervention, 15.8 (SD 1.1) years in control. BMI (kg/m^2) at baseline: Intervention vs. control: 27.6 (SD 7.2) vs. 25.9 (SD 5.8). Inclusion criteria: girls with BMI at or above 75th percentile *n* (intervention) = 89	To evaluate an obesity prevention programme that aimed to increase enjoyment and self-efficacy In high-school based girls. See above. Delivered by research team, PE teachers and school counsellors. Power not stated.	7-months total, 16-week intervention plus 8-week maintenance plus follow-up 1-month later	*n* (intervention) = 81 *n* (control) = 99. The only significant variable was a progression in PA stage based on the Stages of Change Model (p = 0.004).	See above.

				n (control) = 112				
Sahota 2001	RCT Cluster, by school	1	+	**Setting:** Ten primary schools in Leeds, UK. **Participants:** 7–11 year olds, boys and girls, mean age 8 years. *n* (intervention) = 314 *n* (control) = 322	Assessed the impact of a primary school-based intervention which included teacher training, modification of school meals, the development of school action plans targeting the curriculum, physical education, tuck shops, and playground activities. Sahota used a population approach underpinned by the Health-Promoting Schools philosophy and the intervention involved the whole school community including parents, teachers and catering staff. 80% power to detect difference in means of a normally distributed outcome measure of at least 1.8 standard		*n* (intervention) = 292 *n* (control follow-up) = 303 (at 1-year follow-up for weight) Sedentary behaviour was higher in overweight children in the intervention group weighted mean difference 0.3, (95% CI 0.0–0.7).	89% of the actions points were implemented in the ten schools and changes were made to the food provision. Both parents and teachers were supportive of the dietary education and promotion of PA. Parental questionnaires (64% returned) detailed suggestions for improvements such as promotion of healthier break time snacks with enforcement by school, material on healthy eating for children and fun PA ideas. Of the 20 teachers invited, 19 attended and were satisfied training, resources and materials offered. Children had higher scores for knowledge, attitudes and were positive about the intervention

					deviations at 5% significance level.			in focus groups. APPLES intervention was successful in producing changes at the school level, in terms of changing the ethos of the schools and the attitudes of the children, but had little effect on children's behaviour other than a modest increase in the consumption of vegetables.
Sallis, 2003	RCT Cluster, schools randomised by district	1	+	**Setting:** Twenty-four public middle schools (grades 6 to 8) in San Diego County, CA, USA. **Participants:** Mean enrolment across 24 schools was 1109 (SD 356) students per school, of whom 49% were female, 44.5%, were non-white, 39.5% received free or reduced school meals and 36.4% were bussed to school.	**Aim**: To evaluate the effects of environmental, policy and social marketing interventions on PA and fat intake of middle school students. Delivered by research staff, teachers, school food service staff and managers. Power not stated. See above.	Two school years	Number assessed in each group at follow-up not reported Intervention schools increased PA over time at a greater rate than control schools. Boys in intervention schools increased about equally in PA in PE and out of PE, but girls in intervention schools increased their activity mainly through PE. Survey data revealed that the intervention had no significant impact on reported PA or participation in sedentary behaviours.	All 24 schools received an incentive to participate (US$1000 for PE equipment), and intervention schools received an additional US$500 for kitchen equipment and US$2000 for PA programmes or equipment.

				Mean age and mean baseline BMI not reported.				
Story 2003 GEMS-Minnesota	RCT	1	+	**Setting:** Lunchtime clubs in schools in low income areas, Minnesota, USA. **Participants:** 8–10-year-old African American girls, at least 25th percentile for age and gender BMI, with a parent willing to be involved. **Mean age (years):** Intervention: 9.3 (SD 0.9) Control: 9.4 (SD 0.9) **Sex:** Girls only. Intervention *n* = 26 Control *n* = 28	**Aim:** To assess feasibility of obesity prevention programme in African American girls **Intervention:** Lunchtime clubs in school designed to improve nutrition, PA and self-esteem through a range of activities. The intervention which was conducted twice per week, focused on increasing healthy eating and PA. Intervention meetings, designed in a 'club meeting' format, were held twice per week for one hour after school at each of the schools used in the study. The intervention was based on SCT (Bandura) and targeted key points	12 weeks	Intervention *n* = 26 Control *n* = 28 ITT analysis No significant difference between groups for PA (accelerometer and questionnaire) at 12 weeks.	This study was a pilot study to assess feasibility and was not intended to be sufficiently powered to detect a significant intervention effect. Fully powered studies of two of the GEMS pilots are currently underway.

					from three domains: 1) environmental factors such as peer support; 2) personal factors such as knowledge and values; 3) behavioural factors such as goal setting and social reinforcement. **Control:** The control group served as an 'active placebo', non-nutrition/PA condition and focused on promoting positive self-esteem and cultural enrichment. Participants attended monthly Saturday morning meetings (three meetings over 12 weeks). This included arts and crafts; self-esteem activities, creating memory books and a workshop on African percussion instruments. Providers of the			

					intervention included University Staff, Trained African American GEMS staff and school staff. Study not powered (pilot).			
Warren 2003	RCT Individual	1	+	**Setting**: Three primary schools in Oxford, UK. **Participants**: Children aged 5–7 years (children in Year 1 and Year 2). Sex not reported. See above.	Be Smart was a school and family-based intervention to prevent obesity in children aged 5–7 years. There were four conditions: a nutrition group, a PA group, a combined nutrition and PA group and a control group. The intervention ran for 20 weeks over four school terms (approx. 14 months). Power not stated. See above.	20-week intervention over 14 months	Nutrition intervention at follow-up *n* = 42 PA intervention at follow-up *n* = 42. Combined nutrition and PA intervention *n* = 42. Control *n* = 46. Dropout *n* = 46 for weight Only those who completed were included in analysis (not ITT). Some evidence that PA in playground had improved in the intervention groups but no difference in total activity between groups (including outside school).	See above.
Luepker 1996 (CATCH)	RCT Cluster, by school	1	+	**Setting:** Ninety-six public state schools in 12 school districts in California, Louisiana,	To evaluate a school-based intervention including a home programme for the primary prevention of cardiovascular	3 years	Total *n* = 4109 at 3 years (21% dropout for serum cholesterol measurement at 3 years). Intervention students reported significantly more daily vigorous PA	See above.

				Minnesota and Texas. **Participants:** Mean age 8.76 years 2461 of 5106 were girls. Total cohort *n* = 5106 at baseline. Ethnically diverse (white, African American and Hispanic).	disease. PE specialists and teachers had 1 to 1.5 days of training each school year; training also for cooks and teachers. Sample size determined. See above.		than controls (58.6 vs. 46.5 min, $p < 0.003$).	
Manios 1998, 1999, 2002	CCT By school	2	+	**Setting**: Schools in Iraklio and Rethimno (intervention) and Chania (control) Crete, Greece. **Participants:** First-grade primary school children aged 5.5 to 6.5 years; 509 boys and 453 girls. See above.	To evaluate a school-based intervention, involving a health and nutrition element and a physical fitness and activity element, on chronic disease risk factors. Delivered by school teachers and PE teachers. Power not stated. See above.	6 years	Total 831 available at 6 years, 787 assessed (those who did not change schools and completed). Time in leisure time PA intervention vs. control: +281 ($n = 356$) vs. +174 ($n = 285$) min/week, $p < 0.05$	'Know your body program' also included dental health, drug abuse and accident prevention. Results adjusted for baseline values, sex, BMI, change in height and parental education where appropriate.
Evidence of corroboration (external validity)								
Evidence of salience – Is it appropriate for the UK?								

First author	Study design	Research type	Research quality	Study population	Research question and design	Length of follow-up	Main results	Confounders/comments
Smarter Choices – Changing the Way We Travel 2004	Report	N/A	N/A	UK schools	To evaluate alternative modes of transport	N/A	The results of this report suggest that car use can be reduced by 8–15% at engaged schools, but the results are inconsistent. Other benefits may include improved safety and increased awareness of the potential for change in terms of options for alternative modes of transport.	Having a school travel plan coordinator increases the production of school travel plans but there is no evidence that this changes travel patterns or reduces parental fears about traffic danger.
Rowland 2003 Randomised controlled trial of site specific advice on school travel patterns	RCT	N/A	N/A	To evaluate intervention of site-specific advice on school travel patterns	Intervention schools were offered 16 hours of expert assistance over one school year from one of two school travel coordinators who had formal teaching qualifications and road safety experience. Road safety problems and their solutions were identified by meeting with teachers	1 year	Twenty-one London primary schools were randomised. One year post-intervention, nine of eleven intervention schools and none of the control school had travel plans. However, the proportion of children walking,	

					and governors, organising focus groups of parents and pupils, and encouraging the establishment of the school travel working group. The coordinator liaised with relevant parties within the local and health authorities.		cycling, or using public transport on the school journey were similar in intervention and control schools. In the intervention schools, 70% of children walked to school, 24% travelled by car, 6% cycled or used public transport. In the control groups, 71% walked to school, 23% travelled by car, and 7% cycled or used public transport. The proportion of parents who were very or quite worried about traffic danger was similar in the intervention (85%) and control (87%) group. Having a school travel plan coordinator increased the production of school travel plans but there was no evidence that this	

							changed travel patterns or reduced parental fears.	
Department for Education and Skills (2004)	Case study	N/A	N/A		To understand better the influences of re-introduction of National Nutritional Standards for school lunches in 2001 on the provision of food at school lunchtimes.	One time point.	The current National Nutritional Standards for school lunches have failed to promote healthy food choices at lunchtime amongst secondary school pupils in England. In the majority of cases, unrestricted choice of foods at lunchtime was associated with unhealthy food choices. Restricted choice over 1 week (e.g. number of days on which chips were served) was associated with Healthier eating. 82% of schools met all nutritional standards for school meals every lunchtime at the beginning of the service. This had fallen to 47% by	

							the end of service.	
Health Education Trust. A feasibility study into healthier drinks vending in schools (2004)	Feasibility study	N/A	N/A	UK schools	The aim of the feasibility study was to investigate the economic viability of healthier drinks vending provision in secondary schools. Twelve schools participated; schools were chosen to reflect both urban and rural locations and to offer an appropriate mix of size, area and character. The study took a whole school approach. In each school a small working party was set up including senior management, curriculum staff, catering personnel, and representatives from the student council.	N/A	Children will choose healthier options from vending machines, such as mineral water, pure fruit juice and skimmed milk, even when healthy drinks vending machines are set alongside the school's usual vending machine. The key to successful healthy drinks vending is pupil involvement, appropriate location of the vending machine close to the dining area, and continuity of provision (ensuring that the machine is full and in working order).	Evidence of change in total daily consumption of drinks was not assessed. Still awaiting evaluation results from Phase 2. Available at: www.healthedtrust.com

& Barratt 2005				schools in disadvantaged areas of North Tyneside (north-east of England).				
Metcalf et al. 2005	Cross sectional study – not an intervention	N/A	N/A	154 boys and 121 girls in their first year (aged 4–5 years) at 53 urban primary schools in Avon (part of ALSPAC).	To assess levels of PA of children who walk to school compared with those that are driven. Methods used accelerometry.	N/A	Studied children in urban primary schools in Avon. Being driven to school does not affect the overall PA levels of 5-year-olds. Although the proportion of walkers was highest in the lowest SES group, that pattern of results was unchanged when analysed by each social group. Note: the two groups did not differ significantly in either BMI or sum of skinfold thicknesses.

Stratton 2000	RCT/CCT Intervention group randomly selected individual children within one school, control children matched from another school.	N/A	N/A	Two schools in an urban industrialised area of north-west England. **Intervention:** 18 boys and 18 girls aged 5 to 7 years. **Control:** 12 boys and 12 girls of similar age, stature and body mass.	To evaluate the effects of moderate to vigorous PA of primary school children of painting a school playground with bright and colourful markings. Playground space 30 × 30 m in intervention and 40 × 20 m in control schools, numbers in playground between 50 and 200; neither school had playground markings at baseline. **Intervention group:** Designed the markings which were then painted in bright fluorescent colours on the tar macadam including castle, dragon, pirate ship, fun trial, hopscotch, snakes	4 weeks	Intervention *n* = 27 Control *n* = 20 **No significant difference in BMI (kg/m^2):** Baseline Intervention: 22.9 Control: 22.4 Post-intervention Intervention: 23.3 Control: 22.9 The intervention did increase children's mean heart rate and levels of moderate and vigorous activity with significant interaction between these variables; no main effect differences	

					and ladders, etc., with only one football allowed. **Control:** No markings and limited equipment.		between groups suggesting factors other than playground markings stimulated PA in control school such as availability of skipping ropes and balls (also both schools significantly increased duration of playtime).	
University of East Anglia. A National Evaluation of School Breakfast Clubs (ABC). Department of Health 2001	Various	N/A	N/A	Schools in East Anglia	A survey of breakfast club provision and the structures put in place to implement the scheme. A cluster RCT to evaluate the effectiveness of breakfast clubs in terms of nutritional, social, psychological and educational outcomes. Case studies to generate detailed information about process and structures and the experiences of those involved.	Various.	There is evidence for a small but important beneficial effect of breakfast clubs in schools on behaviour, dietary intake, health, social interaction, concentration and learning, attendance and punctuality. This positive impact is reaching many families whose members are at risk of, or are actually experiencing, social exclusion. Considerable support for	

					A child and family study using questionnaires and semi-structured interviews to collect information from parents about socio-economic circumstances, the impacts of the scheme on families, and parents' and children's satisfaction with and views about breakfast clubs. Both qualitative and quantitative data were generated over three main phases of data collection during Spring Term 2000, Summer Term 2000 and Spring Term 2001. Data were collected from 235 schools operating breakfast clubs. Thirty schools (6000 children) were selected for the trial.		breakfast clubs was found from the interviews and questionnaires.

EPPI-Centre (2003b) Children and healthy eating: a systematic review of barriers and facilitators. London: EPPI-Centre, Social Science Research Unit, Institute of Education, University of London.	Systematic review	1	++	Various. *n* = 19 intervention studies.	The aim was to evaluate the effectiveness of interventions to increase 4–10-year-old children's fruit and vegetable consumption, and to assess the barriers and facilitators to having a healthy diet.	Various	Teachers found it difficult to fit nutrition education in to the curriculum. They also felt they lacked in skills, training and support to deliver high quality nutrition lessons. However, fruit tuck shops could be valuable to others areas of learning, such as English and art through promotion exercises, and maths via the handling of money. Success of the interventions seemed to depend to a large extent on the enthusiasm of staff and parents.	
EPPI-Centre, (2001a)	Systematic review	1	++	Various. *n* = 7 intervention studies.	The aim was to evaluate the	Various.	Intervention was well received in most cases, although a recurring theme was that schools lacked the time and resources for such	

Young people and healthy eating. London: EPPI-Centre, Social Science Research Unit, Institute of Education, University of London.					effectiveness of interventions to improve the diets of young people (aged 11–16 years), and to assess the barriers and facilitators to having a healthy diet.		projects. One study noted that young women tended to enjoy the intervention more than young men, and that peer leaders were particularly well received. One intervention met with resistance from teachers and waning enthusiasm from students and parents. In this case, more training for the teachers may have provided more motivation, enthusiasm and skill. Young people's views of barriers and facilitators to healthy eating indicated that effective interventions would: 1) make healthy food choices accessible, convenient and cheap in schools; 2) involve family and peers; 3) address personal barriers to healthy eating, such as preferences for fast food in terms of taste, and perceived lack of will-power.	
EPPI-Centre (2003a) Children and physical activity: a systematic review of barriers and	Systematic review	1	++	Various. *n* = 5 intervention studies (all US-based).	The aim was to evaluate the effectiveness of interventions to increase PA/reduce	Various	In one study, 95% teachers rated the intervention as effective and 65% pupils said they liked the intervention lessons. In another, teachers reported high levels of participation, confidence in the intervention and confidence in themselves to be able to deliver it. Another intervention met with more resistance from school staff, and waning enthusiasm from	

facilitators. London: EPPI-Centre, Social Science Research Unit, Institute of Education, University of London.					inactivity in children aged 4–10 years, and to assess the barriers and facilitators to their participation in PA.		parents. Interventions should address the barriers and facilitators to participation in PA identified by children, by: 1) providing activities that are enjoyable, in a social atmosphere, giving children some choice, and making children aware of how sedentary activities such as TV watching are; 2) involving parents in interventions; 3) improving children's access to PA opportunities.	
EPPI-Centre (2001b) Young people and physical activity: A systematic review of research on barriers and facilitators. London: EPPI-Centre, Social Science Research	Systematic review	1	++			Various	Enthusiasm for the project amongst staff, parents and pupils varied. The main barrier to implementation was a lack of time and resources. In some schools, though, the intervention measures were well received. Adequate training for teachers expected to give nutrition information is important. Young people's views on barriers and facilitators suggest that interventions should: 1) modify PE lessons to suit their preferences; 2) involve family and peers, and make PA a social activity; 3) increase young people's	

Unit, Institute of Education, University of London							confidence, knowledge and motivation relating to PA; 4) make physical activities more accessible, affordable and appealing to young people.	
James 2004	RCT Cluster by class	1	++	See above.	See above.	See above.	One of the authors delivered the intervention.	Average class size was 22 (SD 5).
Loughridge & Barratt 2005	CCT	2	+	As above.	As above.	As above.	Focus groups were conducted in the control school only, and revealed that students viewed their existing water provision as poor, and wanted sufficient supplies of cooled filtered water at school. Implementation would appear simple, and sustainable (my comments).	
Horne 2004	CBA	2	–	See above.	See above.	See above.	Research staff and school staff. No details.	
Wells & Nelson 2005	CCT	2	+	As above.	As above.	As above.	9% of parents of infants who received free school fruit were not aware that their child did so; conversely 40% of parents of junior children who used to receive free fruit at school were not aware that their child no longer did so. The parents of 483 infant pupils who believed (correctly) that their child was receiving free school fruit were asked a question about	

							whether or not they had changed the amount of fruit they gave to the child. The majority (82%) reported not having changed the amount of fruit they provided for their child.	
Sahota 2001	RCT Cluster, by classroom	1	+	See above.	See above.	See above.	Delivered by teachers but the project team provided training for teachers and the project manager also provided input and support.	
Warren 2003	RCT Individual	1	+	See above.	See above.	See above.	The project team delivered the intervention.

Appendix 8

Workplace interventions to prevent obesity

EVIDENCE SUMMARY TABLES

1. BEHAVIOUR MODIFICATION/EDUCATION TECHNIQUES – INCLUDING HEALTH CHECKS AND WORKPLACE-MONITORED DIETS

SUMMARY

Evidence of efficacy for weight management/reduction

Evidence from ten randomised controlled trials (RCTs) and one controlled non-randomised trial (CCT) suggest that worksite behaviour modification programmes such as health screening (a ‘health check’) followed by counselling can result in short-term weight or body fat loss although there was a tendency for weight regain post intervention.

Reductions in body mass/body fat relative to control were noted in eight of the RCTs (Rose 1983 ; Brownell 1985 ; Peterson 1985; Shannon 1987 [data from Erfurt 1991; Gomel 1993 ; Gemson 1995; Hennrikus 1996; Proper 2003]; and one CCT (Cockcroft 1994). There was a wide range of results for the amount of weight lost. The two older studies reported reductions of about1 lb (2.2 kg) per week (Peterson 1985; Shannon 1987 [data from Hennrikus 1996), with a tendency to regain weight for those studies where this was followed up for 6–12 months post intervention (Brownell 1985; Shannon 1987; Gomel 1993). An extended UK-based RCT (Rose 1983) found very small weight reductions in intervention subjects (–0.4% in all men (*n* = 9734) and –0.7% in those at high cardiovascular risk (*n* = 1278) over 5–6 years. A non-randomised UK trial with a weak study design (CCT; Cockcroft 1994) found that those in the advice group lost more weight than those in the control group (*p* = 0.025 for time and advice measures).

A recent UK-based individual RCT looking at a single health check with 5-month follow-up (Hanlon 1995) found no significant difference in body mass index (BMI).

One weak RCT among male blue collar workers in Belgium (Braeckman 1999) resulted in an increase in BMI in the intervention compared with the control group despite reported reduction in energy and percent fat intake.

Evidence of efficacy for diet/physical activity outcomes

There is evidence from a systematic review of trials and six additional RCTs that worksite behaviour modification programmes can lead to improvements in nutrition and physical activity (PA). Evidence of longer term, post intervention benefits is limited.

Nutrition: A systematic review (Janer 2002) found that worksite behaviour modification programmes can show a positive effect on dietary fat intake (ranging from a decrease of 3% to an increase of 1.3% in energy from fat. Programmes can also result in an increase in the consumption of fruit and vegetables, ranging from 0.09 to 0.5 servings per day. Information about long-term effects was limited. The percentage of favourable change maintained at 6 or 12 months with regard to nutrition ranged from 0% to 65%. Successful programmes included a wide range of educational interventions (such as health screening followed by counselling) sometimes accompanied by environmental changes.

Four RCTs with nutrition outcomes were not included in, or were published since, this systematic review. Three RCTs (Sorensen 1996 ; Sorensen 1998; Sorensen 1999) found significant improvements in nutrition and one showed no benefit (Sorensen 2002). Only one trial monitored post intervention effects 1 year after the 2-year intervention (Sorensen 1996) and noted significant decreases in fat intake and increases in fruit and vegetable intake. It appeared from this study that longer, interactive intervention efforts (contests and classes) resulted in more positive outcomes than one-time activities (such as the kickoffs) or more passive efforts (use of printed materials).

Physical activity: There is systematic review evidence (Janer 2002) suggesting significant effects of educational sessions and informative materials on levels of PA. Information on the type of PA in each trial is not provided in the review. Out of nine trials using educational sessions and informative materials, and evaluating outcomes directly related to PA, four reported significant changes. One trial comparing both types of intervention found better results with educational activities focusing on behavioural changes, with 65% of at risk employees exercising weekly, compared with 50% when facilities were offered. Motivationally tailored intervention appeared to be more effective in nearly all the stages of readiness.

Two RCTs not included in, or published since this systematic review noted significant increases in PA in the intervention group (Emmons 1999) or significant increases in both intervention and control groups but no significant difference between groups (Nichols 2000). Only the latter trial had post-intervention follow-up (Nichols 2000; 6 months).

Evidence of corroboration in the UK

Of four intervention studies carried out in the UK (Rose 1983; Hanlon 1995; Cockcroft 1994; Leslie 2002) three (Cockcroft, Leslie and Rose) suggested benefits. In one UK study, individual health checks did not generate threat for most of the participants although the results for weight loss were not significant (Hanlon 1998). In a study addressing barriers to change, men chiefly cited a lack of nutritional information as a barrier to change while women predominantly cited the preferences of family members (Fleming 1997 [4]). Finance was not a factor in this particular study. A single set of case studies suggest that the more successful interventions include an interdisciplinary approach with broad representation including: health and safety and human resources, and implementers from high grades and strategic positions; initiatives integrated into worksite objectives; staff involvement, communication and realistic objectives; activities that go beyond the superficial and address root causes (Health Development Agency 2002).

EVIDENCE TABLE 1: BEHAVIOUR MODIFICATION/EDUCATION TECHNIQUES – INCLUDING HEALTH CHECKS AND WORKPLACE-MONITORED DIETS

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for weight maintenance/reduction								
Hanlon 1994, Hanlon 1995	Individual RCT	1	++	Two workplaces in Scotland; one with internal control (engineering factory) and one serving as external control. *n* = 1371 (of 1632 selected). Mean age 44 years. 89% male	**Aim:** To determine the effectiveness of a health check and assess any particular benefits resulting from feedback of plasma cholesterol concentration or coronary risk score or both. Multi-factorial. Single individual healthcheck with trained counsellor giving feedback on blood cholesterol and risk score. 80% power at $p = 0.05$.	Single health check with 5 month follow-up	86% participation. Low attrition: 17% in intervention, 14% in control. No significant difference for BMI between full health check group and internal control ($p = 0.16$). No differences between groups to suggest that feedback of cholesterol concentration or risk score had additional impact on any of the outcomes.	**Health check:** No details of dietary content and diet assessment by self-reported change. Feasibility depends on resources for individual counselling.
Proper 2003	Cluster RCT	1	+	Three municipal services in Enschede, Netherlands. *n* = 299	**Aim:** To investigate effectiveness of an individual counselling intervention at the workplace. Seven	Nine months.	52% recruitment rate. 66% attended six or seven consultations. Significant reduction in % body fat (–0.79% [95% CI –1.43, –	PACE programme. No allocation concealment. No intention to treat (ITT).

				Mean age approx. 40 years. Approx. 65% highly educated. 25.6% female in intervention and 38.5% female in control group.	individual counselling sessions over 9 months to promote PA and nutrition changes plus written information vs. written information only (control). 90% power at $p = 0.05$.		0.16]; $p = 0.015$).	81% health test completion in intervention but only 70% in control group. Post-intervention effects unknown. Generalisable to motivated individuals. Complex and confusing paper.
Gomel 1993	Cluster RCT	1	+	Australian ambulance service. 28 Worksites $n = 488$ 83% male. Mean age 31–33 years.	**Aim:** Comparative efficiency of four programmes designed to decrease cardiovascular risk factors: Health risk appraisal (HRA) with feedback (30 mins); health education (HE) with standard advice (50 mins); behavioural counselling plus HRA and HE (>2 hours over 10 weeks); or all above plus incentives (e.g. lottery draw).	3 and 6 months, and 1 year.	88% participation. Recruitment = 431. 84% follow up at 12 months. BMI increased significantly over four assessments. Increase was on average 4% less for programmes including behaviour modification techniques ($p = 0.04$). Initially significant decrease in % body fat in these groups (when compared with programmes without behaviour counselling, $p = 0.02$) had returned to baseline levels at end of 12 months.	RCT – cluster + No allocation concealment but intention to treat (ITT) analysis.
Peterson	Individual	1	+	High tech	**Aim:**	16 week	80% attrition with professional	Individual but

1985	RCT			manufacturer. Blue collar industry Massachusetts. *n* = 63 24% male Mean percent over ideal weight 36.6% Average age 46.2 years Assembly line workers *n* = 36 Plant managers *n* = 10 Clerical *n* = 5 Unknown *n* = 12	To evaluate weight loss programmes led by volunteers compared with those led by professionals. 12 sessions.	programme plus 4-month follow-up.	leaders, 48% with volunteer leaders. If just completers, professionally led groups lost weight at a faster rate. Overall weight loss for both interventions including dropouts was 3.3 kg (7.3 lb). If just completers there was an overall weight loss of 8.5 kg (18.7 lb). No significance values stated. Professionally led – cost per kg lost index of US$7.88 and US$12.55 at post-test and follow-up respectively. In self-help condition, cost per kg lost index of US$4.38 and US$5.56 at post-test and follow-up.	stratified randomisation based on degree of overweight. Small study and no baseline data provided. No allocation concealment but ITT analysis. High attrition.
Rose 1983	Cluster RCT	1	+	Twenty-four factories (matched as far as possible for size, nature of industry and region, then one in each pair was randomly assigned to intervention condition). UK	**Aim:** To find out how far health education can change the major coronary risk factors in a population. Advice from factory medical departments about cardiovascular risks. Intensive advice for 13% of the population at high risk. Specific	5 or 6 years	5% of intervention site workforce re-examined per annum. The same 10% in control sites analysed biennially. Very small weight reductions in intervention subjects (–0.4% in all men (*n* = 9734) and –0.7% in those at high cardiovascular risk (*n* = 1278), after 5–6 years. No significance values stated.	No allocation concealment. Analysed by cluster (5% of workforce per annum) therefore ITT analysis not possible.

				18,210 men 40–59 years old	interventions for weight loss (for those >15% overweight (medical staff supplemented a little by a central visiting team).			
Shannon 1987	Assessed by Hennrikus 1996 systematic review. – considered an RCT with partial randomisation			**Site one:** Petroleum refinery **Site two:** Chemical plant – both parts of Atlantic Richfield. Forty-seven blue collar from site one, 56 white collar from site two. Wait list control comparison group.	To evaluate the effectiveness of a programme to promote weight loss and improve participant health behaviours and knowledge of nutrition.	Nine-week intervention plus 1-year follow-up.	103/115 participants (89%). 61% in treatment group completed programme. 84% control group had post-test data. Gender and site not related to weight loss. Weight loss in treatment group (mean 0.94 lb [0.43 kg] per week) significantly greater than control. At 1-year follow-up (data on 14 of 32 completers only), six had maintained weight, four had regained some but not all weight and four had continued to lose.	Original paper unavailable. Data extracted from Hennrikus 1996 .
Erfurt 1991	RCT	1	+	Four manufacturing plants, Michigan USA. Mean age 39–43 years 32–36% were above ideal weight	**Aim:** To compare effectiveness of four models at controlling high blood pressure, obesity and cigarette smoking. 1) Control, Health risk appraisal *n* = 2448.	3 years	Sample of 600 selected for re-screening (500 in site 4). 80–84% re-screened. For those employees overweight by 20% or more at baseline, significant differences across sites in mean weight change. Major improvements in risk levels were found with the addition of routine follow-up	Treated as RCT by Janer 2002. No allocation concealment and no ITT though 75–88% of employees screened at baseline and 80–84% re-screened at follow-up.

				In re-screened sample 87–95% were male, and mean age was 43.7–46.3 years. 66–78% white.	2) As 1) plus media promotion, health improvement classes *n* = 1374. 3) As 2) plus support, encouragement *n* = 2089. 4) As 3) plus activities in worksite *n* = 1893.		counselling and a menu of interventions. Sites one and two showed gains (+3.1 and +0.6 lb [+1.41 and +0.27 kg]) and mean reductions in sites three and four (–1.2 and –4.7 lb [–0.54 and –2.13 kg]) ($p < 0.001$). Average weight gain in site one and weight loss in site four statistically significant ($p < 0.01$ and $p < 0.001$).	
Gemson 1995	Individual RCT	1	+	Large financial services firm in New York City. 161 employees who volunteered by a periodic health examination. 81% male. Mean 46.2 years old in health risk appraisal (HRA) and 46.5 in control. 81% white. 50% with College/professional degree in HRA and 60% in control group.	All the volunteers received a physical examination by a registered nurse and completed a questionnaire. Half were then randomised to receive a computerised HRA with counselling. Controls received no report or counselling. No power calculation reported.	Baseline examination and feedback. 6-month follow-up.	53% re-attended in HRA group and 59% in control group. There were no significant differences in weight between the two groups but a trend towards an improvement in the HRA group.	No allocation concealment. No ITT analysis. Poor follow-up.
Cockcroft 1994	CCT	2	+	London teaching hospital. 297	Volunteers who completed the	Baseline screenin	28% re-attended.	Treat as *very weak* CCT.

				volunteers to an invitation to attend a health screening session run by the occupational health/health psychology units. No socio-economic data provided.	screening questionnaire and health measurements were assigned to results only (control) or to receive advice and set targets for changing their lifestyle (intervention).	g and advice. 6-month follow-up.	Those in the advice group lost more weight than those in the control group (BMI [kg/m^2] in advice group was 24.90 at baseline and 24.36 at follow-up, vs. 24.48 at baseline and 24.49 at follow-up in the controls); $p = 0.025$ for time and advice measures.	UK-based but no allocation concealment, no baseline data, No ITT and poor follow-up.
Braeckman 1999	RCT	1	+	Four worksites in Gent Belgium. *n* = 928 100% men, average age 43.7 (range 35–59) years Reported as predominantly blue collar and White.	**Aim:** To evaluate the effect of a short-term, low intensity nutrition intervention on blood lipids, nutrition knowledge and dietary changes. Individual health check with risk feedback, plus mass media and educational sessions. Control group received a written summary of their results without further information or advice although referred to GP if abnormal values.	3 months	Baseline response 83% (*n* = 770). Follow-up response 82% of baseline respondents (*n* = 638). A net reduction in the intake of total energy and the percentage of energy from total fat was reported in the intervention group (–1.42 kcal [5.95 kJ]/day and –1.56% respectively; $p < 0.05$ in both cases) but BMI increased by 0.26 kg/m^2 ($p < 0.001$) compared with control.	No allocation concealment. Small study (only four sites randomised) and some modest baseline differences. No ITT but >82% follow-up.
	Individual RCT	1	+	Department store workers who	**Aim:** To evaluate the	End of 16-week	57.5% attrition in study 1, 42.6% in 2 and 33.8% in 3.	Individual but stratified

				were Union members. New York City, USA. Lower-middle class socioeconomic status (SES). 100% women. *n* = 172 (40 in study 1, 61 in study 2, 71 in study 3). No difference between studies or treatment groups in mean age, weight, or percentage overweight.	effectiveness of three consecutive weight loss programmes of lay vs. professional group leaders, frequent (four × weekly in study one, three × weekly in studies 2 and 3) vs. once weekly meetings, and programmes on/off site.	programme plus 6 months later (study 1) or 1 year later (studies 2/3).	(Attrition rates lower for groups with frequent meetings.) Attrition rates in study 1 lower in groups led by lay therapists (31 and 50%) than professional (75 and 80%) ($p < 0.05$) and in frequent treatment groups (31 vs. 50%, 75 and 82%) ($p < 0.05$). Average weight loss for all subjects completing treatment in study one at 16 weeks was 3.6 kg and at 6 months, 1.2 kg. No significant difference between groups. Post-treatment mean weight loss in study 2 was 9.2 lb (4.17 kg), and 8.6 lb (3.90 kg) at 1-year follow-up. In study 3 weight loss was 7.3 lb (3.31 kg) at post treatment, and 5.9 lb (2.68 kg) at 1-year follow-up. Attrition, weight loss and maintenance similar in lay and professionally led groups in studies 2/3, but costs per pound loss per participant was US$6.35 for the lay leaders and US$18.81 for the professional. No significance values stated.	randomisation based on degree of overweight. No allocation concealment. No ITT analysis. Incorporates Stunkard 1980

Evidence of efficacy (internal validity) for diet/physical activity outcomes								
Janer 2002	Systematic review	1	+	Literature search date unknown (circa 1984–2000) and Medline+ reference list only. Forty-five controlled studies. Fourteen controlled trials with a nutrition outcome and 13 controlled trials with a PA outcome were included .	Review of workplace health promotion trials re major cancer risk factors (diet, obesity and PA amongst other topics). Studies included an educational intervention (such as health screening followed by counselling) and, sometimes, environmental changes.	Various	**From 14 controlled trials with a nutrition outcome:** The increase in vegetable servings per day was reported in three trials and ranged from 0.09 to 0.19. Five studies evaluated fruit intake and four of these obtained statistically significant increases ranging from 0.11 to 0.24 servings per day. In the three studies reporting both fruit and vegetable use, increases ranged from 0.18 to 0.5 servings per day. Changes in fat intake were statistically significant in six of the ten available studies. The magnitude of the change ranged from a decrease of 3.0% to an increase of 1.3% in energy from fat. Five studies included more than one period of follow-up. The percentage of favourable change maintained at 6 or 12 months with regard to the intake increase or reduction ranged from 30 to 65%. **From 13 controlled trials with a physical activity outcome:** Out of nine trials using educational sessions and	Unfocused review question and wide range of types of intervention and outcomes covered. Errors in paper (reference numbers missing in text). Overlap with other reviews and topics – incentives, PA, etc. NB: Shephard 1992 is a case study looking at a PA initiative – see excluded studies. Two studies cited in an older systematic review Roe 1997 are not included: Hanlon 1995 /Hanlon 1994 [17] and Rose 1983 /Bauer 1985. Both are included as individual studies under weight outcomes.

							informative materials and evaluating outcomes directly related to PA, four reported significant changes. Significant changes were reported in three of four trials offering facilities, time and space. One trial comparing both types of intervention found better results with educational activities focusing on behavioural changes, with 65% of at risk employees exercising weekly, compared with 50% when facilities only were offered. A motivationally tailored intervention appeared to be more effective in nearly all the stages of readiness. Information from the review on follow-up is limited. In a non-randomised controlled study reporting a 7-year follow-up, participation was still 13% – the same as at the end of the intervention period (Shephard 1992).	This review includes the Take Heart (Glasgow 1995) and Take Heart II (Glasgow 1997) studies. ***[?]***
Sorensen 1996	Cluster RCT	1	+	Worksites in manufacturing, communications, public service and utilities, USA Blue collar 51% Managerial 22%	**Aim:** To evaluate the effectiveness of the Working Well intervention on Cancer risk factors. Multi-level interventions at	Two-year intervention and 1-year follow-up.	Overall response to baseline survey 69%; 71% response to follow-up. Attrition not stated. Adjusted difference between intervention and control of % energy from fat consumption – 0.35 (SE 0.16)% (*p* < 0.05).	No allocation concealment. ITT analysis by worksite by only about 70% response at each site.

				Clerical 22.4 Multiple 4.5%* Two groups with 54 sites each (28,000 employees).	individual, community and organisational levels including activities, posters and brochures, self assessment and self-help materials, campaigns and contests, direct education and environmental changes.		Adjusted % increase in fruit and vegetable intake 5.6 (SE 1.3)% – consistently higher in intervention and negligible in control (*p* < 0.001). It appeared that longer, interactive intervention efforts (contests and classes) resulted in more positive outcomes than one-time activities (such as the kick-offs) or more passive efforts (use of printed materials).**	Not included in Roe 1997 or Janer 2002. Complicated statistical analysis. The **Working Well** Trial *Information from Abrams 1994. **Information from Patterson 1997.
Sorensen 2002	Cluster RCT	1	+	Fifteen manufacturing worksites (of 41 eligible) in north-east USA, all with probable use of chemical hazards. Baseline variations between groups. 65–71% blue collar (hourly paid) workers. 12.4–15.6% ≤30 years old. 23.5–18.6% 51–	**Aim:** To assess whether health promotion + occupational health and safety intervention vs. standard health promotion (see above) results in significant smoking cessation and increase in fruit and vegetable intake in workers in general and blue collar workers in particular.	Length of intervention 2 years	80% response at baseline (*n* = 9019) and 65% response at completion (*n* = 7327). 5156 responded on both occasions and data presented on this group. No significant differences for mean changes in fruit and vegetable consumption in either group or between groups. No significant difference between men and women in intervention effect (*p* = 0.31) and no difference by job type (data not shown).	The **WellWorks 2** study. Good allocation concealment. Some baseline differences between groups and no ITT analysis. Intervention to address cancer risk rather than obesity prevention and issue under test in occupational health and safety involvement.

				60 years old. 57–66% men.				
Emmons 1999	Individual RCT	1	+	26 worksites in north-east USA of which 22 sites and 2291 workers were included in the final analysis. Circa 57% male, Mean age approx. 42 years, approx. 53% blue collar, approx. 93% white, approx. 83% completed high school.	**Aim:** To present the results regarding behaviour change found among completers of three health behaviour assessments as part of their worksite's participation in the Working Healthy project. A development from the Working Well Trial (see above) but with a focus on PA. Individually focussed activities and changes to catering and exercise environment vs. self-help.	Length of intervention 2.5 years	63% of eligible workers completed baseline survey. 51% completed interim survey. 83% who completed interim also completed final survey. Employees in the cohort were more likely to be male, older, White, and have higher educational levels. Subjects in the intervention condition were significantly more likely to report engaging in physical exercise at the time of the interim assessment ($p < 0.0001$) and the final assessment ($p < 0.03$), reflecting a 30% increase in activity, compared with a 4.3% increase in control. The intervention group showed a marginal increase in fruit and vegetable consumption at the final survey, a 7% increase vs. a 7% reduction in controls ($p < 0.06$ in the univariate model).	The **Working Healthy Project**. No allocation concealment. 51% completion at interim and no ITT analysis. Included in Proper 2003 review.
Sorensen 1999	Cluster RCT	1	+	Twenty-two community health centres in north-east USA.	**Aim:** To evaluate the results of an intervention to	Length of intervention 19.5 months.	Response rate 87% at baseline ($n = 1359$) and 76% at follow-up. 47% response to both.	**Treatwell 5-a-Day** study. No allocation

				n = 1588 84% female. Age range unknown. 59% white/other 23% Latino 18% non-Latino black 80% educated to at least high school. 2. INCREASED WATER PROVISION

SUMMARY

No relevant studies found.

3. HEALTHIER FOOD PROVISION

SUMMARY

Evidence of efficacy for weight maintenance/reduction
Only one intervention, a controlled before and after study (Cook 2001) was found with a weight outcome. The intervention, which consisted of nutrition displays and a monthly 30-min workshop (6-month intervention and 12-month follow-up), found there was no significant self-reported difference in mean BMI or waist circumference.

Evidence of efficacy for diet outcomes
One systematic review (Seymour 2004) concluded that worksite intervention studies targeting healthier food provision by information strategies such as labelling and/or changes in food availability or cost can encourage healthier eating. Two additional RCTs (Beresford 2001; Steenhuis 2004) were included in, or published since, the review. The US study, with measures 3-, 8- and 12-months post-intervention, found an effect of 0.3 servings of fruit and vegetables per day ($p < 0.05$) (Beresford 2001). This intervention (Seattle 5 a Day) built on lessons learnt from the Working Well Trial (included in the Seymour review, 2004). The study in the Netherlands, which looked at combinations of educational and food supply programmes, found no significant effects on consumption data (Steenhuis 2004).

Evidence of corroboration
The only relevant UK study, a controlled before and after study of the Heartbeat Award Scheme (Holdsworth 2004), suggested that worksite interventions can bring about changes to catering provision that may impact on dietary intakes. This study, with measures taken 6 months before and 6 months after the intervention, found significantly more positive change solely in the intervention sites for increase in fruit consumption ($p = 0.029$), reduction in consumption of fried foods ($p = 0.044$) and sweet puddings ($p = 0.042$), and more change to using lower fat milks ($p = 0.037$).

The authors of a cross-sectional survey in England of Heart Beat Award managers and caterers, government and health professionals, recommended improved promotion of the schemes and better integration with other health programmes (The Research Partnership 2000. Additional data from a single set of case studies found that factors most likely to make a canteen-style five-a-day intervention work are commitment from the top, enthusiastic catering management, a strong occupational health lead, links to other on-site health initiatives, free or subsidised produce and heavy promotion and advertisement at point of purchase (Healthlinks 2003).

European 25.7 vs. 39.7%; ≥ 4 years at	**Aim:** To evaluate effectiveness of health promotion programme targeting dietary behaviours and PA in male hourly-paid workers. Nutrition displays in the cafeteria and monthly 30-min workshop for 6 months. Delayed intervention in control worksite.	After 6-month intervention and at 12 months.	Recruitment 38% at intervention (*n* = 132) and 46% at control (*n* = 121). Follow-up = 94% at 6 months and 89% at 12 months. Statistically significant differences between the intervention and control groups, in mean fat score (*p* = 0.0003), increase in vegetable intake (*p* = 0.007) and PA (*p* = 0.005). There was no significant difference in mean BMI or waist circumference between the groups.	Self-reported nutrition and PA measures. Ethnic variations may limit generalisability to UK.

				high school 50 vs. 29.8%, etc.				
Evidence of efficacy (internal validity) for diet/physical activity outcomes								
Seymour 2004 .	Systematic review	2 (impossible to tell if any included studies were RCTs)	++ (for systematic review overall)	Ten workplace studies, six of which were considered to be a strong or very strong research design.	**Aim:** All articles that included a nutrition intervention with an environmental or policy component conducted in an English-speaking industrialised country.	Various	The authors concluded that of ten worksite intervention studies targeting healthier food provision, most showed statistically significant changes in improved sales of healthier foods. Successful interventions included information strategies (eg labelling) and/or changes in availability and price of healthier foods.	Included studies of 'strong/very strong' research design: Dubois 1996 Jeffery 1993 French 2001 Levin 1996 Schmitz 1986 Wilbur 1981 Some studies had an incentive element.
Steenhuis 2004	Cluster RCT	1	+/– (weak)	The Netherlands. Seventeen worksite cafeterias of large companies or government organizations with mainly white collar workers. *n* = 5425 62% male. Mean age 38 (range 18–64) years. 60% with a high level of education.	**Aim:** To describe a study of effectiveness of two environmental interventions alongside an educational programme in reducing fat intake and increasing fruit and vegetable intake. Four conditions tested: the educational programme; the food	One-month and 6-months post intervention.	30.1% response at baseline. 76.4% of the above group at 1-month post and 61.3% at 6-months post. For the whole study population, no significant effects on consumption data were found for any of the programmes.	No allocation concealment. <80% follow-up with no ITT and some baseline differences. Complex statistical analysis.

					supply programme plus educational; the labelling programme; plus educational and a control group.			
Beresford 2001	Cluster RCT	1	+	Seattle, OR, USA. Twenty-eight worksites with cafeterias. *n* = 2828. Mean age 41.8 years. 58% female. 32% college graduates and a further 23% with postgraduate education. >86% white.	**Aim:** To evaluate the effect of the Seattle 5 a Day worksite programme to increase fruit and vegetable consumption. In each intervention worksite an employee advisory board implemented changes in the cafeteria and targeted individual behaviour (posters, brochures, paycheck inserts, etc.) informed by the stages of change theoretical model.	3-, 8- and 12-months post intervention with cohort of baseline respondents. Two years with cross-sectional data.	Response rate at baseline = 80% on average. At 2-year follow-up response rate = 71% on average. Results from the food frequency questionnaire suggested a fruit and vegetable increase of 0.5 servings per day in the intervention vs. 0.2 in the control worksites, an intervention effect of 0.3 ($p < 0.05$). Other measures of fruit and vegetable consumption, including unobtrusive indicators, supported the effectiveness of the intervention.	**Seattle 5 a Day.** Building on the **Working Well** trial. No allocation concealment. <80% follow-up and no ITT analysis. RCT not included in Seymour 2004 so retained for information.
Evidence of corroboration (external validity)								
Evidence of salience – Is it appropriate for the UK?

Holdsworth 2004	CBA	2	+	Six workplaces in Leicestershire, UK. (Four intervention,	**Aim:** To evaluate changes in employee eating habits following Heartbeat Award	Measures taken 6 months before and 6 months after	Response rate to post-intervention survey (structured food frequency questionnaire) was 73.2% of possible employees in intervention sites, and 62.6% of possible employees post-intervention.	**Heartbeat Award Scheme** **Excluded from efficacy due to study design.**

				n = 453 employees; two control *n* = 124 employees) Intervention groups: Female 70.5% Age 19–45 years 62.2% Control groups: Female 33.5% Age 19–45 years 63.6% 88.8% of intervention, and 78% of control group in top three social class groups. 92.9% of intervention and 90.3% of control were White.	scheme and to determine if this change was due to the intervention. Four intervention worksites had received Heartbeat Award, Minimum criteria for award was that at least one-third of the dishes on the menu were 'healthy choices'. Control sites had been unsuccessful in receiving award.	intervention.	Significantly more positive change solely in the intervention sites for increase in fruit consumption ($p = 0.029$), reduction in consumption of fried foods ($p = 0.044$) and sweet puddings ($p = 0.042$), and more change to using lower fat milks ($p = 0.037$). No comparative changes in control worksites.	Inappropriate control group thus treated as CBA but retained for information since based in the UK. Self-reported dietary change. Self-selection by more motivated individuals inevitable.
Evidence for implementation – will it work in the UK?								
First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question**	**Length of follow-up**	**Main results**	**Confounders/comments**
Healthlinks 2003	Case studies	3	+	Twelve worksites in Merseyside, UK.	Review of worksites implementing the Take Five initiatives	Various.	The factors most likely to make a canteen style five-a-day intervention work are: • Commitment from the top;	Evaluation report of the **Take Five** initiative.

				Factories *n* = 4 Hospital trusts *n* = 2 Local government *n* = 3 Pharmaceutical *n* = 2 Supermarket *n* = 1	to increase fruit and vegetable intakes in canteens.		- Enthusiastic catering manager; - Strong occupational health lead; - Linked to some other health initiative on site (e.g. Health Focus Group); - Free or subsidised produce; - Heavily advertised and promoted at point of sale.	
The Research Partnership 2000	Cross-sectional survey	3	+	Mailed questionnaire to Heart Beat Award (HBA) scheme managers (*n* = 81), local and health professionals who may or may not be involved in HBA or similar schemes (135), HBA caterers (210), non-HBA caterers (75), local government professionals involved with Best Value (71), Local Agenda 21 (140) or Environmental Health Action Plans, LEHAP (99) in England. No socio-economic details.	**Aim:** To assess the status of the HBA scheme as it completes its tenth year, to assess its value as a public health tool and to consider its future development. Questionnaire survey carried out by consultants (The Research Partnership) on behalf of the Health Education Authority.	N/A	Response rate = 24% (811/3244), with a range from the different groups consulted of 3–38% response, higher amongst those directly involved with HBA schemes (e.g. HBA managers 35%, HBA caterers 38%). Of local authority consultees who had stopped using the scheme, the primary reasons were lack of resources, lack of interest and/or a perceived need for a more locally tailored scheme. The main barriers for those who had not started a scheme were lack of resources and perceived low priority or interest. The main benefits for the local population were thought by organisations/caterers running the scheme to be the increased availability of healthy food choices (97%/89%) and a raising of awareness of health issues (71%/80%). HBA managers saw insufficient national publicity as the	Mailed questionnaire responses only and low response rate. Findings also relevant to Community two review.

							main challenge faced by those running schemes, followed by the difficulty in recruiting caterers to apply and insufficient funding. HBA caterers felt that insufficient customer awareness was the main challenge (mentioned by 85% and 43% gave this the top ranking). The authors concluded that ‘essential’ recommendations were improved promotion and research into potential improvements (integration with other health programmes, multi-agency working, enhanced support and guidance to caterers), while ‘desirable’ recommendations were greater flexibility (perhaps via a graded scheme) and improved regional co-ordination.	

4. INCENTIVES – FINANCIAL, COMPETITION AND OTHER

SUMMARY

Evidence of efficacy for weight maintenance/reduction
Three US-based RCTs (Forster 1985]; Jeffery 1985; Jeffery 1993) suggested that payroll incentive schemes were either only effective in the short term (i.e. during period of intervention) or ineffective for weight control. Follow-up data suggested that where weight was lost this was regained during the period (of 6–12 months) after the intervention (Forster 1985). The schemes included weigh-in, health education/group sessions and the provision of self-motivating materials.

Evidence of efficacy for diet/physical activity
One controlled before and after study (French 2001) concluded that, when prices of low-fat snacks in 55 vending machines were reduced by 10, 25 and 50%, the total number of items sold increased by 9, 39 and 93% respectively. The effect on energy consumption was unknown.

Evidence of corroboration
No UK corroborative studies found.

EVIDENCE TABLE 4: INCENTIVES – FINANCIAL, COMPETITION AND OTHER

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for weight maintenance/reduction								
Forster 1985 [220]	RCT	1	+	University of Minnesota, USA employees. *n* = 131 82% women Faculty = 11.5% of group instruction/attendance optional group only. Administrative/techical = 35.7 % overall. Clerical = 57.5% overall. Health promotion practitioner.	**Aim:** To evaluate a weight control programme using financial incentives through payroll deductions; weight loss self-instruction manual and food records for monitoring eating behaviours and calorie intake; weigh ins and group educational sessions 2 × 2 factorial analysis of components.	6-month follow-up. (1-year follow-up in further study.*)	4% participation. Overall attrition 21.4%. Mean weight loss 12.2 lb (5.53 kg) (or 10 lb [4.54 kg] by ITT analysis) was highest in those using self-instruction and not receiving incentives for weight loss, but there was no statistically significant difference between groups. Weight loss was positively associated with attendance at weight ins and educational sessions. Men more likely to achieve goals than women ($p < 0.004$), although small number of men may confound this. (After 1 year, over both studies (Forster (1985) and Jeffery (1985))), 79% regained some weight and 33% regained at least as	Some baseline differences and no allocation concealment. *Forster 1988

							much as they lost. Percentage maintaining post-treatment weight was not statistically significant. Differences between occupational groups of % maintaining post-treatment weight were not statistically significant (*p* = 0.07).*	
Jeffery 1993	RCT	1	+	Minnesota, USA. *n* = 2041 Thirty-two worksites (68.8% private sector in treatment and 56.3% in control). 400–900 employees (55% female in treatment group and 52.9% in control). 41% managerial/professional 41% clerical/sales 18% blue collar Mean BMI for both men and women 10% above actuarial ideals. Professional Health	**Aim:** To evaluate the effectiveness of a work-site health promotion programme in reducing obesity and prevalence of cigarette smoking. Health education classes combined with a payroll-based incentive scheme. Four rounds of 11 bi-weekly sessions over 2 years.	Two years concurrent with intervention.	20% participation in weight control programme. 23% reenrolment. Ineffective for weight and BMI change over 2 years, and no significant differences between treatment and control (all *p* > 0.50). Average weight loss 4.8 lb [2.18 kg] in intervention group. 83% participants in weight control programme were female. 43% were professional, 45% were clerical and 13% were blue collar. Blue collar workers, men and those who were less overweight were less likely to join programme.	No allocation concealment and no ITT but high total response rate (93%). **Healthy Worker Project.**

				Educators.				
Jeffery 1985	RCT	1	+	University of Minnesota, USA employees. *n* = 36 (of 675 invited). Two groups. Female = 86% overall Mean age = 42 years 22% faculty 45% administrative/technical 33% clerical/ Intervention delivered by a Health Promotion practitioner.	**Aim:** Pilot study for above To evaluate the effectiveness of a self-motivation programme of biweekly payroll deductions on weight control. Treatment and delayed treatment. Intervention was a self-motivation programme with incentives through payroll deductions.	6-month intervention + 3-month extension. (1-year follow-up in further study, Forster et al 1998)	6% participation. Attrition 11% in control group. Effective for weight loss in the short term (mean 12.3 lb [5.58 kg]). Weight losses significantly related only to attendance at weigh-ins ($p < 0.001$). Those who re-enrolled for further 3 months were three times more likely to lose weight than those who stopped ($p < 0.005$). Weight regained within 1 year (see above*). There were no statistically significant differences between job categories and age in terms of weight lost. The authors concluded that without continued intervention, worksites do not appear to offer special advantages in aiding weight control (Forster et al. 1988)	Modest baseline differences, no allocation concealment and no ITT analysis. However 94% completed the programme and 88.4% completed more than half the weigh-ins. Generalisable to motivated workers only.

5. INCREASED ACTIVE TRAVEL TO AND FROM WORK – INCLUDE PEDOMETERS

SUMMARY

Evidence of efficacy for weight management/reduction
No studies with weight outcomes found.

Evidence of efficacy for diet/physical activity outcomes
There is evidence from one low quality controlled randomised study carried out in the UK (Mutrie 2002) and one before and after study in Finland (Oja 1991) that workplace promotional strategies can increase the number of people travelling actively to work. The UK study (Mutrie 2002) found that the intervention group was almost twice as likely to increase walking to work as the control group at 6 months (125 min walking per week vs. 61 min in the controls at 6 months; odds ratio (OR) 1.93, 95% CI 1.06, 3.52). The intervention (provision of written interactive materials) was not successful at increasing cycling. Of those who received the intervention at baseline, 25% (95% CI 17, 32) had increased their active commuting stage of change to action of maintenance at 12 months.

Evidence of corroboration
One study carried out in the UK.

Suggestions for improvements that could be made by management included incentives for active commuting, reminders, encouragement of partial active commuting, safe covered cycle storage and on site showers and changing facilities.	

6. PHYSICAL ACTIVITY PROGRAMMES

SUMMARY

Evidence of efficacy for weight management/reduction
There is inconclusive evidence for the effect of physical activity interventions on body weight, BMI and body fat.

Of four RCTs only one (Pritchard 1997) found a significant effect on body weight between intervention and control groups (Pritchard 1997) with one RCT noting a significant before and after difference in the exercise group (2 kg, $p < 0.025$) with no significant difference in the control group (+0.7 kg; Grandjean 1996). Interventions focused on specific exercise sessions, about three times per week, all aerobics, with exception of Grandjean (1996) who encouraged walking, cycling and jogging. Trials were all very small and generally not of high quality. In addition, the amounts of exercise prescribed did not meet the levels recommended in the Chief Medical Officer's report *At Least Five a Week* (London: Department of Health, April 2004, http://www.dh.gov.uk/assetRoot/04/08/09/81/04080981.pdf).

Evidence of efficacy for physical activity outcomes
Results from a systematic review (Proper 2003) support the implementation of worksite PA programmes.

The overall conclusion of the review, based on five RCTs (two of high quality) and three non-randomised controlled trials was that there was strong evidence for a positive effect of PA programmes on PA. One study designated by the reviewers as a high quality RCT, the Working Healthy project (Emmons 1999), evaluated the effect of the programme at both the midpoint (1.25 years) and the endpoint (2.5 years). It was found that participants had significantly increased their self-reported participation in regular exercise by 10.4 (interim) and 11.9% (end) vs. 2.4 and 1.7% for the reference condition. The other study considered as a high quality RCT (Pritchard 1997) showed a greater increase of energy expenditure in the intervention group compared with the reference and diet group after 12 months(+14.6 vs. 6.5%).

Evidence of corroboration
No UK evidence of corroboration.

EVIDENCE TABLE 7: INCREASED ACTIVE TRAVEL TO AND FROM WORK – INCLUDE PEDOMETERS

Evidence of efficacy (internal validity) for weight maintenance/reduction								
Pritchard 1997	RCT	1	+	Business corporation. Overweight men. *n* = 66 Australia.	**Aim:** To compare total and regional body composition after subjects lost weight through change in diet or exercise. 30 minute aerobic exercise programme (minimum 3 × per week, at 65–75% of maximum heart rate), diet programme (reduced fat) or no intervention control. Bi-monthly meetings for all subjects and monthly counselling for intervention.	12 months	Fifty-eight included in analysis. Change in weight and BMI were significantly different in subjects in the intervention groups compared with control ($p < 0.05$). Change in weight –3.0% in exercise groups and –7.2% in diet group vs. +1.0% in control group. BMI –4.4% in exercise group and 8.2% in diet group vs. +1.0% in control.	No allocation concealment, no ITT but 88% follow-up.
Grønningsäter 1992	RCT	1	+	Insurance workers. Physically inactive.	**Aim:** To study the effects of two types of stress-reduction interventions on physically inactive	10 weeks and 6 months	*n* = 79 randomised into groups. Seventy-six included in 10-week analysis, of which 48.7% were women.	No allocation concealment, no ITT *but* 91% follow-up. No specific body

				$n = 193$ Oslo, Norway. Age range 25–67 years All administrative levels of employees represented.	employees. Aerobic exercise (55 min sessions 3 days per week for 10 weeks, at 70–80% of maximum heart rate) vs. stress management vs. no intervention control.		Seventy-two included at 6-month follow-up. Average attendance 80% women and 76% men in aerobic physical exercise group. No effect on body weight. No significance stated.	weight data given.
Grandjean 1996	RCT	1	+	Westinghouse Corporation, Texas, USA. Thirty-seven female blue collar workers.	Walking, jogging and cycling three times per week for 20–60 min vs. control (no intervention).	24-week intervention. No follow-up.	100% follow-up. Significant effect on body weight (2 kg weight loss, $p < 0.025$) between before and after measures in exercise group. No change in control group (+0.7 kg) but non-significant difference between groups. Difference in % fat between control and exercise groups approached but did not reach statistical significance ($p < 0.056$).	No allocation concealment. 100% follow-up.
Lee 1997	RCT	1	+	Thirty-seven female University workers aged 40–61 (mean 48.4). 76% secretarial/administrative.	Self-administered programme of low-impact aerobic exercise and education vs. control (wait list group invited to attend second 12-week programme). No power calculation.	12-week intervention. 24- and 48-week follow-up.	35/37 included in the analysis. No significant effect on body fat or BMI at 24 weeks compared with earlier measures. BMI was significantly higher in the exercise group at 48 weeks than 0,12 and 24 weeks; insufficient control group data at 48 weeks were available for analysis.	No allocation concealment. No ITT analysis but 94% follow-up.

Cook 2001	CBA	2	++	Two South Auckland manufacturing worksites. *n* = 347 at intervention and *n* = 262 in control. Voluntary participation and study open to male hourly paid employees. 40% obese at baseline. Huge baseline variations in intervention vs. control sites. Age (mean ± SD) 35.0 ± 11.2 vs. 42.9 ± 11.7 years . European 25.7 vs. 39.7%. ≥4 years at high school 50 vs. 29.8%, etc.	**Aim:** To evaluate effectiveness of health promotion programme targeting dietary behaviours and PA in male hourly-paid workers. Nutrition displays in the cafeteria and monthly 30-min workshop for 6 months. Delayed intervention in control worksite.	After 6 month intervention and at 12 months.	Recruitment 38% at intervention (*n* = 132) and 46% at control (*n* = 121). Follow up = 94% at 6 months and 89% at 12 months. Statistically significant differences between the intervention and control groups, in mean fat score ($p = 0.0003$), increase in vegetable intake ($p = 0.007$) and PA ($p = 0.005$). There was no significant difference in mean BMI or waist circumference between the groups.	Self-reported nutrition and PA measures. Ethnic variations may limit generalisability to UK.
Evidence of efficacy (internal validity) for physical activity outcomes								
Proper 2003	Systematic review	1	++	Literature search of English language papers	**Aim of review:** To review the effectiveness of	Various.	The overall conclusion from five RCTs (two of high quality) and three non-randomised controlled	The two trials designated as sound RCTs

				from 1980 to 2000. Twenty-six randomised or non-randomised studies including 15 RCTs and 11 non-RCTs in all. 7. INCREASED OCCUPATIONAL HEALTH PROVISION AND/OR REFERRAL TO PRIMARY CARE

SUMMARY

No relevant studies found.

8. INCREASED USE OF STAIRS

SUMMARY

Evidence of efficacy for weight management/reduction
No studies found.

Evidence of efficacy for physical activity outcomes
From one interrupted time series study, there is evidence that environmental improvements may increase stair use. Effective actions included re-decoration, motivational signs and music in the stairwell (Kerr 2004). Another interrupted time series study found that posters alone were not effective (Kerr 2001) but a before and after study (Vanden Auweele 2005) that included an email reminder found a temporary improvement while the sign was in place.

Evidence of corroboration
One UK study suggested that posters alone may cause feelings of ‘laziness’ and ‘guilt’ (Kerr 2001).

Cost-effectiveness data
No cost-effectiveness studies found.

Evidence of efficacy (internal validity) for physical activity outcomes								
Kerr 2004	Interrupted time series	2	++	Single five-storey site (Centers for Disease Control and Prevention [CDC]) in Georgia, USA. 74.2% female. Age ≥18 years. 66.4% white, 28.2% African American. 554 permanent employees and 110 temporary.	**Aim:** To assess the impact of stair use of four sequential environmental changes to the stairwell. 1) New carpeting and paint October 1998; 2) Artwork December 1998; 3) Motivational signs September 1999 4) Music in stairwell October 2001.	3.5 years in all.	Both motivational signs and music significantly increased stair use by 8.9% over baseline ($p < 0.05$).	Other factors may have influenced stair use during the study period. The workforce may have been more motivated given their work in a health promotion area.
Kerr 2001	Interrupted time series	2	++	Two accountancy firms (one nine-storey and one four-storey) in the	A1-sized poster reading 'Stay healthy, use the stairs'.	Two-week baseline plus 2-week	There was no significant effect of the poster on stair use in either site. Site one: OR 1.04 (95% CI 0.92, 1.18). Site two: OR 1.22	Very short-term study. The authors

				midlands, UK.		intervention (4-week in second firm). Questionnaire after further week.	(95% CI 0.96, 1.55). The message, however, made 62% and 47% of respondents respectively feel guilty or lazy.	speculated that the feelings of laziness and guilt may have caused workers to reject the message.
Vanden Auweele 2005	Before and after	2	+	131 women in an almost entirely female (131/135) workplace (a socio-cultural organisation) in Belgium. No socio-economic details provided.	**Aim:** To evaluate the impact of two simple interventions aimed at promoting stair use among female employees at a five-floor worksite. After a baseline week an intervention in the first week involved a health sign placed at the junction between the staircase and the elevator. In the second week an email was sent by the worksite's doctor, pointing out the benefits of stair use. The sign was removed 4 days after the observations in the second week. Follow-up data were collected 4 weeks after the second	One-week baseline collection plus one week with sign, plus one further week following email. Follow-up 4 weeks after second intervention week.	In total, 3146 observations were made. Stair use increased significantly from 69% at baseline to 77% during the week after the first intervention ($p < 0.001$). Compared with the first intervention, stair use increased significantly to 85% in the week after the second intervention ($p < 0.001$). However, stair use decreased to 67% at follow up 1 month after the sign was removed and was not significantly different to baseline ($p = 0.52$).	Short term before and after study only. Reliable data collection (observation) but observers were visible.

					intervention week (i.e. 6 weeks post baseline). No power calculation. Higher education intervention. Observers were sport-management students.

Site one: OR 1.04 (95% CI 0.92, 1.18). Site two: OR 1.22 (95% CI 0.96, 1.55). The message, however, made 62% and 47% of respondents respectively feel guilty or lazy.	Very short-term study. The authors speculated that the feelings of laziness and guilt may have caused workers to reject the message.

9. STRATEGIES TO INFLUENCE WORKPLACES TO INVEST IN THE HEALTH AND ACTIVITY OF THEIR WORKFORCE (INCLUDES EFFECTS ON EMPLOYEE SICK LEAVE)

SUMMARY

Evidence of efficacy

The evidence base for strategies to influence workplaces is weak. Although there are some indications that sick leave is reduced in workers who have received worksite PA interventions the body of evidence is inconclusive. An RCT found no statistically significant difference although a trend to reduced sick leave was evident (Nurminen 2002). A controlled before and after study (Kerr 1993) found a decrease of sick leave in intervention groups and an increase in controls ($p = 0.04$)

Evidence of corroboration

No evidence for UK corroboration found.

EVIDENCE TABLE 9: STRATEGIES TO INFLUENCE WORKPLACES TO INVEST IN THE HEALTH AND ACTIVITY OF THEIR WORKFORCE (INCLUDES EFFECTS ON EMPLOYEE SICK LEAVE)

The studies included below do not relate to weight, PA or diet outcomes. There is no evidence for efficacy in relation to either of these.

DATA SOURCES

Database searches were carried out in October 2004 for papers published from 1990 onwards (1995 onwards for systematic review level evidence).

The following information sources were searched:

AMED (Allied and Complementary Medicine)
ASSIA (Applied Social Sciences Index and Abstracts)
British Nursing Index
CAB Abstracts - Human health and nutrition, agriculture
CENTRAL (Cochrane Controlled Trials Register)
CINAHL (Cumulative Index to Nursing & Allied Health Literature)
Clinical Evidence - http://www.clinicalevidence.org
Cochrane Database of Systematic Reviews
NHS EED (NHS Economic Evaluation Database) - http://www.york.ac.uk/inst/crd
DARE (Database of Abstracts of Reviews of Effects)
Embase
EPPI-Centre - http://eppi.ioe.ac.uk/
ERIC (Educational Resources Information Centre)
Food Standards Agency - http://www.food.gov.uk/science/research/
HDA Evidence Base - http://www.hda-online.org.uk/html/research/effectiveness.html
Health Evidence Bulletins – Wales - http://hebw.cf.ac.uk
HealthPromis
IUHPE (International Union for Health Promotion and Education) - http://www.iuhpe.nyu.edu/pubs/index.html
Medline
NCCHTA (National Coordinating Centre for Health Technology Assessment) - http://www.ncchta.org
NICE (National Institute for Clinical Excellence) – www.nice.org.uk
Public Health Effectiveness (Hamilton, Ontario) - http://www.health.hamilton-went.on.ca/CSCARB/EPHPP/ephpp.htm
PsycINFO
SIGN (Scottish Intercollegiate Guidelines Network) – http://www.sign.ac.uk
Social Science Citation Index (equiv. to Current Contents)
Sociological Abstracts
Sport Discus
Lisa Janzen (Canadian workplace health specialist) contacted.

Update searches

An update search of the same databases was carried out in September 2005 for worldwide intervention and UK corroborative studies. A final search was completed on 1 December 2005 for systematic reviews and controlled trials only in a reduced number of databases: CINAHL, Cochrane, Embase, Medline and PsycINFO.

The search strategies were developed in Medline and adapted for use with the other information sources.

Appendix 9

Community-based interventions to prevent obesity (‘Community 1’)

EVIDENCE SUMMARY TABLES

1. GENERAL PUBLIC HEALTH, OR PUBLIC HEALTH LINKED, INTERVENTIONS FOR THE PRIMARY PREVENTION OF OBESITY

SUMMARY

Evidence of efficacy for weight management/reduction

Twelve randomised controlled trial (RCTs) and one controlled before and after study (CBA) were identified which reported weight outcomes. Results suggest that sustained interventions which focused on diet and activity or provided counselling support were more likely to lead to positive trends in the maintenance of healthy weight/prevention of unhealthy weight gain compared with interventions which focused on physical activity (PA) or diet alone though no firm conclusions can be reached.

Diet and activity

Of the five RCTs which addressed diet *and* activity (Murray 1990; Fries 1993; Jeffrey 1999; Simkin Silverman 2003; Dzator 2004) only one (Simkin Silverman) found a significant prevention of unhealthy weight gain, although Fries and Jeffrey noted positive but non-significant trends. Murray, who compared two eating-management and one weight-loss programme with a PA control group, noted greater weight reduction in the weight loss group immediately after the intervention (10 weeks post-baseline), but this benefit was lost at 1-year follow-up. The latter four studies were based in the USA, one of adult men and women (Murray), one of retirees of both sexes (Fries), one of middle-aged women (Simkin Silverman) and one weak study among younger men and women (Jeffery). All four tended to be among higher socio-economic status (SES) populations. Simkin Silverman was an intensive intervention delivered by behavioural psychologists and nutritionists compared with relatively low-intensity interventions reported by Murray, Jeffrey and Fries. A relatively small RCT of Australian couples (Dzator) found no evidence that the intervention prevented unhealthy weight gain despite reporting improvements in diet.

One relatively large US-based study (Elder 1995) considered the effectiveness of a counselling programme focusing on preventive strategies, including individualised goal-setting for older people. Results appear to suggest that participants were more likely to maintain their weight over a 48-month period than those in the control group.

Diet alone

A CBA trial of a community food skills programme for a mostly female group in eight deprived areas of Scotland (Wrieden 2002) noted a slight decrease in mean weight (–0.6 kg) in the intervention subjects at 6 months post-intervention compared with the slight increase (1.8 kg) seen in control subjects ($p = 0.049$).

Physical activity alone

One US RCT of predominantly older, higher SES, white adults (Stewart 2001) found that information and support provided by trained staff and counsellors resulted in a significant self-reported reduction in body mass index (BMI), compared with no change in BMI among the control group.

Three US-based studies (Coleman 1999; Dunn 1999; Schmitz 2003) found no difference in weight loss between intervention and control groups but did result in significant changes to fat free mass/percentage body fat. Two of these studies were of low intensity (Schmitz focused on strength training, Coleman on daily

30-min walks). One (Dunn) compared ‘exercise on prescription’ with 6-month fitness centre membership for participants. In this study both the intervention and lifestyle group (behavioural intervention to be moderately active on most days) improved their percent body fat.

Two RCTs found no evidence of effect (Pereira 1998; Hillsdon 2002). A low-intensity UK-based study (Hillsdon) among middle-aged adults found no difference in weight between study participants who received a ‘brief negotiation’ or ‘direct advice’ and control group. However, follow-up of participants in this study was poor. Pereira reported no weight differences at 10-year follow-up of US postmenopausal women, although women encouraged to walk as part of the original trial continued to walk significantly more than the control group.

Evidence of efficacy for diet/physical activity outcomes

Dietary outcomes

A high quality systematic review (Pignone 2003) concluded that moderate or high intensity interventions can reduce consumption of saturated fat and increase the intake of fruit and vegetables. Briefer interventions delivered by primary care professionals were also effective but resulted in smaller changes to diet. However, the effect size was to some extent dependent on the number of components included in (i.e. the intensity) of the intervention. Based on complex definitions of effect sizes (for details see Pignone 2003) the authors found that the six studies with three of more components produced medium or large effect sizes.

The findings of the review were supported by three more recent RCTs (Havas 2003; Carpenter 2004; Dzator 2004) and an RCT that was not included in the review (Havas 1998). Carpenter demonstrated improvements to diet in middle-aged women (as measured by a modified healthy eating index) from either group meetings or advice via mail or website with a larger effect from the weekly group meetings. Dzator also found that interactive sessions and/or advice by mail over a 16-week period to couples resulted in improvements to total fat, fibre, and fruit and vegetable intake at 4 months and total fat intake at 12 months follow-up. Marginal improvements were reported in the high intensity versus the low intensity intervention but no significance values were reported.
Two multi-component personalised educational RCTs with lower SES US women, based on social marketing strategies (Havas 1998, 2003), resulted in significant increases in fruit and vegetables in both studies and, also, a reduction in fat and an increase in fibre in the later study (Havas 2003).

Two CBAs were identified (Wrieden 2002; Department of Health 2003), both carried out in the UK. A national before and after evaluation of *Five a Day* pilot projects in five UK communities (Department of Health 2003) concluded that the initiatives stemmed a fall in fruit and vegetable intake against the national trend (a fall in intake in the control group of 0.5 portions per day compared with no change in the intervention group). However a severe lack of methodological detail limits the strength of the conclusions that can be drawn. A community food skills programme for a mostly female group in eight deprived areas of Scotland (Wrieden 2002) resulted in an increase of one portion per week for fruit ($p = 0.047$) immediately post-intervention but this was not sustained at 6-month follow-up.

See also Broader Community Review (Table 1: supermarkets).

Physical activity

One high quality systematic review and nine more recent RCTs considered the effectiveness of interventions to increase PA levels.

The systematic review (Hillsdon 1996) identified a lack of UK-based research but was able to conclude that interventions to encourage walking and non-facility based activity are most likely to lead to sustainable increases in PA (up to at least 2 years). Only two of the more recent RCTs (Jeffery 1999; Schmitz 2003) did not support these conclusions. A small study finding no significant increase in PA among the intervention group (Schmitz) and a further weak RCT where the statistical values were unclear (Jeffery). The majority of studies were among motivated, higher SES groups but were undertaken among both males and females, a range of age groups, and through a range of delivery methods (e.g. mailed information, brief advice, structured programmes and counselling).

Evidence of corroboration in the UK

Of the intervention studies, one RCT focusing on PA (Hillsdon 2002) and two CBAs concentrating on diet change (Wrieden 2002; Department of Health 2003,) were carried out in the UK. In addition, many of the non-UK interventions identified could be generalisable to the UK, particularly for motivated individuals of higher social status.

In terms of implementation, five UK studies were found. Three (Lloyd 1995; Anderson 1998a; Wrieden 2002) considered barriers to dietary change and one considered potential barriers to increasing walking (Vernon 1998). The dietary studies identified practical issues that could reduce the effectiveness of an intervention (e.g. considering concerns around taste, cost, availability and time), but suggest that once these were addressed participants may be receptive to change, particularly in relation to increasing fruit and vegetable consumption. In terms of walking, the most significant barrier was lack of time reflecting findings of RCTs that compliance was likely to be better with less time demanding interventions (i.e. home- rather than facility-based). A weak UK study looking at the role of community recruited and trained nutrition assistants to provide healthy eating advice and support food related activities (Kennedy 1999) found that a fourfold increase in coverage resulted and that the majority of respondents preferred advice from a local person rather than a health professional, perceiving them to be more approachable and easier to access.

EVIDENCE TABLE 1: GENERAL PUBLIC HEALTH, OR PUBLIC HEALTH LINKED, INTERVENTIONS FOR THE PRIMARY PREVENTION OF OBESITY

First author	**Study design**	**Res type**	**Research quality**	**Study population**	**Research question and design** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for weight maintenance/reduction								
Dzator 2004	RCT Individual	1	+	Couples in Perth, Australia recruited by press and media publicity. Average age 29.4 (SD 8.2) years. No further details other than (in discussion) 'Higher socioeconomic status, based on occupational classification, was over-represented'.	**Aim:** To compare the effects of a diet and PA programme in couples. Couples were randomised to a: (1) programme delivered mainly by mail; (2) a combination of mail and interactive group sessions, or (3) control group. Power calculation: *p* = 0.05 with a power of 80% as a minimum. **Delivered by:** Health promotion professionals, including an exercise physiologist, a clinical nurse and a	16-week intervention. 8-month follow-up (1 year after baseline).	81% completed to 16 weeks (111/137). 59% completed to 1 year (81/137). Diets improved up to 12 months after beginning the 4-month programme, mainly in the interactive group. There were no significant differences for BMI at either four or twelve months in or between any of the groups (*p* = 0.210 at 4 months and *p* = 0.121 at 12 months).	No allocation concealment. Unclear whether the diet and PA questionnaires were validated. Intention to Treat (ITT) used. Motivated (volunteer) and higher SES couples.

					dietitian/nutritionist.			
Schmitz 2003	RCT Individual	1	+	Volunteer female staff and students from the University of Minnesota, USA. Self-reported BMI 20–35 kg/m^2. 100% women aged 30–50 (average 41.8, SD 6.4) years. 90% White, 10% African American or Asian. 85% had completed college.	**Aim:** To assess whether reductions in fat from 15 weeks supervised strength training would be maintained over 6 months of unsupervised exercise. Blocked randomisation by age to a 50-min strength training class twice weekly for 15 weeks followed by 6-month membership to exercise facility or no intervention control **Delivered by:** Supervised training by exercise trainer.	15 weeks supervised, then 6 months unsupervised training.	93% (56/60) of all women completed the study. Twice weekly strength training is behaviourally feasible for busy midlife women and the favourable body composition changes can be maintained over time. Over the total 39 weeks of strength training, the treatment group gained 0.89 kg more in fat free mass (*p* = 0.009), lost 0.98 kg more in fat mass (*p* = 0.06), and lost 1.63% more in percent body fat (*p* = 0.006) compared with control. Strength training did not result in any significant weight loss or waist circumference attenuation; however, there was a significant decrease in percent body fat with intervention compared with control.	Numerous exclusion criteria. No allocation concealment or ITT but 93% follow-up. Participants received US$200 for successful completion of the study. Motivated (volunteer), mostly White and higher SES individuals. This study may also be of relevance to the workplace review.
Simkin-Silverman 2003	RCT Individual	1	++	US study, Pennsylvania. 535 healthy premenopausal volunteer women aged 44–50 (mean age 47, SD 1.9) years with	**Aim:** To examine whether a behavioural intervention aimed at lifestyle changes in diet and PA can prevent the rise in weight and low-density-lipoprotein	54 months.	Attendance was consistently excellent, averaging 90%, with 95% (509/535) attending the 54-month assessment. 80% of intervention participants compared with 45% of controls were at or under baseline weight at 18 months, and 55% compared	Data to 18 months and background information reported in Simkin-Silverman 1998 The Women's Healthy Lifestyle Project. Study had 90% power

				average BMI 20–34 kg/m^2 (approx. half with normal weight at baseline). Participants were predominantly white (% not stated), 85% educated beyond high school and 86% employed.	(LDL)-cholesterol often observed during menopause. Intensive intervention to lower dietary fat and encourage PA and modest weight loss via group meetings and personalised plans. Assessment only control group. **Delivered by:** Behavioural psychologists and nutritionists.		with 26% at 4.5 years (p < 0.001), suggesting that weight gain during peri- to postmenopause can be prevented with a long-term lifestyle dietary and PA intervention. The mean weight chance in the intervention group was 0.1 kg below baseline compared with an average gain of 2.4 kg in the control group.	to detect an effect. Essentially White, well educated and motivated (volunteer) women.
Hillsdon 2002 UK Study	RCT Individual	1	+	Healthy sedentary men and women from two medical centres in Wellingborough, UK. n = 1658 Mean age = 54.9 (range 45–64) years 49% male 9.4% non-White 10.3% higher educated 44.8% no	**Aim:** To compare two low intensity communication styles in a one-to-one intervention: 1) Brief Negotiation (BN) with client centred consultations; 2) Direct Advice (DA) with info on benefits of PA; and encouragement 3) No intervention control.	1 year (Intervention phone calls until 8.5 months.)	32% follow-up in BN group 33% follow-up in DA group 62.5% follow-up in control Those who undertook less that one 30-min occasion of PA per week at baseline were less likely to complete the final log book than those doing at least that amount (odds ratio [OR] 0.29, 95% confidence interval [CI] 0.16, 0.53). No significant between group difference in weight change for BN and DA groups: Mean change from baseline at 12	Randomisation not clearly described but allocation concealment used. Low follow-up but ITT.

				education	Both intervention groups received 30 minute baseline intervention and telephone calls at 2, 6, 10, 18, 26 and 34 weeks relevant to intervention. **Delivered by:** Health promotion specialist.		month follow-up (95% CI): BN: 0.0 (–0.2, 0.2) DA: 0.01 (–0.2, 0.2) Between group difference: –0.03(–0.36, 0.30), *p* = 0.86 (adjusted for baseline BMI, age and energy expenditure). No results stated for difference between intervention vs. control in BMI change.	
Stewart 2001	RCT Individual	1	+	Volunteers from two Medicare health maintenance organisations in the US (California?). 66% female. Mean age 74 (SD 6), range 65–90 years. 8.5% minority groups. 18.9% high school education or less. 22% with graduate degree.	**Aim:** To compare the effectiveness of a choice-based PA programme to increase PA levels of seniors with control group who were offered programme at the end of the year Trained staff assisted participants to develop and maintain a PA regimen that they would be capable of sticking with. Information, support and opportunities for skill building were provided through numerous activities	1-year intervention. No follow-up.	Recruitment 85% (893/1053) of those eligible who responded to invitation. Only 173 were randomised to trial but 95% completion (164/173). Individually tailored programmes to encourage lifestyle changes in seniors may be effective. Self-reported data suggested that the intervention group subjects reduced their BMI from baseline by 0.496 kg/m^2 (*p* = 0.0001), whereas there was no significant change in the control group (*p* = 0.004, not significant).	The CHAMPS II Study, based on social cognitive theory. No allocation concealment or ITT but follow-up = 95%. Validated PA measure. Motivated (volunteer) mostly white, older, female majority and higher SES. Many subjects had health problems.

					(including ten workshops). Regular staff initiated phone calls from a counsellor. **Delivered by:** Trained staff and counsellors.			
Coleman 1999	RCT Individual	1	+	Forty-seven sedentary adult volunteer employees at the University of Buffalo, NY, USA (not engaging in vigorous intensity exercise at least three times per week for at least 20 min per session). Average BMI approx. 25.8 kg/m^2. 84% female, average age approx 43.1 (range 18–55) years. Almost exclusively White, well educated and SES 50–53 on a scale of 8–66.	**Aim:** To test different ways of meeting the recommendations for 30 min of moderate intensity activity on most days of the week. Volunteers were randomised to brisk walking 6days per week in: 1) continuous bout; 2) three 10-min bouts; (3) Any combination so long as each bout was at least 5 min. Academic researchers. **Delivered by:** Activity counsellors.	16-week intervention. 16-week follow-up.	77% (36/47) began study and 89% of those (32/36) completed to 16 weeks. A walking prescription of 30 min per day on most days of the week with the choice to walk in as little as 5-min bouts can improve body composition, as well as help sedentary people maintain these improvements over time. Percentage body fat was significantly reduced from baseline to 32-week follow-up in all groups (p = 0.03) although there was no significant change in body weight. No significant effects observed between groups.	No allocation concealment. No ITT but 85% follow-up. Study likely to be underpowered as small study (47 volunteers only from University). Motivated (volunteer), mostly female, white and high SES. Objective measure of activity using the TriTrac accelerometer as well as self-reported measures. Participants deposited US$50, refunded in segments for completion of assessments and good attendance. This paper may also be of relevance to the workplace review.

Dunn 1999	RCT Individual	1	+	Healthy sedentary men and women (self-reported PA of less than 26 and 24 kcal/day respectively) from Dallas, Texas, USA. Most modestly overweight but none >140% over ideal weight. 50.5% women. Average age 46.0 (± 6.6, range 35–60) years. Stated that 'Highly educated' but no details given.	**Aim:** To compare a lifestyle PA programme with traditional structured exercise. Academic research group. Used the Stages of Change model. The structured exercise group received a traditional exercise prescription for 6 months at a fitness centre individualised to participants after first 3 weeks, followed by meetings and correspondence during follow-up. **Delivered by:** **'**Group leaders' and project staff. Higher education study. The lifestyle group received an intensive behavioural intervention to encourage 30 min moderate intensity	6 months intensive. 18 months maintenance.	Of 122 participants in the lifestyle group 89% (109/122) completed to 6 months and 82% (100/122) to 24 months. Of 115 in the structured group 90% (103/115) completed to 6 months and 78% (90/115) to 24 months. In initially sedentary healthy adults, a lifestyle PA intervention is as effective as a structured exercise programme. Over 24 months, neither group significantly changed their weight from baseline (–0.05 [95% CI –1.05, 0.96], *p* = 0.93] kg) and +0.69 [95% CI –0.37, 1.74] kg, *p* = 0.20, but each group significantly reduced their percentage of body fat from baseline (–2.39 [95% CI –2.92, –1.85]%, *p* < 0.001 and –1.85 [95% CI –2.41, –1.28]%, *p* < 0.001) in the lifestyle and structured activity groups respectively. No significant differences between groups (*p* = 0.17 for % body fat and *p* = 0.32 for weight).	Lacks a no-intervention control group. No allocation concealment but ITT used. Unclear how participants were recruited but probably volunteers. Highly educated. Measurement staff were blinded to allocation.

					PA most days but no fitness centre membership, followed by less regular meetings and correspondence. **Delivered by:** 'Group facilitators'			
Jeffery 1999	RCT Individual	1	+/– (weak)	Men and women recruited from diverse sources, Minnesota, USA. *n* = 1226 18.6% men 40.5% of women were low income (household incomes of US$25000 or less per year). Mean age = 38.4 years 90.7% white 89% with at least some college education Average BMI = 26.7 kg/m².	**Aim:** To evaluate effectiveness of low-intensity intervention to prevent weight gain with age. No-contact Control compared with: 1) education through monthly newsletters (questionnaire postcard included) encouraging paying attention to weight and making small changes in diet and exercise habits; and 2) education + incentives (entry into US$100 lottery if questionnaire postcard returned). Intervention subjects had option for participation in	3 years (Newsletters continued throughout 3 years.)	106 women who become pregnant excluded from the analysis. 809/1120 (72%) completed all data collection visits. Significant increase between intervention groups and control in self-reported frequency of healthy weight loss practices (including reducing energy intake, increasing exercise and fruit and vegetables intake and decreasing fat intake) ($p = 0.01$), related to a reduced rate of weight gain over time. Point estimates for rate of weight gain over three years were slightly lower in both intervention groups than control, but differences between all groups not statistically significant, $p = 0.88$.	No description of randomisation, no allocation concealment or ITT. **Baseline differences:** Mean BMI higher in education-only group. Higher % of whites in two education groups (92% and 93%) than in control (87%). Parallel analyses with subjects completing only partial data (1101/1120 – 98.3%) yielded very similar findings and are not described in paper. Pound of Prevention study.

					community activity every 6 months. Annual study visits for all participants. **Delivered by:** Researchers (although 6-monthly activities delivered by various including nutritionists).			
Pereira 1998	RCT Individual	1	+	Volunteer postmenopausal women from the Pittsburg, Pennsylvania, USA. Average age 57.5 ± 4.2 years. No socio-economic data provided but: 'our population of women was basically of the same … socio-economic status' (quoted verbatim from text).	**Aim:** To test the hypothesis that the women randomised to the walking group of a clinical trial were still walking more 10 years later than the women in the control group. Aim of original trial was to investigate the effect of PA on bone loss. The analysis on that this paper was based looks at increases in activity in the subjects of the above trial and factors associated with compliance. **Delivered by:** Original intervention	2-year intervention? (unclear if intervention continued after 2-year follow-up). 10-year follow-up.	85.6% (196/229) were interviewed by telephone at 10 year follow-up. The median self-reported values for both usual walking for exercise and total walking were significantly higher for walkers compared with controls (for both, $p = 0.01$) but there were no weight differences between groups. **In 1985:** BMI (kg/m^2) in walkers 25.9 (SD 4.84) and in controls 24.4 (SD 4.2). **In 1995:** BMI (kg/m^2) in walkers 25.9 (SD 5.02) and in controls 25.7 (SD 4.86).	Two-year results and background info in Kriska 1986 No allocation concealment. ITT carried out and described in detail in Kriska 1986. Telephone interviewers masked to group assignment.

					delivered by exercise leaders.			
Elder 1995	RCT Individual	1	+	Members of health maintenance organisation (HMO), USA. *n* = 1800 76.8% aged 65–74 years 52.5% female 78.5% had income <US$40,000 per year (approximately £21,000) 65.8% had ≥13-years education.	**Aim:** To evaluate the effectiveness of a preventive services intervention trial compared with control. Intervention was 8-week 2-hour workshops with 25 participants in each delivered in community centres. Workshops on self-care and mental alertness. Goal setting delivered via individualised 15 min counselling sessions. **Delivered by:** 'Facilitators'.	8-week intervention. 12- and 48-month follow-up	84% follow-up in intervention and 82% follow-up in control at 12 months. 44.3% follow-up at 48 months across both intervention and control. Repeated-measures analysis showed that the intervention group experienced little change in body mass in the 48-month period Compared with a consistent, though non-significant rise in body mass levels in the control group (*p* ≤ 0.10).	No ITT. No allocation concealment. Difficult to tell if the only difference between groups was the treatment under investigation. Intervention participants received package of preventive interventions including immunizations and clinical tests as part of a larger trial – selected outcome effects may not be solely attributable to the intervention components. Subjects chose to take part in study after being randomly selected for the programme. Therefore subject motivation may have influenced the findings.
Fries 1993	RCT Cluster	1	+	Bank of America Retirees, California, USA. *n* = 4712 Mean age = 68.2 years	**Aim:** To evaluate the effectiveness of low intensity health promotion programme in terms of reduction of health	24 months (Repeat mailings of self-help materials to intervention throughout this	At 12 months 58% follow-up. At 24 months 47% follow-up. Attrition largely attributable to death, loss of eligibility or moving from state of California.	Baseline difference of 1 lb (0.45 kg) between groups in weight over ideal body weight. Group 1 higher at baseline.

				53% Female Highest work grade level = 13.0 (unclear UK comparison).	risk and medical costs. **Group 1:** Low cost (US$30) individualised programme with risk appraisal (signed by physician) and self-help materials delivered entirely by mail. **Group 2:** Risk appraisal with no feedback for first 12 months, then full programme. **Group 3:** Claims data only – control. Research-led. **Delivered by:** Unclear.	time for group 1 and in final 12 months for group 2.)	Non-significant but favourable trend seen at 12 months for weight over ideal body weight, with the between group difference (between group 1 and group 2) being 1 lb (0.45 kg). Group 1 lost 1 lb (0.45 kg) from baseline and group 2 lost 0 lb (0.00 kg).	No allocation concealment. No ITT. High attrition. Possibly generalisable to retirees.
Murray 1990	RCT individual	1	++	208 Participants recruited from the community by a newspaper advertisement in the 'Twin Cities' (Minnesota). Thus participants were	**Aim:** To evaluate several low-intensity intervention programmes designed for the general public to promote dietary change and reduce	Short-term interventions (varying from 4 to 8 weeks) with analysis at 10 weeks (post test) and 1 year (follow-up) after	5% dropped out and a further 14% attended less than half the lessons but an intention to treat analysis was used. Subjects in the weight management programme lost more weight (approx. 5.5 lb [2.49 kg] per person, $p < 0.05$)	No allocation concealment but ITT used. Participants were self-selected. The study was designed to look at cholesterol rather than weight reduction and

				self-selected. Average age 47 (range 25–70) years, 67% female. 89% had completed some education beyond high school, 60% with college degrees. No racial information.	blood cholesterol levels. Participants were randomised to: 1) eating patterns course (four weekly 2-hour sessions on food selection and preparation) including food-preparation/taste-testing component; 2) an identical course without the food-preparation/taste-testing; 3) weight management programme (eight weekly 1-hour sessions); 4) PA programme (four 2-hour sessions with an emphasis on walking). No power calculation. **Delivered by:** Higher education researchers. Classes taught by nutritionists and dietitians recruited from the community.	baseline.	than the control PA group (approx. 1.9 lb [0.86 kg] per person) at post test but both groups returned to within 1 lb [0.45 kg] of their baseline weights at 1 year follow-up. A cholesterol reduction (circa 4%) was maintained to 1-year follow-up in the dietary/weight loss compared with the control (PA) group.	the PA component was used as the control group, thus severely limiting the value of the RCT for weight outcomes. Participants were blocked by gender and past participation in a weight-loss programme.

Wrieden 2002	CBA	2	+	Eight deprived communities in Scotland. **At baseline:** 88% female. Mean age 32.3 (SD 10.2) (range 16–65) years. 72% rented their accommodation, 33% claimed housing benefit, 46% were on income support and 14% received job seekers allowance. Only 4% were employed full time. 64% manual social class, 11% heads of household had never worked. 77% finished full-time education aged ≤16 years, the intervention group having the highest percentage in this category (84%). In all cases a local community worker recruited people to	**Aim:** To develop, implement and evaluate a transferable community-based, food skills initiative aimed at increasing consumption of fibre-rich starchy carbohydrates, fish, vegetables and fruit and decreasing consumption of fat in adults living in areas of deprivation. During 2000–2001 the CookWell programme (ten weekly 2-hour sessions including data) was run in eight locations throughout Scotland for approx 2–3 months in each community (*n* = 6–10 in each intervention group). The development of the programme was informed by preliminary focus groups within the community.	Three-month intervention plus 6-month follow-up. Quantitative evaluations using food diaries, shopping diaries and questionnaires were carried out in intervention and delayed intervention (control) subjects at baseline, immediately post-intervention (circa 3 months) and 6 months later.	Of 113 subjects initially recruited, 93 (82%) completed the baseline assessments and by the 6-month follow-up 63 (56%) had completed some or all assessments. A slight decrease in mean weight (–0.6 kg) was observed for the intervention subjects at 6-months post-intervention and this was significantly different from the slight increase (1.8 kg) seen in control subjects (*p* = 0.049).	The Cookwell study. Reliability of outcome measures unclear and only 56% follow-up.

				take part.	**Delivered by:** Higher education researchers. No power calculation.			

Evidence of efficacy (internal validity) for diet outcomes								
Pignone 2003	Systematic review	1	++	Literature search 1966 – December 2001. Twenty-one RCTs were included, of which 21 study arms looked at patients not selected/identified by risk factors and 13 looked at patients with identified risk factors. Two trials were carried out in the UK (Roderick 1997; Steptoe 1999). Both studies included subjects with identified risk factors for coronary heart disease or with hypcholesterolaemi	**Aim:** To determine the effectiveness of counselling to promote a healthy diet among patients in primary care settings.	Trials had to be of at least 3 months duration with a minimum retention rate at follow-up of 50%.	Moderate- or high-intensity counselling interventions in primary care settings including use of interactive health communication tools (e.g. telephone messages, computer generated mailings), can reduce consumption of saturated fat and increase intake of fruit and vegetables. Brief counselling of unselected patients by primary care providers appears to produce small changes in dietary behaviour, but its effect on health outcomes is unclear. The authors could find no clear relationship between the risk status of patients and the effect size achieved. Studies using a greater number of components (e.g. dietary assessment, family involvement, social support, counselling, targeted advice, goal	Medline only searched but reference list follow-up and experts consulted. Otherwise a sound review methodology.

				a.			setting) had larger effect sizes. Six studies with three or more components produced medium (*n* = 2 studies) to large (*n* = 4 studies) effects (see Pignone for definitions). **Effect of reducing saturated fat consumption:** Six studies achieved large effect (>3% point reduction), five achieved a medium effect (1.3–3% point reduction) and six achieved a small effect (<1.3% point reduction). For the nine studies reporting change in % energy from saturated fat, net reductions ranged from 0.9–5.3% points. From ten studies for increasing fruit and vegetables consumption, three demonstrated small or no increases (<0.3 servings/day), five showed medium increases (0.3–0.8 servings/day), and two showed large increases (1.4–3.2 servings/day) (range 0–3.4 servings/day increase).	
Carpenter 2004	RCT Individual	1	++	Participants recruited from authors' database of subjects who expressed interest in participating in	**Aim:** To determine the effect of a cognitive and behavioural skills building intervention delivered via:	6-month intervention. No follow-up.	98/189 eligible participants randomised (52%). 95% of this group completed 6 months and ITT used. A behaviourally focused	Very small (pilot) study although methodologically strong. Described the majority of subjects as overweight but no BMI

				health related clinical trials, in Dallas, USA. 64% women, average age 49.6 (SD 11.3), range 29–71 years. 87% white. Circa 10% ≤12 years education, circa 30% >16 years education.	1) a small group in 20 weekly meetings [WM]; or 2) correspondence (20 sessions via mail and interactive web site) [CR]; compared with 3) a usual care control group [UC] on improvement in total diet quality. **Delivered by:** Weekly meetings delivered by two staff co-facilitators.		intervention can improve overall diet quality, especially if delivered through small-group meetings, compared with delivery through mail and interactive websites. The WM group significantly improved their Modified Health Eating Index (MHEI) score compared with the CR (*p* = 0.04) and UC (*p* = 0.002) groups. The CR group's improvement in MHEI score was not significantly different from that of the UC group (*p* = 0.19).	data. Used a *modified* form of a validated dietary measure – MHEI adapted from the US Department of Agriculture's Healthy Eating Index. Mostly white, motivated (volunteer) subjects.
Dzator 2004	RCT Individual	1	+	Couples in Perth, Australia recruited by press and media publicity. Average age 29.4 (SD 8.2) years. No further details other than (in discussion): 'Higher socioeconomic status, based on occupational classification, was over-represented in our study'.	**Aim:** To compare the effects of a diet and PA programme in couples delivered by different mechanisms, with control. Couples were randomised to either: 1) programme delivered mainly by mail ('low intensity'); 2) a combination of mail and interactive group sessions ('high intensity'); or 3) control group.	Sixteen-week intervention, Eight-month follow-up (1 year after baseline),	81% completed to 16 weeks (111/137). 59% completed to 1 year (81/137). Diets improved up to 12 months after beginning the 4-month programme, mainly in the interactive group. Both interventions were more effective than control with statistically significant differences at 4 months for a reduction in total fat (*p* = 0.023), grams of fibre (*p* = 0.037) and fruit and vegetable servings consumed (*p* = 0.019).* At 12 months, only the results for total fat remained	No allocation concealment. Unclear whether the diet and PA questionnaires were validated. ITT analysis used. Motivated (volunteer) and higher SES couples.

					Power calculation: *p* = 0.05 with a power of 80% as a minimum. **Delivered by:** Health promotion professionals, including an exercise physiologist, a clinical nurse and a dietitian/nutritionist.		significant (*p* = 0.013).* *Unclear if these results are comparing intervention groups or intervention and control/ There were only marginal improvements in the high intensity intervention group compared with the low intensity intervention group (no significance values given).	
Havas 2003	RCT Cluster with individual analysis	1	+	2066 women (1055 intervention and 1011 control) served by the Special Supplemental Nutrition Program for Women, Infants and Children (WIC) in Maryland. The majority of participants were black (>50%), <30 years, high school graduates, single, unemployed and with incomes <$15,000.	**Aim:** To decrease the percent of energy derived from fat and to increase fruit, vegetable and fibre intake among low-income women served by the WIC programme. Cluster crossover RCT. Intervention participants had a multidimensional intervention, guided by formative research, which included five interactive nutrition sessions, individualised written materials and phone	6-month intervention with 2-month post-intervention follow-up (8 months) and 1 year later.	Of women meeting criteria, 39% at both intervention and control sites agreed to participate. 71.4% of intervention and 74.7% control participants completed the two months survey and 53.1% and 60.2% respectively completed the 1-year follow-up. Mean differences (intervention-control) in change from baseline were for percent energy from fat – 1.62 ± 0.33% (*p* < 0.0001), for consumption of fruit and vegetables 0.40 ± 0.11 servings (*p* = 0.0003), and for fibre intake 1.01 ± 0.31 g (*p* = 0.001). The changes remained significant at 1-year follow-up for the first two outcomes.	No details of randomisation method or allocation concealment although recruiters were blinded re treatment allocation. Intention to treat analysis carried out. Questionnaire piloted but not validated. ITT analysis but 159 participants (7%) were excluding for reporting 'highly unrealistic calorie [energy] intake'. Each woman was given US$20 for completing the post survey and US$20 for 1-year follow-up survey. Meets criteria for a

					calls. Controls received usual WIC care. No power calculation reported. Intervention provided by peer educators. Higher education researchers.			**social marketing** intervention (see methodology).
Havas 1998	RCT Cluster	1	+	3122 low-income women (enrolled in the federally funded Special Supplemental Nutrition Program for Women, Infants and Children, WIC programme) and their children (control condition *n* = 1679, intervention condition *n* = 1443). Subjects recruited during voucher pick-up [66% acceptance during intervention and 87% acceptance during control phase]. Overall the majority	**Aim:** To increase fruit and vegetable consumption among women served by the WIC programme in Maryland. Power calculation to detect 0.5 helping difference. Randomised crossover design. Randomisation by site, analysis by individual and site. The intervention was informed by focus group research and consisted of three components: nutrition sessions by peer educators; printed materials and visual reminders; and direct	Six-month intervention with 2-month (8-months post baseline) and 1 year later (20 months post baseline) follow-up.	Survey completion at 2 months – 75% intervention; 76% of control. At plus 1 year – 64% intervention; 60% control. ITT used. Two months post-intervention, mean daily consumption had increased by 0.56 ± 0.11 servings in intervention participants and 0.13 ± 0.07 servings in control participants ($p = 0.002$). One year later, mean consumption had increased by an additional 0.27 servings in both intervention and control ($p = 0.004$ between groups).	No details of randomisation method or allocation concealment. ITT analysis carried out. More intervention than control participants were black and/or on food stamps and fewer worked. A major concern is the lower baseline consumption of fruit and vegetables in intervention compared with control participants, although the intervention effect was still significant when this baseline difference was controlled for. Questionnaire piloted but not validated. **Ethnic differences:**

				of subjects were black (>50%), <30 years old. single and unemployed.	mail. The control group received the usual WIC programme, which included <10 min of nutrition education. Intervention provided by peer educators. Higher Education researchers.			Subgroup analysis showed that statistically significant changes occurred only among whites and those with at least a high school education. Barriers leading to non-attendance included lack of transportation, work schedules and lack of interest. Each woman was given US$10 for completing post survey. Meets criteria for a **social marketing** intervention (see methodology).
Department of Health 2003	CBA	2	+/–*	National evaluation of *five-a-day* pilot projects in five areas of the UK. No details provided in the executive summary and none available from project despite two approaches (fiveaday@sh.gsi.gov.uk).	**Aim:** To assess the feasibility of implementing an area-wide approach to increasing fruit and vegetable consumption. The intervention included action to improve access to fruit and vegetables by retailers, food co-	1-year intervention with pre- and post-questionnaires.	Response rate information not available but requested by email (see above). The community initiatives stemmed a fall in fruit and vegetable intake against the national trend. There was a fall in intake in the control group by almost half a portion (although baseline data suggested control group had a higher intake by 1.5 portions compared with intervention sites). Overall the intervention had a positive affect	Five-a-day project. Several baseline differences between the control and intervention populations. *Unless response rate information is made available, this study will be potentially severely confounded. Each of the local evaluation sites developed its own

					operatives and targeted promotional activities in the community and by primary health care professionals. Interventions provided by community based cross-sectoral teams in each area. **Delivered by:** Higher education researchers. No power calculation.		on people with the lowest intakes. Those who ate less than five a day at baseline increased their intake by one portion over the course of the study. In contrast, those who ate five or more a day at baseline decreased intakes by about one portion per day. At follow-up, 35% of people in the intervention areas reported improved access to fruit and vegetables compared with 21% in the control area.	evaluation strategy and tools. Due to the variations in methods, it was not possible to compare the results, or draw general conclusion. This paper is relevant to increasing awareness review.
Wrieden 2002	CBA	2	+	Eight deprived communities in Scotland. **At baseline:** 88% female. Mean age 32.3 (SD 10.2), range 16–65 years. 72% rented their accommodation, 33% claimed housing benefit, 46% were on income support and 14% received job seekers allowance. Only 4% were employed full time.	**Aim:** To develop, implement and evaluate a transferable community-based, food skills initiative aimed at increasing consumption of fibre-rich starchy carbohydrates, fish, vegetables and fruit and decreasing consumption of fat in adults living in areas of deprivation. During 2000–2001 the Cookwell	3-month intervention plus 6-month follow-up. Quantitative evaluations using food diaries, shopping diaries and questionnaires were carried out in intervention and delayed intervention (control) subjects at baseline,	Of 113 subjects initially recruited, 93 (82%) completed the baseline assessments and by the 6-month follow-up 63 (56%) had completed some or all assessments. A mean increase equivalent to one portion per week was seen in the intervention group immediately post-intervention for fruit (*p* = 0.047) but no other significant changes were seen. This change was not sustained at 6-month follow-up. Post-intervention quantitative and qualitative assessments suggested that the percentage of people cooking from basic	The Cookwell study. Reliability of outcome measures unclear and only 56% follow-up.

				64% manual social class, 11% heads of household had never worked. 77% finished full time education aged ≤16 years, the intervention group having the highest percentage in this category (84%). In all cases a local community worker recruited people to take part.	programme (ten weekly 2-hour sessions including data) was run in eight locations throughout Scotland for approx 2–3 months in each community (*n* = 6–10 in each intervention group). The development of the programme was informed by preliminary focus groups within the community. **Delivered by:** Higher education researchers. No power calculation.	immediately post-intervention (circa 3 months) and 6 months later.	ingredients increased in the intervention group compared with the control.	
Evidence of efficacy (internal validity) for physical activity outcomes								
Hillsdon 1996	Systematic review	1	++	Literature search 1966–96. Eleven RCTs included of 12 weeks minimum duration; all from the USA. In terms of the location of exercise, seven trials were home-based and seven	**Aim:** To revise and update a previous systematic review of RCTs of PA promotion in apparently healthy, free living adults.	Studies of 12 weeks minimum duration. Seven of the trials included post-intervention follow-up ranging from 2 months to	Interventions that encourage walking and do not require attendance at a facility are most likely to lead to sustainable increases in overall PA. Levels of PA can be increased and the increase can be maintained for at least 2 years. Regular follow-up, which need not be time consuming and expensive, improves the proportion of people able to maintain initial increases.	**Home-based:** Kriska 1986 Lombard 1995 King 1991 Noland 1989 King 1988 King (different arm) 1988 Godin 1987 **Facility-based:** McAuley 1994

				were facility-based.		12 years: Reid 1979; McAuley 1884; Kriska 1886; King 1988; King 1991; Marcus 1993; Lombard 1995.	Five of the seven home-based trials reported a significant positive outcome of the intervention (Kriska, Lombard, King, Noland, King) but only two of the five facility-based trials (McAuley, King). The small number of trials limits the strength of the conclusions and UK research is needed.	King 1988 MacKeen 1985 Reid 1979 Marcus 1993
Dzator 2004	RCT Individual	1	+	Couples in Perth, Australia recruited by press and media publicity. Average age 29.4 (SD 8.2) years. No further details other than (in discussion): 'Higher socioeconomic status, based on occupational classification, was over-represented in our study'.	**Aim:** To compare the effects of a diet and PA programme in couples. Couples were randomised to a: 1) programme delivered mainly by mail; 2) a combination of mail and interactive group sessions; or 3) control group. **Power calculation:** *p* = 0.05 with a power of 80% as a minimum. **Delivered by:** Health promotion professionals, including an exercise physiologist, a clinical	Sixteen-week intervention Eight-month follow-up (1 year after baseline)	81% completed to 16 weeks (111/137). 59% completed to 1 year (81/137). Both interventions were more effective than control with statistically significant differences at 4 months for exercise days per week (0.7 [SE 0.2]% difference from baseline in both intervention groups and 0.2 [SE 0.2]% difference in control group [*p* = 0.048]) but no difference in the high intervention relative to the low intervention group. At 12 months, there was no significant difference between the intervention and control groups. (High intensity intervention 0.3 [SE 0.2]% change from baseline, low intensity intervention 0.5 [0.2]% change from baseline and control 0.3 [0.2]% change from baseline.)	No allocation concealment. Unclear whether the diet and PA questionnaires were validated. ITT analysis used. Motivated (volunteer) and higher SES couples.

					nurse and a dietitian/nutritionist.			
Schmitz 2003	RCT Individual	1	+	Volunteer female staff and students from the University of Minnesota, USA. Self-reported BMI 20–35 kg/m^2. All women aged 30–50 (average 41.8, SD 6.4) years. 90% White, 10% African American or Asian. 85% had completed College.	**Aim:** To assess whether reductions in fat from 15 weeks supervised strength training would be maintained over 6 months of unsupervised exercise. Blocked randomisation by age to a 50-min strength training class twice weekly for 15 weeks followed by 6-month membership to exercise facility or no intervention control. **Delivered by:** Supervised training by exercise trainer.	Fifteen weeks supervised, then 6 months unsupervised training.	93% (56/60) completed the study. Twice weekly strength training is behaviourally feasible for busy midlife women and the favourable body composition changes can be maintained over time. However, there was no significant difference in PA between intervention and control.	Numerous exclusion criteria. No allocation concealment or ITT but 93% follow-up. Energy intake at baseline was higher in the treatment than the control group. Participants received US$200 for successful completion of the study. Motivated (volunteer), mostly White and higher SES individuals. University employees and researchers – relevant to workplace?
Simkin-Silverman 2003	RCT Individual	1	++	US study, Pennsylvania. 535 healthy premenopausal volunteer women aged 44–50 (mean age 47, SD	**Aim:** To examine whether a behavioural intervention aimed at lifestyle changes in diet and PA can prevent the rise in weight and LDL-	54 months.	Attendance was consistently excellent, averaging 90%, with 95% (509/535) attending the 54-month assessment. At both 6 and 18 months, the intervention group had significantly greater overall activity and energy	Data to 18 months and background info reported in Simkin-Silverman 1998 The Women's Healthy Lifestyle Project.

				1.9) years with average BMI 20–34 kg/m^2 (approx. half with normal weight at baseline). Participants were predominantly white (% not stated), 85% educated beyond high school and 86% employed.	cholesterol often observed during menopause. Intensive intervention to lower dietary fat and encourage PA and modest weight loss via group meetings and personalised plans. Assessment only control group. **Delivered by:** Behavioural psychologists and nutritionists.		expended from walking than controls compared with baseline ($p < 0.05$ for all measures). At 54-months the intervention group had significantly greater overall activity ($p < 0.001$) and less energy intake ($p < 0.01$).	Study had 90% power to detect an effect. Essentially White, well educated and motivated (volunteer) women.
Hillsdon 2002 UK Study	RCT Individual	1	+	Healthy sedentary men and women from two medical centres in Wellingborough, UK. *n* = 1658 Mean age = 54.9 years, range 45–64 49% male 9.4% non-white 10.3% higher educated 44.8% no education	**Aim:** To evaluate effectiveness of low-intensity intervention to prevent weight gain with age. 1) Brief Negotiation (BN) with client centred consultations; 2) Direct Advice (DA) with info on benefits of PA and encouragement) with no intervention control.	1 year (Intervention phone calls until 8.5 months.)	32% follow-up in BN group 33% follow-up in DA group 62.5% follow-up in control. Those who undertook less that one 30-min occasion of PA per week at baseline were less likely to complete the final log book than those doing at least that amount (OR 0.29, 95% CI 0.16, 0.53). ITT revealed that both intervention groups and control group significantly increased PA (energy expenditure in kcal [kJ]/kg per week) from baseline with no significant differences between combined	Randomisation not clearly described but concealment allocation used. Low follow-up but ITT.

					Both intervention groups received 30-min baseline intervention and telephone calls at 2,6,10,18,26 and 34 weeks relevant to intervention Power calculation: Sample size of approx 260 per intervention group (allowing for 10% loss to follow-up) was needed for 76% power to detect a difference of 5 kcal [21 kJ]/kg per week between the two intervention groups, and 87% power to detect a difference of 5 kcal [21 kJ]/kg per week between the combined intervention groups (BN + DA) and the control. **Delivered by:** Health Promotion Specialist.		intervention groups and control group: 3.7% difference (95% CI 4.7, 12.5) (*p* = 0.39), and no significant differences in PA (energy expenditure) between both intervention groups (10.2% difference (95% CI –3.9, 26.1), *p* = 0.16). BN groups who completed the study increased their PA significantly more than controls (24 [95% CI 7, 44]%, *p* < 0.01) No significant difference in energy expenditure between DA completers and control. (Values adjusted for baseline energy expenditure, age, gender, health status, employment, education and home ownership.)	
Stewart 2001	RCT Individual	1	+	Volunteers from two Medicare health maintenance	**Aim:** To examine the effectiveness of a	1-year intervention. No follow-up.	Recruitment 85% (893/1053) of those eligible who responded to invitation. Only 173 were	The CHAMPS II Study, based on social cognitive

				organisations in the US (California?). *n* = 173, randomised of 893 eligible 66% female. Mean age 74 (SD 6, range 65–90) years. 8.5% minority groups. 18.9% high school education or less. 22% with graduate degree.	choice-based PA programme to increase PA levels of seniors, compared with control group who were offered programme at the end of the year. Trained staff assisted participants to develop and maintain a PA regimen that they would be capable of sticking with. Information, support and opportunities for skill building were provided through numerous activities (including ten workshops). Regular staff-initiated phone calls from a counsellor. **Delivered by:** Trained staff and counsellors		randomised to trial but 95% completion (164/173). Individually tailored programmes to encourage lifestyle changes in seniors may be effective. The intervention group increased estimated energy expenditure by 487 kcal (2.04 MJ)/week in moderate or greater intensity activities compared with baseline ($p < 0.001$) and by 687 kcal [2.87 MJ]/week in physical activities of any intensity ($p < 0.001$) compared with baseline. Control group changes were negligible. Between-group analyses found changes were significantly different in both measures ($p < 0.05$).	theory. No allocation concealment or ITT but follow-up = 95%. Validated PA measure. Motivated (volunteer) mostly white, elderly, female majority and higher SES. Many subjects had health problems.
Coleman 1999	RCT Individual	1	+	Forty-seven sedentary adult volunteer employees at the University of Buffalo, NY, USA	**Aim:** To test different ways of meeting the recommendations for 30 min of moderate intensity activity on	16-week intervention. 16-week follow-up.	77% (36/47) began study and 89% of those (32/36) completed to 16 weeks. A walking prescription of 30 min per day on most days of the week with	No allocation concealment. No ITT but 85% follow-up. Small study (47 volunteers only from

				(not engaging in vigorous intensity exercise at least three times per week for at least 20 min per session). Average BMI approx. 25.8 kg/m^2). 84% female, average age approx 43.1 (range 18–55). Almost exclusively White, well educated and SES 50–53 on a scale of 8–66.	most days of the week. Volunteers were randomised to brisk walking 6 days per week in: 1) continuous bout; 2) three 10-min bouts; 3) any combination so long as each bout was at least 5 min. Academic researchers. **Delivered by**: Activity counsellors.		the choice to walk in as little as five min bouts can improve body composition, as well as help sedentary people maintain these improvements over time. Objective and subjective PA measures increased significantly from baseline to the end of the 16-week programme and changes were maintained at the 32-week follow-up for all groups ($p < 0.05$ for all measures).	University). Probably highly motivated, mostly female, white and high SES). Objective measure of activity using the TriTrac accelerometer as well as self-report. Objective measure of activity using the TriTrac accelerometer as well as self-report. Participants deposited US$50, refunded in segments for completion of assessments and good attendance. Semi-workplace intervention?
Dunn 1999	RCT Individual	1	+	Healthy sedentary men and women (self-reported PA of less than 26 and 24 kcal (109 and 100 kJ)/day respectively) from Dallas, TX, USA. Most modestly overweight but	**Aim:** To compare a lifestyle PA programme with traditional structured exercise. Academic research group. Used the Stages of Change	6 months intensive. 18 months maintenance.	Of 122 participants in the lifestyle group 89% (109) completed to 6 months and 82% (100) to 24 months. Of 115 in the structured group 90% (103) completed to 6 months and 78% (90) to 24 months. In initially sedentary healthy adults,	Lacks a no-intervention control group. No allocation concealment but ITT used. Unclear how participants were recruited but probably volunteers. Highly educated.

				none >140% ideal weight. *n* = 235 50.5% women. Average age 46.0 ± 6.6 (range 35–60) years. 'Highly educated' but no details given.	model. The structured exercise group received a traditional exercise prescription for 6months at a fitness centre individualised to participants after first 3 weeks, followed by meetings and correspondence during follow-up. **Delivered by:** **'**Group leaders' and project staff. Higher education study. The lifestyle group received an intensive behavioural intervention to encourage 30 min moderate intensity PA most days but no fitness centre membership, followed by less regular meetings and correspondence. **Delivered by:** 'Group facilitators'.		a lifestyle PA intervention is as effective as a structured exercise programme. At 24 months, adjusted mean changes were 0.84 kcal (3.5 kJ)/kg per day (95% CI 0.42, 1.25), $p < 0.001$, and 0.69 kcal (2.9 kJ)/kg per day (95% CI 0.25, 1.12), $p = 0.002$, for the lifestyle and structured activity groups, respectively. Between-group difference not significant ($p = 0.63$).	Measurement staff were blinded to allocation.

Jeffery 1999 .	RCT Individual	1	+/– (weak)	Men and women recruited from diverse sources, Minnesota, USA. *n* = 1226 18.6% men 40.5% of women were low income (household incomes of US$25000 or less per year (approx. £13,000) Mean age = 38.4 years 90.7% white 89% with at least some college education Mean BMI = 26.7 kg/m²	**Aim:** To evaluate effectiveness of intervention to prevent weight gain with age. No-contact control compared with: 1) education through monthly newsletters (questionnaire postcard included) encouraging paying attention to weight and making small changes in diet and exercise habits; and 2) education + incentives (entry into US$100 lottery if questionnaire postcard returned) Intervention subjects had option for participation in community activity every 6 months. Annual study visits for all participants. **Delivered by:** Researchers (although 6-monthly activities delivered by	3 years (Newsletters continued throughout 3 years.)	106 women who become pregnant excluded from the analysis. 809/1120 (72%) completed all data collection visits. Reported exercise decreased less in the two treatment groups than in control. Statistical significance unclear.	No description of randomisation process. No concealment allocation. No ITT. Baseline differences: Mean BMI higher in education-only group. Higher % of whites in two education groups (92% and 93%) than in control (87%). Parallel analyses with subjects completing only partial data (1101/1120 [98.3%]) yielded very similar findings and are not described in paper. Pound of Prevention study.

					various including nutritionists).			
Pereira 1998	RCT Individual	1	+	Volunteer postmenopausal women from the Pittsburg, Pennsylvania area, USA. *n* = 229, average age 57.5 ± 4.2 years. No socio-economic data provided but: ‘our population of women was basically of the same … socio-econ omic status’ (quoted verbatim from text).	**Aim:** To test the hypothesis that the women randomised to the walking group of a clinical trial were still walking more 10 years later than the women in the control group. Aim of original trial was to investigate the effect of PA on bone loss. The analysis on which this paper was based looks at increases in activity in the subjects of the above trial and factors associated with compliance. **Delivered by:** Original intervention delivered by exercise leaders.	Two-year intervention? (unclear if intervention continued after 2-year follow-up). Ten-year follow-up.	85.6% (196/229 women randomised into the original trial) were interviewed by telephone at 10-year follow-up. The median values for both self-reported usual walking for exercise and total walking were significantly higher for walkers compared with controls (for both, $p = 0.01$), with median differences of 706 and 420 kcal (2.95 and 1.76 MJ)/week respectively.	Two-year results and background info in Kriska 1986 No allocation concealment. ITT analysis carried out and described in earlier publication. Telephone interviewers masked to group assignment.

Evidence for implementation – Will it work in the UK?

First author	Study design	Research type	Research quality	Study population	Research question and design	Length of follow-up	Main results	Confounders/comments
Wrieden 2002	CBA	2	+	Eight deprived communities in Scotland. **At baseline:** 88% female. Mean age 32.3 (SD 10.2),	**Aim:** To develop, implement and evaluate a transferable community-based, food skills initiative aimed at increasing consumption of fibre-rich starchy carbohydrates, fish, vegetables and fruit and	Quantitative evaluations were carried out in intervention and delayed intervention (control) subjects at baseline,	Of 113 subjects initially recruited, 93 (82%) completed the baseline assessments and by the 6-month follow-up 63 (56%) had completed some or all assessments.	The Cookwell study. Reliability of outcome measures unclear and only 56% follow-up.

				range 16–65 years. 72% rented their accommodation, 33% claimed housing benefit, 46% were on income support and 14% received job seekers allowance. Only 4% were employed full time. 64% manual social class, 11% heads of household had never worked. 77% finished full time education aged ≤16 years, the intervention group having the highest percentage in this category (84%). In all cases a local community worker recruited people to take part.	decreasing consumption of fat in adults living in areas of deprivation. During 2000–2001 the Cookwell programme (10 weekly 2-hour sessions including data) was run in eight locations throughout Scotland for approx. 2–3 months in each community (*n* = 6–10 in each intervention group). The development of the programme was informed by preliminary focus groups within the community. **Delivered by:** Higher education researchers. No power calculation.	immediately post-intervention and 6 months later (see above). Qualitative interviews were carried out in a sample of intervention and control subjects at the 6-month follow-up.	Participants reported an increase in confidence and pride. The importance of a creche for sessions with familiar workers was crucial to the attendance of participants with young children. Barriers to changing food intake at home included time, demands of caring for young children, taste preferences of family members and dented confidence if a recipe didn't work out well.	
Kennedy 1999	Audit/Evaluation	3	+	Ninety-four members of the community in low-income areas in Bolton, UK. No socio-economic	**Aim:** To explore the role of CNAs in helping to increase coverage of local community dietetic services and to bring about positive changes in the	N/a	50% of the 94 traceable individuals who had been in contact with the CNA for more than a brief session agreed to take	A highly selected group. Questions unclear and exact activities of CNAs unclear. Results could be confounded.

				details were provided of interviewees although 18% of 163 community nutrition assistants (CNAs) contacts lived in deprived areas as classified by census information.	determinants of health eating, within low-income areas of Bolton. The role of the CNAs, who were locally recruited and trained, was to make contact with members of the community, offer introductory talks to groups, run practical activities (e.g. cook and taste), provide healthy eating advice and support food related activities. Members of the community who had been contact with a community nutrition assistant for more than a brief exploratory session took part in the focus group (*n* = 8) and telephone interviews (*n* = 41). No power calculation. **Delivered by:** Higher education researchers.		part. CNAs resulted in a more than fourfold increase in coverage of community nutrition services. More than half (59%, *n* = 41) the respondents selected for telephone interview said they had made changes in their eating habits as a result of contact with the CNAs. When asked about what factors had influenced these changes more than half identified, without prompting, the CNA as having a positive role. The majority of respondents (77%) preferred having a local person rather than a health professional to fulfil this advisory role because local people were perceived as more approachable, easier to access and showing greater empathy.	
Anderson 1998a	Surveys (within RCT)	3	+	Adults recruited at random through a market research agency in Reading	**Aim:** An assessment of perceived barriers to increasing fruit and vegetable consumption as	8 weeks. Questionnaire surveys at	79% of participants randomised completed the study (*n* = 135/170).	Part of the UK *Take Five* study. Short intervention (8 weeks).

				and Glasgow, UK. **Intervention group:** Average age 35.1 (SD 12.4) years, 74% female, 68% non-manual, 11% unemployed. BMI 25.0 (SD 4.5) kg/m^2.	part of a nutrition education intervention. **Delivered by:** Original RCT probably delivered by higher education researchers.	baseline and 8 weeks.	Belief evaluations pre- and post-study indicated that the support of family and friends, food costs, time constraints and shopping practicalities were barriers to greater consumption to increase fruit and vegetable intake. Perceived situational barriers to increasing intakes were limited availability at work canteens, take-aways, friends' houses and at work generally. Following the intervention the number of visits to the shops was perceived as a greater barrier for increasing intakes of fruit and vegetables. Perceived practical opportunities for increasing intakes highlighted drinking fruit juice, taking fruit as a dessert, having fruit as a between meal snack and eating two portions of vegetables with a meal.	Questionnaires, based on the theory of planned behaviour, were pre-tested though not previously validated. Subjects paid compensation (amount not stated) at end of study.
Vernon 1998	Cross-sectional survey	3	+	Members of the general public living in Salisbury , UK who had requested	**Aim:** To evaluate the 'Doorstep Walks' scheme, a pack detailing ten local walks and	N/a	229 questionnaires returned (71% follow-up) and 61% uptake.	Study design did not allow for an analysis by pre-intervention activity level, which limits

				a walking pack. *n* = 322 71% female	benefits of PA, devised by 'Salisbury Walking Forum', an alliance of local groups. Questionnaires issued to collect demographic information and identify motivations and barriers to walking. **Delivered by:** Salisbury walking forum, an alliance of local groups.		By far the most frequently given reason for non-participation (60%) was the shortage of free time, although other barriers were having no one to walk with (15.6%), having no walks near their home (14.4%), being fearful of walking the routes unaccompanied (12.2%, physically unable (11.1%), needed more encouragement (8.9%) and cost restriction (11.1%).	application of the findings.
Lloyd 1995	Surveys (within RCT)	3	+/–	Volunteers in Reading, UK, recruited through newspaper advertisements, aged 18–55 with a BMI of 20–29.9 kg/m^2. **Experimental group:** 22% men, age 35.1 ± 11.3. No socio-economic data provided.	**Aim:** To examine perceived and actual barriers to dietary fat reduction. Subjects were allocated to control or an experimental group receiving instruction on dietary fat reduction. 'Barrier' questionnaires to subjects in the intervention group (*n* = 45) at 4, 8, 12, 16 and 20 weeks. Analysis concentrates on first questionnaire, since more people attempted change in first two weeks than at other times in the study. **Delivered by:**	20-week intervention No post-intervention follow-up.	87% (61/70) subjects completed the study. Over the first 2 weeks of the study, of dietary changes attempted, reducing intake of cakes, biscuits, snacks and cheese was not popular, whereas increasing intake of fruit and vegetables was one of the most well liked changes. Perceived barriers pre-intervention (reduction in taste, ease of shopping and expense) reflected the actual problems encountered. One of the	RCT for efficacy rejected as 1. Unclear data on methodology (e.g. unexplained large number in intervention compared with control group) and weight outcomes. Unclear whether the questionnaire was validated (although referenced) and limited methodological information. Treat as marginal +. Subjects paid £100. on completion of the study.

					State Registered Dietitian or MSc level nutritionist		most consistently reported problems was that of reduction in taste quality of the diet. Other problems included an increase in cost, decrease in convenience, lack of family support for certain changes, and an inability to judge the fat content of the diet.	

2. OPPORTUNISTIC IDENTIFICATION AND LIFESTYLE/EXERCISE ADVICE ON REFERRAL IN PRIMARY CARE SETTINGS FOR PRIMARY PREVENTION OF OBESITY

Evidence of efficacy for weight management/reduction

Nine RCTs reported weight or body composition outcomes, of which three looked at general health advice, one looked at diet interventions alone, and five looked at PA interventions alone. One systematic review looked at exercise training programmes, some of which included diet, in early postmenopausal women.

The results suggest that interventions that provide general advice, addressing both diet and activity, are more likely to prevent unhealthy weight gain than those focusing on diet or activity alone. Of those focusing on PA alone, a more positive outcome was found when interventions were delivered by facilitators from more than one discipline.

General health advice/screening – diet and activity

Three UK based RCTs (Imperial Cancer Research Fund (ICRF) 1994, 1995; Family Heart Study Group (FHSG) 1994**)** were identified with the intensity of intervention based on participants risk score. One RCT (ICRF 1994) found no effect on BMI at 1 year, but a 1.4% reduction in BMI in the intervention group compared with the control at 3 years ($p < 0.005$) (ICRF 1995). The two RCTs from the same study had different control groups. FHSG (1994) reported that the weight of the intervention group was lower by an average 1 kg compared with controls and the proportion of patients with high BMI (≥30 kg/m^2) were lower in intervention than control (no significance values stated). Both interventions were delivered by nurses.

Diet alone

The health check and diet-only RCT (John 2002) reported no difference in weight loss between intervention and control groups ($p = 0.68$) at 6 months.

Physical activity alone

Five RCTs (Taylor 1998; Halbert 2000; Lamb 2002; Elley 2005; Tully 2005) reported weight outcomes in PA interventions. Three RCTs consisted of serially reinforced advice/motivation by telephone after an initial consultation/advice session (Halbert 2000; Lamb 2002; Elley 2005). One study in the UK encouraged intervention participants to attend ‘health walks’ (Lamb 2002), one study in New Zealand looked at a general practitioner (GP) intervention for sedentary 40–79 year-olds and one study in Australia looked at an exercise specialist intervention in a population of older adults (≥60 years; Halbert 2000). Two RCTs looked at exercise advice or prescription alone, both in the UK. One advised non-supervised walking for healthy sedentary people aged 50–65 years (Tully 2005) and one looked at GP exercise referral to a leisure centre for 40–70-year-olds, the majority of whom were overweight or obese (Taylor 1998).

None of the five RCTs showed a significant effect for weight loss at follow-up (of up to 37 weeks depending on study) although positive trends were noted in two studies (Elley, Taylor), one showing a reduction in skinfold thicknesses up to 16 weeks (Taylor). One study (Halbert) showed a significant weight gain in women in the intervention group ($p = 0.01$). Two of the interventions were delivered by facilitators from more than one discipline (Elley: GP/practice nurse and exercise specialist; Lamb: physiotherapist and local health walks coordinator), two were delivered by an exercise specialist alone (Halbert, Taylor) and one was unsupervised (Tully).

The systematic review of exercise training in early postmenopausal women (Asikainen 2004), where some of the interventions were combined with diet, found an improved body composition in 9 of 18 studies. The best effect was in the three studies of overweight women that combined training and diet, but six of the studies with positive results included some women within the normal weight range.

Evidence of efficacy for diet outcomes

One systematic review and four more recent RCTs provide some evidence that interventions can result in changes to dietary intake.

A systematic review (Ashenden 1997; ten studies with diet outcomes, all randomised) reported that dietary advice trials were very mixed in interventions employed and study populations. Of four trials directly assessing dietary change by collecting data on fat and fibre intake, one found very positive results, one found no significant difference on either measure and two found significant differences for one measure but not the other.

Four RCTs published since the systematic review were identified. With the exception of one (Steptoe) the RCTs had predominantly white samples, two were UK-based (Steptoe, John) with one based in a low-income area (Steptoe). Two studies gave dietary advice by physicians in routine consultations (Delichatsios, Beresford), and two were provided by research nurses (Steptoe, John). Three of the RCTs (Delichatsios 2001; John 2002; Steptoe 2003) reported that individually tailored intervention resulted in increases in self-reported fruit and vegetable intake between 3 months (Delichastsios), 6 months (John) and 12 months (Steptoe) between 0.6 portion per day (Delichatsios) to 1.4 portions per day (John) compared with control groups. Steptoe reported increased consumption (at 12 months) in both a nutrition advice and tailored behaviour intervention, but stated significantly higher intake in the tailored behaviour intervention (0.6 portions per day, $p = 0.021$). Beresford (1997) measured changes in fat intake, which were significantly larger at 3 and 12 months in the intervention group.

Evidence of efficacy for physical activity outcomes

Three systematic reviews (Eakin 2000; Eden 2002; Morgan 2005), all retained because of the limited overlap, and including four UK RCTs (Stevens 1998; Taylor 1998; Harland 1999; Lamb 2002), plus one more recent study from New Zealand (Elley 2005), provide some evidence that primary care-based interventions can increase PA levels.

One systematic review concluded that counselling adults in a primary care setting is moderately effective in the short term (Eakin 2000), and one that evidence was ‘inconclusive’ (Eden 2002). Interventions tailored to the participant characteristics and which offered written materials to patients produced stronger results. The most recent systematic review (Morgan 2005) concluded that exercise referral schemes appear to increase PA levels in certain populations, namely those that are not sedentary but already slightly active, older adults and those who are overweight but not obese.

The systematic reviews were unpicked to look at the four UK studies in more detail. One UK RCT which gave physiotherapist run advice sessions to sedentary 40–70-year-olds and encouraged the intervention group to participate in lay led walking schemes reported no significant between group differences in self-reported PA at 12 months and no effect on weight loss (see above). However, when only completers were analysed, the intervention was more effective than advice only (Lamb 2002). Taylor (1998) was an exercise referral scheme intervention with weight outcomes only, discussed above. Harland (1999) was an incentives study (see Table 3) offering vouchers entitling free access to leisure facilities. Increased PA scores were reported at 12 weeks, but this increase was not maintained in the long term (12 months). Stevens (1998) provided a consultation followed by a personalised 10-week programme to sedentary 45–70-year-olds. There was a significant net 10.6% reduction in the proportion of people classed as sedentary in the intervention compared with the control group at 8-months follow-up.

The recent New Zealand-based RCT of oral and written advice from GPs or practice nurses plus motivational phone calls by an exercise specialist reported a significant difference between intervention and control including the proportion undertaking 2.5 hours exercise per week ($p = 0.003$) at 12 months (Elley 2005).

Evidence of corroboration in the UK

Two systematic reviews, seven qualitative studies, two RCTs (one suspended), four cross-sectional surveys, one evaluation and survey and one evaluation of case studies provided evidence of UK corroboration.

Barriers to change

A systematic review (Keller 1999) found that that individual perceptions of self-efficacy (‘I believe I can exercise regularly’) are important and strongly related to exercise behaviour and that clinicians can help facilitate these perceptions. Four additional studies (Horsefall Turner/Wealden District Council 1997; Martin 1999; See Tai 1999; Hardcastle 2001) where participants had been referred to an exercise prescription at a leisure centre revealed a variety of barriers to adherence. These included the importance of social support (all), time (Martin; See Tai; Horsefall Turner) the gym environment and time spent with instructors (Hardcastle, Martin and Horsefall Turner). Other barriers were illness and injury, work pressure, transport, programs not appropriately tailored, lack of money. Knowing where facilities are at the start of the programme increased likelihood of completing a programme by 3.5 times ($p = 0.043$) (See Tai 1999). A qualitative study of guided walks (Ashley 1999) found that *Health Walks* were a sustainable form of exercise, but planning and promotion activities should take into account the seasons and varying needs of walkers (grades of difficulty, evening walks for workers, etc.) as well as emphasising the social benefits.

Data from two RCTs where the intervention was delivered by nurses (Baron 1990; John 2004) reported patients’ barriers to healthy eating included partners and children disliking recommendations and the difficulty of preparation and finding food outside of the home. Only 10% and 8% respectively reported these barriers in the Baron study, but 37 of 40 people reported at least one barrier in John.

Patients’ views of health professional advice

One cross-sectional survey of mainly white, UK patients (Duaso 2002) suggested that significantly more respondents would have liked to have received advice than did ($p < 0.001$). Women found the advice more helpful than men ($p < 0.05$). Hardcastle (2001) demonstrated the importance of encouragement from GPs in promoting PA in addition to participant commitment and confidence. However, a cross-sectional survey (Vernon 1998) on the effectiveness of walking packs found that the major barrier was lack of time (60%) rather than motivation by a GP or health professional (14%). A small qualitative study (Fuller 2003) found that couples viewed general practice as a place for treatment of illness and disease rather than provision of dietary advice. Health was only one of many factors influencing their daily decisions about food and they were concerned about contradictory messages.

Attendance at UK exercise referral schemes

A systematic review of four RCTs and five evaluation studies of UK exercise referral schemes (Gidlow 2005) found that attendance was generally poor. Approximately 80% of participants who took up referral dropped out before the end of the programme. More women than men took up referral (60 vs. 40%) but there was no evidence of higher attendance in women.

Health professionals in primary care

Activity: One evaluation of case studies of PA promotion schemes in primary care (Biddle 1994) revealed that success depends on the qualities of key personnel in contact with participants and establishing a programme depends on the enterprise of an energetic innovator. A qualitative study (Smith 1996) reported that referring practice members saw exercise promotion as a therapeutic as opposed to a preventive option and tight referral criteria was a barrier. Data from a suspended RCT (Fielder 1995) found that barriers to recruiting patients to a GP-led programme included time, overly complicated questionnaires and lack of financial incentive for the health professionals.

Diet: A qualitative study by Fuller (2003) reported that GPs viewed general practice setting as a place for treatment of illness and disease, and their advice was affected by personal preference (younger, females doctors being more enthusiastic). GPs were concerned that dietary advice could damage their relationship with patients. Hopper (1995) reported that practice nurses gave dietary advice more frequently than GPs. Time was the main barrier for GPs to training and offering dietary advice. The primary health care workers surveyed felt that their practice population was not sufficiently motivated to follow dietary advice.

Community pharmacies

Six qualitative studies, two of pharmacy contractors/advisors (Keene 1995; Ursell 1999) and four of community pharmacists (Benson 1995; Moore 1995; Ursell 1999; Coggans 2000) cited time, confidential space, training issues and cost issues (including loss of revenue) as barriers to increasing health promotion. Two of the studies (Benson 1995; Coggans 2000) noted concerns that giving lifestyle advice was ‘interference’.

One qualitative study of consumers (Anderson 1998b) found that only 40% thought it was the usual job of the pharmacist to give health promotion advice although 92% said that they would pick up health information leaflets at the pharmacy. In another study (Coggans 2000) less than 32% reported that they would seek information or help on healthy eating and only 23% would seek help on exercise at the community pharmacy. Conclusions from a Delphi study of health professionals (Coggans 2000) were that factors that facilitate pharmacy staff/customer interaction should be addressed as well as enhancing perceptions of pharmacists as key players in the health care team who provide a confidential service.

EVIDENCE TABLE 2: OPPORTUNISTIC IDENTIFICATION AND LIFESTYLE/EXERCISE ADVICE ON REFERRAL IN PRIMARY CARE SETTINGS FOR PRIMARY PREVENTION OF OBESITY

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for weight maintenance/reduction								
Asikainen 2004	Systematic review	1	++	Literature search 1996 – November 2002. Comprehensive search strategy but English language studies only included. Twenty-eight RCTs included, 18 of which had a weight or body fat outcome (1804 subjects in all); three of these were for overweight subjects and combined exercise and diet. Location of studies not described.	**Aim:** To evaluate data on exercise training studies with special reference to improving health in early postmenopausal women.	Duration range for weight loss studies was 12 weeks to 1 year.	Body composition was improved in 9 of 18 studies. The mean weight loss ranged from 2 to 10 kg in 12 weeks to 1 year (note: the best results were accomplished in the three studies with overweight participants that used training and diet). The most effective exercise prescription for losing body fat was 30–60 min of walking or other aerobic training at 45–75% VO_{2max} on 3–5 days per week for 15 weeks to 1 year, or strength training with weight machines twice per week for 1 year. In the training studies where participants were not overweight, adipose tissue was not lost as often as with overweight participants. The authors concluded that health professionals should recommend to sedentary women in early menopause who have fitness or weight concerns, a programme of at least 30 min of daily moderate walking in one to three bouts in addition to resistance exercises	Review found in update search: unpicking not possible within timeframe for completion but six of nine studies with positive outcomes included women within normal weight range. Few studies reported in detail how randomising was performed, if there were power calculations, if staff were blinded, ITT analyses. Some did not report drop out, attendance or injury rates.

							twice per week.	
Elley 2005	RCT Cluster	1	++	All sedentary 40–79-year-old patients visiting general practitioner during study period, in eastern Waikato region of New Zealand. *n* = 878 Mean age = 57.9 years 66.5% female 47% low economic status 28% with post-high school qualification 77% European origin	**Aim:** To assess long-term effectiveness of a clinician based initiative in general practice that provides counselling on PA. GPs and practice nurses prompted by patient to give oral and written advice on PA during usual consultations. Exercise specialist continued support by phone (three calls over 3 months). Control received usual care. **Power calculation:** Sample size of 800 patients from 40 practices (power = 90%). **Delivered by:** GPs/practice nurses and exercise specialist.	12 months	85% follow-up of enrolled patients at 12 months. Very slight BMI (kg/m^2) reduction in both groups but no significant difference between intervention and control for BMI reduction (–0.06 [95% CI –0.24, 0.12], *p* = 0.5).	In the intervention group 385 patients received intervention from general practitioner and 66 patients received intervention from practice nurse.
John 2002 UK Study	RCT Individual	1	++	Healthy participants aged 25–64 years recruited from a primary care health	**Aim:** To evaluate the effectiveness of a brief negotiation	6 months	95% follow-up in both groups. **No difference in weight loss between groups:**	Self-reported values are susceptible to reporting bias, so results should be interpreted with caution.

				centre, Thame, Oxfordshire, UK. *n* = 690 Mean age = 46 years 51% female 49% Social Class I and II 10% Social Class IV and V 'The general practices had few patients from ethnic minorities.'	method to encourage an increase in fruit and vegetables to at least five portions/day. Intervention group received health check followed by 25 min tailored dietary negotiation. Two-week reinforcing phone call and letter sent at 3 months. Control received intervention 6 months later. **Delivered by:** Trained research nurses.		Self-reported weight loss (kg) was 0.6 (SD 2.6) in both intervention and control groups. Adjusted between group difference in change* 0.1 (95% CI –0.4, 0.6), *p* = 0.68. *Adjusted for baseline value and sex.	Same study as John 2004.
Tully 2005	RCT Individual	1	+	Thirty-one healthy, sedentary 50–65-year-olds identified by searching the medical registers of three urban general practices in Belfast, UK, and subsequent selection by questionnaire. Overall recruitment rate = 5.9% (31/527).	**Aim:** To examine the effects of 30 min of self-paced, non-supervised, brisk walking, 5 days per week on the health and fitness of people aged 50–65 years. Intervention group (*n* = 21) instructed to walk briskly for 30 min, five days per week for	12 weeks. No longer-term follow-up.	81% completion and 90% adherence to protocol in intervention group. 90% completion in control group. The mean time spent walking by the intervention group was 27.72 ± 9.79 min/day. No significant changes were found in weight-related measures in either group.	No allocation concealment and no ITT although >80% completion. Participants likely to be highly motivated – overall recruitment rate = 5.9%. The authors noted that reported adherence was high suggesting greater acceptability of a pedometer-driven home-based model (vs. leisure centre exercise protocol).

				No socio-economic details provided.	12 weeks (all in one session or bouts of no less than 10 min). They were asked to record in a diary the time spent walking and the number of steps using a pedometer. Control group (*n* = 10) asked to maintain habitual lifestyle. No power calculation. Intervention delivered by higher education researchers.			
Lamb 2002 UK Study	RCT Individual	1	+	Men and women aged 40–70 years taking <120 min of moderate intensity activity per week. Reading, UK. *n* = 260 48.8% male Mean age = 50.5 (SD 7.8) years	**Aim:** To compare health walks, a community-based lay-led walking scheme versus advice only (from a primary health care professional) in middle-aged adults. Intervention and control took part in a 30 min standardised advice session led by a physiotherapist. Intervention given information about health walks and received up to three	6 months and 1 year	Loss to follow-up at 12 months was approximately 27% in each group. No statistically significant differences between people lost to follow-up and those who remained in the trial. No significant within-group changes from baseline in BMI at 12 months: –0.01 kg/m² reduction in advice group and –0.002 kg/m² reduction in Health walks group. Between group difference –0.009 (95% CI –0.39, 0.194).	Low follow-up, analysis by ITT. Related qualitative study below (Ashley).

					motivational phone calls from a local health walk coordinator. Control received no further intervention. Power calculation: Sample size of 100 people for each group (power = 90%). An additional 30% included to allow for loss to follow-up. **Delivered by:** Physiotherapist and local health walks coordinator.			
Halbert 2000	RCT Individual	1	++	Adults aged ≥60 years who were healthy, sedentary and living in the community. Adelaide, Australia. *n* = 299 Mean age = 67.5 years 46% Male	To determine whether provision of individualised PA advice by an exercise specialist in general practice, reinforced at 3 and 6 months, is effective in modifying PA, compared with no advice control. **Delivered by:** Exercise specialist.	12-month follow-up.	Follow-up of 88%. Over 12 months there were no statistically significant changes from baseline in body weight within either the control or intervention group. Weight decreased in men in the intervention and control groups and in women in the control group but increased in intervention group women ($p = 0.01$). (Values for gender not stated so unclear if significance value for intervention women only.) **Control group values:**	Generalisable to older adults only.

							Baseline = 74 (71.8–76.1) kg and 12 months = 73.6 (71.5–75.8) kg Intervention group values: Baseline = 75.9 (73.8–78) kg and 12 months = 76.0 (73.9–78.1) kg No between group difference stated. ***[ranges or 95%CI?]***	
Taylor 1998	RCT Individual	1	+	142 recruits from 345 men and women, aged 40–70 years and identified as smokers, hypertensive of overweight on medical records in East Sussex general practices. Circa 37% men. No socio-economic details provided.	**Aim:** To examine the effects of a GP exercise referral programme on modifiable coronary heart disease risk factors. The exercise group received a Health Education Authority leaflet on preventing coronary heart disease and was offered 20 half-price sessions over 10 weeks at a leisure centre. Patients engaged in moderate and vigorous aerobic activity in a semi-supervised informal environment. The control group received the leaflet but no further intervention.	Ten-week intervention. Outcomes measured at 0, 8, 16, 26 and 37 weeks.	41% (142) of the 345 invited to enter were randomised. 50% (71) provided data at all assessments, 41% of the exercise and 69% of the control group. 87% of those referred used the prescription and 28% (high adherers) (45% of obese patients) did at least 15 sessions. The exercise group reduced sum of skinfold thicknesses by 8.1 (95% CI 2.9, 13.3)% more than the control group, up to 16 weeks after baseline. High adherers (≥ sessions attended) reduced sum of skinfold thicknesses by 9.2 (95% CI 0.9, 17.5)% more than the control group up to 26 weeks.	Randomisation by random numbers but no allocation concealment. Assessments were not blinded. ITT analysis not carried out other than for the physical self-perception assessment. Baseline measures were broadly similar but there are more obese participants in the intervention group (30 vs. 18%) suggesting a potential weakness in randomisation. Overall there were 83% overweight or obese subjects in the intervention group and 71% overweight or obese subjects in the control group. Objective measures of weight and skinfold thickness. PA (Blair's)

					Intervention provided by higher education researchers. The assessment was by a postgraduate exercise scientist and the outcomes measured by a 'trained researcher'. A power calculation was based on a 4 mmHg blood pressure reduction.			and physical self-perception (PSPP) measures well referenced and probably validated. See also companion corroborative study, Taylor 2005
Imperial Cancer Research Fund 1995 UK Study	RCT Cluster	1	+	Patients aged 35–64 years in 1989 from five urban general practices. Bedfordshire, UK. *n* = 11090 Mean age = 49 years Area chosen for mixed urban and suburban setting, range of heavy and light industry and varied demographic profile.	**Aim:** To determine the effectiveness of health checks (risk factor counselling and negotiation of targets), performed by nurses in primary care, in reducing risk factors for cardiovascular disease and cancer. Control received health check at least 1 year later. Structured dietary assessment. No description of PA component. **Delivered by:** Nurses.	Three years (although mutually arranged (or structured for some risks) follow-up visits during this time, and some randomised to annual health checks).	Comparison of groups within the randomised population. Intervention was 2205 invited for re-examination in 1992–93 after an initial health check in 1989–90. Control group was 1916 randomly allocated an initial health check in 1992–93. Follow-up in control was 81.3% (1916 of 2783 randomised*) of those randomised. Follow-up in intervention was 82.2% (1160 of 2205 randomised*) of those who attended their first health check. *Excluding those who moved from the area. Dietary advice led to a small difference in BMI in intervention groups compared with controls but	Different levels of risk factor received different levels of intensity of intervention. Follow-up sessions for all patients at mutual agreement of nurse and subject. No allocation concealment. ITT analysis carried out.

							failed to reduce the proportion of the population with obesity. At follow-up, mean BMI was lower in intervention group than in control by 1.4% ($p < 0.005$).	
Imperial Cancer Research Fund 1994 UK Study	RCT Cluster	1	+	See above.	See above.	1 year (Although mutually arranged [or structured for some risks] follow-up visits during this time.)	Comparison of groups within the randomised population. Intervention was 2136 patients invited for re-examination in 1990–92 after an initial health check in 1989–90. Control was 3988 attending first check in 1990–92. Follow-up in control was 79.1% (1908 of 2760 randomised, excluding 348 who had moved). Follow-up in intervention was 77.8% of those who attended their first health check (1616 of 2136 randomised, excluding 60 who had moved [= 2076]) At 1 year, no significant difference between groups in BMI (kg/m^2): 0.16 (95% CI –0.06, 0.38). When analysis restricted to attendees a significant difference was found (1.2%) in BMI between intervention and control (significance not stated).	See above. Treated as separate study from above as different control group.
Family Heart	RCT Cluster	1	+	Male patients on GP lists aged 40–	**Aim:** To measure change	1 year	73% response rate to initial questionnaires	No description of randomisation process

Study Group 1994 UK study				59 years in 26 practices in 13 towns, and their partners, UK. *n* = 12472 59.8% male Mean age men = 51.5 years Mean age women = 49 years	in cardiovascular risk factors achievable in families over 1 year by a nurse-led cardiovascular screening and lifestyle intervention in general practice. Intervention received 1.5-hour screening and risk-related lifestyle advice. Internal and external controls received screening 1 year later. **Delivered by:** Nurses.	(Although intervention subjects followed up during this time according to risk score.)	At 1 year, 88% follow-up in intervention males, and 85% follow-up in intervention females. Non-returnees twice as likely to be smokers, more overweight than returnees and with a slightly lower prevalence of diagnosed disease. At 1 year, in the intervention group, weight among returnees was lower by an average 1 kg compared with the internal and external control groups (no significance stated). At 1 year, the proportion of patients with high BMI (≥30 kg/m^2) were lower in the intervention group than in controls (no significance stated).	and no allocation concealment. No ITT analysis re weight outcomes. Follow-up during year dependent on risk score. Substantially more subjects in external control than intervention and internal control. Little baseline data given.

Evidence of efficacy (internal validity) for diet outcomes								
Ashenden 1997	Systematic review	1	+	Literature search year of inception – May 1995. Thirty-seven randomised trials included in all. Ten to modify dietary behaviour.	**Aim:** To explore how effective lifestyle advice provided by GPs is in changing patient behaviour.	Range of follow-up, 3 months to 2 years in ten dietary advice trials.	The dietary advice trials were very mixed in interventions employed and study populations. Of four trials directly assessing dietary change by collecting data on fat and fibre intake only one found positive results, one found no significant difference on either measure and two found significant differences for one measure but not the other. Six trials measured changes in lipid levels (outcome not included in rapid review).	Literature search did not include unpublished trials – may introduce bias. Dietary advice: Logsdon 1989 Cupples 1994 Imperial Cancer Research Fund OXCHECK 1994 Baron 1990* Koopman 1990 Cohen 1991 Beresford 1992

								Campbell 1994 Family Heart Study Group 1994* Tomson 1995 *UK or Irish study
Delichatsios 2001	RCT Cluster	1	+	Adult primary care patients. New England, USA. *n* = 504 (of 1183 eligible) **Intervention:** Mean age = 49.9 ± 12.5 years 77.4% female 83% white 62% with at least a bachelor degree. **Control:** Mean age = 56.8 ± 12.9 years 63.1% female 97% white 56.9% with at least a bachelor degree.	**Aim:** To evaluate a multifaceted nutrition intervention to improve dietary habits among adult primary care patients. Intervention vs. control. Intervention comprised brief personalised recommendations at routine office visits and mailed personalised dietary recommendations, verbal endorsement and motivational phone calls to set targets. US$5 incentive offered for	Three-month follow-up survey (although intervention taking place during this time).	85% follow-up in intervention group. 92% follow-up in control group. Adjusting for age, sex, race and baseline intake, the change in self-reported fruit and vegetable intake in the intervention group was significantly higher than control (0.6 [95% CI 0.3, 0.8] servings/day. No intervention effect on dairy products. (no significance stated).	No allocation concealment. ITT analysis carried out. Some baseline differences. Mean age higher in control group. % of African Americans higher in intervention group. Self-reported outcomes – validated questionnaire. Meets criteria for a **social marketing** intervention (see methodology).

					completion of baseline survey and US$5 for final survey. **Delivered by:** Primary care physician or nurse practitioners and trained telephone counsellors. Nutritionist if necessary.			
Steptoe 2003 UK Study	RCT Individual	1	++	Patients from a primary care centre in a deprived, ethnically mixed, inner city area, UK, aged 18–70 years. *n* = 271 61% female 26% Black 3% Asian 70% White 68% in low-income category. 34% in receipt of benefits.	**Aim:** To measure the effect of brief behavioural counselling in general practice on consumption of fruit and vegetables in adults from a low income population. Two × 15 min counselling (2 weeks apart) on: 1) nutrition counselling (education and	12 months	At 12 months, 81% follow-up in behavioural counselling group, and 80% follow-up in nutrition counselling group. Consumption of fruit and vegetables increased from baseline to 12 months by 1.5 and 0.9 portions per day in behavioural and nutrition groups (mean between group difference 0.6 [95% CI 0.1, 1.1] portions, *p* = 0.021). The proportion of participants eating five or more portions a day increased by 42% with behavioural counselling and 27% with nutritional counselling in the two groups (mean between group difference 15 [95% CI 3, 28]%, *p* = 0.019). There were significant between-group differences suggesting that one	No allocation concealment. ITT analysis carried out. No true control group and low recruitment (12%).

					information); or 2) behavioural counselling (tailored advice). **Delivered by:** Research nurses.		counselling intervention was more effective than the other. Differences were maintained when analysis restricted to 177 participants with incomes ≤£400 per week.	
John 2002 UK Study	RCT Individual	1	++	See above.	See above.	See above.	95% follow-up in both groups. Self-reported daily fruit and vegetable intake increased by a mean 1.4 (SD 1.7) portions in the intervention group and by 0.1 (SD 1.3) portion in the control group (between group difference = 1.4 [95% CI 1.2, 1.6], *p* < 0.0001).* Mean difference of 1.3 (95% CI 0.9, 1.6) daily portions between intervention and control for 'pre-contemplators', 1.6 (95% CI 1.2, 1.9) daily portions for 'contemplators' and 1.3 (95% CI 0.9, 1.7) daily portions for those in 'action' (all *p* values < 0.001). *Adjusted for baseline value and sex.	Self-reported outcomes.
Beresford 1997	RCT Cluster	1	+	Adult patients from six primary care clinics in Puget Sound, Seattle, USA. *n* = 2111* (of 3490 eligible)	**Aim:** To evaluate the effectiveness of a low-intensity dietary intervention in primary care practice in	3 months and 12 months	86.1% follow-up at 12 months. Both groups reduced their self-reported fat intake (% energy from fat) from baseline but at both 3 and 12 months, changes from baseline were significantly larger in the intervention group compared with control.	* As reported in abstract (value of 2121 given in text). Allocation concealment used but no ITT analysis.

				51% ≥ 65 years 68% female 91% White 28% income <US$25,000.	lowering dietary fat intake and raising dietary fibre intake. Physicians gave intervention patients a self-help booklet and brief motivational message during routine appointment. Reminder letter 2 weeks later. Control was usual care. **Delivered by:** Physicians.		**At 3 months:** Mean intervention effect –1.04 (95% CI –1.67, –0.41), $p < 0.01$. At 12 months mean intervention effect –1.20 (95% CI –1.68, –1.73), $p < 0.01$. The corresponding differential change in fat score was –0.046 (95% CI –0.074, –0.018), $p < 0.01$ at 3 months and –0.044 (95% CI –0.073, –0.016), $p < 0.01$ at 12 months.	
Evidence of efficacy (internal validity) for physical activity outcomes								
Eden 2002	Systematic review	1	++	Literature search 1994 – March 2002. Seven RCTs and one CCT included rated as 'good' or 'fair' quality.	**Aim:** To determine whether counselling adults in primary care settings improves and maintains PA levels.		Evidence is inconclusive that counselling adults in the primary care setting to increase PA is effective. Among six controlled trials with a usual care control group, the effects of counselling on PA were mixed with three trials showing statistically significant increases in PA and the remaining three trials showing no effect. Because most studies had at least one methodological limitation, it was difficult to rigorously assess the efficacy of	Included trials: Physically Active for Life 1999 Norris 2000 Smith 2000 Kerse 1999 Change of Heart 1999 Burton 1995 Activity Counseling Trial 2001 Swinburn 1998

							interventions. More evidence is needed.	
Eakin 2000	Systematic review	1	++	Literature search 1980–98. Fifteen RCT or quasi-experimental controlled trials reviewed.	**Aim:** To summarise primary care based interventions for increasing PA and make recommendations for integrating successful strategies into practice.		Primary care-based PA counselling is moderately effective in the short term, although there is considerable variability across studies. Studies in which the interventions were tailored to participant characteristics and which offered written materials to patients produced stronger results. Of ten studies reporting 0- to 11-month post-intervention outcomes, seven reported statistically significant PA outcomes. Of the seven studies reporting post-intervention outcomes at 12 months or longer, three reported statistically significant outcomes.	Included studies: [studies not referenced by Eakin] Goldstein 1999 Bull 1998 *Stevens 1998 *Swinburn 1998 Marcus 1997 Calfas 1996 Dowell 1996 Burton 1995 Elder 1995 Graham Clarke 1994 OXCHECK 1994 Lewis 1993 Logsdon 1989 Kelly 1989 Reid 1979
Morgan 2005	Systematic review	1	+	Literature search to 2002. English language studies only. Nine RCTs included, four of which were from the UK – see comments.	**Aim:** To review current evidence of effectiveness for exercise referral schemes. Studies had to be based in primary care settings.	Limited information in review. Unpicking required (and done for UK studies only).	Exercise referral schemes appear to increase PA levels in certain populations, namely those who are not sedentary but already slightly active, older adults and those who are overweight (but not obese). However, increases in the level of PA may not be sustained over time.	Included since updates older reviews but of lesser quality. No unpublished studies sought and English language studies only included. Little detail of quality methods and appraisal probably undertaken by one reviewer only. UK studies all unpicked: Taylor 1998; Stevens 1998; Harland 1999;

								Lamb 2002
Elley 2005	RCT Cluster	1	++	See above.	See above.	See above.	85% follow-up of enrolled patients at 12 months. Mean total energy expenditure increased by 9.4 kcal (39 kJ)/kg per week (*p* = 0.001) and leisure exercise by 2.7 kcal (11 kJ)/kg per week (*p* = 0.02) or 34 min/week more in the intervention group than in the control (*p* = 0.04). The proportion of the intervention group undertaking 2.5 hours/week of leisure exercise increased by 9.72% (*p* = 0.003) more than in the control group (number needed to treat 10.3).	See above.
Lamb 2002 UK Study	RCT	1	+	See above.	See above.	See above.	Loss to follow-up at 12 months was approximately 27% in each group. No statistically significant differences between people lost to follow-up and those who remained in the trial. There were no significant between group differences (between intervention groups) in self-reported PA at 12-month follow-up by intention to treat analysis (between group difference = 6 [95% CI –5, 16.4])%. In people who completed the trial, health walks was more effective than giving advice only in increasing moderate intensity activity above 120 min/week (between group difference = 13 (95% CI 0.003, 25.9)%, *p* = 0.05).	
Stevens	RCT	1	+	714 people aged	**Aim:**	10-week	1288/2253 approached completed	Randomisation method

1998				45–74 years from two London general practices classed as not active (i.e. sedentary or low/high intermediate activity). Circa 42% men, 54% economically active, 85% white, 29% degree level, 34% no qualifications. All on the surgery lists in the targeted age group were sent a PA questionnaire.	To assess the (cost) effectiveness of a primary care based intervention aimed at increasing levels of PA in inactive people aged 45–74 years. **Intervention subjects:** Consultation with exercise development officer and personalised 10-week programme combining leisure centre and home-based activities. **Control subjects:** Information on local leisure centres. Higher	intervention. Assessment 8 months after randomisation.	questionnaires (57%). 714 were randomised. Of 363 randomised to intervention 35% (126) attended the first consultation and 25% (91) returned for the second consultation at the end of the 10-week programme. There was a net 10.6 (95% CI 4.5, 16.9)% reduction in the proportion of people classified as sedentary in the intervention group compared with the control group, 8 months after baseline. The intervention group also reported an increase in the mean number of episodes of PA per week compared with the control group (an additional 1.52 (95% CI 1.14, 1.95) episodes.	not described. No concealment allocation. Self-reported PA measures but using a validated tool (Blair's 7-day recall). ITT analysis used. Most PA was undertaken away from the leisure centre and the authors concluded that environmental efforts to encourage activities not requiring attendance at a leisure centre may have a greater impact.

					education/health promotion researchers. Intervention by one exercise development officer. No power calculation.			

Evidence of corroboration (external validity)

Evidence of salience – Is it appropriate for the UK?

Evidence for implementation – Will it work in the UK?								
First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question**	**Length of follow-up**	**Main results**	**Confounders/comments**
Gidlow 2005	Systematic review	3	++	Literature search to October 2003 for UK exercise referral interventions. Nine studies met the inclusion criteria: four RCTs and five evaluations of existing schemes.	**Aim:** To explore the attendance of UK exercise referral schemes (ERS), who attends them, why participants drop out of schemes and to compare evaluations of existing ERS with RCTs. Method of participant recruitment was the only marked difference between the two types of study. In RCTs and evaluations, rates of referral uptake and	The durations of the interventions were 10 (*n* = 5), 12 (*n* = 2) or 14 weeks (*n* = 1), although one RCT lasted 2 years despite reporting 10-month outcomes.	Attendance was generally poor; approximately 80% of participants who took up referral dropped out before the end of programmes. More women than men took up referral (60 vs. 40%) but there was no evidence of higher attendance in women. None of the participant characteristics reported were consistently associated with attendance. Most of the reasons for attrition and negative comments from participants related to practical problems associated with attending leisure facilities.	

					attendance were varied but comparable. All interventions were facility-based.			
Keller 1999	Systematic review	3	++	Literature search 1990 – June 1998. Twenty-seven primary and secondary prevention studies included.	**Aim:** To provide a critical systematic review of research using social cognitive theory in exercise research.		Individual perceptions of self-efficacy ('I believe that I can exercise regularly') are important and strongly related to exercise behaviour. Intervention studies demonstrated that participation in an exercise programme promoted self-efficacy and that programmes designed to increase outcome expectations and self-efficacy significantly increased exercise behaviour. Clinicians can facilitate perceptions of self-efficacy by verbal persuasion, modelling exercise behaviour and discussing the positive physical effects of PA.	Worldwide review. Unknown if any of the studies were based in the UK.
John 2004	Qualitative study (from RCT)	3	++	Purposive sample* (of patients not selected as contemplating change) from participants in an RCT examining effectiveness of a nurse-led intervention to increase fruit and vegetables intake. Thame, Oxfordshire, UK.	**Aim:** To examine the barriers to fruit and vegetables consumption after a 6-month trial. Participants asked at initial intervention interview to anticipate barriers and	Interviews carried out 2 weeks after 6-month follow-up.	Barriers anticipated and experienced: • Women reported children and male partners as obstructive to attempts to increase fruit and vegetables consumption. Men reported that partners were supportive. • Additional time needed to prepare food. • Perceived expense of fruit and vegetables. Barriers discovered during intervention: • Problems of getting fruit and vegetables while travelling.	*Sample selected to include those likely to have experienced different barriers. Same study as John 2002.

				n = 40 Mean age 45.9 years 47.5% female Social class I and II = 47.5% Social class III M, III NM, IV and V = 52.5% 72.5% had reported an increase in fruit and vegetables consumption.	discussed barriers at 6-month follow-up. Semi structured interviews carried out at respondents' homes by independent researcher to explore barrier issues in greater depth. **Delivered by:** Intervention by nurses.		• Problems when routine is disrupted at weekends. • 37 of 40 people reported at least one barrier, but 29 of 40 still reported increasing their fruit and vegetable consumption.	
Taylor 2005	Qualitative study (from RCT)	3	+	142 recruits from 345 men and women, aged 40–70 years and identified as smokers, hypertensive of overweight on medical records in East Sussex general practices. Circa 37% men. No socio-economic details provided.	**Aim:** To examine the effects of a GP exercise referral programme on modifiable coronary heart disease risk factors. See Taylor 1998 for details.	Ten-week intervention. Outcomes measured at 0, 8, 16, 26 and 37 weeks.	The exercise group became significantly ($p < 0.05$) more positive about their physical self-worth, physical condition and physical health (but not their physical appearance) than did the control group between baseline and subsequent assessments.	Interviews at eight weeks identified that 50% were positive, 35% had mixed feelings and 15% had only negative comments about the concept of GP referral to a leisure centre-based exercise programme. Concerns included the long waiting time before the introductory session, lack of staff support in a sometimes crowded and noisy exercise room and inconvenient times (off peak hours 09.00–17.00 hours only).

								See Taylor 1998 for quantitative results.
Fuller 2003	Qualitative Study	3	+	GPs *n* = 15 (eight female, seven male) and 30 patients (15 married couples in social class 3, 4 or 5 with young children) from general practices in the Lothian area of Scotland, UK.	**Aim:** To investigate the view of GPs and their patients about healthy eating and the provision of healthy eating advice in general practice. **Delivered by:** N/a.	N/a	GPs and couples saw the general practice setting as a place for treatment of illness and disease. Interviews with couples revealed that health was only one factor that appeared to influence day-to-day decisions about food choice, and that they felt expert messages were contradictory. They felt 'bombarded' by healthy eating information, particularly from the media. GP advice affected by personal preferences and greater enthusiasm was displayed by younger and female doctors. GPs felt that dietary advice may damage their relationship with patients.	Very small sample size, is likely to be underpowered to detect an effect if one exists.
Duaso 2002	Cross-sectional survey	3	+	Patients from a general practice in north-east of England. *n* = 516 (from 3612 eligible) Age range = 17–45 years Characteristics below for responders only (*n* = 316) 59.2% female	**Aim:** To examine patients' recall and perceptions of lifestyle counselling received from practice nurses, and whether patient needs were met. Structured postal	N/A	63% response rate (316 of 516). Those with unhealthy behaviour profiles seem to have received more advice. There appears to be a discrepancy between patients' expectations of lifestyle advice from the practice nurses and the receipt of such advice. Significantly more respondents would have liked to have received advice on diet, weight reduction and exercise than actually received it ($p < 0.001$).	Low response rate. Under-reporting by patients may have occurred due to memory or not recognising advice for what it was.

				Mean age male = 34.1 years and female 33.6 years White, male = 92% Female = 97% In full time employment, male = 98%, female = 72%	questionnaire with letter from GP and stamped self-addressed envelope included. **Delivered by:** Lifestyle counselling by nurses.		On average, patients found the advice received from the practice nurses very/fairly helpful, but significant difference between male and female perceptions: most women found the advice very/fairly helpful while male patients more dubious ($p < 0.05$).	
Hardcastle 2001	Qualitative study	3	++	Older women newly referred by their GP to an exercise programme at a local leisure centre. *n* = 15 Age range = 50–80 years	**Aim:** To explore past and current experiences of PA and perceptions of what blocks/motivates older women to be active. One 20–40 min semi-structured interview in leisure centre cafeteria (based on 'life story' technique), and two follow-up interviews at 5 and 10 weeks. **Delivered by:** Unclear,	10 weeks	80% of the women appeared to have initiated the idea for referral with their GP and the data show an informal network whereby referred women advocate exercise in the community. The data show a lack of commitment, confidence and encouragement from the GPs in promoting PA and referring to exercise programmes. The data show that social support appears to be crucial for some older people, especially regarding instruction and the interpersonal skills of the exercise instructor.	Questions posed during interviews unknown. Very small sample size, is likely to be underpowered to detect an effect if one exists.

					possibly exercise practitioner/instructor.			
Martin 1999	Qualitative data from retrospective analysis	3	+	Finishers (16 male and 26 female) and non-finishers (12 males and 23 females) of a 10-week GP referral exercise prescription programme, Margate, Kent, UK. Mean age = 52.9 years 51% had BMI >25 kg/m^2.	**Aim:** To examine characteristics of finishers and non-finishers of a GP exercise referral scheme. Semi-structured telephone interviews conducted by an independent interviewer **Delivered by:** Unclear.	N/A	Finishers were less reliant on social support and more likely to report tangible health benefits. Non-finishers relied on support from others when attending the gym. Both finishers and non-finishers felt intimidated by others at the gym and felt it was not a comfortable environment for older people. Also, there was feeling in both groups that initial exercise programmes not appropriately tailored. Reasons for non-finishing were mainly illness and injury, but work pressures, time and transport problems were also cited.	Programme had been running for 3 years – responses may be susceptible to recall bias so reliability of results is limited. Content of semi-structured interviews not reported. Results suggest that methodology used was too crude to accurately measure complex characteristics that determine differences between finishers and non-finishers.
See Tai 1999	Cross-sectional survey	3	+	Inner-city general practice patients referred to an exercise prescription at a local leisure centre. *n* = 152 71% female Age range 16–75 years	**Aim:** To examine factors that affect adherence to a GP referral to exercise prescription scheme at a local leisure centre.	N/A	Adherers to exercise programme were significantly older than non-adherers (p = 0.026). Previous barriers to exercise included lack of money, having no energy, not knowing about local exercise facilities, having no partner to exercise with, not being fit enough and having no time. A significantly higher proportion of those who cited 'lack of money' as a barrier	May be of particular relevance to GPs in deprived urban area where high morbidity co-exists with low incomes. Same programme as Smith 1996

					Demographic and barriers data collected at baseline and analysed for adherers and non-adherers. **Delivered by:** Referral by GPs and associated staff. Delivered by trained fitness consultant and referred back to GP.		dropped out of the programme than those who did not cite it as a barrier (55.3 vs. 44.7%, *p* = 0.024). Those who cited 'not knowing about local exercise facilities' as a barrier were 3.5 times more likely to complete the programme (*p* = 0.043).	
Ashley 1999	Qualitative questionnaire study	3	++	336 participants of a Health Walks scheme in Woodley in the Thames Valley and 22 walk leaders. **Walkers:** 78% female. Mean age 58 (SD 10.2), range 27–83 years. 2% unemployed, 47% retired, 11% home-makers. Primarily white (Woodley is 96% White).	**Aim:** To determine the effectiveness of Health Walks in an urban area, specifically looking at how the local development of schemes can be coordinated. Questionnaire study of walkers and walk leaders.	N/A	47% response (*n* = 476) to 768 surveys but only 366 had attended at least one walk and, thus, completed the questionnaire. 22/29 walk leaders (76%) completed questionnaires. The Health Walks programme was a sustainable form of exercise for the majority of participants; 90% said they would continue with the programme. The three main motivators for walk leaders were companionship, ownership of the scheme and appreciation of their commitment to the organisation. Recommendations from the research included:	Study funded by the Countryside Agency and British Heart Foundation. There were a higher proportion of respondents who had completed more than two Health Walks and women than found in Health Walks participants generally. Given the higher proportion of regular attenders, the high percentage saying they would continue walking should be treated with caution.

				Researchers probably from Oxford Brookes University.	**Delivered by:** Volunteer walk leaders.		• take into account the seasons, and varying needs (levels of difficulty, evening walks for workers etc.) in promotion and planning; • emphasise the social aspects; • target participants via general practice, including close links with local health centres; • emphasise the importance of moderate daily activity (e.g. errands by foot rather than by car).	Qualitative study linked to RCT in Lamb
Vernon 1998	Cross-sectional survey	3	+	Members of the general public living in Salisbury, UK, who had requested a walking pack. *n* = 322 71% female	**Aim:** To evaluate the 'Doorstep Walks' scheme, a pack detailing ten local walks and benefits of PA, devised by 'Salisbury Walking Forum', an alliance of local groups. Questionnaires issued to collect demographic information and identify motivations and barriers to walking. **Delivered by:**	N/A	229 questionnaires returned (71% follow-up) and 61% uptake. Few respondents (14%) thought that 'having the walks recommended by a GP or health professional' was an important motivating factor. By far the most frequently given reason for non-participation (60%) was the shortage of free time, although other barriers were having no one to walk with (15.6%), having no walks near their home (14.4%), being fearful of walking the routes unaccompanied (12.2%), physically unable (11.1%), needed more encouragement (8.9%) and cost restriction (11.1%). GP surgeries cited as the single most common place to find out about the initiative.	Study design did not allow for an analysis by activity level, which limits application of the findings.

					Salisbury walking forum, an alliance of local groups.			
Smith 1996	Qualitative study	3	++	Clinical and support staff (23 of 40) in 10 (of 14) general practices involved in referring patients to exercise prescription programme in Inner-London leisure centre. GPs *n* = 16 Practice Nurses *n* = 4 Practice Managers *n* = 4 Receptionist *n* = 1 34.8% male (all GPs)	**Aim:** To identify practices' reasons for joining exercise referral scheme, perceptions of benefit of scheme, selection criteria for referral and reported personal behaviour. Semi-structured interviews carried out at practices. **Delivered by:** N/A	N/A	Referring practice members saw exercise promotion as a therapeutic option, rather than an instrument for primary prevention. Legal implications of referring patients led to over-caution and frustration among referring practice members at not being able to refer the people they considered most in need of the scheme. (Family Health Services Association [FHSA] criteria allowed only 'low risk' patients to be referred). Majority of participants said they participated in some form of sport or leisure activity. The main reason for not doing so was lack of time due to work or social commitments.	May be of particular relevance to GPs in deprived urban area where high morbidity co-exists with low incomes. Same programme as See Tai 1999
Horsefall Turner/Wealden District Council 1997	Evaluation and survey	3	+	Patients referred by GPs to exercise prescription who presented themselves at leisure centre. East Sussex, UK.	**Aim:** To evaluate Wealden District council's Oasis programme of exercise	N/A	1994 (January–July), 21.9% completers. Males more likely to complete than females (27.4 vs. 19.1%). Older patients more likely to complete. Patients referred by GPs who referred the most patients were more likely to complete. Risk category did not affect adherence.	1994. Follow-up of non-adherers stopped when time ran out. 1997 (and 1994?). Data presented on those who were referred and

				1994: *n* = 729 65.4% female >75% aged ≥41 years **1994–1997:** *n* = 627, 66% female Mean age 52 years, range 16–87	referral from GPs to a leisure centre in terms of factors affecting adherence, client views and physiological data. **Two evaluations:** 1994 – Adherence characteristics examined through initial consultation data – non-adherers telephoned. 1997 – questionnaire survey of sample of 192 participants. **Delivered by:** Referred by GP, delivered by programme staff (including fitness instructors and		Principle reasons for non-completion were patient too busy (32.5%) or had become ill or injured (28%). Significant number dropped out due to insufficient supervision or that programme too boring. Other factors were expense and transport. December 1994 – May 1997: 43% completed (47% of males who started and 41% of females). No major differences in completion rates found according to initial fitness or location. Clients referred for medical complaints such as hypertension or arthritis appear to demonstrate better adherence than those referred for stress or weight loss. Adherence significantly better for medium-risk groups compared with high- and low-risk groups. Questionnaire sample biased towards adherers, but general satisfaction with programme. Area identified for improvement was amount of time staff have to spend with clients.	presented themselves at the leisure centre. 1994–1997. Sample selection criteria not given.

					liaison nurse) and referred back to GP.			
Fielder 1995	RCT (suspended)	1	N/A (as trial suspended)	Sedentary patients aged 18–64 years from seven general practices within a 4-mile radius of the local leisure centre. *n* = 38 (out of 900 patients needed to show an effect). RCT suspended.	**Aim:** To assess whether referral to a leisure centre programme was a major factor leading to increased PA. This paper aims to examine data from the RCT to understand failure of trial. **Delivered by:** Referral by GP and fitness assessment presumably from leisure centre staff.	N/A	Slow rate of recruitment into trial. GPs cited the increase in time spent with patients, complicated nature of questionnaire, lack of space for patient to fill in questionnaire and lack of financial incentive for GP as reasons for this.	Suspended RCT as trial did not achieve required sample size.
Hopper 1995	Cross-sectional survey/case study	3	+	Active GP practices in on Sheffield Health Authority's GP practice list. *n* = 100 Primary health care workers	**Aim:** To investigate level of advice given on dietary matters, methods used to give this advice and nutritional		Interviews conducted in 46 of 100 active practices (46% response rate). Practice nurses gave dietary advice more frequently than GPs ($p < 0.05$) and GPs were more likely ($p < 0.05$) to give verbal advice only, whereas practice nurses tended to take a dietary history and give both written and verbal advice. Most GPs	Unknown if questionnaire was validated. Low response rate.

				interviewed $n = 58$. GP $n = 36$ (83% male, mean age 56 years). Practice nurse $n = 22$ (100% female, mean age 35 years).	knowledge and attitudes towards nutrition by Sheffield Primary Health Care Trusts (PHCT), GPs and practice nurses. Structured questionnaire administered by interviewer. **Delivered by:** N/a.		surveyed mentioned the major constraint to offering dietary advice was time. All practice nurses and half of GPs surveyed were interested in attending a nutrition course, but the majority of GPs cited time as a barrier to this. A large proportion of primary health care workers felt that their practice population was not sufficiently motivated to follow dietary advice.	
Ursell 1999	Qualitative study	3	+	Community pharmacists (CPs) ($n = 96$, random sample), lead health authority pharmaceutical advisors and medical directors of public health ($n = 26$) in the West Midlands. No socio-economic information provided. Researchers from the School of Pharmacy, Aston	**Aim:** To examine the attitudes of CPs and those responsible for pharmaceutical policy at health authority level towards a role for community pharmacy in public health provision. Postal questionnaire. **Delivered by:** N/A	N/A.	Overall response rate = 48%. CPs 44%, public health directors 62% and lead pharmaceutical advisors 69%. The proportion of CPs (50%) who perceived the current role of the pharmacist in public health provision to be 'very important' was significantly greater than the corresponding group of policy makers (11%, $p < 0.01$). Lack of time was cited by 62% of CPs as the most important constraint preventing pharmacist involvement in public health promotion while financial issues were considered the most important constraint by 40% of policy-makers. When asked about possible solutions to aid pharmacy involvement, pharmacist	Brief report and very little methodological detail provided. The questionnaire does not appear to have been validated.

				University.			inclusion in primary care group function was considered essential by 27% and 79% of policy-makers and CPs respectively. The need for increased funding (73%, 96% respectively) and appropriate training (67%, 70%) were both highly regarded. The authors tentatively proposed that, given the disparity of views, a clear dialogue on the issue should be established between CPs and policy-makers.	
Anderson 1998b	Qualitative study	N/a	++	Consumers (*n* = 592) interviewed in six pharmacies in Barnet. 74% female. 40% ≥60 years old. 85% white European, 15% unemployed, 35% retired. 90% regular pharmacy users. Researchers probably from Kings College London.	**Aim:** To investigate whether consumers came to the pharmacies for advice on general health matters, read health promotion leaflets and had heard of the Barnet Health Authority High Street Health Scheme (HSHS). **Delivered by:** N/A	N/A.	Many consumers do not currently perceive that there is a role for community pharmacists in health promotion. The GP's surgery was felt to be the most convenient place to get advice about staying healthy, and the GP the best person from whom to get it. The pharmacist was rated second, above the media, although only 15% of respondents had ever asked the pharmacist for general health advice. Only 40% thought that it was the usual job of the pharmacist to give advice about staying healthy although 92% said that they could pick up health information leaflets at the pharmacy. The authors concluded that pharmacist training alone would not change the public's perception of pharmacists. There was no significant variation in responses according to age, race or	Health authority-funded project.

							employment status although women were more likely to get advice from the media.	
Keene 1995	Qualitative study	3	+	Pharmacy contractors based in West Glamorgan. *n* = 48 (of 50)	**Aim:** To examine present state of health education among pharmacists, perceived costs and benefits, and factors to increasing health education activity. Questionnaires with open and closed questions, interviews of up to 1 hour and ethnographic notes. **Delivered by:** Academic and Health Authority researchers.	N/A	Great majority of contractors expressed support for engaging in health promotion but some qualified it with arguments of it being a significant waste of resources and a diversion from core activity of dispensing. Two-fifths of respondents saw time as the strongest constraint against health promotion, one-fifth mentioned space and just under one-third referred to cost. Majority saw training as an essential part of developing pharmacy services, but concerns about co-ordination of training and lack of time for training featured prominently in the comments.	Survey small in scale and range.
Moore 1995	Qualitative study	3	++	Community pharmacists in Kingston and Richmond FHSA, UK.	**Aim:** To identify health promotion activities, and	N/A.	Pharmacists' activities in health promotion were 2.5 times more likely to be reactive rather than proactive. Barriers to health promotion experienced	

				n = 30 (of 34 approached)* *Reasons for refusal include lack of time, illness of pharmacists or unwillingness to participate.	barriers to improving and increasing health promotion activity in community pharmacies. Structured interviews by a research pharmacist. **Delivered by:** N/A		by community pharmacists were lack of time and space, need for a consulting area, desire for payment by the FHSA, need for training, insufficient support from their local health promotion unit, lack of regular contact with health promotion facilitator and the need for more staff.	
Coggans 2000	Qualitative survey, Delphi analysis and literature review	3	++	1) Semi-structured interviews with 60, 30 pharmacists and 30 pharmacy assistants, in community pharmacies in Scotland. 2) Dephi exercise with 25 health professionals. 3) Literature review. Pharmacy customers: 68% female, 7% <20 years, 22% ≥60 years. 19% higher managerial and 7% long-term	**Aim:** To find out what aspects of health promotion are pharmacy customers most receptive to and what methods are appropriate for the delivery of pharmacy health promotion. Research carried out by the Pharmaceutical Services	N/A	Although virtually every customer reported that they were happy to discuss health information with the pharmacist or assistant, <32% reported that they would seek information or help in the community pharmacy on healthy eating and only 23% would seek information or help on taking exercise. Pharmacists were willing and eager to discuss a range of health issues with customers, although there was some reluctance in relation to lifestyle issues, as well as awareness of the limitations arising from lack of privacy. Conclusions from the survey and Delphi study were that factors that facilitate pharmacy staff/customer interaction should be addressed as well as enhancing perceptions of pharmacists as key players in the health care team who provide a confidential service.	

				unemployed.	Division of the Scottish Executive Health Department. **Delivered by:** N/A			
Benson 1995	Qualitative study	3	+	Purposive sample of ten practicing community pharmacists in the UK to obtain geographic and socio-economic range. All white, Anglo-Saxon. Six women, four men. Researcher background unknown (National Pharmaceutical Association/King's College).	**Aim:** To explore pharmacists' perceptions of the nature of their health education role, the practicalities of implementing this role and the obstacles to be overcome. **Delivered by:** N/A	N/A	There was considerable uncertainty about the health education role of pharmacists. There were profound concerns among the respondents that a health education role required 'interference' in patients lives and that health education was often not income generating, a barrier for pharmacies since they run as commercial enterprises. The authors concluded that a paradigm shift would be needed to overcome the barriers of the pharmacist's traditional inclination to a product orientated approach and ethical concerns about interference.	Small sample and all White. Paper lacked methodological detail – example quotes rather than detailed summary provided.
Biddle 1994	Evaluation of case studies	3	+	Structured sample of 50 (of 173) PA promotion schemes in primary health care (20 practice managed and 30 leisure centre managed).	**Aim:** To identify existing PA interventions and any evaluations of them and identify criteria	N/A	Success of PA promotion depends on qualities of key personnel in contact with participants, in particular appropriate training in health promotion techniques and counselling for exercise. Establishing a scheme depends on the enterprise of an energetic innovator.	

				Sample structured in order to get examples from a range of environments and participant profiles. Primary health care facilitators interviewed *n* = 50.	for and barriers to success. Structured questionnaire checklists delivered over the phone (or mailed if lack of time). **Delivered by:** N/A		In most schemes participants are predominantly middle-aged women, often overweight.	
Baron 1990	Survey within RCT	3	+	Patients on the lists of a group general practice in Abingdon, Oxford, UK. Intervention subjects from an RCT investigating the effect of nutrition advice by a nurse in general practice. *n* = 187 52% male Mean age = 41.6 years	**Aim:** To examine difficulties encountered by intervention subjects (queried at 1, 3 and 12 months) with the dietary recommendations. Intervention received 30 min session with nurse aimed at lowering fat and increasing fibre intake. Booklet and two follow-up sessions at 1 and 3 months	3 months and 12 months	89.3% follow-up in intervention group at 12 months. Dietary intervention appeared to be well accepted by the intervention group. 8% thought the recommended regimen was hard to prepare or difficult to find in restaurants. 10% of the intervention group noted that they or their families disliked the recommendations and subjects with this complaint were more likely to drop out of the study.	No allocation concealment. No ITT analysis. Number of subjects evaluated for difficulties encountered with the dietary advice vary because of losses to follow-up and missing data.

					Delivered by: Intervention by nurse.			

3. INCENTIVES

SUMMARY

Evidence of efficacy for weight management/reduction

Only one RCT conducted in the USA (the Pound of Prevention study) reported weight outcomes (Jeffery 1999). This low-intensity intervention to prevent weight gain comprised of education or education with incentives (entry into a US$100 lottery) compared with a control. After a 3-year follow-up significant differences were reported between intervention groups and control with a higher reported frequency in healthy weight loss practices. This was related to a non-significant reduced rate of weight gain over time. No weight gain differences were found between the treatment groups.

Evidence of efficacy for diet/physical activity outcomes

One multifaceted RCT to improve dietary habits among adult primary care patients (Delichatsios 2001) offered an incentive of US$5 for completion of the baseline survey and again for the final survey for those in the intervention group. The intervention group reported a positive effect for fruit and vegetable consumption (an increased of 0.6 servings per day). No effect was found for dairy products.

Two PA incentive interventions (both RCTs – one conducted in the UK and the Pound of Prevention study in the USA) demonstrated a positive short-term effect for PA outcomes. Harland (1999) offered vouchers entitling free access to leisure facilities and reported increased PA scores at 12 weeks and increased vigorous activity in the intervention participants. However, this increase was not maintained in the long-term (12 months). Jeffery (1999) reported that exercise decreased less in the education and education plus incentives groups however statistical significance is unclear.

Evidence of corroboration in the UK

Only one study (Harland) was undertaken in the UK. No other evidence of corroboration was identified.

EVIDENCE TABLE 3: INCENTIVES

First author	**Study design**	**Research type**	**Research quality**	**Study population**	**Research question** (include power calculation if available)	**Length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for weight maintenance/reduction								
Jeffery 1999	RCT Individual	1	+/– (weak)	Men and women recruited from diverse sources, Minnesota, USA. *n* = 1226 18.6% men 40.5% of women were low income (household incomes of ≤US$25000 per year) Mean age = 38.4 years 90.7% white 89% with at least some college education Mean BMI = 26.7 kg/m².	**Aim:** To evaluate the effectiveness of low-intensity intervention to prevent weight gain with age. No-contact control compared with: 1) education through monthly newsletters (questionnaire postcard included) encouraging paying attention to weight and making small changes in diet and exercise habits; and	3 years (Newsletters continued throughout 3 years.)	106 women who become pregnant excluded from the analysis. 809/1120 (72%) completed all data collection visits. Significant increase between intervention groups and control in self-reported frequency of healthy weight loss practices (including reducing calories, increasing exercise and fruit and vegetables intake and decreasing fat intake) (*p* = 0.01), related to a reduced rate of weight gain over time. Point estimates for rate of weight gain over three years were slightly lower in both intervention groups than control, but differences between all groups not statistically significant, *p* = 0.88.	Also included in Table 1. No description of randomisation process. No allocation concealment. No ITT analysis. **Baseline differences:** Mean BMI higher in education-only group. Higher % of whites in two education groups (92% and 93%) than in control (87%). Parallel analyses with subjects completing only partial data (1101/1120 [98.3%]) yielded very similar findings and are not described in paper. Pound of Prevention Study.

					2) education + incentives (entry into US$100 lottery if questionnaire postcard returned). Intervention subjects had option for participation in community activity every 6 months. Annual study visits for all participants. **Delivered by:** Researchers (although 6 monthly activities delivered by various including nutritionists).			

Evidence of efficacy (internal validity) for diet outcomes								
Delichatsios 2001	RCT Cluster	1	+	Adult primary care patients New England, USA.	**Aim:** To evaluate a multifaceted preventive nutrition intervention to improve	3-month follow-up	85% follow-up in intervention group. 92% follow-up in control group.	No description of randomisation process. No allocation concealment. ITT

				n = 504 (of 1183 eligible) **Intervention:** Mean age = 49.9 ± 12.5 years 77.4% female 83% white 62% with at least a bachelor degree **Control:** Mean age = 56.8 ± 12.9 years 63.1% female 97% white 56.9% with at least a bachelor degree	dietary habits among adult primary care patients. Intervention vs. control. Intervention comprised mailed personalised dietary recommendations, verbal endorsement and motivational phone calls to set targets. US$5 incentive offered for completion of baseline survey and US$5 for final survey. Control comprised no intervention. **Delivered by:** Primary care physician or nurse practitioners and trained telephone counsellors. Nutritionist if necessary.	survey (although intervention taking place during this time).	Adjusting for age, sex, race and baseline intake, the change in fruit and vegetable intake in the intervention group was higher than control (0.6 [95% CI 0.3,0.8] servings/day. No intervention effect on dairy products.	analysis used. Some baseline differences. Mean age higher in control group. Proportion of African Americans higher in intervention group.
Evidence of efficacy (internal validity) for physical activity outcomes								
Harland 1999 UK Study	RCT Individual	1	++	Adults aged 40–64 years attending routine surgeries in one urban general practice in a socio-economically disadvantaged area of Newcastle, UK. *n* = 523 42.5% male 52% employed 10% unemployed	**Aim:** To evaluate the effectiveness of combinations of three methods to promote PA versus a control intervention. Brief (one interview) or intensive (six interviews over 12 weeks) motivational interviewing with or without financial incentive (30 vouchers entitling free access to	12 months	81% response rate at 12 weeks and 85% at 1 year. More participants in the combined intervention groups reported increased PA scores at 12 weeks than controls (38 vs. 16%, difference 22 [95% CI 13, 32]%, $p < 0.001$, with a 55% increase observed in those offered six interviews plus vouchers. Vigorous activity increased in 29% of	One urban general practice in a socio-economically disadvantaged area Less subjects per group in final analysis than required by power calculation, therefore study a little short on power.

				and seeking work 13% unable to work due to illness 72% manual occupational class (III, IV, V)	leisure facilities) and a no intervention control group. Group 1 *n* = 105 – Brief intervention Group 2 *n* = 106 – Brief intervention and vouchers Group 3 *n* = 104 – Intensive intervention Group 4 *n* = 102 Intensive intervention and vouchers 107 participants per group required to detect a difference between success rates of 40% to 60% at 80% power and 5% significance level. **Delivered by:** Interviews by trained health visitor.		intervention participants and 11% of controls (difference 18 [95% CI 10, 26]%, $p < 0.001$) but differences between the four intervention groups were not significant. Short-term increases in activity were not sustained regardless of intensity of intervention.	
Jeffery 1999	RCT	1	+/– (weak)	See above.	See above.	See above.	106 women who become pregnant excluded from the analysis. 809/1120 (72%) completed all data collection visits. Self-reported exercise decreased less in the two treatment groups than in control. Statistical significance unclear.	See above.

Evidence of corroboration (external validity)								
Evidence of salience – Is it appropriate for the UK?

Update searches

An update search of the same databases was carried out in September 2005 for worldwide intervention and UK corroborative studies. A final search was completed on 1 December 2005 for systematic reviews and controlled trials only in a reduced number of databases: CINAHL, Cochrane, Embase, Medline and PsycINFO.

The search strategies (see part c, supporting information) were developed in Medline and adapted for use with the other information sources. Additional papers (*n* = 18) were located from reference lists or in the searches carried out for the broader community review, or were suggested by the Guidance Development Group.

EXCLUDED REFERENCE LISTS

Papers excluded due to lack of time

Paper	Reason for exclusion
Barr SI, Yarker KV, Levy-Milne R, Chapman GE. Canadian dietitians' view and practices regarding obesity and weight management. *Journal of Human Nutrition and Dietetics* 2004;17(6).	Non-UK corroborative – excluded due to lack of time.
Barras C, Bloom *N*, Cook S, Luzhansky Z, Skinner B. Hand in Hand: Encouragement and facilitation of support and self-help group use. *Internet Journal of Health Promotion* August 1996.	Non-UK corroborative – excluded due to lack of time.
Bebetsos E, Chroni S, Theodorakis Y. Physically active students' intentions and self-efficacy towards healthy eating*. Psychological Reports* 2002;91(2):485–95.	Non-UK corroborative – excluded due to lack of time.
Black DR, Blue CL, Coster DC, Chrysler LM. Corporate social marketing: message design to recruit program participants. *American Journal of Health Behavior* 2002;26(3):188–99.	Non-UK corroborative – excluded due to lack of time.
Blackburn GL, Waltman BA. Physician's guide to the new 2005 dietary guidelines: How best to counsel patients. *Cleveland Clinic Journal of Medicine* 2005;72(7); 609-618.	Non-UK corroborative – excluded due to lack of time.
Bryant C, Lindenberger J, Brown C, Kent E, Schreiber JM, Bustillo M, et al. A social marketing approach to increasing enrollment in a public health program: A case study of the Texas WIC program. *Human Organization* 2001;60(3):234–46.	Non-UK corroborative – excluded due to lack of time.
Bull F, Schipper E, Jamrozik K, Phil D. How can and do Australian doctors promote physical activity? *Preventive Medicine* 1997;26(6):866–73.	Non-UK corroborative – excluded due to lack of time.
Clark T, Sleath B, Rubin RH. Influence of ethnicity and language concordance on physician–patient agreement about recommended changes in patient health behaviour. *Patient Education and Counselling* 2005;53(1):87–93.	Non-UK corroborative – excluded due to lack of time.
Clemmens D, Engler A, Chinn PL. Learning and living health: College students' experiences with an introductory health course. *Journal of Nursing Education* 2004;43(7):313–8.	Non-UK corroborative.
Croft JB, Temple SP, Lankenau B, Heath GW, Macera CA, Eaker ED, et al. Community intervention and trends in dietary-fat consumption among black-and-white adults. *Journal of the American Dietetic Association* 1994;94(11):1284–90	Non-UK corroborative – excluded due to lack of time.

THE EFFECTIVENESS OF BROADER COMMUNITY-BASED INTERVENTIONS TO PREVENT OBESITY

EVIDENCE SUMMARY TABLES

EVIDENCE TABLE 1: SUPERMARKETS AND SHOPS

- **Point of choice (point-of-purchase) prompts**
- **Educational videos**
- **Group teaching sessions**
- **Mass media and supermarket**
- **Food 'deserts' – within corroborative section**

SUMMARY

Evidence of efficacy for weight management/reduction
No studies were found that reported weight outcomes.

Evidence of efficacy for diet/physical activity outcomes
Dietary outcomes

Point-of-purchase: Two good quality reviews with limited overlap (Roe 1997; Seymour 2004) concluded that informational point-of-purchase strategies in supermarkets can increase the purchase of targeted items. Both reviews looked at all types of research study. Seymour (2004) noted that the longer (2-year) multi-component studies showed the greater intervention effects but no data were provided. Roe (1997) noted that point-of-choice programmes supported by informational brochures and local promotion had a positive effect on sales of at least some items in two of the three good quality studies while the intervention was in place. The magnitude of the effect ranged from 1–2% of total market share of healthier food items. The third study showed no effect on sales.

Two randomised controlled trials (RCTs) of point-of-purchase interventions in supermarkets have been found to date (Kristal 1997; Steenhuis 2004). One found no decrease in total fat intake (Steenhuis 2004) and the other found no increase in fruit and vegetable consumption (Kristal 1997), although Kristal noted a borderline statistically significant 8.4% increase ($p < 0.07$) in the percentage of intervention store shoppers in the action or maintenance stage of dietary change. Unpicking to extract data from any other RCTs included in the systematic reviews was carried out. No RCTs were included and none of the studies appeared to meet the rapid review criteria of control group and 3-months follow-up.

Educational videos: Two studies of educational videos included in the systematic review by Roe (1997) resulted in a reduction in fat intake of purchases of 4–5% while the intervention and feedback were provided.

Computer-based intervention: An RCT to assess the direct and mediated impact of a self-administered, computer-based intervention on supermarket shoppers (Anderson 2001) found that the treatment group was more likely than the control group to attain goals for fat at the end of the intervention ($p < 0.001$) and follow-up ($p < 0.05$), although the low initial response and compliance rate suggest that these results could be from a motivated subgroup. There was a trend towards goal attainment for fibre and fruits and vegetables post-intervention ($p < 0.1$), but this was not significant.

All the interventions were in supermarkets and none of the studies was carried out in the UK. Most of the subjects in the three RCTs were women, as might be expected in this setting.

Physical activity
No studies were found that reported physical activity (PA) outcomes.

Evidence of corroboration in the UK
In terms of corroboration, nine UK-based corroborative studies were found, only two of which had a direct bearing on the point-of-purchase interventions summarised above.

Point-of-purchase
The study by Knox (2001) combined a cross-sectional survey and interviews to determine those factors most important for successful reduced-fat product development and to seek consumers' views on perceived barriers to reduced fat intake. 69.3% of consumers felt that nutritional information on food products was helpful. Those in lower socio-economic groups appeared more likely to find information on products more difficult to understand (p = 0.021), whilst those in higher socio-economic groupings appeared more likely to attribute confusion to conflicting dietary advice (p = 0.002). Confusing nutritional labelling information and conflicting dietary advice were barriers to making informed decisions. 59% of consumers were of the view that reduced fat foods were inferior in taste compared with full fat products, and over 90% considered taste to be the most important criteria in the selection of both meat and dairy products.

A qualitative study of 14 low-income middle-aged women (Dibsdall 2002) reported that while the women found media messages (from television [TV] and radio programmes, magazines or newspapers) surrounding healthier eating confusing they were aware of and agreed with the basic recommendations for a healthier diet. Participants reported good control of food availability and budgets but buying 'more' foods such as more fruits and vegetables was beyond their budgetary control. Irrespective of the healthiness of their diet, the participants displayed a basic lack of motivation to change eating behaviours.

Food deserts
Six publications addressed the specific issue of 'food deserts'. A before and after study (Wrigley 2003) and companion qualitative studies (Whelan 2002; Wrigley 2004) looking at the effect of the opening of a supermarket in a deprived, previously poor-retail-access community in Leeds, and a cross-sectional comparison of dietary intake vs. retail access in Newcastle upon Tyne (White 2004). Neither study provides evidence of a 'food desert' effect on dietary intake. In Newcastle the data did not demonstrate a relationship between most indicators of healthier eating and factors relating to the local retail environment. Knowledge and relative affluence were the key indicators. Individuals in the lowest socio-economic quintile were less aware of current healthy eating messages than those in the top quintile. Poor knowledge was consistently associated with less healthy eating, as well as with other measures of a less healthy lifestyle (e.g. low levels of PA and smoking) (White 2004). In Leeds, the affect of improved retail provision did not improve population intakes of fruit and vegetables although the group that switched to the new store increased their consumption by 0.23 portions per day (Wrigley 2003).

A potentially biased study in Northern Ireland (Furey 2001) found that 11% of consumers self-reported a concern regarding food poverty issues and the authors concluded that some non-car owners and lower income family units cannot achieve a healthy affordable diet. Another study carried out in England (Caraher 1998) found that one-third of women, compared with 7.7% of men, cited transport as a major factor limiting their choice of food. Cost rather than quality is the major issue for those in lower income brackets when deciding where to shop (Furey 2001; Whelan 2002). One study found, however, that this constraint applied to younger women only while older women tended to be less worried about the cost of food and more enthusiastic regarding buying foods that would be perceived as healthier (Whelan 2002). For the elderly, the main issues related to physical access constraints (Whelan 2002).

A very weak cross-sectional evaluation of a fruit and vegetable home delivery scheme found that 74% of participants reported eating more fruit and vegetables while on the scheme and 42% reported that they were eating more fruit and vegetables after than before the scheme (Ali 2001).

EVIDENCE TABLE 1: SUPERMARKETS AND SHOPS

Evidence of efficacy (internal validity) for weight maintenance/reduction								
Overall strength of evidence of efficacy for weight outcomes = no evidence found								

Evidence of efficacy (internal validity) for diet outcomes								
Point of choice/purchase prompts								
Seymour 2004	Systematic review	2	++	Literature search from 1970 to June 2003. Thirty-eight studies reviewed including ten grocery store interventions of which the authors regarded six as strong or very strong research designs, including one RCT; i.e. most studies graded research type 2.	**Aim:** All articles that included a nutrition intervention with an environmental or policy component conducted in an English-speaking industrialised country.	The studies varied in length from 1 week to 2 years.	The general conclusions of this wide-ranging review of point-of-purchase behaviour were that interventions in 'limited access' sites (i.e. where few other choices were available) had the greatest effect on sales of targeted (healthier) food choices. Eight interventions used only information strategies and, of these, five reported increased sales of targeted items. There was little evidence to suggest that any particular combination of information strategies was more successful than any other. The longer (2-year) multi-component informational studies showed the greatest intervention effects. The remaining two interventions used strategies of availability, access or incentives as well as information (Kristal 1997, see below and Curhan 1974). Curhan	None of the studies appeared to be in a UK setting. Although a good review the evidence tables lacked detail in terms of significance values and the quality assessment methods used.

							compared four interventions of which the most successful was increasing produce display space to 200% of original allocation; this significantly increased sales (from 28–59% depending on the type of produce).	
Roe 1997	Systematic review	1	++	Literature search to 1996. Seventy-six studies (37 RCTs, 29 cohort studies, nine uncontrolled before and after studies, one crossover study of three parallel interventions). **Supermarket settings:** One RCT, three controlled cohort studies judged to be of good quality, one RCT and one uncontrolled study judged to be moderate quality and two poor quality cohort studies, i.e. most studies graded research type 2. Seven studies were based in the USA and one in Canada.	To review health promotion interventions to promote healthy eating in the general population. Little information on who provided interventions. Information is provided for only two studies – one study delivered by the authors and the other by a dietitian.	Follow-up periods were minimal or non-existent. Six of eight studies assessed the impact immediately after the intervention while two studies followed-up outcomes 4 weeks post-intervention. No summary information for supermarket settings. Where assessed, effects generally only lasted as long as the intervention was in place.	Point-of-choice programmes supported by informational brochures and local promotion had a positive effect on sales of at least some low fat or 'healthier' items (items that aid reduction in fat intake and/or increased fibre, fruit and vegetable intake) in two of the three good quality studies while the intervention was in place. The magnitude of the effect ranged from 1–2% of total market share. The third study showed no effect on total sales of low fat or 'healthier' items (i.e. aid reduction in energy, fat and dietary cholesterol intake). (Good quality studies: Ernst 1986; Rodgers 1994; Levy 1995.) Two studies of educational videos (Winett 1988, 1991) resulted in a decrease in the fat content of purchases of 4–5% energy while the intervention and feedback were provided. The educational videos used various forms of modelling, goal-setting and feedback addressing nutrition education, personal control of diet, options for new purchases.	Good quality but relatively dated systematic review. No UK trials in supermarket settings.
Steenhuis 2004	RCT Cluster	1	+	2203 clients of 13 Dutch supermarkets.	**Aim:** To assess the effect of nutrition education with or without shelf	Six-month intervention with questionnaires	48% response to pre-questionnaire, 80% (of this 48%) responded to the 2-month and 83% to the 6-month post-	No allocation concealment. Self-reported fat intake by questionnaire. Intention

				Clients were 80% female, medium education, mean age 46 years, mean BMI 24.3 kg/m^2.	labelling on reduced fat intake. Supermarkets were randomised to: 1) no intervention (control); 2) education alone (posters, brochure, recipe cards, self-help manual etc.); 3) education with shelf-labelling of low-fat products. **Delivered by:** University researchers. No power calculation.	at 1 month pre- and 2 and 6 months post-intervention.	intervention questionnaires. No significant effects were found for the educational intervention, alone or with the labelling, compared with control, on total fat intake and the psychosocial determinants of eating less fat.	to treat (ITT) poorly addressed. All supermarkets followed up but variable questionnaire responses. Meets criteria for a **social marketing** intervention (see methodology).
Kristal 1997	RCT Cluster	1	+	Eight supermarkets in Iowa, USA. No demographic differences between stores. 84% of respondents were women, even age distribution, 18 to ≥65 years old, 28% considered themselves ‘farm families’.	**Aim:** To evaluate whether a supermarket point-of-purchase intervention could increase shoppers’ consumption of fruit and vegetables. Four stores were randomised to an educational intervention (flyers, signs, recipes, coupons, food demos, store staff dressed as vegetables) and four to control. **Delivered by:** Probably a	Eight-month intervention and 1-year follow-up (i.e. 4 months post-intervention).	**Overall response rates to exit interviews:** 59.8% in intervention (I) and 67.2% in control (C) stores, and similar at baseline and follow-up. Response rates to take home survey 74.5% (I), 72.3% (C) at baseline and 77.5% (I & C) at follow-up. Compared with change in control shoppers, the percentage of intervention store shoppers in the action or maintenance stage of dietary change increased by 8.4% but this was non significant ($p < 0.07$), and there was no corresponding increase in fruit and vegetable consumption.	No allocation concealment. No ITT analysis. Not included in the review by Matson–Koffman (reason unknown – may have been excluded by the authors or missed by the search strategy).

					combination of higher education research and supermarket employees. No power calculation.			
Computerised intervention								
Anderson 2001	RCT individual	1	+	USA supermarkets, probably Virginia but not stated. Participants were 96% female, 92% White, mean income of US$35,000 and mean education of 14.8 ± 2.1 years. Participants (self-selected) were recruited in five supermarkets during face-to-face contact followed by a mail-back of enrolment materials. An expression of interest was acknowledged when a shopper returned at least some part of the enrolment packet.	**Aim:** To explore the extent to which treatment effects were mediated by social cognitive variables using measures of self-efficacy (for buying, preparing, eating and serving lower fat and higher fibre foods and more fruits and vegetables) and outcome expectations shown to explain nutrition behaviour among food shoppers).* Based on a self-administered, computer-based intervention on nutrition behaviour in supermarket food shoppers. Individuals randomised to tailored information and regulation strategies delivered in 15 brief weekly segments, or control.	15-week intervention plus 6-months follow-up.	795 expressed interest and 363 recruited. At end of intervention all controls and 87% intervention group completed questionnaires. At follow-up 62% control and 49% intervention provided full questionnaire and receipt data. The treatment group was more likely than the control group to attain goals (i.e. personalised nutritional goals set during the intervention) for reducing fat intake at the end of the intervention ($p < 0.001$) and at 6-month follow-up ($p < 0.05$). There was a trend towards goal attainment for increasing fibre and fruit and vegetables intake post-intervention ($p < 0.1$) but this was not significant.	Nutrition for Life (NFL) computerised intervention. No allocation concealment. No ITT. Subjects were highly motivated. Participants received US$10 for completing enrolment forms, US$10 for baseline, US$15 for post-test food frequency questionnaires (FFQs) and Food Beliefs Surveys and US$20 for follow-up FFQs. Participants also received US$5 per week for returning annotated food shopping receipts during baseline, US$7 per week during the intervention and US$10 per week during follow-up. *Social cognitive theory suggests nutrition goal-setting and self-regulation may directly improve participants’

					Delivered by: Higher education researchers and supermarket employees delivered intervention. Computerised element self-delivered. No power calculation.			nutrition-related behaviour.

Point of choice/purchase								
Knox 2001	Cross-sectional survey and qualitative interviews	3	+	**Product development personnel:** Qualitative interviews (*n* = 47) with key food product development personnel from 27 food companies throughout Northern Ireland and England. **Consumers:** Qualitative interviews (*n* = 90) followed by survey (*n* = 1004) of customers in retail	**Aim:** 1) To determine those factors most important for successful reduced fat product development; and 2) to gain insight into the consumer view of reduced fat foods and to determine barriers to the uptake of reduced fat foods from the consumer	N/a Cross-sectional plus interviews.	**Consumer qualitative:** Ninety-six approached, 90 interviewed (60 in Northern Ireland and 30 in England) in store and 68 (75.5%) returned for a debriefing interview on exiting the store. **Consumer survey:** More than 3000 people approached, 2148 refused to participate (32.8% response rate). **Qualitative:** Uptake or rejection of reduced fat	Sample characteristics for the key food product development personnel and details of interviews not provided Low response rate to questionnaire. Largely female

				outlets in Northern Ireland and England. **Qualitative sample:** 90% female, age distribution slightly skewed towards the 40s. **Survey sample:** 77.5% female, age was normally distributed. **Qualitative:** 34.4% housewives or retired. **Survey:** Sample slightly biased towards the lower middle class and upper working class. 64.8% held GCEs or about with a large proportion holding no formal qualification (20.6%).	perspective Product development personnel described their experiences to provide insight into problems encountered re development, launch and marketing of reduced fat products.* **Consumer qualitative:** 10–15 min interview re food choices. **Survey tool:** Dietary views and attitudes. Participants were interviewed prior to commencing shopping and were asked upon leaving the store if they thought the interview had influenced their purchases and were requested to provide the researcher with a copy of their till receipt (i.e. interviewed before		foods influenced by health concerns, ‘goodness of fit’ with dietary health strategies, particularly weight reduction, perceived inferior sensory attributes of the products and scepticism towards reduced fat foods and fat claims. Although none of those who said they were influenced by the interview had bought reduced fat products, 5% of respondents said they had thought more about their purchases as a result of the interview. 66% of those re-interviewed on leaving the store believed that the interview would not influence subsequent purchases. **Survey:** 69.3% of respondents felt that nutritional information on food products was helpful. Lower socio-economic groups appeared more likely to find information difficult to understand (*p* = 0.021), whilst those in higher economic groupings were significantly more likely to attribute confusion to conflicting dietary advice (*p* = 0.002). Reported barriers to uptake of reduced-fat food products – confusing nutritional labelling information and conflicting dietary advice makes it difficult to make informed decisions. Authors commented that participants were sceptical of advice offered and	sample and likely to be motivated. Compliance for consumer qualitative interviews was high (94%) although the sample consisted of 81 females and nine males. Compliance for the consumer survey was very low at 33%. *Qualitative interviews with product development available but not considered of relevance to this review.

					bought groceries). **Delivered by:** Higher education researchers probably. No power calculation.		claims made for reduced fat foods. 59% indicated that reduced-fat foods were inferior in taste and over 90% felt that taste was the most important criteria in selecting meat and dairy products. Those reporting barriers more likely to be male, young, sceptical to products and claims, report lack of will power and concerns on expense. Uptake associated with being female, older, belief that reduced fat products are healthier, concern about health and body weight, and adopting a dietary health strategy).	
Dibsdall 2002	Qualitative	3	+	Fourteen middle-aged women from a low-income Housing Association in Norwich. Women had a mean age of 51.3 years, all had some profession other than housewife although only seven were in full-time, low-paid employment.	To provide an in-depth account of the beliefs and experiences pertaining to food and health from a specific group of low-income women. Letters were sent to residents inviting them to take part in a health study. Individual semi-structured 50 min interviews were conducted by one researcher. Long-term health (particularly cancer) and healthy eating, (particularly fruit	Interviews between July and September 2000 No follow-up.	Women reported being confused by messages surrounding healthy eating. However, participants were aware of and agreed with the basic recommendations for a healthier diet, high in fruits and vegetables and low in fats, sugars, and salts. ‘Fresh’, ‘natural’ and ‘organic foods’ were seen as healthier, whereas processed food and foods containing chemical additives were perceived as less healthy, even possible causes of cancer. Participants reported good control of food availability and budgets, but that purchasing organic foods and buying ‘more’ foods such as more fruits and vegetables was beyond their budgetary control. Irrespective of the healthiness of their diet, the participants displayed a basic lack of motivation to change eating	Small sample size and low response rate to invitations to participate (9%) may have led to the possibility of selection biases. NB. Authors state that they expected the low response rate from the letters inviting study participation ‘given the commitment required from respondents,

					and vegetable consumption), were explored. Audiotaped interviews were transcribed verbatim, coded and analysed by two people and themes were identified for each interview. **Delivered by:** Higher education researchers. No power calculation.		behaviours.	the lack of incentive and the knowledge that individuals from low income groups in the UK generally refuse such invitations'.
Food deserts								
Wrigley 2003	Before and after study	2	+	Local authority housing estate area of Leeds (Seacroft) – within the top 5% most deprived wards in England. Essentially a low-income, compoundly deprived, White area. **Respondents at baseline:** 82% female. 9% 17–24 years and 22% ≥65 years. 20% in full time work, 24.7% employed at home, 5.5% unemployed. 72.5% GCSE or below. 16.5% income of <£5000 per annum, 13% >£20,000 and 17.5% refused information. Household	**Aim:** To assess the impact of a retail provision intervention (the opening of a retail centre including a Tesco store in the locality) on food consumption patterns, and by extension diet-related health, in a deprived, previously poor-retail-access community. Two waves of study in June/July 2000 (before, approximately	Before and after study.	Of 3000 households contacted, 1009 respondents completed the 'before' wave of the survey (34%) and 615 completed the 'after' wave (21%, or 61% of the baseline respondents). Of respondents completing both waves, 45% switched to the new store, claiming ease of access and convenience. Those who didn't switch were concerned about the expense of the store (28%) and its large size and layout (21%). Across the 615 respondents who completed both waves, mean consumption of fruit and vegetables increased insignificantly by 0.4 portions per day (from 2.88 to 2.92). The group that switched to the new store (*n* = 276) increased their	Survey was pre-tested. Power calculation used although detail unclear. Attempts to get representative sample were made. Links with Whelan 2002 . Authors confirmed (3 June 2005) that 'the bias introduced as a result of the attrition (between

				deprivation score: 0, (least deprived) 25.5%; 1, 29.4%; 2, 30.2%; 3, 11.9%; 4 (most deprived), 1.5%.	5 months before the opening of the new store) and in June/July 2001 (after, 7–8 months beyond the opening of the new store). Seven-day food-consumption diary, plus interviewer-administered household questionnaire. **Delivered by:** Fieldwork by market research team and survey designed by university researchers, market research team and J. Sainsbury. Power calculation used but statistical power not stated.		consumption by 0.23 (2.66 to 2.89; *p* = 0.034) portions per day compared with those who did not switch (*n* = 339) (–0.13; 3.07 to 2.94, *p* = 0.178).	waves 1 and 2 which they checked very carefully) was fairly minimal'.
Whelan 2002	Qualitative	3	++	Residents in the Seacroft area of Leeds, a 'food desert' prior to a major improvement in food retail accessibility. Thirty-three women and two men aged 18–40 years. Area mainly deprived housing estates with a 'smattering' of private housing.	**Aim:** To explore individual food shopping behaviour, consumption patterns and attitudes towards a healthy diet. Five focus groups (between five and ten members)	N/a. Focus groups.	Recruitment rate unknown. Younger women, especially those with low incomes, were more concerned about cost rather than the quality of the food bought. This often led to foods being bought exclusively in budget stores, which may have imposed important constraints on what was available to purchase. When asked 'What influenced the foods they bought', older women tended	Recruitment and complete details of sampling frame not reported. Links with Wrigley 2003 . The focus groups were not composed

					sampled opportunistically. **Delivered by:** Higher education researchers. No power calculation.		to be less worried about the cost of food and more enthusiastic regarding buying foods that would be perceived as healthier. For the elderly, the main issues related to physical access constraints.	of members of the main Seacroft sample. Author confirmed 5 July 2005.
Wrigley 2004	Qualitative	3	++	Residents in the highly deprived Seacroft area of Leeds. Recruitment was conducted by experienced fieldworkers and five of eight groups consisted of residents who had switched their main food shopping source in the post-intervention period to the new store. Forty-nine participants comprised eight focus groups in age gradients 17–34 years (*n* = 4), 35–54 years (*n* = 2), >45 years (*n* = 1) and >55 years (*n* = 1). Focus groups were predominantly composed of socio-economic group D/E. Focus groups were conducted in September 2002 (a little over 1 year on from the main post-intervention household-questionnaire surveys and 1 year 10 months	**Aim:** To explore the impact of increased physical access to full-range retailing in the area, assess the views of the residents who had switched their main food sources as a result of the intervention compared with those who had not and to investigate the perceptions of the impact of the intervention on food consumption habits and their potential to eat a more healthy diet. **Delivered by:** Higher education researchers. No power calculation.	N/a. Focus groups.	77% of those recruited attended with the exception of groups 1 and 2. Walking to the 'main' food source, with its associated flexibility and cost-savings, had become a viable option for the majority of focus group participants and physical access coping strategies had significantly altered. However, economic access constraints (with the exception of certain direct reductions in the transport costs of food shopping) had for many remained fundamentally unaltered. Overall, there was little evidence (if any) from the focus groups concerning the impact of the new store on the potential of participants to eat a more healthy diet. What evidence there was suggested that a minority of participants were using the transport cost savings associated with improved access to full-range food retail provision to buy fresh food.	Focus groups 1 and 2 (younger switchers) where nine individuals had been recruited for each group only four and three respectively attended. Total number recruited unclear. Participants give small monetary incentive to attend the focus groups. Focus group residents not drawn from the main Seacroft sample (author confirmed 6 July 2005).

				from the opening of the new store) at a variety of venues in the vicinity of the intervention store and lasted approximately 75–90 min. Groups were moderated by a qualitative researcher. Each session was audio taped, transcribed and analysed by the moderator using standard content analysis.				
White 2004	Cross-sectional survey	3	++	Representative sample of households and individuals in Newcastle upon Tyne and all retail outlets selling food, as well as data on access to retail outlets and socio-economic data. Retail outlets were surveyed to get details on type, size and opening hours plus the range, cost and quality of 33 commonly eaten food items. Surveyed sample were >16 years old, 59% women, 95% White European and 37% in full-time employment. The sample of households was slightly biased towards higher socio-economic status,	**Aim:** To determine the relationship between dietary intake and socio-economic factors at individual, household and neighbourhood levels and retail access to a 'healthy' and affordable diet, to determine if food 'deserts' exist and, if so, to describe their characteristics. Food Standards Agency report. **Delivered by:** Higher education researchers. No power calculation.	N/a. Cross-sectional survey with multi-level modelling.	5044 individuals (of 6162, 83% response rate) in 3153 households (of 17801 contacted – 18% response rate) completed the main surveys. 560 retail outlets (of 658 approached, 85% response) were surveyed. Individuals in the lowest socio-economic quintile were less aware of current healthy eating messages than those in the top quintile. Poor knowledge was consistently associated with less healthy eating, as well as with other measures of a less healthy lifestyle (e.g. low levels of PA and smoking). The availability of the full range of foods, the 'healthy' and the 'unhealthy' baskets was not socio-economically patterned by area and there were no significant cost variations. The data did not demonstrate a relationship between most indicators of healthier eating and	Unknown if questionnaire validated but otherwise a good study. Low household response rate indicates selection bias toward those of higher socio-economic status.

				and of individuals to older age groups and women, compared with the Newcastle population as a whole. An initial random sample of 11,266 private households was selected using the Post Office's Postcode Address File (PAF). Each selected household was sent a questionnaire pack, addressed to the householder and a pre-paid envelope. The main food shopper was asked to complete the questionnaire. As a result of a poorer than anticipated response rate a further sample of 6535 households was selected using the same procedure 3 months later. Respondents were asked if they and other household members were willing to take part in the individual survey. Those who agreed were added to the Phase 2 study sample list and sent an individual questionnaire.			factors relating to the local retail environment. The authors concluded that key predictors of healthy eating are primarily dietary knowledge, relative affluence and a 'healthy' lifestyle, so it seems unlikely that those people whose diet is 'less healthy' than desirable would eat more healthily if supplied with improved retail provision.	
Furey 2001	Range of qualitative/ quantitative methods	3	+	A range of research methodologies were employed in locations throughout Northern	**Aim:** To identify possible locations of food deserts in Northern	N/a	The authors concluded that certain user groups in Northern Ireland (non-car owners and lower-income family units) cannot	A good range of research methods were used and

				Ireland. Of the (stratified random sample of) food shoppers interviewed half were from rural and half from urban locations. 77% were female and the majority were aged ≥65 years. The social class status was skewed towards the lower socio-economic classes because the fieldwork was largely conducted in housing estates and 51% fell into the unemployed, casual worker, housewife or retired groups with only 12% professing themselves as social class A or B.	Ireland, quantify their characteristics, establish which consumer groups are affected and make recommendations to negate the effects of food deserts. Quantitative methods included a consumer questionnaire, comparative shopping exercises, and shopping diaries. Qualitative methods included consumer focus groups and interviews with retail managers. **Delivered by:** Higher education researchers. No power calculation.		achieve an affordable, healthy diet – possibly to the detriment of their health status. 11% of Northern Ireland consumers self-reported a real concern regarding food poverty issues, suggesting simultaneous financial constraints on food choice as well as the market-inflicted physical access difficulties. 82% noticed how their seemed to be fewer food stores than previously, while two thirds argued the town centre food store was more convenient than the edge of town.	combined. Little detail of study questions was provided, nor was there a discussion of the researchers' viewpoint or potential limitations of the study. Potential for bias cannot be ruled out.
Caraher 1998	Cross-sectional survey	3	+	The Health Education Authority's (HEA) 1993 Health and Lifestyles survey. 5553 interviews with 16–74-year-olds at a random sample of addresses in England, stratified by NHS region.	Corroborative evidence to look at the issues of access to food and the influences people face when shopping for a healthy food	N/a	9% of social group I and II respondents report no concern with what they eat compared with 24.9% in class III manual and 21.2% in classes IV and V. A higher proportion of individuals in the lower income brackets (11% lowest vs. 7% highest income	Results were weighted as far as possible to allow for potential bias due to the policy of interviewing

				The Registrar General's six-group social class classification was used.	basket. No power calculation. **Delivered by:** Data from the HEA survey carried out by Market & Opinion Research International (MORI).		bracket) and people aged ≥55 years use local shops (10.5 vs. 7.9% 35–54-year-olds). The major issue for those in the lowest income bracket in deciding where to shop is cost (47.3%) whereas speed and convenience is the key issue for the highest income groups (69.4% of the highest income group). The quality of food and the range of healthy foods were cited by less than 10% of respondents as factors in deciding where to shop. 12.7% of men compared with 5.4% women cited not knowing how to cook as a restriction on their choice of food. When asked about factors they felt limited their choice of food, a third of women compared with 7.7% of men cited transport as a factor.	only one person per household and to compensate for the under-representation of certain age groups. Self-reported data.
Fruit and vegetable delivery scheme								
Ali 2001	Cross-sectional survey	3	+	Two London estates. Fifty-one households ('51 individual members'), recruitment details not reported. 66% respondents were aged between 25 and 59 years, 16% male, 39% in work (full or part time). 24% White, White British, or English. 18% Black African, 10% Caribbean/Black, Afro-Caribbean/Caribbean 47% on state benefits.	**Aim:** To explore whether fruit and vegetable delivery schemes met a need on the estates and to see what lessons could be learned to help future projects. Survey with qualitative and quantitative sections to evaluate two 6-week pilot fruit and vegetable delivery schemes. Survey	N/a. Cross-sectional	Fifty-one households completed information about circumstances survey, 75% (*n* = 38) completed the views and experiences survey. 74% of people who filled in survey questionnaires said they ate more fruit and vegetables while on the scheme. 42% of people of filled in survey questionnaires said that they were eating more fruit and vegetables after than before the scheme. 45% of people who filled in the	Data analysis may not be rigorous. Some conclusions drawn through use of additional unreported data. Self-reported fruit and vegetable intake.

					conducted after the pilot scheme (time difference not reported). **Delivered by:** Evaluation group led by the project worker and a Health First researcher. No power calculation.		questionnaire listed convenience/ease of access to fruit and vegetables as a benefit. 97% said they would use a new scheme if it was set up.	

EVIDENCE TABLE 2: RESTAURANTS AND CAFÉS

SUMMARY

Evidence of efficacy for weight management/reduction
No studies were found that reported weight outcomes.

Evidence of efficacy for diet/physical activity outcomes
Dietary outcomes

Point-of-purchase: Four systematic reviews were found. They looked at all types of research study, 28 primary studies in all, and had limited overlap. Two were good quality (Roe 1997; Seymour 2004) and two much lower quality (Holdsworth 1998; Matson-Koffman 2005). All the reviews concluded that informational point-of-purchase or choice strategies increased the consumption of targeted items. Seymour (2004) reported that most of the restaurant studies reported some significant increased sales of targeted menu items but no data were provided. Roe (1997) concluded that point of choice promotions led to an increase in sales of promoted items by 2–12% total market share but the effect generally only lasted as long as the intervention was in place. Since the reviews lacked detailed information, unpicking was carried out. Of the 28 primary studies, none met the rapid review inclusion criteria (a control group and at least 3-months follow-up).

A single RCT was found that was not included in any of the reviews and was carried out in the UK (Stubenitsky 2000). This found that provision of an acceptable lower fat, lower energy main course dish in a restaurant setting had a direct effect on fat and energy intake, was not compensated for in other components of the meal and was not affected by consumer knowledge of the ‘lower fat’ nature of the dish (through menu text). For the group choosing the target dish who were served the full fat version, their total energy and fat intakes during the meal was increased compared with those served the lower fat option [$F(3,80) = 5.27$, $p = 0.0002$ and $F(3,80+13.82$, $p \leq 0.0001$].

Physical activity
No studies were found that reported PA outcomes.

Evidence of corroboration in the UK:
Five UK corroborative studies were found of relevance to eating out.

In a cross-sectional survey of 14-year-olds in London (Watt 1996) the most frequently cited factor perceived as being helpful to promote future changes in general eating habits was strong will power (83.3%). Other important factors included wider availability of healthy foods (67.3%), support from family (66.7%), advice from doctors (58.2%), cheaper healthy foods (53.3%) and better food labelling (50.0%). Between the social classes, a difference emerged for friends’ support, information booklets, wider availability of healthy foods, costs of healthy foods and own will power, with these being considered more helpful by individuals from non-manual households ($p < 0.05$). A companion qualitative study (Watt 1997) found that 'healthy foods' were considered to be largely irrelevant, unappealing and expensive by most young people interviewed, and not readily available outside their own homes. In contrast 'fast foods' were considered part of their independent lives, commonly eaten with friends, associated with enjoyment and relaxation, ready available, appealing and inexpensive. Parental disapproval appeared to be part of their appeal.

From a questionnaire study of public eating places (Warm 1997) reported that Heartbeat Awards (HBA) premises compared with controls were more likely to report that they offered what they perceived as a healthy dish ($p < 0.001$) and they also recorded an increase in purchases of brown rice ($p < 0.001$) and more low-fat spreads ($p < 0.05$,for public eating places). The data were self-reported and there is potential for bias. Another study of HBA public eating premises (Holdsworth 1997) found that the main influences were quality of food (72.2%), affordable prices (60%), good service (53.3%), variety of choice (48.5%) and location (42%). The availability of healthy food choices (30%) was least often selected, but nearly twice as many women (34%) as men (17.2%) said that this influenced their choice of eating-place ($p = 0.014$). Availability of healthy food choices was more important to those aged ≥45 years (40.5 vs. 25.5% of ≤45-year-olds; $p = 0.016$).

A qualitative study of community cafés in Glasgow (Simons 2004) made the following recommendations for increasing healthy choice sales: the need for a strong lead to provide coordination and support; café staff should be actively involved, trained and supported; promotion to be encouraged and best practice shared between cafes; healthy options to be competitively priced and to include 'special offer' incentives.

Evidence of efficacy (internal validity) for weight maintenance/reduction								
No evidence found.								
Evidence of efficacy (internal validity) for diet outcomes								
Seymour 2004	Systematic review	2	++	Literature search from 1970 to June 2003. Thirty-eight studies reviewed including five restaurant interventions, only one with a strong research design but no RCTs.	**Aim:** All articles that included a nutrition intervention with an environmental or policy component conducted in an English-speaking industrialised country.	The studies varied in length from 4 weeks to 1 year	The general conclusions of this wide-ranging review of point-of-purchase behaviour were that interventions in 'limited access' sites (i.e. where few other choices were available) had the greatest effect on food choices. The authors reported that most of the restaurant studies reported some significant increased sales of targeted menu items. Not enough information was provided to assess the exact number with significant positive results. All used some form of information strategy (such as symbols or labels to promote low fat items) and, overall, providing information in the restaurant setting appeared to be associated with increased purchase of targeted items, suggesting that the specific strategies were not as important as the act of intervening.	None of the studies appeared to be in a UK setting. Although a good review the evidence tables lacked detail in terms of significance values and the quality assessment methods used.
Roe 1997	Systematic review	2	++	Literature search to 1996. **Catering settings:** Fifteen studies (one RCT, eight	To review health promotion interventions to promote healthy eating in the general population.	Range of timescales. Two weeks to 6 months in catering settings.	Point of choice promotions used in five of fifteen studies and all four of the restaurant studies, used signs to encourage selection, backed up with written educational and promotional	Good quality but relatively dated systematic review. No UK trials in restaurant settings. The

				uncontrolled before and after studies, five cohort studies, one crossover study of three parallel interventions) in all including community, school and work outlets (three judged to be of good quality) but only four in public restaurants (none judged to be good quality) – i.e. most studies graded type 2.	Information on who delivered the interventions not provided.		materials such as posters, information boards, fliers and table tents (nb: assumed that table tents are three-dimensional table displays). These led to an increase in sales of promoted items by 2–12% but the effect generally only lasted as long as the intervention was in place.	restaurant studies were all assessed as moderate quality (three uncontrolled studies and one crossover study) – i.e. no restaurant RCTs. **Restaurant studies:** Mayer 1986 Colby 1987 Wagner 1988 Albright 1990 **University studies:** David-Chervin 1985 Meiselman 1994 (study 1) Meiselman 1994 (study 2)
Matson-Koffman 2005]	Systematic review	2	+	1970 – October 2003 (more comprehensive search from 1990). Sixty-five pre-1990 and 64 in 1990 or later intervention studies of all research types (authors report as 26 experimental studies, 51 quasi-experimental studies and 50 non-experimental studies). Of the nutrition studies, 33 looked at the availability of nutritious foods and	To review the literature to determine whether policy and environmental interventions can increase people's PA or improve their nutrition. Studies published pre-1990 are only briefly summarised. Study designs for individual studies are not reported and are referred to as 'large scale trials'.	Not stated for pre-1990 studies. Follow-up periods for studies published between 1990 and 2003 ranged from 4 weeks to 10 years to three years for post-1990 studies.	From this narrative review (with some data on post-1990 but no data provided on pre-1990 studies) the authors made the following recommendations: • Use point-of-purchase strategies, including menu and shelf labelling, to increase purchases and consumption of healthier foods. • Promote policies and environmental supports that increase supply and access to healthier foods and beverages in vending machines, restaurants and cafeterias, including more fruits and	Supermarket and restaurant studies were combined (see also Evidence Table 1). Recent but confusing review of varied study types and outcomes. No unpublished studies included. Study quality assessed but doesn't appear to have been taken into account in the summary. The analysis of results was different for pre and post-1990 studies. Follow-up periods have not been reported for all of the studies

				29 at point-of-purchase strategies in supermarkets and restaurants. Studies pre-1990 only briefly summarised. Study designs of individual studies not reported and referred to as 'large scale trials'. None of the restaurant studies were RCTs. No post-1990 UK studies. Pre-1990 unknown. PA data not extracted as better review.
Holdsworth, 1998	Systematic review	2	+	Literature search date unknown. Twenty-one nutrition labelling schemes at the point-of-purchase published between 1978 and 1993 (13 pre-1990 and eight 1990 or later). Of the 21 studies six (three prescriptive, two descriptive and one prescriptive replaced by a	To review point-of-choice nutrition labelling schemes in catering establishments to describe the variety of schemes and determine the characteristics of effective interventions, including both descriptive and prescriptive labelling.	Range of timescales. Eight weeks to 12 months in public eating places and 4 weeks to 16 months in universities.	Most of the studies reviewed demonstrated some positive short-terms benefits from schemes although it is unclear which is the most effective labelling format, i.e. labelling of healthier food choices or providing nutrient information.	Literature search dates have not been reported. Varied study types and outcomes. No details of the methods used for quality appraisal. Number of papers identified and methods of the selection process not reported. Many of the interventions were of short duration, had short-term follow-up

				consumer driven scheme) were conducted in public eating places and four (descriptive labelling) in university settings. None of the restaurant studies were RCTs.				periods and few had a control group. The majority of the schemes were from the USA. **Public eating places:** Scott 1979 Dubbert 1984 Wagner 1988 Albright 1990 Heartbeat Award Scheme 1990 Green 1993
Stubenitsky 2000	RCT	1	+	279 members of the public booking a meal at a restaurant during the week in which the study was being held. Mixed age group but majority 'somewhat older than average age' – 11.6% ≤34 years old, 22.8% 35–49 years old, 25% 50–64 years old, 40.6% ≥65 years old. Silver service training restaurant at a City College Hotel School in Norwich. Actually refers to	To examine the influences of nutritional information and consumer characteristics on meal quality expectations, food selection and subsequent macronutrient intakes of consumers offered a reduced-fat option in a restaurant. Subjects seated in different parts of the restaurant were presented with menus differing only in printed information accompanying one target dish – smoked haddock with Welsh rarebit. Four groups:	Questionnaires handed out after ordering and before meal was served; repeated after meal was finished with modified wording relating to actual perception of meal just eaten; and final questionnaire re attitudes and beliefs towards eating 'healthy eating' options in a catering environment, 'completed following the entire meal'.	Subjects in the older age group differed in absolute terms from those in younger groups but this did not significantly influence the direction of any of the outcome measures. Menu information had no effect on total energy and fat intake among the three groups receiving the RF (reduced fat) target dish The proportion of subjects choosing alternative options was not influenced by the presence of information on the menu ($p \geq 0.05$). For the FFB group choosing the target dish, their total energy and grams of fat intake was increased compared with those served the lower fat option [$F(3,80) = 5.27$, $p = 0.0002$ and $F(3,80) = 13.82$, $p \leq 0.0001$]. No consistent pattern in	No allocation concealment. ITT analysis used. Subjects in this study tended to be older than average, which might have some influence on results although direction of outcome measures was the same in all age groups. Most of the subjects were regular visitors to this restaurant, hence uniformly high pre-meal expectations based on prior experience. Nutritional calculations were based on amount and type of food served, as practical considerations meant leftovers could not be

				two separate weeks in June and October 1996 but results appear to have been aggregated between the two as no distinction is made.	1) Full-fat blind (FFB) – no additional information, full-fat food served. 2) Reduced-fat blind (RFB) – no additional information, reduced-fat food served. 3) Reduced-fat informed (RFI) – 'this is a lower fat option' – reduced-fat food served. 4) Reduced-fat informed with details (RFID) – 'This lower fat option is prepared with reduced-fat cheese and skimmed milk' – reduced-fat version served. **Delivered by:** Training school. No power calculation.		differences between pre-meal (expectation) ratings and post-meal (actual) ratings between the four groups. FFB group had significantly lower expected liking, taste and texture rating than the other three groups [$F(3,80) = 3.98$, $F(3,80) = 6.52$ and $F(3,80) = 3.9$; all $p < 0.05$]. Did not find differences in overall meal fat and energy intake of subjects informed versus not informed of their main course dish (RFI vs. RFB). Provision of menu information did not have a significant effect on pre-meal expectation ratings. Provision of an acceptable lower fat, lower energy main course dish in a restaurant setting had a direct effect on fat and energy intake, which was not compensated for in other components of the meal, and was not affected by consumer knowledge of the 'lower fat' nature of the dish (through menu text). Measures of meal expectations, actual acceptance and perceived matching of expectations were also not affected by this information.	measured. Accuracy of actual intake data would have been enhanced by this but effect would be expected to be small compared with that observed for meal composition. Unclear whether questionnaires were validated. Self-reported behaviour.

Simons 2004	Qualitative	3	+	Customers and staff at 13 community cafés in greater Glasgow, plus stakeholders in the project. No socio-demographic details provided.	**Aim:** To assess the effectiveness of the five components of the Scottish Healthy Choices Award intervention in the 13 cafés that took part in the pilot. Each café was visited for a full day by a researcher and as many customers, staff and volunteers interviewed as possible. Interviews were also undertaken with 12 stakeholders (Greater Glasgow NHS Board, mobile chefs, NHS Health Scotland, Project management team etc.) face-to-face or by telephone. **Delivered by:** Collaboration of NHS, city and local organisations in Glasgow. Evaluation carried	N/a	A large number of recommendations for the scheme were made including: the need for a strong lead to provide coordination and support; café staff should be actively involved, trained and supported; promotion to be encouraged and best practice shared between cafes, healthy options to be competitively priced and to include ‘special offer’ incentives.	Uncontrolled evaluation study – effectively a series of case studies with stakeholder interviews.

					out by independent consultants. No power calculation.			
Holdsworth 1997	Cross-sectional survey	3	+	Eleven eating places in Leicestershire with the HBA (one hotel, two leisure centres, two public houses, two restaurants, four cafés), all in rural locations. Customers completing the questionnaire were adults aged 16–80 years, two-thirds <45 years, 78.5% were female and 97.4% were White. One-third was from social class group 1, and one-third from group 4, and only 13.2% in the HBA target group 3.	**Aim:** To evaluate customers' perspectives of the HBA Scheme in 11 public eating places. A self-completed structured questionnaire was administered to all customers at the establishments on the day the researcher visited. **Delivered by:** Evaluation was carried out by University researchers. No power calculation.	N/a	Of 377 customers approached, 271 completed questionnaires (72%). The response rate varied between establishments from 47.5% to 100%. The main influences on choice of eating place were quality of food (72.2%), affordable prices (60%), good service (53.3%), variety of choice (48.5%) and location (42%). The availability of healthy food choices (30%) was least often selected but nearly twice as many women (34%) as men (17.2%) said that this influenced their choice of eating place ($p = 0.014$). Availability of healthy food choices was more important to those aged ≥45 years (40.5 vs. 25.5% of the <45-year olds; $p = 0.016$).	Most outcomes related to awareness – possible relevance to awareness review.

Between the social classes, a difference emerged for friends' support, information booklets, wider availability of healthy foods, costs of healthy foods and own will power, with these being considered more helpful by individuals from non-manual households ($p < 0.05$) than manual.	relevance to schools review.
Warm 1997	Evaluation	3	++	Public eating places (including hotels, guest houses, public houses and leisure centres), workplace canteens/restaurants and education establishments 'within the former Wessex region' – more specific details are not reported.	To compare the differences between premises with and without the HBA (current catering practices including their purchasing, promotion and availability of healthy food options and cooking procedures).	N/a	497 HBA premises and 495 control premises without the award were sent postal questionnaires. Response rates were 76% (n = 380) and 62% (n = 306) respectively. 39% of those surveyed were public eating places. 76% of premises believed they offered healthier meals, although most premises did not have to	Greater response rate from establishments holding award. Bias may have been introduced by award-holders in over reporting the provision of healthy foods and by

					Delivered by: Regional group in Wessex Regional Health Authority. Unclear precisely who sent out or analysed the questionnaires.		change either their purchasing or cooking practices in order to achieve the levels required to receive the award. HBA premises compared with controls more likely to offer what they perceived as a healthy dish ($p < 0.001$) and recorded an increase in purchases of brown rice ($p < 0.001$) and more low-fat spreads ($p < 0.05$ for public eating places). Although 81% of HBA premises compared with 55% of controls indicated that they actively promoted healthy eating ($p < 0.001$ for comparison), public eating places were the least likely to do so. Both HBA and control premises indicated that there had been an increased demand for more healthy food over the last 5 years with active premises seeing a larger increase in demand than control sites (76 vs. 61%, $p < 0.001$). This change in demand for healthy food had led to more than 90% of premises altering the food served. Increased customer demand was proposed as a motivation to possibly selling more healthy food in	providing more healthy choices than non-respondents. Unannounced site visits could have assessed the extent of potential biases but were not conducted. Self-reported behaviour. Unclear if questionnaire validated.

							the future (58 and 66% for HBA and controls, respectively).	

EVIDENCE TABLE 3: RELIGIOUS ORGANISATION-BASED

SUMMARY

Evidence of efficacy for weight management/reduction

No studies were found that reported weight outcomes.

Evidence of efficacy for diet/physical activity outcomes

Dietary outcomes

Only one study was found that included White as well as Black and ethnic minority groups (BMEGs). Solely BMEG studies will be considered in a future review.

Physical activity

No studies were found that reported PA outcomes.

Evidence of corroboration in the UK

No UK corroborative studies were found.

EVIDENCE TABLE 4: ENVIRONMENTAL CHANGES AND FACILITIES TO PROMOTE PHYSICAL ACTIVITY

- **Active travel vs. car travel**
- **Stair-climbing**
- **Access to space and facilities for physical activity**
- **Safer routes to school**

Note: According to the rapid review parameters, only intervention studies with a control group are included in evidence tables. In two topic areas of this review, stair climbing and walking/cycling trails, the only available evidence comes largely from uncontrolled before-and-after studies with a high potential for bias and, in the case of stair climbing studies, largely short term. Since this is the best available evidence on topics of relevance to the obesity prevention guidelines, they have been included in this review for information and comment by the Guidance Development Group (GDG).

SUMMARY

Evidence of efficacy for weight management/reduction

No studies were identified with weight outcomes.

Evidence of efficacy for diet/physical activity outcomes

Physical activity

Active travel vs. car travel: One good quality systematic review (Ogilvie 2004, including nine UK studies) concluded that targeted behavioural change programmes with tailored advice can change the travel behaviour of motivated subgroups, resulting, in the largest study, in a shift to walking and cycling from car use by about 5% of all trips at a population level compared with a shift towards car use by 2% in the control groups. The review indicated that single studies of commuter subsidies and a new railway station also showed positive effects. The balance of best available evidence about publicity campaigns, engineering measures and other interventions suggested that they have not been effective.

Point-of-decision prompts to stimulate stair-climbing: Two systematic reviews, one good quality (Kahn 2002, including two UK studies) and one more recent but lower quality (Foster 2004b, including eight UK studies) concluded that educational materials such as posters and stair riser banners have a weak positive effect on stimulating stair climbing. Foster 2004b found that most studies saw a short-term effect for up to 3 months though one study saw an effect (+29%) 6 months after baseline. Kahn (2002) noted a range of effect sizes (observed a net increase in stair use compared with baseline levels) from a 5.5 to 128.6%. Three before and after studies were published since these reviews, two in the UK (Adams 2002; Webb 2005) and one in Australia (Marshall 2002). Studies found either no increase in stair use (Adams 2002) or a short-term increase (Marshall 2002; Webb 2005). Marshall (2002) found that stair use dropped to baseline levels 10 weeks into the 12-week intervention. A very weak study (Webb, 2005) compared a 2-week phase of stair riser banners with an identical message followed by 2- weeks with different messages. Stair use increased significantly during both phases compared with baseline but there was no significant different between the two phases. A further study with a very weak study design comparing stair- to escalator-use in a Stockholm rail station (Faskunger 2003) found that, with only one ascending escalator, 35.2% of the population decided to climb the stairs. With two ascending escalators, stair use dropped to 18.2% ($p = 0.000$).

Creation of space for physical activity: One good quality systematic review (Kahn 2002 , all US studies of varying designs) found strong evidence that creation of or enhanced access to places for PA combined with informational outreach activities is effective in increasing levels of PA. Examples of interventions were access to fitness equipment in fitness or community centres and creation of walking trails. One more recent controlled before and after (CBA) trial carried out in the USA (Brownson 2004) and two more recent before and after studies of multi-purpose trails, one in the USA (Evenson 2005) and one in Australia (Merom 2003) have been published. A study of six communities with walking trails compared with comparison communities (Brownson 2004) reported no statistically significant intervention effects although two subgroups showed trends to a positive net change in rates of 7-day total walking in the intervention communities; people with high school degrees or less and people living in households of lower annual incomes (≤US$20,000). Evenson (2005) found that 2 months following the building of a multi-use trail, there was no demonstration in increase of PA amongst adults living within 2 miles (1.6 km) of the trail. Conversely Merom (2003) found that a promotional campaign for a local trail reached and influenced cyclists living within 1.5 km of the trail.

Safer routes to school: One RCT (Rowland 2003) found that assistance from a school travel coordinator did not change children's travel patterns or substantially affect parental fears about the safety of the journey to school. At 1-year follow-up the adjusted odds ratio (OR) for walking, cycling or using public transport in intervention schools was almost identical to that in control schools (0.98, 95% confidence interval [CI] 0.61,1.59).

Evidence of corroboration in the UK

Active vs. car travel
A cross-sectional survey (Foster 2004a) found that, for UK women, the perceived safety of walking during the day and lack of shops within walking distance were significant barriers to walking. Environmental perceptions were not related to the number of women walking for more than 150 min per week whereas having a park within walking distance was significantly associated with this measure in men. Data from two sets of case studies (Sustrans 2004, Department of Transport 2003) provide evidence for improvements in active travel as a result of: (1) improving the walking and cycling environment (e.g. traffic calming, good crossings, lighting); (2) providing better facilities (e.g. cycle stores, traffic free routes); and (3) influencing behaviour (e.g. involving the community, educational schemes, guides, maps and leaflets). Experience from a mass media campaign in Scotland (Wimbush 1998) suggested that a TV advertisement and helpline encouraged motivated individuals (callers to the helpline) to walk more but there was no effect on the population as a whole.

Two years after implementation of the City of London's congestion charging scheme (Transport for London 2005) it was estimated that 5000–10,000 former car journeys (10–20%) had transferred to cycling, walking, motorcycle, taxi or car share since implementation. Before and after street surveys found that walking and public transport were perceived to have improved in comfort and overall quality. Cycle and powered two-wheeler safety were perceived to have improved.

Point-of-decision prompts to stimulate stair-climbing: A large number of stair-climbing studies have been carried out in the UK that provide weak evidence of effectiveness and these are summarised above. Evidence from a worldwide systematic review (Kahn 2002, including two UK studies) suggested that tailoring the prompts either by specifying the benefits of stair use or by customising the sign to appeal to specific populations (e.g. ethnic groups, obese people) may increase intervention effectiveness and that signs were effective for both men and women (three studies). One UK study (Adams 2002) found evidence that prompts could be guilt-inducing (see also workplace review).

Creation of space for physical activity
One systematic review of consultation studies (Cole-Hamilton 2002) and four individual studies (Coakley 1992; Hillman 1993, 1996; Davis Mulvihill 2000) were found.

The systematic review of 93 consultation studies in England (Cole-Hamilton 2002) found that barriers to play for school-age children are fears for their own safety, in particular: bullies; dirty unkempt play areas and parks; the lack of things to do; traffic; lack of facilities for disabled children. Children using staffed provision like: staff who listen; staff who are funny, friendly and fair; having a say in what they do; staff who can deal with conflicts between children.

A qualitative study of English children (Mulvihill 2000) concluded that barriers to PA for 5–11-year-olds were lack of their and parents' time and, for some, expense. Parental barriers were lack of time, lack of safety and the poor condition of local parks. Children aged 11–15 years old stressed the importance of the social aspects of PA and cited cost and lack of transport in rural areas as barriers. A reduction in PA in young women was notable and cited barriers included feeling intimidated by young men, lack of time and lack of self-confidence. Safety was the main parental concern and parents believed that PA declined in females of this age.

A weak report of cross-sectional surveys of English 7–11-year-olds (Hillman 1993) noted that in 1971, three-quarters of 7–11-year-olds were allowed to cross roads on their own. By 1990 this had fallen to one-half. 50% were allowed to use buses in 1971 compared with one in seven by 1990. Bicycle ownership increased from two-thirds in 1971 to 90% in 1990 but only one-quarter was allowed to use them on the roads compared with two-thirds in 1971. Nearly four times as many children were driven to school in 1990 compared with 1971. Boys were allowed far more independence than girls; three in five of the boys could cross roads alone, compared with two in five girls **in 1990.** The primary concerns of parents were danger from traffic, children's reliability and fear of molestation.

A qualitative study of young people in London (Coakley 1992) concluded that young women were less likely than young men to see sport as compatible with adulthood. Financial constraints had a significant impact on sport participation in both sexes. Young women mentioned parental constraints and the influence of boyfriends as affecting their leisure choices whereas young men tended to 'do what they wanted'. For 13–16-year-olds encouragement from parents was particularly important; for people >16 years old adult advocates and role models were more likely to be important. Decisions about sport participation reflected past experiences and were often associated with feelings of discomfort and embarrassment in young women.

A cross-sectional and focus group study of 9–11- and 13–14-year-olds (Davis 1996) found that children were aware of the health promotion messages but felt considerable environmental constraints. Many were not allowed to play outdoors, use local parks or cycle to school – or they did not feel comfortable doing so. Girls especially were restricted in how late they were allowed out. In the children's views, traffic danger, 'stranger danger' and social and cultural factors interact to create barriers to keeping healthy and active. Neither study looked at attitudes to dance, yoga or other 'non-sport' forms of PA.

Safer routes to school: There is good corroborative evidence from the UK that Safer Routes to School (SRTS) schemes can be effective (i.e. at odds with one identified RCT). A series of before and after studies in Worcestershire (Parker 2003) found that, when both a school travel plan (STP) and SRTS programmes were in place, there was a 3% increase in walking, a 4% reduction in single-occupancy car use and a 1.5% increase in car sharing. Bus and cycle use remained largely static. A selected series of 30 case studies of school travel initiatives in the UK (Department for the Environment, Transport and the Regions 1999) found, in the ten schools that reported data, an overall increase in cycle use and decrease in car travel. Effects on walking and bus travel were variable. Another scheme (Jones 2001) found a considerable increase in walking and cycling to school 3 years after the intervention. From baseline, bus use increased considerably (from 44 to 53% to school and from 50 to 56% home) while walking (23–26%, 27–29%) and cycling (3–7%, 3–7%) also increased.

Cross-sectional and focus group surveys (DiGuiseppi 1998; Derek Halden Consultancy 1999; Dixey 1999, 1998; Jones 2001) provide powerful evidence that children would like to walk, cycle or take the bus to school but perceived and actual dangers have led to increased vigilance by parents and reduced activity in children.

One ongoing longitudinal study (EarlyBird, Metcalf 2004) found that being driven to school did not affect the overall PA of 5-year-olds.

A Scotland-wide study of SRTS schemes (Derek Halden Consultancy 1999) included the following recommendations: encourage publicity that identifies for local communities that their involvement can make a real difference; note that many of the measures that can be taken forward within schemes are effective, simple and cheap to implement; reinforce the need to achieve wide ownership at the outset and a good understanding among partners of their complementary aims; ensure that there are clearly defined roles for the project champion; emphasise that projects should be designed for sustainability and publicise success stories.

EVIDENCE TABLE 4: ENVIRONMENTAL CHANGES AND FACILITIES TO PROMOTE PHYSICAL ACTIVITY

Definitions

Physical activity

Any force exerted by skeletal muscle that results in energy expenditure above resting level. The term PA therefore includes the full range of human movement, from competitive sport and exercise to active hobbies, walking, cycling, or activities of daily living. PA per se is a complex, multi-dimensional behaviour.

Exercise

Planned bouts of PA usually pursued for personal health and fitness goals. Exercise is a subset of PA, which is volitional, planned, structured, repetitive and aimed at improvement or maintenance of any aspect of fitness or health.

Sport

A subset of PA, which involves structured competitive situations governed by rules. In Europe, sport is often used in a wider context to include all exercise and leisure PA. The Council of Europe European Sports Charter 1993 defines sport as '… all forms of PA which, through casual or organised participation, aim at expressing or improving physical fitness and mental well-being, forming social relationships or obtaining results in competition at all levels'.

MET

MET stands for 'metabolic equivalent task'. 1 MET = a person's metabolic rate (rate of energy expenditure) when at rest. MET values are assigned to activities to denote their intensity and are given in multiples of resting metabolic rate. For example, walking elicits an intensity of 3–6 METs, depending on how brisk the walk is.

Evidence of efficacy (internal validity) for weight maintenance/reduction								
No intervention studies with weight outcomes.								

Evidence of efficacy (internal validity) for diet outcomes								
Evidence of efficacy (internal validity) for physical activity outcomes								
Active travel vs. car travel								
Ogilvie 2004	Systematic review	1	++	Literature search from earliest date to December 2002. Twenty-two controlled or uncontrolled prospective and controlled retrospective studies included (three RCTs, seven controlled non-randomised trial [CCTs], 11 uncontrolled and one controlled prospective study).	To assess what interventions are effective in promoting a population shift from using cars towards walking and cycling and to assess the health effects of such interventions.	Study lengths varied from 1 to 60 months.	Targeted behavioural change programmes can change the behaviour of motivated subgroups, resulting (in the largest study) in an increase of around 5% of all trips undertaken by walking and cycling. Single studies of commuter subsidies and a new railway station also showed positive effects. The balance of best available evidence about publicity campaigns, engineering measures (such as 20 mph zones or bypasses [England], extending existing cycle route networks [The Netherlands, Germany], new cycle routes [England], downtown auto-restricted zone [Boston, MA, USA]) and other interventions suggests that they have not been effective. The targeted behavioural change programmes (six studies of four interventions) offered an intervention	**UK trials:** Barrell 1995 Hodgson 1998 Social Research Associates 1999 Mutrie 2000, 2002, Babtie Group 2001 Sustrans 2002a, 2000b Rowland 2003 Only three RCTs included but still treated as type 1 research.

							to a motivated subgroup only or information and advice tailored to peoples' particular requirements, or both (e.g. leaflets, time tables, maps, trial free bus or bike passes, personal travel diaries).	
Point-of-decision prompts								
Centres for Disease Control and Prevention 2001 - Summary Report Kahn 2002	Systematic review	2 Before and after studies only.	++	Literature search 1980–2000, English language publications only. Ninety-four studies included of which five were on point-of-decision prompts to encourage stair use (all before and after studies).	A systematic review of community interventions to increase PA.	No information on intervention lengths provided.	There is sufficient evidence that point-of-decision prompts are effective in increasing levels of PA, as measured by an increase in the percentage of people choosing to take the stairs rather than an elevator or escalator. Range of effect sizes (observed increase in stair use compared with baseline levels) from a 5.5% net increase to 128.6%. Findings from several of the studies suggest that tailoring the prompts either by specifying the benefits of stair use or by customising the sign to appeal to specific populations (e.g. ethnic groups, obese people) may increase intervention effectiveness. Signs were effective for both men and women (three studies). None of the studies measured outcomes other than the percentage of people using the stairs, and none attempted to ascertain possible permanence of their reported effects.	Good review and quality assessment undertaken. Point-of-decision prompts for stair use: Two UK studies (Blamey 1995; Kerr 2000), both of which were included in the review by Foster (2004b). Summary also available as Centres for Disease Control publication 2001. Studies conducted in shopping centres, train/bus stations and university Library.
Foster 2004b	Systematic review	2 Before and after studies only.	+	Literature search from earliest date – December 2001. Sixteen uncontrolled before and after studies of educational	A systematic review of studies that used environmental interventions to increase health-enhancing PA.	Length of intervention and follow-up mostly not stated but text suggests that the majority	A number of before and after studies suggest a weak effect of educational materials (e.g. posters and stair riser banners) on stimulating stair climbing. Most studies have seen a short-term effect for up to three months and one study saw an	No unpublished studies sought. No critical appraisal undertaken of included studies. **UK studies:**

				materials on stair use (eight based in the UK).		were more than 3 months.	effect (+29%) 6 months after baseline (Kerr 2001c).	Blamey 1995 Mutrie 1996 Kerr 2000, 2001a, 2001b, 2001c, 2001d, 2001e
Webb 2005	Before and after (interrupted)	2	–	A shopping mall in England with a 24-step staircase and adjacent escalators. 32,597 ascending pedestrians observed. 54% were women, 80% appeared younger than 60 years and 21% were classified as non-White.	**Aim:** To systematically compare the effects of stair riser banners featuring eight different messages with the effects of banners that repeated a single message. No power calculation. Higher education researchers. Same message: Eight banners saying 'Keep fit' interspersed with three saying 'Take the stairs' were fitted to alternate stair risers. Different messages: 'Stay healthy', 'Free exercise', 'Work your legs', 'Daily exercise', 'Keep fit', 'Easy exercise', 'Be active', 'Exercise your heart'.	Two-weeks of baseline observation followed by 2 weeks when banners with the same message were displayed and a further 2 weeks when banners with different messages.	Stair climbing increased significantly between baseline and the intervention period (OR 2.45, 95% CI 2.14, 2.40) from 7.0% using the stairs at baseline, compared with 14.2 and 13.6% respectively, in the single- and multiple-message phases. There was no significant difference between the single message and multiple message condition. Throughout the study, males, White persons, those <60 years and those without baggage climbed the stairs more than their counterparts (all *p* < 0.001). However, no significant interactions occurred between demographic characteristics and either intervention phase.	Very short-term before and after study only. No post-intervention follow-up, although analysis suggested no significant changes in stair or escalator use over successive weeks of the intervention. Activity was measured by observation with 95% interobserver agreement. Number of observations for each period not reported so not possible to confirm the % increases claimed by the authors. Poor study and not included in evidence statements.
Adams 2002	Before and after (time series)	2	+	All users of the stairs and lifts in the medical school of the University of Newcastle upon Tyne.	**Aim:** To use a theoretically based, systematic approach to design and evaluate a stair promotion	The posters were in place for 4 weeks with data collected at baseline and	No increase in stair use was measured in response to the intervention. Stair use comprised 20.1% of all upward journeys pre-intervention, 20.6% at week 1 and 19.5% at week 4 (*p*>0.05).	Time series studies inherently low quality, although a fair and unobtrusive method of observation was

					intervention in conjunction with the target group. **Intervention:** A time-series study building on lessons learnt from users' views on attitudes to stair climbing (from 73 semi-structured interviews; methodology not provided) and to the most acceptable and potentially effective messages and slogan. **Delivered by:** Researchers at the University. **Power:** Eight hours of observation to detect a 50% increase in stair use = 90% power.	at weeks 1 and 4.	Interviews post-intervention suggested that the posters were considered good but probably not effective, they were informative and guilt-inducing, and encouraging people to climb five flights of stairs was overambitious. Although the authors aimed to leave the posters in place for at least 12 weeks and to collect data at baseline and at weeks 1, 4 and 12 the intervention was terminated after the fourth intervention week. As no significant difference was detected between stair use at baseline and at one or four weeks, authors hypothesised that a delayed effect at 12 weeks would be unlikely.	employed (observation from fifth floor, with simultaneous observation from inside stairwell and from one of the lifts, of distance and direction of all journeys made over a 45-min period). There was unauthorised removal of 29/39 posters during the intervention.
Marshall 2002	Before and after (interrupted)	2	+	Australian hospital. No population data provided.	**Aim:** To evaluate whether a stair-promoting intervention could increase the use of the stairs over the elevator in a healthcare facility. The intervention included motivational signs and footprints. Numbers using the	Time series design over 12 weeks. Data were collected before, during and after displaying a signed intervention during weeks 4–5 and 8–9.	Stair use significantly increased from baseline after the first intervention phase (weeks 4–5) (1%, *p* = 0.02; OR 1.05, 95% CI 1.01, 1.10), but stair use decreased back towards baseline levels after the intervention was removed (between weeks 6 and 7). Stair use did not significantly change from baseline after re-introduction of the intervention (weeks 8–9). Lastly, stair use decreased below the initial baseline	Uncontrolled time series study is an inherently weak design. Data collection included unobtrusive monitoring and looks reliable. Power calculation carried out but no sign of application.

					stairs were recorded by an objective, unobtrusive motion-sensing device and research assistant observation; self-report data from hospital staff working on floors four and five were also collected. **Delivered by:** University researchers. No power calculation.		level during the final weeks of evaluation (weeks 10–12). There was no significant change in self-reported stair use by hospital staff.	Total number of observations not provided.
Faskunger 2003	Observational field study	2	+/–	Observation of 1614 people using the stairwell (51 steps) and escalator during rush hour in a Stockholm suburb train station. No details of Study population.	To investigate stairwell and escalator use in a train station where the setting was modified during the intervention (one or two ascending escalators) to increase understanding of how PA could be promoted in such an environment. **Delivered by:** University researchers. No power calculation.	One-hour observation of commuters (*n* = 1614) in a situation with one (*n* = 854) or two (*n* = 760) ascending escalators.	With only one ascending escalator, 35.2% of the population decided to climb the stairwell. With two ascending escalators, stairwell use dropped to 18.2% (*p* = 0.000). Some people taking the escalator decided to walk up it, however (data not provided).	Uncontrolled study design and brief data collection (1-hour observation only). No baseline data. May be highly confounded.
Space for physical activity								
Kahn 2002	Systematic review	2	++	Literature search 1980–2000, English language publications only.	A systematic review of community interventions to increase PA.	No information on length of follow-up.	There is strong evidence that creation of or enhanced access to places for PA combined with informational outreach activities is	Good review and quality assessment undertaken.

				Ninety-four studies included (type not specified so assumed no RCTs) of which ten looked at creation of or enhanced access to places for PA combined with informational outreach – community-wide campaigns or mass-media campaigns.			effective in increasing levels of PA. Examples of interventions were access to fitness equipment in fitness or community centres and creation of walking trails. Informational outreach interventions included point-of-decision prompts, see above, and mass media campaigns. Outcome measures varied but from five studies reporting the effect on frequency of PA the median increase was 48.4 (interquartile range 21.0–83.8)%. The intervention was effective for diverse populations including Black ethnic groups (two studies).	**Enhanced access to space:** No UK studies (all USA) and eight were carried out in the workplace.
Brownson 2004	CBA	2	+	Six rural intervention communities in Missouri and six comparison communities in Arkansas/Tennessee with similar socio-demographic characteristics. Female 77% in intervention, 74% in control sites. Age group ≥18 years old. White race 70% intervention, 64% control; Black 29%, 34%; other 1%, 2%. Education < high school 29%, 21%; college graduate 14%,	**Aim:** To determine whether a multi-level ecologic intervention is effective in increasing PA at the community level and to examine intervention effectiveness for various high-risk groups (e.g. persons of lower income). The intervention was developed with community input and included tailored newsletters based on information provided by participants, walking clubs, fun and awareness days, walk-a-thons, etc.	Baseline and follow-up survey at approximately 2-year intervals with intervention between times.	No information given on participation rate for completion of form leading to tailored newsletter or refusal rates to random phone questionnaire. A community-wide change in walking rates in rural communities was not documented. Although two subgroups showed trends to a positive net change in rates of 7-day total walking in the intervention communities; people with high school degrees or less and people living in households of lower annual incomes (≤US$20,000) no studied group showed a statistically significant net intervention effect.	The Bootheel Heart Health Project. Controlled before and after study only. Intervention was less intense than planned. No participation/attrition information. Self-reported outcomes. Data appear to be from separate cross-sectional surveys rather than cohorts.

				17%.	Telephone survey using random-digit dialling to households with working phones. **Delivered by:** Intervention by an academic team working with community coalitions and local governments. Questionnaire administered by trained interviewers. No power calculation.			
Evenson 2005	Before and after	2	+	366 randomly selected adults (≥18 years) living within 2 miles (3.2 km) of a segment of a multi-use trail in Durham, central North Carolina. Most participants were in good health, had ≥16 years of education; approximately two-thirds were women, one-third were non-Hispanic Black and two-thirds lived within 1 mile (1.6 km) of the trail.	A prospective evaluation of the impact of building a multi-use trail (i.e. cycle path), in terms of change in PA levels among nearby residents. **Delivered by:** University researchers. No power calculation.	Data collected 2 years before and 2 months after opening of trail.	Baseline (2 years pre-trail construction) response rate 47.2% (*n* = 685 out of 2125). At follow-up 63.7% of those who responded at baseline completed the interview (*n* = 436 but 48 had moved away and 22 lived >2 miles (3.7 km) from the trail, leaving *n* = 366). Two months following the building of a multiuse trail, there was no demonstration in increase of PA amongst adults living within 2 miles (3.2 km) of the trail.	Good before and after study but inherently weak design and poor response rate. Some differences between those who completed the baseline and the follow-up survey (more likely to be non-Hispanic White and male). Did not appear to include promotion of trail.

Merom 2003	Before and after	2	+	Adults aged 18–55 years of age who lived around a newly constructed Rail Trail (part of the NSW state-wide 'BikePlan' but designed for walking as well as cycling) in Sydney, Australia. Adults were randomly sampled from an 'inner' area within 1.5 km of the trail and an 'outer' area, bike owners only, 1.5–5 km from the trail. Two-thirds of the sample were inner-city residents, 57% male. 54% had a more than high school education, 34% from a non-English speaking background. In the outer area there were more males (64%), reflecting bike ownership.	**Aim:** To assess the impact of a local promotional campaign (including press advertisements with maps, radio promotion, brochure and map distribution, around a newly constructed Rail Trail in Western Sydney. Pre- and post-campaign telephone surveys were used. Objective concurrent monitoring of daily bike counts was carried out. Promotional campaign delivered by the NSW Road and Traffic Authority. **Delivered by:** Evaluation carried out by Health Service Epidemiology Unit/NSW University. No power calculation.	3 months. No follow-up.	At baseline, 65% sampled households agreed to participate and 568 (73%) completed the baseline interview. 450 (79%) of the cohort completed both interviews. The campaign reached and influenced cyclists in the inner area. Inner cyclists increased mean cycling time by 0.19 (SD 1.5) hours while outer cyclists decreased cycling time (–0.24 [SD 1.6] hours). Mean daily bike counts in the monitored areas increased significantly after the trail launch ($p < 0.001$).	Good before and after study although inherently weak study design.
Safer routes to school								
Rowland 2003	RCT cluster	1	++	Children aged 6–7 or 9–10 years in 21 primary schools in London (Camden and Islington). Sex ratio unknown.	**Aim:** To evaluate the effect of site specific advice from a school travel coordinator on school travel patterns.	One-year intervention plus 1-year follow-up.	21/41 schools (51.2%) agreed to participate and were randomised. The survey questionnaires were administered to parents of children aged 6–7 or 9–10 years and had an 85% response rate.	The study size and duration were constrained by time and resources. it is not clear whether any practical road

				54% White, 18% Black, 15% Asian, 15% other.	Intervention schools (*n* = 11) received 16 hours of expert assistance over one school year. Road safety issues were identified by meetings with teachers and governors, organising focus groups of parents and pupils and encouraging the establishment of a school travel working group. It is unclear where the intervention was conducted. **Delivered by:** School travel coordinators (funded by Camden and Islington Health Action Zone). No power calculation.		Assistance from a school travel coordinator did not change children's travel patterns or substantially affect parental fears about the safety of the journey to school. At 1-year follow-up the adjusted OR for walking, cycling or using public transport in intervention schools was not significantly different to that in control schools (0.98, 95% CI 0.61, 1.59).	safety/engineering solutions were implemented (e.g. speed reduction, crossing patrols – see corroborative evidence).

Active vs. car travel								
Transport	Audit/ev	3	+	General London	**Aim of**	Scheme	Comparing 2003 with 2002, there was an	The effects

for London 2005	aluation			population and commuters	**congestion charging:** To reduce congestion, to make radical improvements in bus services, to improve journey time reliability to car users, to make distribution of goods and services more efficient. Net revenues of £90 million were generated in 2004/5 and have been largely spent on improved bus services. **Delivered by:** Government. No power calculation.	introduced in February 2003. Annual evaluations.	increase of 37% in the number of people entering the charging zone by bus. In 2004 a further 12% increase compared with 2003 was registered. A decrease of 7% of underground journeys to the congestion zone was noted in 2003 but this recovered to 2002 levels in 2004. An increase in two-wheeled travel (pedal cycle and powered two-wheeler) was reported but no figures are provided. Of an estimated 40,000–45,000 car journeys transferred to other methods (60–70% of former terminating car movements), it was estimated that 5,000–10,000 journeys (10–20%) transferred to cycle, walk, motorcycle, taxi or car share since the introduction of the scheme. Before and after street surveys found that walking and public transport were perceived to have improved in comfort and overall quality. Cycle and powered two-wheeler safety were perceived to have improved. Negative and positive responses to the scheme were voiced and it was difficult to isolate the perceived impacts on the local neighbourhood and quality of life. In general the scheme was perceived to have been more successful than expected.	on PA are incidental to the aims of the scheme and limited information has been gathered.
Foster 2004a	Cross-sectional survey	3	+	Survey of 4265 nationally representative English adults aged 16–74 years.	To examine the relation between adults' perceptions of the social and physical environment and their self-reported walking behaviour. **Delivered by:** Department of	N/a Cross-sectional survey by 30-min interview.	In women, perceived safety of walking during the day (OR 0.53, 95% CI 0.31, 0.88) and no shop within walking distance (OR 0.72, 95% CI 0.52, 0.99) were associated with any reported walking occasions. Perceptions of the environment were not related to women walking ≥150 min/week. In men, having a park within walking distance was associated with walking ≥150 min/week (OR 2.22, 95% CI 1.18, 4.35). No other significant associations were found.	Unclear if questionnaire was validated, self-reported data, although reliable statistics and the sample was probably

					Health 3-year health promotion campaign. Trained interviewers from a social marketing company interviewed participants at home. No power calculation.			representative.
Sustrans 2004	Selective case studies	3	+	Various locations in England. No socio-demographic details.	A Sustrans action plan for increasing walking and cycling based on good practice guidance in three areas from 50 case studies in England. **Delivered by:** Case studies selected by Sustrans.	Varies for each case study.	The action plan provides evidence through the descriptions of 50 case studies for successful outcomes as a result of: 1) Improving the walking and cycling environment (e.g. introducing safety and security measures such as traffic calming, charging for cars, pedestrian crossings, CCTV, cycle lanes, lighting, cleaner streets). 2) Providing better facilities for walking and cycling (e.g. cycle stores, seats, drinking fountains, traffic free routes). 3) Influencing travel behaviour (e.g. educational/promotional schemes, led walks/cycle rides, guides, walking/cycling incentive schemes, cycle proficiency training).	Selected case studies with limited description of methodology although some studies include PA outcome measures.
Department of Transport 2003	Series of case studies	3	+/–	UK-wide case series. No population data given.	A collection of case studies of community projects that illustrate (in the authors' words) that 'for virtually every aspect of walking policy and promotion of walking there is … a good idea	Data not provided.	Using illustrations from case studies where the amount of walking was increased, the authors summarised good practice in developing pedestrian schemes as including: • an evaluation and audit of pedestrian needs; • community involvement; • good road crossings; • signs (e.g. high quality maps) and lighting; • home zones – making the road a shared area for both cars and pedestrians; • car user charging;	Very brief selected descriptions of case studies with no methodological information and very little in the way of data.

					that works'. **Delivered by:** Case studies selected by Department of Transport.		- walking schemes (rural areas, to work, to school).	
Wimbush 1998	Evaluation incorporating before and after	2	+	Scotland-wide mass media campaign. **Nationwide pre- and post-survey:** Representative of Scottish population. 'Fitline' callers (a free, direct-response telephone helpline service): 59% female. All ages included, 8% <16 years; 20% >55 years. 40% manual and 60% non-manual. Only 15% inactive at baseline.	**Aim:** To evaluate a national campaign involving a 40-second TV advertisement, a telephone helpline (with information pack for callers) and encouragement to local radio stations to run programmes. Target population people aged 30–55 years, who were not regular exercisers. Evaluation involved pre- and post-campaign population surveys and baseline and follow-up surveys (at 10 weeks and 1 year) of a random sample (*n* = 700) of helpline callers	Mass media campaign for 4 weeks in autumn 1995 with second four week burst in spring 1996. National evaluation pre- (June 1995) and post- (June 1996) campaign. Fitline callers at baseline (time of first call) and 10 weeks and 1 year after initial call.	Response rate to baseline survey individual questions varied from 62–86%. Of 700 randomly selected and consenting callers, 490 (70%) interviewed at 10 weeks and 283 (58%) at 1 year. In the population surveys, although knowledge and awareness increased, there was no change in the number of days in the last week on which respondents had spent at least 30 min walking, the mean number of days being 4.26 in June 1995 and 4.13 in June 1996. Among Fitline callers, 48% of the respondents claimed to be more physically active than they had been at last contact, 46% were exercising at the same level and 7% were less active.	Uncontrolled before and after a weak study design. Fitline callers are likely to be highly motivated, so will not be representative of the general population. All outcomes self-reported.

					who consented to be followed up. **Delivered by:** Campaign by the Health Education Board for Scotland and Government national survey. Fitline caller surveys by University researchers. No power calculation.			
Space and motivation for physical activity								
Mulvihill 2000 [	Qualitative	3	++	Paired interviews and focus groups with 163 children (aged 5–15 years) and 52 parents in six geographical areas of England – at schools, youth clubs and a shopping mall. Combination of urban/suburban and rural sites in Manchester, Durham, Leicester, Birmingham, London and Devon. A purposive sample was selected (guided by teachers) to reflect the diversity of socio-economic background, ethnicity and PA levels. The authors claimed a bias towards lower socio-economic groups (as	**Aim:** To provide, using qualitative methods, information concerning the reported perceptions of, motivations for, and barriers to PA among young people aged 5–15 years. **Delivered by:** Fieldwork carried out by higher education researchers. No power calculation.	N/a	**Children aged 5–11 years:** PA was considered pleasurable and good for you. Parents determined whether or not children walked to school and how far they were allowed to cycle. They also facilitated attendance at out of school activities. Barriers to activity were seen by the children as the lack of their own, and parents, time. Expense was a barrier for a small number. **Parents of children aged 5–11 years:** Parents perceived their children as energetic and PA as highly beneficial but requiring more work by the parents. Time was considered a barrier, including whether children walked to school or not. Parents also agreed that organised PA was expensive but lack of funds were not a barrier. Lack of safety and the poor condition of local parks were barriers. **Children aged 11–15 years:** The transition from primary to secondary	High quality study but lack of detail on sampling methods and no summary of Study population (though information provided for each site in appendices).

				measured by receipt of free school meals), lower levels of PA and young women aged 13–15 and data were provided, spread across four appendices with no summary analysis.			school led to a reduction in PA in young women, some of whom felt that teachers did not always treat them seriously in sports. Social aspects of PA (hanging out, shopping, dancing) were important. Young women felt intimidated and embarrassed by young men when playing sport and felt the latter generally played too vigorously. Young men preferred to play with their own sex as girls were seen as having a poorer ability and lower interest. Barriers included cost and lack of late transport in rural areas. Barriers for girls included feeling self-conscious and lack of time. Choices at this age were not influenced by parents. **Parents of children aged 11–15 years:** A number of parents felt they had to encourage their children to be physically active though others regarded their children as very active. Safety was a parental concern particularly at night. General belief that interest in PA declines with age, especially in girls.	
Cole-Hamilton 2002	Systematic review of observational studies	3	++	In May–July 2001 the Children's Play Council contacted organisations in England known to have undertaken Best Value Reviews of children's play and asked for copies of any consultations with school-age children and young people about children's free time. 108 reports were received (93 consultations and >13,000 subjects) and analysed for common themes and interests of	**Aim:** To review the attitudes and activities of children and young people to look at their free time activities in general and at their views of provision. The research was carried out by the Children's Play	N/a	Children play in the streets, local parks and recreation fields, open spaces and play areas. They like physically active outdoor and indoor pursuits, meeting friends, quiet activities, a choice of activities. Barriers to play for children are: fears for their own safety, in particular bullies; dirty unkempt play areas and parks; the lack of things to do; traffic; lack of facilities for disabled children. Children using staffed provision like: staff who listen; staff who are funny, friendly and fair; having a say in what they do; staff who	Excellent summary of themes from 93 separate studies. However, no analysis of results in terms of gender, age, ethnicity.

				children, young people and parents. (An additional systematic review was also carried out for publications from 1995 onwards looking for evidence to substantiate the arguments for play and is reported in this publication.)	Council, an alliance of national and regional organisations and local authorities.		can deal with conflicts between children.	
Hillman 1993	Cross-sectional survey	3	+/–	English school children aged 7–11 years in five areas. No further detail provided.	Two cross-sectional surveys in 1971 and 1990. **Delivered by:** Unknown. No power calculation.	N/a	In 1971, three-quarters of 7–11-year-olds were allowed to cross roads on their own. By 1990 this had fallen to one-half. One in two were allowed to use buses in 1971 compared with one in seven by 1990. Bicycle ownership increased from two-thirds in 1971 to 90% in 1990 but only one-quarter were allowed to use them on the roads compared with two-thirds in 1971. Nearly four times as many children were chauffeured to school in 1990 compared with 1971. Boys were allowed far more independence than girls, three in five of the boys could cross roads alone, compared with two in five girls (in 1990?). The primary concerns of parents were danger from traffic, children's reliability and fear of molestation.	A very weak paper with no methodological detail and no citations to follow-up. **Consider exclusion?**

Coakley 1992	Qualitative	3	++	Thirty-four men and 26 women aged 13–23 years (only three older than 18 years) from an industrial area south-east of London. 85% were White, native [sic] Britons, 15% were Black, Indian or Asian. About 75% from working class families, remainder from middle class families. Half of the interviewees were chosen because of their active involvement in sport and half identified by teachers or program organisers as dropouts or non-participants.	Qualitative study by semi structured interview (45 min) in conjunction with a media-marketing campaign by the British Sports Council in 1985 to 'sell' sport participation to young people, especially 14–18-year-olds working-class youth who had quit or never participated in sport. **Delivered by:** Study commissioned by the regional Sports Council and higher education researchers carried out the interviews. No power calculation.	N/a	Most young people chose leisure activities they thought would prepare them for adult roles or to do adult things (i.e. be independent and autonomous). Young women were more likely to conclude that sport had nothing to do with adulthood while young men were more likely to see sport as compatible with adulthood. Participation was more likely if it was seen as an avenue for extending or displaying competence. Financial constraints had a significant impact on sport participation in both sexes. Young women mentioned parental constraints and the influence of boyfriends as affecting their leisure choices whereas young men tended to 'do what they wanted'. For 13–16-year-olds encouragement from parents was particularly important; for people over 16 years adult advocates and role models were more likely to be important. Decisions about sport participation reflected past experiences and were often associated with feelings of discomfort and embarrassment in young women.	Generally a good study. Attitudes to non-'sport' forms of PA (e.g. dance/yoga) were not considered.
Davis 1996	Questionnaire and focus group – qualitative	3	+	9–11- and 13–14-year-old pupils from four schools in areas of Birmingham with an 'above-average concentration of heads of households in lower occupational classes'. One primary and one	**Aim:** To build an understanding of children's and young people's perceptions of risk and patterns of decision making on transport.	N/a	Children were aware of the health promotion messages that walking and cycling were 'healthy' and that being active was important but felt considerable environmental constraints on their activities. Many were not allowed to play outdoors, use local parks or cycle to school – or they did not feel comfortable doing so. Girls especially were restricted in how late they	Little clarity on data analysis provided and focus group members were not randomly selected. Attitudes to PA

				secondary in the inner suburbs and one primary and one secondary in the outer suburbs.	Semi-structured questionnaire completed by 492 pupils and focus-group discussions with one group from each class taking part in the questionnaire. **Delivered by:** University researchers (health and transport research group). No power calculation.		were allowed out. In the children's views, traffic danger, 'stranger danger' and social and cultural factors interact to create barriers to keeping healthy and active.	from sport and non-sport (e.g. dance/yoga) were not considered.
Safer routes to school								
Parker 2003	Series of before and after studies	2	+	Schools in Worcestershire. No population details provided. Example safer route to school (SRTS) measures were engineering improvements – lighting, crossings, junction changes, traffic calming, footway enhancements, improved school entrances, bus waiting areas. Example STP measures were secure cycle parking, lockers and storage, dry waiting areas, educational	An evaluation using uncontrolled before-and-after methods of 87 SRTS schemes and eight STPs implemented across the county. **Delivered by:** County Council. In all cases, the development and implementation was undertaken with all members of the school community, including questionnaire surveys of pupils at	Ongoing.	From before and after travel surveys at a 1-year interval (using a 'hands up' design) at schools with SRTS measures alone, there was an increase in walking but at the expense of other sustainable travel methods and single occupancy car use also increased. Where STP and SRTS programmes were in place there was a 3% increase in walking, a 4% reduction in single-occupancy car use and a 1.5% increase in car sharing. Bus and cycle use remained largely static.	Series of before and after case studies and no controls (other than SRTS only schools). It is not possible to tell if the changes recorded are a direct result of the STP/SRTS programmes. Annual surveys will be undertaking at schools and longitudinal data will be available at a later date.

				materials (project work, assignments), cycle proficiency training, car sharing, promotional materials (newsletters, posters), rescheduled bus time-tables, maps.	each school. No power calculation.			
Jones 2001	Before and after study and surveys	2	+	Secondary school in East Grinstead, West Sussex. No socio-demographic details.	**Aim:** To develop a SRTS scheme by asking the pupils themselves what problems were deterring them from walking, cycling or using public transport to get to school. The scheme included sheltered cycle parking for upper school, new pedestrian and cycle access, enhanced signing, speed reduction, footway and carriageway maintenance and was implemented and informed by baseline, and 1- and 3-year post-intervention pupil surveys. **Delivered by:** West Sussex County Council.	Ongoing scheme with 1- and 3-year follow-up.	Response rate unknown. At baseline 28% of pupils travelled to school, and 18% travelled home from school by car. Three years after the intervention, these values had dropped to 13 and 7%. Bus use increased considerably (from 44 to 53% to school and from 50 to 56% home), while walking (23–26%, 27–29%) and cycling (3–7%, 3–7%) also increased. At the 3 year survey, cycling was cited as the preferred mode of transport for boys, while girls expressed a preference for the bus. ‘Too dangerous’ was the reason 12% of pupils give for not walking and 14% for not cycling – yet fewer than 7% of the walkers and cyclists themselves said it was dangerous.	Uncontrolled before and after study. Sampling methods for the surveys and response rates unknown. Intervention seems to be a comprehensive, multi-component scheme.

					No power calculation.			
Derek Halden Consultancy 1999	Case studies and surveys	3	++	Scotland-wide. SRTS is a UK-wide campaign. SRTS plans tend to include the following measures: • improved safety and accessibility for walkers and cyclists (e.g. pedestrian crossings, speed cameras, maps); • measures to enhance personal skills of children (e.g. pedestrian and cycle skills training, cycle maintenance training, road safety in curricula); • measures to enhance participation (e.g. publicity, community involvement in promotion/implementation, project evaluation).	**Aim:** To prepare an inventory of SRTS in Scotland and to prepare draft guidance for best practice on such schemes. **Delivered by:** Evaluation by private consultancy commissioned by the Scottish Office Central Research Unit. No power calculation.	Ongoing schemes.	Council and cycle charity (Sustrans, Spoke) questionnaires delivered to all 32 Scottish Unitary Councils, Sustrans the national sustainable transport charity and Spokes the cycle campaign group. 32/34 replied = 94%. Questionnaires were also sent to practitioners taking forward 89 active projects, *n* = 152. 127/152 replied = 84%, but only 51 fully completed since many projects not sufficiently advanced to answer all questions (covering 36 of 89 active projects = 40%). Overall practitioners considered that the presence of vehicles in the vicinity of the school, particularly those of parents of school children, is the major concern, and that improving safety and accessibility for walkers was the main aim, particularly for children crossing busy roads. The authors recommendations for SRTS guidance included: • encourage publicity that identifies for local communities that their involvement in SRTS can make a real difference; • note that many of the measures that can be taken forward within schemes are effective, simple and cheap to implement; • reinforce the need to achieve wide ownership at the outset and a good understanding among partners of their complementary aims; • ensure that there are clearly defined roles for the project champion; • emphasise that projects should be designed for sustainability; • publicise success stories.	Good corroborative evaluation with case studies supported by survey data.

Department of Employment, Training and Rehabilitation 1999	Case series	3	+	Thirty case studies (15 urban, seven inner city, eight rural) of existing school travel initiatives in the UK selected from 92 schools identified through work by Sustrans and the University of Westminster. The 50 schools were selected to give a range of catchment areas, school types, travel patterns, travel plan initiatives and 30 of these were chosen for detailed study.	**Aim:** Case studies of selected school travel initiatives. Questionnaire and interviews with local authorities, school teachers (and sometimes governors), travel mode split survey. The school travel plans varied but common initiatives were engineering changes including traffic calming, car banning and safe routes, improved facilities (e.g. cycle parks), education/promotion **Delivered by:** Schools. No power calculations.	Ongoing.	Only ten of the case studies reported before and after travel arrangements and a common result was an increase in the number of students cycling to school. Of the ten schools, walking increased in four, decreased in six; cycling increased in eight and stayed the same in two; bus travel increased in three, decreased in two and stayed the same in four. Car travel increased in one, decreased in six and stayed the same in three.	Selected case studies. 30 selected from 92. Different sets of data collected within each case study. No overall summary and very difficult to compare results and draw conclusions
Dixey 1999 Dixey 1998	Two surveys plus interview	3	++	Seven primary schools in housing estates on the fringes of Leeds. Sex and age range unknown. Described as predominantly White and working class areas with a mix of council and private housing; relatively disadvantaged with a range of social problems (including high	**Aim:** To present findings of a study regarding supervised journeys, actual and preferred modes of travel, and parent's perceptions of danger. Data were collected from children and parents in 1995 and	1 year.	Response rate unknown (though 75% quoted for the childrens's' questionnaire). 1043 children's and 758 parents' questionnaires returned in 1995, 933 children's and 544 parents' in 1996. From the questionnaire results, the parents and children differed significantly from each other in how they would prefer to get to and from school. Almost 40% would prefer to cycle. A quarter would prefer to travel by car, which is similar to the proportion that does. More	Unclear how many people were surveyed; unclear if survey tool validated. However, combination of quantitative and

				traffic areas) drug users, strangers and litter in the estate used for the qualitative research). Intervention provided by Leeds Road Safety Unit.	1996 to inform an educational road safety education programme (no description). A questionnaire was used (teacher supervised for the children) – questions/details of survey not reported. Interviews were also carried out with 32 mothers of primary school children in one of the estates, (1-hour semi-structured interview). **Delivered by:** University research evaluation. Interviews by professional interviewer.		parents would prefer to use a car than do so. From the qualitative research it appeared that a high profile given to the vulnerability of children in public places has resulted in parents becoming ever vigilant and subjecting children to increased surveillance. Parents had practical ideas about making their environment safer. There was considerable consensus that there were inadequate facilities for young people. Increased school security was also seen to have improved general feelings of safety.	qualitative research and overall good quality study. Nearly one-half of the questionnaire respondents had no paid employment and one-third did not own a car. Of 52 mothers surveyed, 11 had no partner, 19 had no paid employment.
Metcalf 2004	Longitudinal survey	3	++	154 boys and 121 girls in their first year (aged 5 years) at 53 urban primary schools in the UK. Socio-economic details collected but not reported. Recruitment details not provided.	**Aim:** To measure the activity cost of the school run in young children in the EarlyBird study. The children wore uniaxial accelerometers during waking hours for five consecutive schooldays and the weekend. Mode of transport and school	N/a	No attrition reported. Being driven to school does not affect the overall PA of 5-year-olds. Twice as many children walked to school as were driven by car with no significant gender bias – median time 7 min; median distance 0.7 km. Total weekly activity of children walking to school compared with those travelling by car was identical ($p = 0.97$) and the additional activity reported by walkers during the school journey was only 2% of the total weekly activity.	Recruitment details were not provided. Objective measure of PA – uniaxial accelerometers worn during waking hours. The EarlyBird study is

					journey time were assessed by questionnaire and with the RAC's online route planner. Power calculation – 80% to detect a significant difference of 12% school journey activity and 8% total weekly activity.		The authors stated that although the proportion of walkers was highest in the lowest socio-economic group (C 78%, B 63%, A 62%) the pattern was unchanged across groupings. The two groups did not differ in either BMI or sum of skinfold thicknesses.	longitudinal and data for older children will be available in due course.
DiGuiseppi 1998	Cross-sectional	3	++	Survey of primary school children in two inner London boroughs (Camden and Islington). Excluding independent schools (data unavailable), respondents were 54% White, 18% Black, 14% Asian, 15% other, and similar to the school populations.	**Aim:** To survey the travel patterns of urban primary school children to inform the development of strategies to reduce school-related car travel. **Delivered by:** Survey carried out by university researchers, funded by the two London boroughs and the local Health Authority. No power calculation.	N/a	Thirty schools (97%) agreed to participate. Of 2476 enrolled children, 2086 (84%) returned usable questionnaires. Adults accompanied 84% of children to and from school. Most children (61%) were rarely or never allowed out without an adult for school or leisure. Only 3% of bicycle owners were allowed to cycle on main roads. 90% of parents were very or quite worried about abduction or molestation and 89% were very or quite worried about traffic. The strongest predictors of car travel to school were car ownership, greater distance to school, attendance at an independent school, and parental worry about abduction. The authors concluded that parents who currently drive their children might forgo the car for safe, convenient alternatives that address their fears.	Good quality cross-sectional survey.
Thomas 2004	Qualitative	3	–	Series of interviews around the UK with children aged 10–11 years.	**Aim:** To establish childrens' attitudes to their environment and how this affects them.	N/a	In order of frequency and emphasis, children cited traffic, strangers/criminals, being lost, bullying, trains and terrorism as dangers. The overall level of deprivation impacted on children's access to quality space. The authors concluded that new ways should be	Potentially highly flawed study. No methodology description

					Four locations (with large Pakistani, African-Caribbean/Black African, White and disadvantaged populations). **Delivered by:** Unclear (see confounders). No power calculation		found to facilitate environmental education through out of school learning and green school design and children from disadvantaged backgrounds should be given more opportunities to access quality public space.	. Roles of researchers unclear (Demos, 'green alliance'). Results appear consistent across the minority/disadvantaged groups included in study.

EVIDENCE TABLE 5: MULTI-COMPONENT CITY-/COUNTY-/STATE-WIDE INTERVENTIONS WITH POTENTIAL FOR LOCAL IMPLEMENTATION

SUMMARY

Overall, five CBA studies were identified (Osler 1993; Shelley 1995; Baxter 1997; O'Loughlin 1999; Huot 2004) of which one (Baxter) was based in the UK. All five were multi-component interventions aimed at reducing cardiovascular risk factors (including smoking) in adults and employing a range of educational and behavioural strategies such as workshops, seminars, point of choice, educational materials and local multi-media components. Three were broadly city-wide (O'Louglin, Baxter, Osler) and two were county-/state-wide (Huot, Shelley), one with suburban and rural components (Huot). Two looked at lower income populations (O'Loughlin, Baxter).

There was very little evidence of benefit from these interventions in terms of weight, diet and/or PA outcomes.

Evidence of efficacy for weight management/reduction

Three CBA studies measured weight outcomes (O'Loughlin, Baxter, Shelley). O'Loughlin and Baxter looked at lower income populations. None of the studies noted a significant reduction in weight or BMI in the intervention compared with the control communities although Shelley recorded a trend towards weight reduction in the intervention group.

Evidence of efficacy for diet/physical activity outcomes

Four CBAs measured dietary outcomes (Huot, O'Loughlin, Baxter, Osler). Three measured no difference in dietary outcomes between the intervention and control areas (Huot, O'Loughlin, Osler). The UK study (Baxter) observed a single significant change, in that 8.7% more people drank low-fat milk in the intervention population ($p < 0.001$). The authors believed that this change in was largely attributable to a 'wake up to semi-skimmed milk' promotion – leaflets were delivered to 11,000 households over a 2-year period.

Three CBAs measured PA outcomes (O'Loughlin, Baxter, Osler). None of the studies detected a difference between control, although two (O'Loughlin, Osler) noted an increase in PA in both intervention and control populations.

Evidence of corroboration in the UK

One of the studies (Baxter) was carried out in Rotherham, UK.

Cost-effectiveness data

Baxter estimated the cost per life-year gained as £31 in 1997 (but this was based on a reduction in smoking of 6.9% as well as an increase in semi-skimmed milk consumption of 8.7%).

Evidence of efficacy (internal validity) for weight maintenance/reduction								
O'Loughlin 1999	CBA	2	+	St Henri, Montreal, Canada – adults in a low-income, inner city neighbourhood with a population of 25,000. Independent sample survey and longitudinal survey of 52% of independent sample. At baseline in independent sample: *n* = 849 in intervention and *n* = 825 in control. Mean age (years) 38.8 (12.8) in intervention and 36.9 (11.7) in control. 47.3% male in intervention and 52.8% male in control. 72.9% completed high school in intervention and 77.4% in control. 28.4% with insufficient household income	**Aim:** To evaluate the impact of a 4-year community based cardiovascular disease prevention program among adults aged 18–65 years in a low-income inner city neighbourhood. 'Coeur en santé St-Henri' included smoking cessation workshops, nutrition education, menu-labelling and point of choice education, mailed print education materials and screening. No power calculation provided. **Delivered by:** Coeur en santé St-Henri 'run from an ordinary public health department'. Unclear who delivered	Four-year intervention. Three-year follow-up from baseline for repeat independent sample survey and 5-year follow-up from baseline for longitudinal survey (18 months post-intervention).	**Independent sample survey:** Baseline: 79.3% response rate in intervention: 77.8% response rate in control. Follow-up: 70.6% response rate in intervention and 67.2% response rate in control. **Longitudinal survey:** Intervention: 423/849 = 50% follow-up. Control: 396/825 = 48% follow-up. The participation rate in activities was only 2–3%. There were few community-wide programme benefits. In the independent sample there were no statistically significant differences between intervention and control in the OR of BMI ≥27 kg/m^2 (*p* = 0.466) at follow-up. In the longitudinal cohort survey the percentage of subjects with mean BMI ≥27 kg/m^2 increased in intervention by 9.5% and in control by 9.3 (OR 1, 95% CI 0.7,	Reliance on self-report, use of telephone surveys, loss to follow-up in the longitudinal cohort study, and contamination of control site. Also relevant to awareness-raising review.

				in intervention and 33.8% in control Subjects from random samples selected from residential telephone directories.	interventions.		1.6)%.	
Baxter 1997	CBA	2	+	Adults aged 18–64 years in Rotherham, UK. Two intervention areas with a high incidence of coronary heart disease (Swinton and Wath) were compared with a control area (Maltby) with a similar record for coronary heart disease and socio-economic composition. Jarman deprivation scores (and values)/unemployment rates (and values) for intervention areas of Swinton = 12 (1.5)/10 (11.3) and Wath = 9 (–1.2)/7 (10.4) compared with control area Maltby = 14 (3.5)/12(11.8).	**Aim:** To determine whether a community-based coronary heart disease health promotion project was associated with changes in lifestyle risk factors and to estimate whether such an approach was cost-effective. Subjects for the separate cross-sectional surveys at baseline and post-intervention (4 years) randomly selected from the Rotherham Family Health Services Authority register. Power calculation assumed 2% smoking reduction over 3 years. No power calculation for weight control. **Delivered by:**	Four years with surveys at baseline and 4 years.	Response rates to questionnaire 82–86%. There were no weight benefits. Overweight increased in all areas between baseline and follow-up and there were no significant differences in weight change between the intervention and control areas.	The Action Heart health promotion intervention: Incorporating elements of behavioural change (e.g. weight control clinic, stop smoking groups), education (course, leaflets, library resources), empowerment (action heart clubs), medical (screening checks), social change (institutional action heart charter). Questionnaire validated in previous research (references provided). Socio-economic differences between study and control sites so study essentially before and after. Self-reported outcomes. Excellent response rate.

					Health Authority/higher education researchers.			
Shelley 1995	CBA	2	+	Adults in the county of Kilkenny, south-east Ireland (*n* = approximately 70,000) and reference county with shared demographics. **Intervention sample:** Baseline: *n* = 792 (53.3% male, 42.9% aged 35–44 years, 29.4% aged 49–54 years, 27.7% aged 55–64 years). Follow-up: *n* = 802 (50.2% male, 44.4% aged 35–44 years, 31.9% aged 45–54 years, 23.7% aged 55–64 years). **Reference sample:** Baseline: *n* = 604 (51.7% male, 40.2% aged 35–44 years, 32.1% aged 45–54 years, 27.7% aged 55–64 years). Follow-up: *n* = 631	**Aim:** To assess the results of the Kilkenny Health Project in terms of the effect on the major cardiovascular risk factors. Outcomes evaluated by means of population surveys of independent samples in Kilkenny and in equivalent control community. Programme included leaflets, training seminars for health, education and catering personnel, nutrition counselling service and coverage in local media. **Power calculation:** The sample size (900 in intervention and 600 in reference communities) gives a power of 80%, at a two-sided significance level of 5%, to detect differences between the two communities	Five-year health promotion project, with measurements at baseline and 5 years later.	'The final response rates for the surveys were in the range of 70–75% of the self-selected sample' (no data provided). Mean BMI increased by 0.4 kg/m² in men in the intervention area compared with by 1.0 kg/m² in the controls ($p < 0.01$). For women increases were 0.4 and 1.3 kg/m² respectively ($p < 0.01$) in women. The end result was a net but non-significant reduction in BMI gain in both males and females in the intervention compared with the control communities.	Baseline survey in reference group may have taken place after intervention started (1986). Possible contamination of reference group by national media (see above). Self-selected sample. Different cross-sectional samples. No intervention control (although may have seen some national media: 'national media used as little as possible in the early years of the project'.

				(49% male, 43.3% aged 35–44 years, 32.5% aged 45–54 years, 24.2% aged 55–64 years) No socio-economic details provided. Self-selected recruitment – sample of 2000–3000 subjects selected from the register of electors and subjects asked if they wanted to participate. Chosen to ensure spread of age and sex.	of at least 20% in the prevalence of any risk factor. **Delivered by:** Survey nurses.			
Evidence of efficacy (internal validity) for diet outcomes								
Huot 2004	CBA	2	+	Suburban and rural communities in Montreal, Canada. Adults were all parents targeted through their grade 4–6 children at school. Control communities were selected with similar socio-economic data. Pre- and post-analysis was through independent samples and there	**Aim:** To evaluate the dietary impact of multiple community-based cardiovascular disease prevention programmes by means of a validated, self-administered FFQ. **Suburban programme:** Local media articles, taste-testing sessions, meetings/conferences, games in local stores, walking clubs.	Five-year intervention with baseline and 4-year assessment.	Response rates varied among sites from 65% to >80%. Only 4% of the suburban intervention community participated in activities. 19% of the rural group said they had participated in a heart health activity while 15% of the control group also reported involvement, indicating contamination. The interventions did not have any measurable effect on dietary behaviours either within or between groups.	The urban programme was school-based and is not summarised here. Clear differences between the pre and post-test groups could have seriously confounded the results. The Ammerman FFQ was validated with 70 adults and a test/pre-test reliability of 0.78 recorded. Self-reported weight and PA reported in companion paper? – no reference given.

				were variations in socio-economic data at post- compared with pre-test (see confounders). Pooled data (very similar for intervention and control groups): circa 55% female. Mean age circa 40 (SD circa 5.7) years. Primary school education or less at baseline circa 13% and follow-up circa 6%. College or above education at baseline circa 36% and at follow-up circa 46%. Separate data were not provided for rural and suburban communities.	**Rural programme:** Local newspaper articles, screening sessions for hypertension/cholesterolaemia, supermarket tours, healthy recipe booklets, food tasting and cookery sessions, conferences, walking clubs. No power calculation. **Delivered by**: Suburban – unknown. Rural – local volunteers. Evaluation by higher education researchers.		The suburban sites showed improvements in diet in both experimental and control groups while the rural sites showed deterioration in both groups (all non significant). The authors proposed several possible explanations for lack of effect including the difficulty of involving the community in events, cross contamination, problems with the dietary measure and bias from the study design.	
O'Loughlin 1999	CBA	2	+	Adults in St Henri, Montreal, Canada – low-income, inner-city neighbourhood with a population of 25,000. Independent sample survey and longitudinal survey. At baseline in independent survey – *n* = 849 in intervention and	**Aim:** To evaluate the impact of a 4-year community-based cardiovascular disease prevention programme among adults aged 18–65 years in a low-income inner city neighbourhood. Participation rate in activities was only 2–3% and there were few community-wide programme effects. In the independent sample survey models for physical inactivity, the adjusted OR for infrequent leisure time PA	Reliance on self-report, use of telephone surveys, loss to follow-up in the longitudinal cohort study, and contamination of control site.

				control. 72.9% completed high school in intervention and 77.4% in control. 28.4% with insufficient household income in intervention and 33.8% in control Subjects from random samples selected from residential telephone directories.	and screening. No power calculation provided. **Delivered by:** Coeur en santé St-Henri 'run from an ordinary public health department'. Unclear who delivered interventions.		in intervention was 1.9 compared with 2.8 in control, indicating that PA increased more in control group, but this did not reach statistical significance (p = 0.063). In the longitudinal cohort survey there were no significant declines in the prevalence of physical inactivity between communities, both of which reported an increase in PA (+16.3% in the intervention and +13.5% in the control communities).	
Baxter 1997	CBA	2	+	Adults aged 18–64 years in Rotherham, UK. Two intervention areas with a high incidence of coronary heart disease (Swinton and Wath) were compared with a control area (Maltby) with a similar record for coronary heart disease and socio-economic composition. Jarman deprivation scores (and values)/unemployment rates (and values) for intervention areas	**Aim:** To determine whether a community based coronary heart disease health promotion project was associated with changes in lifestyle risk factors and to estimate whether such an approach was cost-effective. Subjects for the separate cross-sectional surveys at baseline and post-intervention (4 years) were randomly selected from the Rotherham Family Health Services Authority register. Power calculation	Four years with surveys at baseline and 4 years.	Response rates to questionnaire 82–86%. No PA changes were detected between baseline and follow-up in either the intervention or the control group.	The Action Heart health promotion intervention: incorporating elements of behavioural change (e.g. weight control clinic, stop smoking groups), education (course, leaflets, library resources), empowerment (action heart clubs), medical (screening checks), social change (institutional action heart charter). Questionnaire validated in previous research (references provided). Socio-economic differences between study and control sites so study essentially before and after. Self-

				of Swinton = 12 (1.5)/10 (11.3) and Wath = 9 (–1.2)/7 (10.4) compared with control area Maltby = 14 (3.5)/12(11.8).	assumed 2% smoking reduction over 3 years. No power calculation for PA outcomes. **Delivered by:** Health Authority/higher education researchers.			reported outcomes. Excellent response rate.
Osler 1993	CBA	2	+	Adults in two municipalities in rural Denmark. Control municipality had comparable population parameters. **Intervention:** *n* = 1010 (1989) and *n* = 1003 (1990). 52% female, 84% married or cohabiting, 56% with more than 3 years education and 20% with none. Age range 20–65 years, 78% between 25 and 54 years old. **Control:** *n* = 1092 (1989) and *n* = 1109 (1990). 50% female, 83% married or	**Aim:** To assess the effect of a community-based cardiovascular disease prevention project on awareness and health behaviours. Activities (fitness tests, exercise, smoking cessation programmes, safety education and demonstration of how to buy healthy food). Heart Week organised after 6 months with activities and mass media (cinema, newspaper and radio) campaign. **Delivered by:** Volunteers organised by a paid project coordinator, led by a steering committee	Intervention throughout 12 months? One-year follow-up from baseline (6 months from ‘Heart week’).	51% of total sample (intervention and control) responded to cross-sectional surveys in 1989, and 59% of total sample responded in 1990. Response rate lowest amongst men aged 20–24 years and highest amongst women aged 44–65 years. Unmarried and divorced people under-represented in sample. 28% did more exercise with no difference between intervention and control area. 13% and 15% reported being physically inactive in intervention and control areas at baseline. At follow-up 20% reported being physically inactive in both areas. Age ($p = 0.01$) and health beliefs (own effort is important) ($p < 0.001$) predicted attained changes in PA.	Low response rate. Evaluation of study possibly not sufficiently sensitive to detect an acceleration of an already observed upturn in health behaviour in Denmark. Integration of programme into community social organisations didn’t appear to work. Difficult to recruit volunteers and elements of group activities and face-to-face interaction were of limited proportions and based on self-selection, and the project ended up as a pure mass media campaign.

				cohabiting, 54% with more than 3 years education and 19% with none. Age range = 20–65 years, 75% between 25 and 54 years.	with members of the Health Council under the local Health Administration. No power calculation provided.

Update searches
An update search of the same databases was carried out in September 2005 for worldwide intervention and UK corroborative studies. A final search was completed on 1 December 2005 for systematic reviews and controlled trials only in a reduced number of databases: CINAHL, Cochrane, Embase, Medline and PsycINFO.

The electronic search strategies (see part c, supporting information) were developed in Medline and adapted for use with the other information sources. Additional papers were identified from reference lists and (*n* = 7) by members of the GDG.

Appendix 11

THE EFFECTIVENESS OF INTERVENTIONS TO PREVENT WEIGHT GAIN TARGETED AT BLACK AND MINORITY ETHNIC GROUPS, AT VULNERABLE GROUPS AND AT INDIVIDUALS AT VULNERABLE LIFE-STAGES

EVIDENCE SUMMARY TABLES

EVIDENCE SUMMARY TABLE 1: INTERVENTIONS TO PREVENT WEIGHT GAIN, OR IMPROVE BEHAVIOURS ASSOCIATED WITH THE MAINTENANCE OF A HEALTHY WEIGHT (DIET AND ACTIVITY), IN BLACK AND MINORITY ETHNIC GROUPS

SUMMARY

Sixteen randomised controlled trials (RCTs) were included overall within Black and minority ethnic groups (BMEGs). Ten RCTs in adult African American or Black American populations were identified (four included only females), six RCTs in 8–10-year-old African American girls (Baranowski 1990; Stolley 1997; Baranowski 2003; Beech 2003; Robinson 2003; Story 2003) (one study included both mothers and their daughters and reported outcomes for both [Stolley 1997], another study included both adults and their children [Baranowski 1990]), one RCT in 11–15-year-old African American adolescents [Wilson 2002], and one study in Black preschool children (Fitzgibbon 2005). All the studies were published between 1997 and 2005, with the exception of Baranowski, which was published in 1990. All were conducted in America and five of the RCTs in adults were set in churches. Seven adult RCTs had follow-up between 5 and 30 months duration, seven RCTs that included children had 12- to 14-week follow-ups and one RCT in preschool children had a 2-year follow-up.

Regarding the adult RCTs, mean age ranged from 37 to 60 years; mean age in the two family interventions was 31–32 years (Baranowski 1990; Stolley 1997). 73–80% of the study populations consisted of females, with a mean BMI ranging from 29 to 33 kg/m^2 and dropout rate ranging from 0 to 44% and sample size varying from 52 (Newton & Perri 2004) to 1325 (Hall 2003). Although the study by Hall and colleagues (2003) was targeted at minorities and assessed outcomes according to race, only 28% of the population were classified as ‘Black’. All the other included studies in this section were virtually exclusively in African American or Black American populations.

Four RCTs concentrated on a dietary intervention in adult Black/African American populations (three studies specifically focussing on increasing fruit and vegetables and one study of a low-fat diet). Two RCTs concentrated on an exercise only intervention (walking) in adults and another ten studies had a diet and exercise intervention. Two of the ten adult RCTs reported weight, eight reported dietary intake (five studies focussing solely on fruit and vegetable intake). Two studies that conducted physical activity (PA) interventions (walking) reported PA outcomes only and two diet and exercise studies reported energy expenditure (Baranowski 1990; Yanek 2001). The four GEMS pilot studies and the study in preschool children reported weight, dietary intake and PA, two other studies that included children reported dietary intake only (Stolley 1997; Wilson 2002) and another study including children reported PA outcomes only (Baranowski 1990).

Evidence of efficacy for weight management/reduction

Two RCTs were identified which reported weight outcomes out of nine studies that included adults (Yanek 2001; Hall 2003). The study by Hall and colleagues (2003) showed modest but statistically significant decreases in weight (–1.4 kg), BMI (–0.6 kg/m^2), waist (–1.9 cm) and hip (–0.9 cm) circumference in Black American women following a low-fat diet for 6 months. Yanek and colleagues (2001) showed a significant reduction in BMI (–1.1 kg/m^2) and waist (–0.66 inches [1.7 cm]) circumference but not weight or % body fat at 1 year in African American female churchgoers following a diet and moderate aerobic activity intervention.

Eight RCTs were identified in African American/Black American children with four studies conducted as pilots for one trial (GEMS). All eight studies included diet and PA components and all the GEMS pilots included an active control. Two studies randomised either a mother and child dyad (Stolley 997) or a family unit, which included one or two adults and varying number of children living in the same household (Baranowski 1990). Mothers were actively involved in on of the GEMS pilot studies (Beech 2003). All four GEMS pilot studies reported no change in BMI at 12-weeks follow-up, two studies did not report weight outcome data at 12 weeks for the children, but one of these studies reported 'no weight change' between intervention and control group mothers (Stolley 1997) and the other study reported 'no significant differences' between groups for anthropometric measures (Baranowski 1990). Seven of the studies were not adequately powered to detect weight changes at 12–14 weeks. Ethnic minority children from Head Start programmes in Chicago that received a 14-week diet and PA intervention (Hip Hop to Health Jr) had significantly smaller increases in BMI compared with control children at 1-year follow-up (0.06 vs. 0.59 kg/m^2; difference –0.53 kg/m^2 (95% confidence interval [CI] –0.91, –0.14), $p = 0.01$; and at 2-year follow-up, 0.54 vs. 1.08 kg/m^2; difference –0.54 kg/m^2 (95% CI –0.98, –0.10), $p = 0.02$, with adjustment for baseline age and BMI. This study was adequately powered.

Evidence of efficacy for diet/physical activity outcomes

Diet

Seven adult RCTs reported dietary intake with four studies aimed at increasing fruit and vegetable intake amongst African American churchgoers (Campbell 1999; Resnicow 2001, 2004, 2005). Two of the fruit and vegetable interventions (Campbell 1999; Resnicow 2001) acted as parent studies for the third fruit and vegetable study (Resnicow 2004). In all four studies, fruit and vegetable intake was significantly increased in the intervention church populations up to 2 years, and one study reported significant difference in % energy intake from fat (Resnicow 2004). A culturally tailored diet and PA intervention significantly increased fruit and vegetable intake at 1 year compared with controls, who received education materials only; motivational telephone counselling had an additive effect (Resnicow 2005). A low-fat dietary intervention produced significant decreases in % energy intake from fat (–10.98%) and total energy intake (–379 kcal [–1.59 MJ]) at 6 months in postmenopausal Black American women (Hall 2003). A diet and moderate aerobic activity intervention produced significant decreases in total energy intake (–117 vs. –7 kcal [–490 vs. –29 kJ]) and total fat intake (–8.1 vs. 2.3 g/d) but not % energy from fat (Yanek 2001) at 1 year. Saturated fat intake (–2.1 oz [59 g]) and % energy from fat (–7.9%) was significantly reduced at 12 weeks in African American mothers following a diet and PA intervention (Stolley 1997).

Physical activity

Two adult RCTs promoted walking and included a home-based element, among sedentary ethnic minority populations. Both studies significantly increased the amount of walking in all participants from baseline to follow-up, but brief education was just as effective as adding mail and telephone counselling (Chen 1998) and a culturally tailored programme was no more effective than the standard programme (Newton 2004). One study including diet and moderate aerobic activity failed to show a significant difference in energy expenditure between intervention and control at 1 year (Yanek 2001). A culturally specific low-fat diet and aerobic exercise intervention in Black American families did not produce significantly increased metabolic equivalent tasks (METs) or energy expenditure at 14 weeks compared with control; both significantly increased energy expenditure from baseline (Baranowski 1990). A culturally tailored diet and PA intervention significantly increased PA at 1 year compared with controls, who received education materials only; however, motivational telephone counselling did not increase effectiveness of the culturally tailored diet and PA intervention (both active interventions increased PA compared with controls).

Within the RCTs in girls, all four GEMS pilots failed to show significant difference between study groups with regard to dietary intake or PA at 12 weeks (NB: controls were active controls in GEMS). There were a few exceptions: the parent and child intervention groups combined significantly reduced intake of sweetened drinks compared with non-active control in the Memphis GEMS study (Beech 2003). The Stanford GEMS pilot showed significant reduction in television (TV) viewing in the intervention group (Robinson 2003). The GEMS Minnesota pilot (Story 2003) and the study by Stolley (1997) both showed significant reduction in % energy from fat in the intervention girls. The Hip Hop to Health Jr study demonstrated only one significant difference between intervention and control preschool children regarding diet/activity outcomes and this was a difference in % energy from saturated fat at 1-year follow-up (11.6 vs. 12.8%, $p = 0.002$).

Amongst African American adolescents, social cognitive theory (SCT) and SCT plus motivational interviewing to increase fruit and vegetable intake, were equally effective compared with control at 12 weeks (Wilson 2002). The children of a family diet and exercise intervention actually decreased activity (METs) compared with the control children who increased activity (METs) and energy expenditure (Baranowski 1990).

Evidence of corroboration in the UK

Six population surveys, two reviews and two intervention studies of diet and PA in BMEG populations in Britain were identified for corroborative evidence. The majority focused on South Asian women and one focused on White Irish adults. Another two non-UK surveys including African Americans were also included.

EVIDENCE TABLE 1: INTERVENTIONS TO PREVENT WEIGHT GAIN, OR IMPROVE BEHAVIOURS ASSOCIATED WITH THE MAINTENANCE OF A HEALTHY WEIGHT (DIET AND ACTIVITY), IN BLACK AND MINORITY ETHNIC GROUPS

(A) ADULTS

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
Hall et al. 2003 Women's health trial: feasibility study in minority populations RCT 1++ **Aim:** To examine the effect of a low-fat diet on anthropometric and biochemical variables in postmenopausal women of diverse ethnic backgrounds.	**Eligibility criteria:** Postmenopausal women 50–79 years, consuming diet with at least 36% total energy derived from fat. Women were 165% above ideal body weight, special minority focussed recruitment. Women taking medications to lower blood lipids or insulin were excluded. This study was included in the review because not only was it in minority ethnic groups but it met all our inclusion criteria, i.e. the subjects were not all obese at baseline. **Setting:** Atlanta, Alabama and Miami, USA, multi-site. Intervention *n* = 1325 Control *n* = 883 56% non-Hispanic White, 28% Black, 16% Hispanic; mean age 60 years.	**Intervention:** Reduce total fat intake to 20% or less of total energy, also reduce saturated fatty acids and cholesterol, increase fruits, vegetables and wholegrain, no emphasis on reduced energy intake, weight loss or exercise; groups of 8–15 led by research nutritionist, weekly sessions for initial 6 weeks, then monthly for 9 months, then quarterly. **Control**: Control group received pamphlet on general dietary guidelines. **Follow-up:** Minimum 6 months and maximum 18 months. The duration of follow-up varied because the end of the study was the same for all participants, regardless of the date when they joined the study.	**Lost to follow-up**: Intervention: 649 of 1720 Control: 234 of 649 (see confounders/comments) **Weight (kg):** Mean difference between baseline and 6 month follow-up measurements. Negative values indicate positive health changes with intervention compared with control. White –1.4 (–1.9 to –0.99) Black –1.7 (–2.27 to –1.02) Hispanic –1.2 (–2.31 to 0.00) **BMI (kg/m^2):** White –0.6 (–0.72 to –0.38) Black –0.6 (–0.88 to –0.41) Hispanic –0.5 (–0.90 to –0.03) **Waist (cm):** White –1.7 (–2.27 to –1.08) Black –1.9 (–2.71 to –1.08)	Funded by National Cancer Institute and the National Heart, Lung and Blood Institute Women were randomised over 18-month period and the duration of follow-up varied because the stop date was same for all participants, regardless of their entry date. Many women were recruited relatively late in the study with administrative censoring prior to their schedules 12 or 18 month visit. A large number of women (*n* = 1720) completed the 6-month visit and this represented 81% of the women randomised to the intervention group and 74% of the women

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
	Baseline BMI (kg/m^2) (mean) Intervention White 27.8 (SD 4.6) Black 30.1 (SD 4.3) Hispanic 29.2 (SD 4.4) Control White 28.1 (SD 4.5) Black 30.5 (SD 4.3) Hispanic 29.8 (SD 5.5)		Hispanic –0.9 (–2.44 to 0.59) **Hips (cm):** White -1.7 (–2.22 to –1.12) Black –0.9 (–1.67 to –0.17) Hispanic –0.9 (–2.44 to 0.59) **Diet:** Fat (% energy) White –11.9 (–12.97 to –10.8) Black –10.98 (–12.28 to –9.29) Hispanic –5.7 (–8.52 to –2.78) Energy (kcal/d) White –306 (–402 to –210) (–1.28 [–1.68 to –0.88] MJ) Black –379 (–510 to –247) (–1.56 [–2.13 to –1.03] MJ) Hispanic –695 (–948 to –442) (–2.91 [–3.97 to –1.85] MJ) **Authors' conclusion**: In older White, Black and Hispanic women, a long-term low-fat dietary intervention in the absence of any particular focus on reducing energy intake was accompanied by modest but generally statistically significant	randomised to the control group. The change in total number of participants at baseline and 6-month interval primarily reflects follow-up time available from randomisation rather than dropout. Some degree of under-reporting of dietary intakes likely as degree of weight loss was less than would be expected by reported decreased energy intake – occurred in both intervention and control groups. Power calculations were not reported so it is not clear if the study was sufficiently powered to detect a significant effect of intervention when compared with control.

			decreases in weight and anthropometric indices. **Physical activity:** Not reported.	
Yanek et al. 2001 Project Joy RCT 1+ **Aim:** To test nutrition and PA interventions in the church environment to reduce cardiovascular risk in urban communities where most African American women are regular churchgoers.	**Eligibility criteria:** African American women aged ≥40 years regularly attending Inner city churches in Baltimore with known level of high interest and participation in local activities, 80% African American congregation, average Sunday attendance at least 150 individuals, no currently active programme in weight control, exercise or smoking cessation for women aged ≥40 years, churches stratified by denominations. Pregnancy, myocardial or stroke, renal dialysis or undergoing treatment for cancer were exclusions. **Setting:** Baltimore, MD, USA. SP *n* = 267 SI *n* = 188 SH *n* = 74 529 women in total from 16 churches.	**SI intervention:** Behavioural model based on standard group methods with weekly sessions including weigh-in and group discussion then 30–45 min nutrition education module that included taste test or cooking demonstration (standardised for initial 20 weeks and taught by study staff who were female African American health educators), 30 min moderate intensity aerobic activity (could include brisk walking, water aerobics, Tae Bo and varied between churches), goals behaviours included 30 min or more exercise 5 to 7 days per week, five servings fruits and vegetables every day, 25 g fibre/day, fat consumption ≤40 g/day, 1200–1800 kcal [5.02–7.53 MJ] per day, sodium intake ≤2400 mg/day , smoking cessation. **SP intervention:** Same as above supplemented with spiritual and church cultural component which included group prayers and health messages enriched with scripture and	**Lost to follow-up**: 44% (235 of 529) Intention to treat (ITT) analysis carried out (i.e. on the 529) Results combined for SP and SI groups (see confounders/comments). **Weight:** Mean change intervention vs. control at 1 year: Weight (lb): –1.1 (SE 0.42) vs. 0.83 (SE 0.52) (–0.50 [SE 0.19] vs. 0.37 [SE 0.24] kg) BMI (kg/m^2): –1.1 (SE 0.42) vs. 0.14 (SE 0.09)* Waist (inches): –0.66 (SE 0.11) vs. –0.007 (SE 0.20)* (–2.79 [SE 0.28]	Intensive community involvement in design and pilot of study to encourage cultural relevance and ownership; intervention based on community action and social marketing model. Most women from churches randomised to self-help group were not interested in the intervention and so recruitment was lower. SP and SI significantly more likely to return for follow-up; completers significantly older, lower income, less likely to be employed and attended more sessions.

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
	Mean age 52–54 years, most had completed high school, three out of four were employed, slightly more than half had hypertension, more than two out of five had arthritis. **Baseline BMI (kg/m^2):** SP+SI: 32.6 (SD 7), *n* = 455 SH: 31.7 (SD 8), *n* = 74	PA conducted with gospel music or praise or worship dance. **SH intervention:** Control group of non spiritual, self-help interventions, received all Project Joy educational materials plus American Heart Association guidelines and no further help except a hotline number for consultation from professional Project Joy health educators. **All groups:** Separate retreats held for each church following baseline assessment to kick-start the programme. **Follow-up:** 1 year.	vs. –0.02 [SE 0.51] cm) Body fat (%): –0.37 (SE 0.11) vs. –0.11 (SE 0.10) **Diet:** Mean change intervention vs. control at 1 year: Energy intake (kcal/d): –117 (SE 16) vs. –7 (SE 32)* (–489 [SE 67] vs. –29 [SE 134] kJ/d) Total fat (g/d): –8.1 (SE 0.99) vs. –2.3 (SE 2.0)* % Energy from fat: –1.7 (SE 0.27) vs. –1.2 (SE 0.47) Energy expenditure (kcal/d): 38 (SE 21) vs. 28.2 (SE 45) (159 [SE 88] vs. 118 [SE 188] kJ/day) ***Significant** **Physical activity:** Not reported.	SI and SP became very similar as women in SI women initiated prayer and scripture of their own accord. Power calculations were not reported so it is not clear if the study was sufficiently powered to detect a significant effect of intervention when compared with control.

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
			Authors' conclusions: Intervention participants achieved clinically important improvements in cardiovascular disease risk profiles after 1 year that did not occur in the self-help groups; church-based interventions can significantly benefit cardiovascular health of African American women.	
Stolley 1997 Cluster RCT 1+ **Aim:** To examine the effectiveness of a culturally specific obesity prevention programme for preadolescent girls and their mothers. Mothers were included in the study for numerous	**Eligibility criteria:** African American girls (7–12 years old) and their mothers living in Chicago's inner city and attending a local Cabrini-Green tutoring programme (to address educational needs of children living at the poverty level). Chicago, USA **Intervention:** *n* = 32 mother–daughter pairs **Control:** *n* = 30 mother–daughter pairs **Mean age:** Mothers:	**Intervention:** Culturally specific low fat, low-energy diet and increased PA (including meal planning, tasting, music and dance, one session low-impact aerobics delivered by qualified staff from the tutoring programme). Two forms of incentives were offered; in return for participating in each of the health screenings, mothers received US$25.00 and daughters received US$10.00. As well as this each mother-daughter pair received US$5.00 gift certificate for a local grocery store chain at the end of each week's session. **Control:** General health programme. This programme was run similar to the	**Lost to follow-up:** At the end of the intervention 22% (*n* = 11) of mothers and 17% (*n* = 11) of daughters had dropped out the study. **Weight:** Weight of women remained unchanged from baseline in both intervention and control group. No data on weight change in daughters reported. **Diet:** Significant reductions in intervention mother's daily saturated fat intake (–2.1 oz [59 g], $p < 0.05$) and %	Thinner mothers were more likely to drop out The drop out mothers had a mean weight of 158 lb (71.7 kg), whereas the finishers had a mean weight of 179 lb (81.2 kg) ($p < 0.05$). 62% of the mothers and 19% of the daughters were obese and analyses of baseline values on all dependent variables showed no differences across treatment and control groups. It is not clear if the study

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
reasons: 1) they are the primary people who shop and cook for their families; 2) girls would more likely to attend regularly if their mothers also attended; 3) girls are more likely to make and maintain positive eating behaviour changes if they received support and role modelling from their mothers; 4) mothers are more likely to support changes in their daughters behaviours if they played a role in the change.	Intervention = 31.5 years Control = 33.7 years Daughters: Intervention = 9.9 years Control = 10.0 years **Intervention mothers:** 56% unemployed, 72% single, mean years education 11.4. **Control mothers:** 60% unemployed, 70% single, mean years education 11.3. **Baseline BMI (kg/m^2):** Mothers, intervention: 29.1 (6.7) Mothers, control: 30.8 (8.7) Daughters, intervention: 18.4 (4.0)(Daughters, control: 20.1(6.4) **% Overweight:** Mothers: Intervention group: 31.4% Control group: 38.7% Daughters: Intervention group: 7.9% Control group: 16.3% Not reported if the differences	treatment group, with control subjects meeting in small groups (*n* = 7–10) with group leaders. The focus of each session was on general health topics such as communicable disease control, relaxation techniques and stress reduction (i.e. not a culture-specific curriculum). The groups attended separate programs for 1 hour per week for 11 weeks. **Follow-up:** Post-test at 12 weeks.	energy from fat (–7.9%, $p < 0.001$) compared with controls. For daughters, authors found a significant effect of group on saturated fat, dietary cholesterol intake and percentage daily fat. Percentage of energy as fat in the treatment group diet was 39.1 at baseline and 35.2 at post-test ($p < 0.05$). To assess changes in eating behaviour during over the course of the intervention 2 × 2 (Group × Time) repeated measures multivariate analysis of variance (MANOVA). For daughters there was a Group × Time interaction for percentage of energy from fat, i.e. daughters reduced their percentage of energy from fat over the 12 weeks. **Authors' conclusions:** Intervention mothers exhibited significant decrease in intake of saturated fat and	was sufficiently powered to detect a significant effect of intervention compared with control. Randomisation was by cluster and analysis was by individual, which may limit reliability of the results.

First author, study design, research type, quality, weight	**Study population**	**Intervention details and length of follow-up**	**Results**	**Confounders/comments**
	between groups was significant at baseline.		dietary fat. Results of the study were stronger for treatment mothers than for treatment daughters. Daughters in the treatment group reported only minor changes in their percentage of energy from fat as post treatment. Mothers appeared to be more concerned about their health and weight status than the daughters, the majority of whom were normal weight. **Physical activity:** Not reported.	
Baranowski et al. 1990 Cluster RCT 1– **Aim:** To improve diet and increase PA among a sample of predominantly low-income,	**Eligibility criteria:** Inclusion: Families (people living in the same household) of self-identified Black American ethnicity with a child in the 5th, 6th or 7th grades, healthy and willing to participate. Exclusion: Diagnosed chronic illness that would impose dietary or exercise restrictions.	**Intervention:** Culturally specific, one 90-min evening education session followed by two fitness sessions per week which were followed by fruit juice and low-fat low-salt snack for 14 weeks. Educational sessions included individual counselling (10–20 min each session with each family), small group education (20 min) and minimised lecturing/maximised participation.	**Lost to follow-up:** Not reported. **Weight:** Data not reported but authors report no significant differences between groups regarding anthropometric measures. **Diet:** Reported in another	Study participants were not self-selected – families were vigorously recruited from Black American students enrolled in 5th, 6th or 7th grade private and public schools (included home visits to recruit). There were significant

Black American families	**Setting:** Galveston, TX, USA. Intervention: *n* = 50 families (63 adults, 64 children) Control: *n* = 44 families (51 adults and 56 children) **Mean age (years):** Adults Intervention: 31.8 Control: 32.9 Children Intervention: 10.6 Control: 10.9 **Gender:** Intervention: 21% male, 79% female Control: 12% male, 88% female **Socio-economic data** Unemployed: 22% of subjects in both the intervention and control group were unemployed. Family income no more than US$15000 (this value is not corrected for the 2004 inflation value): Intervention: 91%	Included testimonials, aerobic activity and snack components; located in a convenient building within the community (formerly a Black high school). Aerobic activity sessions in a fitness centre (gym was refitted as modern fitness facility). Incentives included free transport and babysitting, weekly raffle, family fitness album containing picture of family taken each time attended evening session, sun visors, jump ropes, exercise shorts, etc; reminders and monetary rewards for accurately completing food and activity records; low fat, low-energy diet and increased PA (including meal planning, tasting, music and dance, one session low-impact aerobics). This occurred for first 7 weeks then in response to low participation and comments from participants – small group education component was dropped and didactic information included in the individual family component, participants no longer required to attend education session before the fitness session nor required to complete daily food and activity record; Black professionals hired for key staff positions. Providers of the intervention were University staff, exercise physiologists and qualified fitness centre staff.	publication, which has been ordered for appraisal. **Physical activity:** Energy expenditure in METs (a validated way of measuring energy expenditure. It is a way of expressing the rate of energy expenditure from a given PA) Adults (pre–post) Intervention: 241.4 (SD 22.8) – 247.8 (SD 46.6), *n* = 50 Control: 235.5 (SD 16.1) – 248.0 (SD 29.4), *n* = 48. Pre to post changes were detected in METS for both intervention and control group adults. Post values for energy expenditure were higher than pre values in both the intervention and control group ($p < 0.01$). In children an interaction effect in METs indicated a decrease in activity for the intervention group and an increase in activity for the control group ($p < 0.01$).	problems with lack of adherence to the intervention. Only eight out of 60 adults and ten of 64 children attended more than half the fitness sessions. The average participation across all education/fitness sessions was 28%. The authors suggest that factors such as a bomb scare, hurricane alert, centennial celebration and start of school year may have affected attendance. It is not clear if the study was sufficiently powered to detect a significant effect of intervention when compared with control. Randomisation was by cluster and analysis was by individual, which may limit reliability of the

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
	Control: 83% NB. The federal poverty level for a family of four (2004) is US$18.850. Less than high school education: Intervention: 13% Control: 27%, ($p < 0.05$) In both groups subjects were Predominantly blue collar and clerical. **Baseline BMI:** Not reported.	**Control:** No contact. **Follow-up:** 14 weeks.	No differences were detected between the intervention group and control groups on indicators of cardiovascular fitness (pulse or blood pressure). **Energy expenditure in kcal per week (7-day exercise recall):** Adults (pre–post) Intervention: 19,073 (SD 6152) – 19,592 (SD 6630) (79.80 [SD 25.73] – 81.97 [SD 27.74] MJ per week), *n* = 50 Control: 17,483 (SD 4941) – 18,544 (SD 4958) (17.15 [SD 20.67] – 77.59 [SD 20.74] MJ per week), *n* = 48 Adult METs were significantly increased ($p < 0.01$) in both intervention and control from pre to post 14 weeks; post values were higher than pre values in both intervention and control for energy expenditure, and the intervention adults had consistently higher values	results.

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
			than control. A significant interaction effect ($p < 0.05$) was detected on weight and body surface area. However, this was probably due to two males in the intervention group who lost a significant amount of weight **Authors' conclusions:** The intervention programme did not increase the aerobic activity/PA in intervention group families. Although adults reported moderate energy expenditures (2499 kcal/day [10.46 MJ/day] in the control group and 2724 kcal/day [11.40 MJ/day] in the intervention group), there was little aerobic activity after our programme, except among children. The frequency of PA at the end of the intervention was highest ($p < 0.05$) among children in the intervention group who attended more than half of the fitness sessions (5.4 times per week)	

First author, study design, research type, quality, weight	**Study population**	**Intervention details and length of follow-up**	**Results**	**Confounders/comments**
			and was identifiable between those attending none (2.5 times per week) or less than half the sessions (2.8 times per week). No differences were detected among adult subjects. Programme ineffectiveness was not due to the subjects already being fit or engaging in exercise outside of the intervention but could have been due to the fact of low final participation rates in the intervention programme.	
Physical activity				
Newton & Perri 2004 RCT 1+ **Aim:** To compare the effects of three home-based exercise promotion programmes for improving	**Eligibility criteria:** African American, 30–69 years, sedentary lifestyle (<1 hour per week leisure time PA over previous 12 months), free from significant medical illnesses. **Setting:** Florida, USA PA (physician advice control): *n* = 10 SB (standard behavioural counselling): *n* = 22 CS (culturally sensitive counselling):	This study was part of a larger study which had a physician advice group and four groups that varied in frequency and intensity of exercise, (walk 3–4 or 5–7 days per week, at 45–55% or 65–75% of their heart rate reserve (no further details reported); participants within each active intervention group had different frequency and intensity of exercise prescribed but this was similar across groups. Participants could be prescribed to walk 3 or 4 (M) days or 5 to 7 days per week (H). In addition they received an intensity prescription of 45–55% or 65–	**Lost to follow-up:** PA: zero SB: 5 (23%) CS: 4 (15%) **Weight:** Not reported. **Diet:** Not reported. **Physical activity:** Number of days of exercise completion (derived from PA)	CS and SB produced significant improvements in cardiorespiratory fitness (VO_{2max}) that was superior to PA. It is not clear if the study was sufficiently powered to detect a significant effect of intervention when compared with control groups.

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
cardiorespiratory fitness in sedentary African American adults.	*n* = 20 **Age (mean) (years):** PA: 47.3 SB: 44.0 CS: 45.0 Majority were female (81%) married (59%) had some college education or greater (92%) were working full-time (86%) and had personal income of at least US$25,000 per year (75%). **Baseline BMI (kg/m^2):** PA: 30.18 (SD 8.58), *n* = 10 SB: 32.02 (SD 4.94), *n* = 22 CS: 31.65 (SD 7.17), *n* = 20 Not all subjects were obese; no significant difference.	75% of their heart rate reserves (no further details reported) This meant the four intervention groups were made up of the four intensity frequency combinations: LM, LH, HM, HH. The duration of exercise for intervention subjects was set at 30 min. **Physical activity:** Minimal treatment, met with physician who gave general advice on exercise based on national guidelines and American Heart Association booklet ‘Exercise and Your Heart’, followed by monthly (× six) physician-led meetings of various health topics. All subjects in this group were African Americans. **SB:** Ten × group sessions over 6 months (weekly month 1, biweekly months 2–3, monthly months 4–6); led by counsellors with graduate training in exercise and/or behavioural science held in university hospital, attended groups as part of larger study (see above) The subjects in the SB condition attended groups with predominantly White group members and White group leaders (70% of the participants recruited into the larger walking study were White); written	showed that there was no significant difference between SB, CS and PA groups at 6 months ($p = 0.679$). However, within group analyses showed that participants in the CS and SB groups significantly increased their frequency/days per week of walking (only walking was assessed in the study from baseline to 6 months ($p < 0.05$). Note: subjects in the CS and SB groups were the only groups to significantly increase their days walking from baseline to 6 months ($p < 0.05$). **Authors conclusion:** The study showed that CS produced significant improvements in cardiorespiratory fitness that was superior to PA. Subjects in the CS groups showed significantly greater improvements in cardiorespiratory fitness compared with those in the	

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
		materials and key behavioural components were goal setting, self-monitoring, problem solving, relapse prevention. **CS**: Identical to SB with exception that all group participants were African American, led by African American counsellors, conducted at suite located in African American community, materials designed to address socio-cultural concerns regarding exercise. **Follow-up:** 6 months	PA group. Subjects in the CS group also were more satisfied with various aspects of their treatment than were members of the other two groups. Although all three groups led to increases in self-reported PA but only the CS treatment demonstrated significant improvements ($p < 0.05$) in cardiorespiratory fitness. The results also showed that the culturally sensitive group produced additional positive changes in social support and participant satisfaction.	
Chen et al. 1998 RCT 1+ **Aim:** To evaluate a minimal intervention programme designed to promote walking among	**Eligibility criteria:** Women not currently exercising more than once per week or walking more than 90 min per week, able to speak comprehend and read English, free of any heart disease, at least 6th grade education. **Setting:** San Diego, USA Mean age 37 years, 58% married or living with partner, 63% employed	**Intervention:** Subjects received two pamphlets published by the American Heart Association (AHA). The first was ' Exercise and Your Heart' (a 32-page pamphlet with guidelines for beginning and maintaining an exercise program). The second, 'Silent Epidemic: the truth about women and heart disease' is a 27-page booklet on heart disease and risk factors in women. Subjects also received the Stanford walking kit and one-page tip sheet salient to ethnic minority women	**Lost to follow-up**: Significantly more women were lost to follow-up at 5 months in the intervention group, compared with control: (19 of 62 [30%] in intervention vs. 4 of 63 [6%] in control; $p < 0.05$). **Weight:** Not reported. **Diet:**	It is not clear if the study was sufficiently powered to detect a significant effect of intervention when compared with control.

			ethnic minority women;	
Diet				
Resnicow 2005 Healthy Body Healthy Spirit trial RCT (cluster) 1+ **Aim:** To test effectiveness of culturally targeted self-help intervention compared with standard education materials.	**Setting:** Sixteen Black churches in Atlanta metropolitan area, USA **Mean age:** Intervention 2: 46.6 years Intervention 1: 45.9 years Control: 46.3 years **Female (%):** Intervention 2: 78% Intervention 1: 76.1% Control: 74.2% More than 60% had income >US$40,000 **Completed college or higher:** Intervention 2: 44.9% Intervention 1: 50.0% Control: 41.2% Majority middle to upper socio-economic status (SES) African Americans. Intervention 2: *n* = 304 Intervention 1: *n* = 335	**Intervention 2:** Culturally targeted self-help nutrition and PA materials plus 4 telephone counselling calls based on motivational interviewing. **Intervention 1:** Culturally targeted self-help nutrition and PA materials. **Control:** Standard nutrition and PA materials Nutrition intervention focused on increasing fruit and vegetable consumption. Intervention and follow-up = 1 year.	1056 adults recruited and 906 followed up at 1 year (86%). **Mean change in fruit and vegetable intake at 1 year:** Intervention 2: 1.13 servings Intervention 1: 0.44 servings Control: 0.17 servings (mean of 2-, 19- and 36-item FFQs). Total time of PA increased significantly more in interventions 1 and 2 compared with group 1 for ‘all activity’, over 3 METs, and ‘exercise items’ (using CHAMPS instrument). Authors conclude there was a clear additive effect for motivational interviewing (intervention 2) on fruit and vegetable intake, whereas motivational interviewing did not enhance intervention 1 for PA measures.	Churches received financial incentives to participate.

	Control: n = 267			
Resnicow et al. 2004 Body and Soul Cluster RCT 1++ **Aim:** To test the impact of the intervention when delivered by volunteer members of African American churches with less training, monitoring and support (real-world conditions).	**Eligibility criteria:** African American adults attending church. **Setting:** California, south-east and north-east. 1022 individuals across 15 churches. Intervention group n = 8 churches. Comparison group n = 7 churches. Number of participants in the study n = 854. All subjects were African American, 73–76% female, mean age 51 years, 60% married or living with partner, 50% had household income >US$50,000 and almost 70% reported at least some college education. **Baseline BMI:** Not reported.	**Intervention:** Churches agreed to implement several core church wide activities including a kick-off event, forming a project coordination committee, conducting at least three church-wide nutrition events plus one additional event involving the pastor and making at least one policy change; The American Cancer Society (ACS) provided churches with implementation manual and trained a volunteer liaison within each church; all individuals received *Eat For Life* cookbook which contained recipes submitted by church members from Eat for Life Trial and contained at least one-quarter serving fruit or vegetable per serving and low in fat; each church received a video developed for the study targeting fruit and vegetable intake using spiritual and secular motivational messages and lasting 18 min for public screening; motivational interviewing provided to individuals for voluntarily enrolled (unlike church-wide activities) provided by lay members (mainly with degree and background in a helping profession) who received training by ACS staff. The intervention lasted for 6 months and individuals which did not	**Lost to follow-up**: 15% intervention, 17% comparison (no significant difference). 854 of 1022 assessed in total at 6 months **Weight:** Not reported. **Diet:** At 6 months, participants in intervention group reported significantly greater consumption of fruits and vegetables than those in comparison group, adjusted post-test difference was 0.7 servings per day based on a two-item measure and 1.4 servings for the 17-item measure change in fruits was 0.4 servings (2-item) and 0.9 servings (17-item, 0.15 attributable to increase in fruit juice); change in vegetables was 0.2 (2-item) servings and 0.5 servings (17-item).	Constructed from two independent interventions to increase fruit and vegetable intake among African Americans in African American churches in southern USA 'Black Churches United for Better Health' and 'Eat for Life'. (Both parent trials included in this review.) Funded by ACS. Primary costs for the motivational interviewing training (trainer fees US$750 per day). Churches received US$5 incentive per completed baseline interview and again at 6-month follow-up plus US$500 if obtained completed questionnaires for at least 90% of their baseline participants.

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
		respond to the 6-month post-test questionnaire were contacted by telephone by trained staff from the University of North Carolina and offered to receive a second questionnaire by mail or to complete it over the phone. **Control:** No details reported. **Follow-up:** 6 months. Two measures of fruit and vegetable intake were obtained at baseline and the 6-month follow-up. One was the National Cancer Institute (NCI) 19-item fruit and vegetable FFQ that assessed dietary intake over the past 4 weeks. Two items assessing French fry intake were excluded from the questionnaire, which left 17 items. The second measure was composed of two items used to assess usual fruit and vegetable intake that had a separate item for total fruits and total vegetables consumed each day.	There was a small but significant difference between groups in % energy from fat (32.8 [SE 0.27] in intervention vs. 33.7 [SE 0.31]; *p* < 0.05) in control. **Authors' conclusion:** Positive effects on behaviour change can be achieved in real-world conditions. Effect sizes were smaller but significant compared with parent efficacy trials **Physical activity:** Not reported.	Self-report. It is not clear if the study was sufficiently powered to detect a significant effect of intervention when compared with control. Authors report that all 15 churches 'reached the baseline quota of 60 participants'. Randomisation was by cluster and analysis was by individual, which may limit reliability of the results.
Resnicow et al. 2001 Eat For Life Trial	**Eligibility criteria:** African American adults attending Baptist and Methodist churches. **Setting:**	**Intervention**: Culturally sensitive multi-component self-help intervention: 23 min video, cookbook with recipes submitted by members that contained at least one-	**Lost to follow-up**: 150 of 1011 dropped out. (15%) Control attrition: 33%	This study was used in the development of Resnicow 2004, not same participants.

Cluster RCT 1++ **Aim:** To increase fruit and vegetable intake in African Americans delivered through Black churches.	Atlanta, USA. **Churches:** *n* = 14 Control group: *n* = 4 Self-help intervention with one telephone cue call: *n* = 6 Self-help group with one cue call and three counselling calls: *n* = 4 Total number of subjects in the study: *n* = 1011 The number of participants per church averaged 72 (range 53–130) Mean age 44 years, 73% female, 54% married or living together, 45% income >US$39,999, 9.3% less than high school education. **Baseline BMI:** Not reported.	quarter serving fruit or vegetable per serving and low in fat; other education materials and quarterly newsletter. **Intervention 1:** Above plus one telephone call 2 weeks after baseline health fair to cue participants to use materials. **Intervention 2:** Above plus one telephone call 2 weeks after baseline health fair to cue participants to use materials plus three counselling calls based on motivational interviewing at 3, 6 and 10 months from baseline. Providers of the intervention included University researchers, national non-governmental health agency and the National Institutes of Health. To encourage participation, churches were provided with a US$10 donation for each adult subject (up to 60 per church) that completed baseline assessment. Churches received incentives ranging from US$250 to US$2000 (from the NCI depending on the proportion of baseline participants that attended the post-test health fair.	Culturally sensitive multi-component self-help intervention with one telephone cue call, attrition: 6% Culturally sensitive multi-component self-help intervention with one cue call and three counselling calls, attrition: 18% Dropouts were significantly younger, less likely to be married, to attend church more times per week and more likely to report alcohol use in the past 30 days. **Weight:** Not reported. **Diet:** At 1 year, the increase from baseline in fruit and vegetable intake was largest in Intervention 2; net difference between intervention 2 and control: 1.38, 1.03, 1.21 daily servings of fruits and vegetables (2-, 7- and 36-item FFQs respectively). Net	Dropouts were significantly younger, less likely to be married, less likely to attend church more times per week and more likely to report alcohol use in last 30 days. This study had power to detect a difference of one half serving of fruits and vegetables between intervention group 2 and control, with a power of 0.80 and alpha 0.05 Randomisation was by cluster and analysis was by individual, which may limit reliability of the results.

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/comments
		Control: Received standard nutrition education materials initially and culturally sensitive intervention materials 1 year post-test i.e. they received their intervention materials 1 year after the post-test. **Follow-up:** 1 year. **Diet**: Multiple measures of dietary intake were obtained to provide a converging estimate of actual intake. All subjects completed a seven-item FFQ, based on the behavioural Risk Factor Surveillance System that assessed fruit and vegetable intake in the past month. A two-item measure was used to assess usual fruit and vegetable intake. The third instrument was a 36-item fruit and vegetable FFQ, based on the Health Habits and History Questionnaire that was developed for this particular study.	difference between intervention 2 and intervention 1 was 1.14, 1.10 and 0.97 servings (2-, 7- and 36-item FFQs respectively) ($p < 0.05$). NB. Fruit and vegetable intake increased in both interventions compared with the control group. **Authors' conclusions:** Motivational interviewing when given in conjunction with a culturally appropriate multi-component self-help intervention appears to be a promising strategy for modifying dietary behaviour. **Physical activity:** Not reported.	
Campbell et al. 1999 The Black Churches United For Better Health Project	**Eligibility criteria:** African American church members. **Setting:** Fifty Black churches in ten rural counties in eastern North Carolina, USA.	**Intervention:** Based on a holistic approach that focussed on numerous factors to help improve fruit and vegetable consumption. This included targeting activities at individual, social network and community levels; used PRECED-	Response rate was 77.3% **Weight:** Not reported. **Diet:** Mean difference (portion	Funded by NCI. (B) CHILDREN

Weight				
Fitzgibbon 2005 Hip Hop to Health Jr RCT 1+	African American and Latino minority children (3–5 years old) in 24 Head Start sites in Chicago. **Mean age (months):** Intervention: 48.6 (SD 7.6) Control: 50.8 (SD 6.4) **% Female:** Intervention: 49.7% Control: 50.5% **% Black:** Intervention: 99% Control: 80.7% **Baseline BMI (kg/m^2):** Intervention: 16.5 (SD 1.5) Control: 16.7 (SD 2.0)	Reduction in fat, increase in fibre, increase in PA and inclusion of family are main elements of intervention. Theoretical base is combination of social learning theory and transtheoretical model of stages of change. Children had 45 min, three times per week for 14 weeks, hands-on learning about go and grow foods (' foods that will help you go and grow') vs. slow foods (' will make you slow'), using puppets of characters from each of the food groups. Parents had weekly newsletter, homework (compensated US$5 if completed), and twice weekly 30-min low-impact aerobic classes at children's Head Start sites. Control had 20-min class once per week for 14 weeks, spent on general health	14-week active intervention plus 2 years follow-up. Intervention *n* = 179 Control *n* = 183 Intervention children had significantly smaller increases in BMI compared with control children at 1-year follow-up (0.06 vs. 0.59 kg/m^2; difference –0.53 (95% CI –0.91, –0.14) kg/m^2, *p* = 0.01; and at 2-year follow-up, 0.54 vs. 1.08 kg/m^2; difference –0.54 (95% CI –0.98, –0.10) kg/m^2, *p* = 0.02, with adjustment for baseline age and BMI. Demonstrated only one significant difference between intervention and control children regarding diet/activity	Trial was piloted for 3 weeks where elements were changed. Curriculum materials translated and taught in both English and Spanish. Twelve of the sites were randomly assigned to receive the intensive intervention and 12 were assigned to the general health intervention.

		activity. Parents had weekly newsletter,	outcomes and this was a difference in % energy from saturated fat at 1-year follow-up (11.6 vs. 12.8%, *p* = 0.002).	
Baranowski 2003 GEMS – Baylor RCT 1+ **Aim:** To prevent obesity in African American girls.	**Eligibility criteria:** Eight-year-old African American girls, at least 50th percentile for age and gender BMI, with a parent willing to be involved, children needed access to internet, aimed at middle-income families, Texas, USA Intervention: *n* = 16 Control: *n* = 19 **Mean age:** Intervention: 8.3 (SD 0.3) years Control: 8.4 (SD 0.3) **Sex:** Girls only.	**Intervention:** All participants received below plus self-esteem enhancement and cultural awareness programme. **Control:** Set in a day summer camp (4 weeks) then in homes (8-week internet intervention), the intervention was delivered by trained personnel in camp and researchers via a website, aimed at increasing fruit and vegetable and water consumption and enhance PA. **Follow-up**: 12 weeks.	ITT analysis. **Weight, diet and physical activity:** No significant difference between groups for BMI, waist circumference, PA (accelerometer, checklist and questionnaire), or dietary intake at 12 weeks. There were diet differences in lower total energy (–231 kcal [–966 kJ]) and the total % of energy from fat, greater consumption of water and fruit juice and lesser consumption of sweetened beverages. It was also shown that the treatment group girls heavier at baseline showed a trend (*p* < 0.08) toward lower BMI compared with the heavier girls in the control group. Only subjects in the intervention group improved.	This study was a pilot study to assess feasibility and was not intended to be sufficiently powered to detect a significant intervention effect. Fully powered studies of two of the GEMS pilots are currently underway.
Beech 2003 GEMS-Memphis RCT	**Eligibility criteria:** African American girls, 8–10 years old, at least 25th percentile for age and gender BMI, able to participate in physical education (PE) classes at	School- and home-based intervention delivered by a trained researcher and a community lay health educator. **Intervention 1:**	ITT analysis, 100% follow-up. **Weight, diet and physical activity:** No significant difference	This study was a pilot study to assess feasibility and was not intended to be sufficiently powered to

1+ **Aim:** To prevent obesity in African American girls.	school, with a parent willing to be involved. Set in low-income areas, Tennessee, USA **Sample size** Intervention 1: *n* = 21 Intervention 2: *n* = 21 Control: *n* = 18 **Mean age:** Intervention (child): 8.7 (SD 0.8) years. Intervention (parent): 9.1 (SD 0.7) years . Control: 8.9 (SD 0.8) years. Mean age of parents varied from 34 to 39 years and was significantly different between groups (older mothers in control group). **Socio-economic data:** 35% total household income less than US$20,000 per year (i.e. low income, as earlier definition), 50% of girls lived in female-headed households. **Baseline BMI (kg/m^2) of the children:** Intervention 1: 25.5 (SD 7.4). Intervention 2**:** 23.0 (SD 5.6). Control: 22.6 (SD 5.6). Therefore, the baseline measurements show that the	Child-targeted intervention with girls only, 30 min hip-hop aerobics (also promote enjoyment) and 30 min healthy eating (decrease high-fat foods, increase water/reduce sweetened beverages, increase fruit and vegetable intake, promote healthy nutrition-related behaviours; take home element and gift incentives; 12 × weekly 90 min sessions. **Intervention 2:** Parent-targeted intervention with parents only, 25 min dance segment and 25 min interactive and didactic nutrition components 12 × weekly 90 min sessions. **Control:** Three × monthly 90 min sessions to improve self-esteem (nutrition and PA not addressed). **Follow-up:** 12 weeks.	between groups for BMI, waist circumference, PA (accelerometer and questionnaire), or dietary intake at 12 weeks with the exception of: parent and child intervention groups combined were consuming significantly fewer sweetened drinks (34% less, $p = 0.03$) compared with the control group at 12 weeks. **Authors' conclusion:** Study demonstrates feasibility, acceptability and efficacy of culturally relevant obesity prevention intervention in preadolescent African American girls and their parents/caregivers.	detect a significant intervention effect. Fully powered studies of two of the GEMS pilots are currently underway. Based on SCT Twelve-week non-randomised feasibility study conducted before this intervention. The control received less contact than intervention groups, which may have contributed to difference in effect between groups.

	subjects are not obese and although the mean BMI of intervention group 1 shows they are slightly overweight. Significance of these differences are not reported. **Baseline BMI of parents:** Not reported.			
Robinson 2003 GEMS-Stanford RCT 1+ **Aim:** To prevent obesity in African American girls.	**Eligibility criteria:** African American girls (8–10 years old), at least 50th percentile for age and gender BMI, with a parent having a BMI >25 kg/m^2, willing to be involved. Set in Oakland and Palo Alto, CA, USA. Intervention: *n* = 28 Control: *n* = 33 **Mean age:** Intervention: 9.5 (SD 0.8) years. Control: 9.5 (SD 0.9) years.	**Intervention:** After-school dance classes set in community centres designed to improve PA, reduce sedentary behaviours and enhance diet. The intervention called START (Sisters Taking Action to Reduce Television) was delivered by trained university-based dance instructors and a female African American intervention specialist. The programme consisted of daily dance classes during school weeks and reducing TV viewing time was covered in five home-based lessons. Four community lectures were also provided. **Control:** The control intervention was implemented to be an up-to-date information-based health education programme to promote healthful diet and activity patterns. It included presenting monthly community health lectures, delivered by volunteers from the African American task forces of the local chapters of the AHA and the American Diabetes Association. The content of the newsletter focussed on reducing risks for	ITT analysis. **Weight, diet and physical activity:** No significant difference between groups for BMI, waist circumference, PA (accelerometer and checklist), or dietary intake at 12 weeks. Significantly less TV viewing in the intervention group at 12 weeks (*p* = 0.007). At follow-up, the treatment group reported 23% less media use, relative to controls (–4.96/21.33) and a significant decrease in total household TV use relative to controls.	This study was a pilot study to assess feasibility and was not intended to be sufficiently powered to detect a significant intervention effect. Fully powered studies of two of the GEMS pilots are currently underway.

		obesity, heart disease, stroke, hypertension and diabetes and included age-related and culturally targeted educational materials. **Follow-up:** 12 weeks.		
Story 2003 GEMS-Minnesota RCT 1+ **Aim:** To prevent obesity in African American girls.	**Eligibility criteria:** 8–10-year-old African American girls, at least 25th percentile for age and gender BMI, with a parent willing to be involved. Set in low-income areas, Minnesota, USA Intervention: *n* = 26 Control: *n* = 28 **Mean age:** Intervention: 9.3 (SD 0.9) years. Control: 9.4 (SD 0.9) years. **Sex:** Girls only.	**Intervention:** Lunchtime clubs in school designed to improve nutrition, PA and self-esteem through a range of activities. The intervention which was conducted twice per week, focused on increasing healthy eating and PA. Intervention meetings, designed in a 'club meeting' format, were held twice per week for 1 hour after school at each of the schools used in the study. The intervention was based on SCT (Bandura) and targeted key points from three domains: 1) environmental factors such as peer support; 2) personal factors such as knowledge and values; and 3) behavioural factors such as goal setting and social reinforcement. Providers of the intervention included University Staff, Trained African American GEMS staff and school staff. **Control:** The control group served as an 'active placebo', non-nutrition/PA condition and focussed on promoting positive self-esteem and cultural enrichment. Participants attended monthly Saturday morning meetings (three meetings over	ITT analysis. **Weight, diet and physical activity:** No significant difference between groups for BMI, waist circumference, PA (accelerometer and questionnaire), or dietary intake at 12 weeks. % Energy from fat (parental reported) and low-fat food practices (parental reported) were significantly better in intervention group compared with control.	This study was a pilot study to assess feasibility and was not intended to be sufficiently powered to detect a significant intervention effect. Fully powered studies of two of the GEMS pilots are currently underway.

		12 weeks). This included arts and crafts; self-esteem activities, creating memory books and a workshop on African percussion instruments. **Follow-up:** 12 weeks.		
Baranowski et al. 1990 Cluster RCT 1– **Aim:** To improve diet and increase PA among a sample of Black American families.	**Eligibility criteria:** Inclusion: Families (people living in the same household) of self-identified Black-American ethnicity with a child in the 5th, 6th or 7th grades, healthy and willing to participate. Exclusion: Diagnosed chronic illness that would impose dietary or exercise restrictions. **Setting:** Galveston, TX, USA. Intervention: *n* = 50 families (63 adults, 64 children) Control: *n* = 44 families (51 adults and 56 children) **Mean age (years):** Adults Intervention: 31.8 Control: 32.9 **Gender:** Intervention: 21% male, 79% female Control: 12% male, 88% female **Unemployed:**	**Intervention:** Culturally specific, one 90-min evening education session followed by two fitness sessions per week which were followed by fruit juice and low-fat low-salt snack. Fourteen weeks, educational sessions included individual counselling (10–20 min each session with each family), small group education (20 min) and minimised lecturing/maximised participation and included testimonials, aerobic activity and snack components. Located in a convenient building cherished by the community (formerly a Black high school). Aerobic activity sessions in a fitness centre (gym was refitted as modern fitness facility). Incentives included free transport and babysitting, weekly raffle, family fitness album containing picture of family taken each time attended evening session, sun visors, jump ropes, exercise shorts, etc; reminders and monetary rewards for accurately completing food and activity records; low fat, low-energy diet and increased PA (including meal planning, tasting, music and dance, 1 session low-impact aerobics); this occurred for first 7 weeks then in response to low	**Lost to follow-up:** Not reported, average 28% participation. **Weight:** Data not reported but states that no significant differences between groups regarding anthropometric measures. **Physical activity:** 1) Energy expenditure in METs per week (7-day exercise recall): Children (pre – post) Intervention: 238.1 (SD 22.3) – 231.2 (SD 14.3), *n* = 59 Control: 231.2 (SD 12.0) – 237.2 (SD 21.8), *n* = 52 2) Energy expenditure in kcal per week (7-day exercise recall): Children (pre – post) Intervention: 9559 – 9684 (40.00–40.52 MJ/week),	*Not* self-presenting volunteers, families were vigorously recruited from Black American students enrolled in 5th, 6th or 7th grade private and public schools in Galveston, TX, USA (included home visits to recruit). Only 8 out of 60 adults and 10 of 64 children attended more than half the fitness sessions, average participation = 28%. Bomb scare, hurricane alert, centennial celebration and start of school year may have affected attendance. Diet outcomes reported in another publication but not relevant

	22% both groups. **Family income less than US$15,000:** Intervention: 91% Control: 83% **Less than high school education:** Intervention: 13% Control: 27%, $p < 0.05$ **Mean age children (years):** Intervention: 10.6 Control: 10.9 Predominantly blue collar and clerical. **Baseline BMI:** Not reported.	participation and comments from participants – small group education component was dropped and didactic information included in the individual family component, participants no longer required to attend education session before the fitness session nor required to complete daily food and activity record; Black professionals hired for key staff positions. **Control:** No contact. **Follow-up:** 14 weeks	*n* = 59 Control: 10,226 – 11,031 (42.77–46.15 MJ/week), *n* = 52 For the children an interaction effect in METs indicated a decrease in activity in the intervention group and an increase in activity in the control; control children increased energy expenditure more than the intervention children. **Authors' conclusions:** Programme did not achieve goal of increased habitual aerobic activity for the intervention group families, final participation was low therefore it is not surprising there was no differential effect of the programme on activity or fitness.	outcomes for this report (sodium only). It is not clear if the study was sufficiently powered to detect a significant effect of intervention compared with control.
Diet and /or physical activity				
Wilson et al. 2002 Cluster RCT 1+ **Aim:** To assess the effects of SCT plus	**Eligibility criteria:** Inclusion: Healthy 11–15-year-old African Americans from three middle schools, normotensive, no pre-existing cardiovascular disease or chronic disease, not currently taking medications, within 30% ideal weight for height.	**SCT:** SCT principles which include education, behavioural skills training, feedback and reinforcement; increase fruit and vegetable intake to six to eight servings per day and increase aerobic activity to 30–60 min/day for 7 days per week by the end of the programme; all	**Lost to follow-up:** SCT + MI = 17% SCT only = 30% Control = 31% **Weight:** Not reported.	Control group all male and SCT + MI had significantly greater number of married parents. Significantly more

motivational interviewing to increase fruit and vegetable intake in African American adolescents.	**Setting:** Richmond, Virginia, inner-city area, USA. SCT + MI (Social Cognitive Theory and Motivational Interviewing): *n* = 17 SCT only: *n* = 20 Control: *n* = 16 **Mean age:** 11–15 years. **Gender (male/female):** SCT + MI: 8/9 SCT only: 7/13 Control: 16/0 **Weight:** SCT + MI: 52 (SD 9) kg SCT only: 57(SD 22) kg Control: 53 (SD 19) kg	participants recruited from and took part in after-school intramural sports programme Team Up, 3 × per week and a fruit and vegetable cooking class 1 day per week. **SCT + MI:** As above with additional 30 min of self-presentation videotapes where participates given interview questions prior to interview and asked to generate several coping strategies to increase fruit and vegetable intake and PA that they had used as effective coping strategies, then videoed and allowed to view videos. **Control:** Twelve weekly sessions to maintain usual diet and exercise, general health related issues provided in education materials. **Follow-up:** 12 weeks. Providers of the intervention were the research team and school staff.	**Diet:** Pre – post fruit and vegetable servings/per day: SCT + MI: 2.6 (SD 1.4) – 5.7 (SD 2.2), $p < 0.05$ SCT: 2.5 (SD 1.2) – 4.8 (SD 2.4), $p < 0.05$ Control: 2.3 (SD 1.0) – 3.3 (SD 2.1), $p>0.05$) Correlation analyses revealed that only the SCT + MI group showed that dietary self-concept and dietary self-efficacy were both significantly ($p < 0.05$) correlated with post treatment fruit and vegetable intake and change in fruit and vegetable intake, respectively. **Physical activity:** 'No significant time or group effects for any of the physical activity measures.' **Authors' conclusion:** These findings suggest that the change in fruit and vegetable intake in the SCT + MI group resulted from strategic self-presentation, which induced positive shifts in self-concept and self-efficacy. It appears that SCT + MI and SCT alone were both effective	people were lost to follow-up in the SCT + MI group, compared with SCT alone and control groups. The study lacked sufficient power to detect a significant difference in fruit and vegetable intake between groups.

			at increasing fruit and vegetable intake compared with control. (Study reports in relation to fruit and vegetable intake and PA that no interaction or main effects were significant). The two active treatments changed significantly from baseline to follow-up on intake of fruit and vegetable but the control group did not.)	
Stolley 1997 Cluster RCT 1+ **Aim:** To examine the effectiveness of a culturally specific obesity prevention programme for preadolescent girls and their mothers.	**Eligibility criteria:** 7–12-year-old African American girls and their mothers living in Chicago's inner city and attending a local Cabrini–Green tutoring programme (to address educational needs of children living at the poverty level). Chicago, USA. Intervention: *n* = 32 mother–daughter pairs. Control: *n* = 30 mother–daughter pairs. **Mean age (years):** Intervention: 9.9 Control: 10.0 **Baseline BMI (kg/m^2)** Daughters, intervention: 18.4 (4.0) Daughters, control: 20.1 (6.4)	**Intervention:** Culturally specific low-fat, low-energy diet and increased PA (including meal planning, tasting, music and dance, one session low-impact aerobics). Providers of the intervention included researchers and staff from the Cabrini Green tutoring programme. Financial incentives were also given. In return for taking part in each of the health screenings, mothers received US$25.00 and daughters received US$10.00. Additionally, each mother daughter pair in attendance got a US$5.00 gift certificate for a local grocery store chain at the end of each week's session. **Control:** General health programme. Twelve weekly 1-hour meetings then every 3 months for 15 months.	**Lost to follow-up**: At the end of the intervention 22% (*n* = 11) of mothers and 17% (*n* = 11) of daughters had dropped out the study. **Weight:** Not reported. **Diet:** Intervention girls had significant reductions in % energy from fat (–3.9%, $p < 0.05$) compared with controls. **Weight:** Weight of women remained unchanged from baseline in both intervention and control group. No data on weight change in daughters reported.	This study had a number of limitations which will affect reliability of the results: There were very few participants, a large proportion of which dropped out of the study. Analyses were not by ITT. Outcomes were only reported for 12 weeks follow-up. Weight outcomes were not reported for daughters. Finally, it is not clear if

	19% of daughters were obese at baseline.	**Follow-up:** 18 months.	**Diet:** Significant reductions in mother's daily saturated fat intakes (–2.1 oz [59 g], $p < 0.05$) and % of energy from fat (–7.9%, $p < 0.001$) with intervention when compared with controls. Intervention daughters reported only minor changes in % energy from fat. **Authors' conclusions:** Intervention mothers exhibited significant decrease in intake of saturated fat and dietary fat. Results of the study were stronger for treatment mothers than for treatment daughters. Daughters in the treatment group reported only minor changes in their % energy from fat as post-treatment. Mothers appeared to be more concerned about their health and weight status than the daughters, the majority of whom were normal weight.	the study was sufficiently powered to detect a significant effect of intervention compared with control.

Fox 2004	Case studies	South Asians (mainly at risk for heart disease).	Best practice guide to support delivery of heart disease services to South Asian communities in UK.	N/a	**Coventry 5-a-day scheme:** Provides people with money-off vouchers to spend on fruit and vegetables (£2 per week for 4 weeks, participants required to spend £4 of their own money at same time), valid in two stores in each area plus city centre and market, linked with delivery scheme that charges 50p to deliver, which can come off the voucher; free recipe cards, community nutrition scheme can give one-on-one help on preparing and cooking food in people's homes; there is evidence of groups of people shopping together. **The Coriander Club, Spitalfields City Farm:** Group of Bangladeshi women who get together and grow vegetables, two weekly gardening days and one weekly healthy cookery class, take home the vegetables in return for labour on the farm, growing vegetables is culturally acceptable hobby and opportunity to be physically active; Coriander Club is member of Taste of a Better Future project which is a national network of ethnic minority women's food growing groups (40-plus groups) set up in 1999, 40-plus group using spaces on housing estates and disused inner city plots to grow organic fruit and vegetables; as well as nutritious foods they enjoy making friends, sharing skills and bolstering communities. **Birmingham Food Net:** Cook and taste sessions run by community food workers, evaluation at end of five-session course shows participants (high South Asian population) include more fruit and vegetables, fish, cereals and starchy foods, use less oil and change to unsaturated fats; some report being more physically active and have learnt about healthy eating; some have had little exposure to education sessions, some women need convincing they have more to learn about cooking, some have low-level of knowledge about healthy eating, but all link diet with health.

					Bradford Trident Healthy Living Project weight management programme: Twelve-week group programme, emphasis on food and diet, discuss recipes, cooking methods, food labels, encouraged to keep food diaries, many have lost weight, learn recipes from all over world, low-budget recipes, active participation and ownership and empowerment are vital principles, subsidised health and fitness club membership given as incentive at end of programme. **Dietary intervention in high risk families with coronary heart disease in Ealing:** Family-based programme in cardiology department at Ealing hospital, cardio-protective diet emphasising low glycaemic index approach, shopper and cook attend as well as the patient, hold classes in evenings to ensure high attendance, lowers cholesterol by 18%, systolic blood pressure by 3 mmHg, body weight by 3.7 kg compared with a conventional care group, and persist beyond 1 year beyond completion of intervention programme and has impact on children (low intensity, easy to put into practice in primary care with modest extra resources. **Walking for Health in Wolverhampton:** Asian Community Walking Developer promotes walking within the community, she leads five different weekly group walks and trains volunteers, important to build trust and friendship into the meetings, gift voucher incentive of £1 for each five led-walks a person does, can collect up to £20 in vouchers to use in shops and leisure facilities in Wolverhampton. **Sitara:** Women-only project in West Yorkshire (75% South Asian), activities include exercise to music, swimming, aquafit, weights room, circuits and sauna; entailed hard work, co-operation and commitment to overcome problems around cultural issues, self-financing, prices kept low, holds four sessions per week and attracts up to 300 visits per week, couldn't have worked without commitment of all organisations involved (Primary Care Trusts [PCTs], council, local leisure). **Hamara Healthy Living Centre, Leeds:** Includes men's walking group, father-and-son swimming sessions and circuit training, participants encouraged to train as volunteers; sister organisation,

					Leeds Health Focus runs women's aerobic classes and women-only swimming, activities are designed around needs of participants, outreach work includes encouraging taxi drivers to incorporate PA into everyday lives (cleaning taxis), Hamara trainers offer after school aerobics and circuit training, basketball, football and cricket to four local schools (there is now a waiting list). **Al-Badr Health and Fitness:** New fitness centre in East London serving entire Muslim community; encourages and enables Muslim men and women to participate in physical fitness and health awareness programmes, state of the art equipment, separate male and female sessions (no male staff during female sessions) advertised on website.
Women's Health Initiative Study Group, Women's Health Initiative Dietary Modification Trial	FFQ as part of RCT	Postmenopausal women (USA).	To assess adherence to a low-fat diet.	5 years	This paper describes adherence to a low-fat dietary pattern (<20% energy from fat, five or more fruit/vegetable and six or more grain servings daily) in years 1 and 5 of the Women's Health Initiative Dietary Modification Trial, which was designed to examine the effects of a low-fat dietary pattern on risk of breast and colorectal cancers and other chronic diseases in postmenopausal women. Participants were randomly assigned to a low-fat dietary intervention arm (40%, *n* = 19,542) or a usual diet control arm (60%, *n* = 29,294). Women in the intervention arm completed 18 group sessions during the first year, followed by quarterly annual maintenance sessions. Adherence was assessed as control minus intervention (C – I) group differences in % total energy from fat as estimated by a FFQ. Based on these self-reported dietary data, mean C – I was 10.9 % points of energy from fat at year 1, decreasing to 9.0 at year 5. Factors associated with poorer adherence were being older, being African American or Hispanic (compared with White), having low income, and being obese. Group session attendance was strongly associated with better dietary adherence.
French 2000	Survey	Women aged 25–45 years, enrolled in Pound of Prevention Study	To examine demographic, behavioural and dietary correlates of frequency of fast food restaurant	3 years	Twenty-one percent of the sample reported eating three or more fast food meals per week. Frequency of fast food restaurant use was higher among younger women, those with lower income, non-White ethnicity, greater body weight, lower dietary restraint, fewer low-fat eating behaviours, and greater TV viewing. Intake of several other foods, including fruits and vegetables, did not differ by frequency of fast food restaurant use.

		(USA).	use.		
Williams 1999	Uncontrolled 6-week study.	Fifteen overweight or obese Asian women in Old Trafford, Manchester.	Examine perceptions of and change in weight from a healthy eating and exercise intervention.	17-month follow-up after 14-week programme.	45-min low-impact stretch and tone exercises to music led by fitness instructor each week for 14 weeks; home exercise advice; dietitian then gave advice regarding increasing fruit and vegetable intake, reducing amount of fat and oil in cooking, reducing intake of fatty and sugary foods; link worker available to interpret. Ten of 13 women lost weight, median weight loss after 14 week: –2.6 kg (range –0.7 to –10.7); from 14 weeks to 17 months eight of the women lost weight with median of –2.4 kg (range –0.4 to –7.5). Formal methods of recruiting had very little impact, verbal recommendation of the group by link worker and participants was more effective, intervention fulfilled social and weight loss functions and both functions were interrelated and affected weight, difficulty getting to venue and needs of family coming first were cited as reasons for none attendance; women who said they would definitely re-attend were generally those with a higher BMI.
White 1998	Review of interventions.	Papers published in English language 1985–96 in minority ethnic groups.	To review the effectiveness of health promotion in minority ethnic groups.	Various.	Dearth of relevant research on nutritional health promotion among minority ethnic groups in UK; 29 studies, 19 studies in African American population, two in UK that were supplementation studies in infant and toddlers (not relevant here); 13 of 29 studies demonstrated some degree of effectiveness, though only seven judged effective for their main nutritional aims in minority ethnic groups; educational approaches (one-to-one, group or community-wide in homes, schools or community settings); policy measures (school food policies); and technological measures (food supplements) demonstrated some degree of effectiveness; behavioural modification was more likely to be effective in European origin groups than minority ethnic groups (when compared), few studies can be directly applicable to UK, most were experimental or demonstration studies; many community-based projects to promote healthy eating in ethnic minorities in UK were identified in 'grey' literature, lacked formal evaluation and any sound evidence of effectiveness.
Bush 1998	Review	South Asians,	To evaluate opportunities fro	Various.	**South Asians:** GP clinic in Leeds for screening for coronary heart disease risk factors; high

		African Caribbeans, White Irish in UK.	and barriers against good nutritional health in minority ethnic groups.		attendance thought due to interpreter, increase in number of families reducing fat in cooking and changing to vegetable oil, several patients lost weight and a lot of women wanted to lose weight but had difficulty reconciling with family eating patters, failure to take up advice explained by family commitments, habit, health beliefs, environment and finances. Primary care initiative in Tower Hamlets, The Healthy Eastender project; dietary advice and materials appropriate to minority ethnic groups including Bangladeshi and African Caribbean– no evaluation. Dietary survey of Bengali women in Tower Hamlets concluded that unfamiliar food objects without verbal explanations are not likely to be recognised and pictures alone may not convey messages – implications for dietary surveys in this population. **African Caribbean:** Primary care initiative in Tower Hamlets, The Healthy Eastender project; dietary advice and materials appropriate to minority ethnic groups including Bangladeshi and African Caribbean – no evaluation. Studies in Manchester and Birmingham showed that African Caribbeans purchased more expensive imported Caribbean foods and because of lower incomes they spent a larger proportion on food. **White Irish:** Lack of intervention with Irish migrants in Britain. Lifestyle intervention in workplace in Galway aimed specifically at women concluded key to promoting healthy eating is in providing access to healthy options in canteen and reinforcing availability of these options through clear, simple and specific messages.
Carroll 2002	Literature review, survey, case studies and uncontrolled trial pilot	South Asian Muslim women in UK.	How effective is ‘exercise on prescription’ in promoting PA in South Asian women in UK?	6 weeks for pilot study.	**Case studies:** West Pennine Health Authority: ‘A prescription for exercise’ Bradford Health Authority: ‘Bradford encouraging exercising people’ Leicestershire Health Authority: ‘Activity for life’ Birmingham Health Authority: ‘Exercise for prescription’ Blackburn with Darwen: ‘Fitness for life’

	intervention with interviews.				Women expressed positive effect of exercise on health and well-being, increased energy levels and motivation, social aspects, but many significant barriers: access, cost, childcare, cultural codes of conduct, language, racism and religious discrimination. Exercise on Prescription schemes suffer following shortcomings: 1) some areas have special provision for Asian Muslim women but many areas do not; issues with promoting the scheme in general and specifically for South Asian women; 2) dependent upon commitment of staff vital especially when lack of continuous funding, programmes are short-term and oversubscribed, and difficult for women to finance continuing exercise; 3) dependent upon good communications between multi-agencies that are not used to working together; 4) lack of clarity regarding roles and functions; 5) no direct links between community and the agencies to encourage participation (poor awareness and access to schemes); 6) lack of evaluation/monitoring of schemes; 7) difficulties with location of facilities (need to use local community facilities), inadequate public transport, fears of safety of walking; 8) need for more Asian members of staff at leisure facilities to communicate and understand needs of Asian women and availability of written materials in appropriate languages; 9) difficult to provide women-only sessions, female instructors; 10) need to consider childcare facilities; 11) GPs and leisure centre staff and instructors need to be supportive and receive appropriate training. The pilot programme ‘Exercise to Health’ in Beeston, Leeds, was seen as being successful by both providers and women who participated (14 women interviewed at 6-week follow-up), good attendance and far more demand for the service than could be met. Women were willing to pay if had to, but only if classes were kept local, expectations were fulfilled, energy levels increased and more motivated, happier

					and healthier with positive attitude towards continuing exercising.
Health Education Authority, 1999	Survey	England	To evaluate health and lifestyle in BMEGs.	N/a	Indian, Pakistani and Bangladeshi people reported lower levels of familiarity with terms such as ‘starchy foods’, ‘dietary fibre’ and ‘fat’, and knowledge of foods high in these terms was poor; Indian women most likely not to have time to exercise; good understanding amongst all ethnic groups that exercise was important to maintain health; some reasons for not exercising appear specific to ethnic minority groups such as modesty, fear of mixed sex activity and of going out alone (not confined to Muslims); language and culture were otherwise rarely mentioned as perceived barriers; low levels of knowledge of recommended levels of physical exercise were reported, unemployment and patterns of employment had significant impact on levels of PA.
Rai, 1997	Survey	UK-wide	To evaluate PA.	N/a (cross-sectional)	Barriers to exercise are not culturally specific (barriers similar in White adult population and South Asian and Black communities; differences faced by South Asian Muslim women were related to importance of Islam and being Muslim. Mainly enjoyment but also habit, appearance, health, being a role model to children and social benefits were factors that motivated physically active people. Similar to rest of UK, South Asian people said low participation in PA due to low motivation (could be due to high level of stress in this population which could be caused by poverty and racism). No fundamental cultural or religious reasons for prohibition of PA amongst South Asian population. Lack of time, burden of domestic duties and family responsibilities cited as main barriers to participation. South Asians give low priority to PA; part of normal everyday life and concept of paying for it was strange; self-conscious about body size or shape. Lack of privacy, dress-codes, separate sex provision, actual or potential experiences of racism all acted as barriers to exercise, also ‘not fitting in’, high costs, personal safety, transport, opening hours, childcare facilities.
Asian Arts & Leisure	Survey	South Asian	To evaluate use of local leisure	N/a	South Asian women emerged as particular cause for concern; barriers included poor knowledge of English language, nervousness about dress, acceptance by

Planners, 1996		population in Hounslow	facilities.	(Cross-sectional)	other service users and possible injury.
Shelley 1995	Population survey	White Irish	To evaluate cardiovascular risk changes following 5-year health promotion community programme.	Five years – population survey (cross-sectional) before and after programme in Kilkenny and reference country (Offaly).	Kilkenny Health Project for cardiovascular disease prevention; BMI increased in men and women in intervention and reference counties; resources should be targeted at those with least education and those at increased risk of coronary heart disease (CHD) fish, chicken, fruit and vegetables eaten more frequently post-intervention.
Majmudar 1995	Survey	South Asian women in Bristol	To evaluate PA.	N/a (cross-sectional)	South Asian women most likely not to exercise were those >24 years old who were less fluent in written and spoken English. Fear of racial harassment discourages women from walking or jogging alone and using public transport to get to leisure facilities.
Verma 1994	Survey	Six non-European (with national distribution) ethnic groups in Manchester, UK	To evaluate PA.	N/a (cross-sectional)	Women of all ethnic groups who would like to take part in exercise have many common barriers. South Asian women, particularly Pakistanis and Bangladeshis, suffer additional barriers to exercise related to culture and custom (expected approval of other members of community, including religious teachers, parents, siblings and friends). Religion powerfully reinforced the authority and behaviour patterns which appeared to reduce participation; racism acted as constraint.

EVIDENCE SUMMARY TABLE 2: INTERVENTIONS TO PREVENT WEIGHT GAIN, OR IMPROVE BEHAVIOURS ASSOCIATED WITH THE MAINTENANCE OF A HEALTHY WEIGHT, IMPROVE DIET AND INCREASE ACTIVITY LEVELS, IN VULNERABLE GROUPS (LOW-INCOME, LOW-LITERACY, SPASTIC CEREBRAL PALSY, DOWN'S SYNDROME AND LEARNING DIFFICULTIES)

SUMMARY

Six of the 14 RCTs of BMEGs were of low-income subjects. Both of the pregnancy studies were in low-income women. None of the seven smoking studies or the study during menopause was in low-income populations. Three further studies were identified here in low-income populations, one which separately recruited low-income women and analysed results by income for the women only (Jeffery 1997, Pound of Prevention study), one study in Mexican American mainly women with low-income and low-literacy (Howard-Pitney 1997) and one study in low-income Mexican American 10-year-old schoolchildren (Trevino 2004, 2005). The results of these three studies and three further studies, one study in children with spastic cerebral palsy, one study in adults with learning difficulties and one study in adults with Down's syndrome, are reported here.

Two of the studies included in the BMEGs were in low-come populations; one in a church-setting that significantly increased fruit and vegetable consumption (Campbell 1999) and one partially home-based study that showed brief education was just as effective as adding counselling to increase amount of walking (Chen 1998). Two of the GEMS pilots recruited African American mothers and girls from low-income areas (Beech 2003; Story 2003). One family-based intervention targeted single mums with children living at the poverty level (Stolley 1997) and another family intervention included 83–91% with less than US$15,000 annual income (Baranowski 1990).

One of the studies that aimed to prevent excessive weight gain during pregnancy was set in an obesity clinic for low-income women (Polley 2002) and the other study in pregnancy included 40% women who had household incomes below 185% federal poverty line and analysed weight outcome by income.

Evidence of efficacy for weight management/reduction

Low-income women who received the intervention to prevent excessive weight gain during pregnancy had a significantly reduced risk of excessive gestational weight gain (OR 0.41, 95% CI 0.20, 0.81); overweight women within this subgroup were at significantly reduced risk of retaining more than 2.27 kg at 1 year postpartum (OR 0.24, 95% CI 0.07, 0.89). The RCT of diet and exercise using a stepped care approach to prevent excessive weight gain in pregnancy was effective in reducing the frequency of excessive weight gain in normal weight women (58 vs. 33% gained above recommended weight, intervention vs. control), but had no significant effect among overweight women, with a trend in the opposite direction.

The low-intensity diet and exercise intervention 'The Pound of Prevention Study' showed no significant difference by treatment group (education, education plus lottery incentive and control) at 1 year regarding weight (education plus lottery incentives: 3.23 [SE 0.98] lb [1.47 {SE 0.45} kg]; education only: 2.11 [SE 0.99] lb [0.96 {SE 0.45} kg; control: 1.30 [SE 0.72] lb [0.59 {SE 0.33} kg]). The authors suggest intervention may be having a greater impact on high- than low-income women. A culturally specific low-fat dietary intervention in Mexican American women of low-literacy and low-income, set in California (both included 6-weeks intervention vs. standard nutrition, with intervention having further 12 weeks maintenance) failed to increase the effect of a stand nutritional education course without maintenance period, and there was no weight change in either group at 18 weeks but the study was not powered to detect any changes in weight. Mexican-American children from economically disadvantaged households who received a diet and exercise intervention to prevent diabetes (none had diabetes at baseline) did not improve % body fat compared with control at 1 year.

A 9-month aerobic exercise programme (45 min, four times per week) in 9-year-old children (*n* = 20) with spastic cerebral palsy, set in Germany reported ‘no changes’ in fat mass compared with an average 1.1 kg increase in the control group. A 12-month intervention to reduce obesity using health practitioner input with adults with learning difficulties in Manchester, UK, showed that in the control group obesity levels deteriorated in 10.2%, remained the same in 81.6% and improved in 8.2%. In the intervention group 10.5% deteriorated, 63.2% remained the same and 26.3% improved. Mean BMI did not appear to significantly differ from baseline or between groups at 1 year. (The mean BMI in the intervention group was significantly higher than in the control at baseline, BMI 34 vs. BMI 28 at baseline.) A 12-week cardiovascular and strength exercise programme in adults with Down’s syndrome showed a significant difference between groups ($p < 0.01$) with a slight reduction in weight at 12 weeks whereas control group weight increased. BMI was not significantly different between groups at 12-weeks.

It is important to note that in both the two adult studies (in adults with learning difficulties and Down’s syndrome) the majority of participants were obese (69% in total in adults with Down’s syndrome).

Evidence of efficacy for diet/physical activity outcomes

One study significantly increased the amount of walking in all participants from baseline to follow-up, but brief education was just as effective as adding mail and telephone counselling in low-income previously sedentary ethnic minority women (Chen 1998). One church-based intervention significantly increased fruit and vegetable intake amongst low-income African Americans (Campbell 1999).

Saturated fat intake (–2.1 oz [59 g]) and % energy from fat (–7.9%) was significantly reduced at 12 weeks in African American mothers following a diet and PA intervention (Stolley 1997). A culturally-specific low-fat diet and aerobic exercise intervention in low-income Black American families did not produce significantly increased METs or energy expenditure at 14 weeks compared with control; both significantly increased energy expenditure from baseline (Baranowski 1990).

The parent and child intervention groups combined significantly reduced intake of sweetened drinks compared with non-active control in the Memphis GEMS study (Beech 2003). The GEMS Minnesota pilot (Story 2003) and the study by Stolley (1997) both showed significant reduction in % energy from fat in the intervention girls. The children of a family diet and exercise intervention actually decreased activity (METs) compared with the control children who increased activity (METs) and energy expenditure (Baranowski 1990).

The RCT to prevent excessive weight gain during pregnancy in low-income women reported a lack of significant effect of the intervention on changes in intake of high fat foods and changes in exercise level from recruitment to 30 weeks were not related to treatment condition or BMI (Polley 2002).

The low-intensity diet and exercise intervention ‘The Pound of Prevention Study’ showed no significant difference by treatment group (education, education plus lottery incentive and control) at 1 year regarding dietary intake or PA. The authors suggest intervention may be having a greater impact on high than low-income women.

Within the low-literacy, low-income population, both the intervention and the standard nutrition education group significantly reduced % energy from fat. Within the cerebral palsy children, PA ratio (24-hour energy expenditure/resting energy expenditure) did not differ between intervention group and control group but both significantly increased from baseline. Mexican American children from economically disadvantaged households who received a diet and exercise intervention to prevent diabetes (non had diabetes at baseline) dietary fat intake did not differ between groups ($p = 0.52$). Using a modified Harvard step test the change in physical fitness score between pre-intervention and post-intervention was significantly different between intervention and control children after adjusting for age and pre-intervention BMI ($p < 0.003$). It is important to note that the PA outcomes are based on a smaller sample of the original cohort (Trevino 2005) and the dietary outcomes are based on the larger cohort sample (Trevino 2004).

Evidence of corroboration in the UK
No corroborative evidence was identified regarding PA and low-income populations. The health practitioner intervention to reduce obesity in adults with learning difficulties was conducted in Manchester, UK, and so has direct relevance to this population within the UK.

EVIDENCE TABLE 2: INTERVENTIONS TO PREVENT WEIGHT GAIN, IMPROVE DIET AND INCREASE ACTIVITY LEVEL IN VULNERABLE GROUPS (LOW-INCOME, LOW-LITERACY, SPASTIC CEREBRAL PALSY, DOWN'S SYNDROME AND LEARNING DIFFICULTIES)

<tr>
<td>Jeffery & French 'Pound of Prevention' study, 1997

RCT
1+

Aim:
To examine whether weight gain can be prevented using low-intensity intervention.</td>
<td>Eligibility criteria:
Age 20–45 years, not currently pregnant or having given birth within 12 months, not currently in treatment for serious medical or psychological disorder, willingness to participate for 3 years.

Setting:
Four local health departments in the Minneapolis/St Paul, Minnesota metropolitan areas.

Sample size (numbers analysed, numbers randomised by treatment group not reported, 404 in total):
Education plus lottery incentives: <i>n</i> = 82
Education only: <i>n</i> = 82
Control: <i>n</i> = 150

60% of high-income and 20% of low-income women were</td>
<td>Education only:
Behavioural and educational messages: pay attention to weight by weighing yourself at least once per week, eat two servings of fruit each day, eat three servings of vegetables each day, reduce intake of high-fat foods, walk three times per week for at least 20 min; monthly newsletter to deliver above messages; postcard sent with newsletter to be returned by participants with questions about whether participant has completed the above messages and opportunity to write any questions of which a selection will be answered in next month's newsletter; face-to-face education to individuals twice in first year held by health department nutritionist covering basic nutrition and exercise principles.

Education plus lottery incentives:</td>
<td>Lost to follow-up:
14% did not differ between groups but differed significantly within low-income women across treatment groups compared with high-income women and men across treatment groups; see table below for the proportion completing 1-year follow-up by treatment group and participant type.
<table>
<tr><th></th><th>Education only</th><th>Education and lottery</th><th>Total</th></tr>
<tr><td>Men</td><td>74</td><td>66</td><td>70</td></tr>
<tr><td>High-income women</td><td>78</td><td>81</td><td>80</td></tr>
<tr><td>Low-income women</td><td>57</td><td>67</td><td>62</td></tr>
<tr><td>Total</td><td>70</td><td>73</td><td>72</td></tr>
</table>
Weight:
No significant difference by treatment group in any of the participant subgroups at 1 year.

Education plus lottery incentives: +3.23 (SE 0.98) lb (1.47 [SE 0.44] kg).
Education only: +2.11 (SE 0.99) lb (0.96 [SE 0.45] kg).
Control: +1.30 (SE 0.72) lb (0.59 [SE 0.33] kg)</td>
<td>Additional recruiting for low SES women; low-income defined as self-report of US$25,000 per year or less, low-income women paid US$20 for completing initial 1.5-hour assessment.

Because of the different ways participants were recruited and differed regarding risk of weight gain, participants were subgrouped and analysed</td>

</table>

Frequency per week of each activity multiplied by estimated intensity score in METs
Increased walking was associated with less weight gain in women ($p < 0.01$), in high-income women ($p < 0.06$) and low-income women.

Authors’ conclusion:
These results suggest the intervention may be having a greater impact on high than low-income women. The only significant treatment effect was observed at one year was an increase in the frequency of reported weighing amongst subjects in the intervention group.

Among men and high-income women, early results relating to weight gain were encouraging and if

	Intervention: 31 years Control: 31 years **Education, % 12 years or less:** Intervention: 78% Control: 76% **Hispanic:** Intervention: 58% Control: 59% **Family income <US$10,000 per year, %:** Intervention: 63% Control: 66% **Baseline BMI:** Not reported.	educator, to improve knowledge and nutrition choices of low-income families from different ethnic backgrounds, five lessons on food guide pyramid, one on food safety and meal-planning; didactic presentation with handouts and recipes; received no maintenance intervention. **Follow-up:** 18 weeks	Energy from saturated fat, %: –0.9 (SD 1.2), *p* = 0.02 Net change, SNAP vs. control from 6 weeks to 18 weeks: Total dietary fat, g/d: +4.5 (SD 17.4), *p* = 0.39 Total saturated fat, g/d: +1.5 (SD 6.7), *p* = 0.44 Energy from total fat, %: –0.4 (SD 2.4), *p* = 0.56 Energy from saturated fat, %: –0.3 (SD 1.0), *p* = 0.45 **Authors' conclusion:** Results of the study indicate that SNAP's nutrition education curriculum for low income, low literacy was significantly ($p < 0.05$) more effective in achieving fat-related nutritional changes than a strong alternative general nutritional curriculum. The general nutrition curriculum showed equal or better improvements on components (which was not evaluated in this study, e.g. daily nutrition requirements and food safety) the results showed significant gains ($p < 0.05$) for SNAP participants in fat-related nutrition knowledge, attitudes, self efficacy and percentage of energy from total and saturated fat (which was reduced over 5 months 37.1 to 33.2% and 13.3 to 11.9%, respectively. Although both groups reduced their total daily energy intake by more than 300 kcal (1.26 MJ), it was shown that SNAP classes made better choices than the general nutrition group about energy levels in	results. Randomisation was by cluster and analysis was by individual, which may limit reliability of the results. It is not clear if the study was sufficiently powered to detect a significant effect of intervention compared with control.

First author, study design, research type, quality, weight	Study population	Intervention details and length of follow-up	Results	Confounders/ comments
			their diet by selecting lower fat foods. Although the curriculum showed significant ($p < 0.05$) results for dietary reductions in fat intake, BMI showed no change. This is probably due to the fact that SNAP emphasised eating less fat but not necessarily less energy, did not mention exercise and only touched upon the potential weight benefits that dietary fat reduction might achieve.	
Trevino 2004, 2005 Cluster RCT 1+	**Eligibility criteria:** Not clearly described. **Participants:** Fourth-grade students. **Setting:** Elementary schools located in low-income inner city neighbourhoods of the San Antonio Independent School District, TX, USA. Intervention (five schools): *n* = 200 Control (four schools): *n* = 187 **Age (mean):** Intervention: 9.8 years Control: 9.7 years 97% of students were Mexican	To evaluate the effect of the Bienestar Health Program (programme designed to reduce risk factors associated with the onset of type 2 diabetes) on physical fitness in low-income Mexican American children. The Bienestar Health Program was based on SCT and designed to decrease dietary fat and increase dietary fibre consumption and to promote participation in moderate to vigorous PAs. Programme activities were bilingual and included a parent education and involvement programme, a classroom health and PE curriculum, a student after-school health club and a	**Lost to follow-up:** All fourth grade students were invited to participate. 88% returned parental consent forms. Complete data was collected from 387 students (78%). Of 189 students in control group at baseline, complete data collected from 187. All 200 students in the intervention group at baseline returned complete data. **Weight at follow-up:** Not reported in Trevino 2005. In Trevino 2004 (larger sample of same study): % body fat, adjusted difference intervention ($n = 619$) vs. control ($n = 602$) +0.18 (95% CI, –1.75 to 2.11), $p = 0.56$ **Dietary intake:** Not reported in Trevino 2005; in Trevino 2004 dietary fat intake did not differ between groups ($p = 0.52$). **Physical activity (from Trevino 2005):** Outcome reported is physical fitness measured using a modified Harvard step test. Change in physical	All except body fat data are from Trevino 2005 paper. Parents and students who participated in the programme received coupons denoted in dollar amounts as an incentive and reinforcement, which could be exchanged for merchandise. These papers report interim

intervention design with a comparison group. **Aim:** To evaluate health practitioner input to improve healthy living and reduce obesity for adults with learning difficulties.	Intervention: *n* = 38 Control: *n* = 50 **Age (mean):** Intervention: 37.12 (SD 8.75) years Control: 43.32 (SD 10.97) years 43% of total group were women, 57 % men. No significant differences in gender between intervention and control groups. People in the intervention group were significantly less likely to be in adult placement or family homes and more likely to be in dispersed housing. **Baseline BMI (kg/m^2):** 97% of the intervention group and 64% of the control group were initially classified as overweight or obese. Statistically significant differences between the intervention and control groups for initial weight and BMI. The control group had a lower initial weight (mean 70.4 [SD 17.22] kg) than the input	support to improve their lifestyle. The intervention incorporated home visits, advice, design of activity programmes in conjunction with support staff and relatives, providing health promotion information. The assessment addressed issues such as: current PA levels; previous activities enjoyed; likes and motivations; support available; current dietary strategies in place; barriers to a healthy lifestyle; provision of resources. **Length of intervention:** 12 months. **Follow-up:** No further follow-up after 12-month intervention.	intervention group but this is not entirely clear from the data presented. **Body mass index (kg/m^2):** Control: Baseline BMI: 28.35 (SD 6.45); 6 months BMI 28.70 (SD 6.39); 1 year BMI 28.76 (SD 6.4). Intervention: Baseline BMI 34.89 (SD 5.72); 6 months BMI 34.57 (SD 5.49); 1 year BMI 34.28 (SD 5.58). In the control group obesity levels deteriorated in 10.2%, remained the same in 81.6% and improved in 8.2%. In the intervention group 10.5% deteriorated, 63.2% remained the same and 26.3% improved. **Diet:** Not reported. **Physical activity:** Not reported. **Authors' conclusions:** There was greater weight reduction in the intervention group (see above)	resource centres who did not receive HLC and outcome measures were measured by day centre and physiotherapist (HLC measured outcomes in intervention group).

Evidence for implementation – Will it work in the UK?

First author	Study design	Study population	Research question	Length of follow-up	Main results
Chapman 2005	As above.	Adults with learning difficulties in Manchester, UK	As above.	As above.	The intervention involved a physiotherapist employed to act as an HLC. The HLC provided input to individuals referred for support to improve their lifestyle.
Food Standards Agency (FSA) 2003	Review.	Low-income, UK	To review food and low-income initiatives in UK.	Various,	Great deal of existing work to tackle food poverty by local sector health workers running statutory initiatives focussing on individual behaviour change. Very low numbers of projects are reporting actual changes in behaviour or attitudes. Structural factors on not being addressed. Consultation with the community is not being done. Other agencies as well as health sector need to get involved.

Tingay 2003	Questionnaire	Subjects attending ten general medical practices in inner-city London.	To evaluate experiences of food insecurity in relation to income.	N/a	Responses were obtained from 431/495 (87%) subjects. Overall 87 (20%) of subjects were classified as food insecure. Food insecurity was negatively associated with household income (*p* = 0.004). University-educated subjects (8%) were less often food insecure than all others (26%). Subjects who were food insecure were less likely to report eating fruit daily (food secure 48%, food insecure 33%, *p* = 0.017) or vegetables or salads daily (food secure 56%, food insecure 34%, *p* = 0.002). Experiences of food insecurity may be common in households with incomes at the level of the UK national minimum wage or lower.
Dibsdall 2003	Questionnaire survey	Participants were 680 low-income men and women, aged 17–100 years. Homes owned by a large UK housing association.	To determine low-income consumers' attitudes and behaviour towards fruit and vegetables, in particular issues of access to, affordability of and motivation to eat fruit and vegetables.	N/a	Age, employment, gender, smoking and marital status all affected attitudes towards access, affordability and motivation to eat fruit and vegetables. Few (7%) participants experienced difficulty in visiting a supermarket at least once a week, despite nearly half having no access to a car for shopping. Fruit and vegetables were affordable to this low-income group in the amounts they habitually bought; purchasing additional fruits and vegetables was seen as prohibitively expensive. Less than 5% felt they had a problem with eating healthily and yet only 18% claimed to eat the recommended five or more portions of fruit and vegetables every day. Findings from this particular group suggest that, of the three potential barriers, access and affordability were only a small part of the 'problem' surrounding low fruit and vegetable consumption.
Kennedy 2001	Review of SUPER project	Low-income adults in Liverpool.	To identify the various benefits and obstacles involved and to identify links with progress at the local level.		The European Food and Shopping Research Project (SUPER project) was established under the World Health Organization (WHO) European network of Healthy Cities to help local projects implement the principles of health promotion (World Health Organization, 1986). This paper describes the SUPER project and its implementation in Liverpool (1989–97), where levels of unemployment, deprivation and ill health are amongst the highest in the UK. Research consistently demonstrates that low-income households find it difficult to adopt healthy eating guidelines. Contrary to popular belief, this is due to economic and circumstantial barriers such as lack of income, access to shops, or inadequate storage and cooking facilities, not lack of

					nutrition knowledge (Dobson et al. 1994) More recent attempts involve tailoring nutrition education to the socio-cultural needs of poorer groups and the development of local food initiatives such as ‘cook and taste’. Here, participants are shown how to implement guidelines under difficult financial circumstances. However, critics argue this fails to address the real issue of food poverty: lack of money. Moreover, previous work demonstrates that this type of approach is labour intensive and is unable to reach a sufficiently large proportion of those in need to be cost-effective (Kennedy et al. 1998). More recent work suggests that although worthy, most projects reach a small population and are rarely sustained beyond initial funding (McGlone et al. 1999). The emphasis is on changing the physical and social environment to facilitate lifestyle changes by individuals (Vaandrager et al. 1992). The stated aims of SUPER are: • to describe the food patterns, nutritional problems and food policy issues in five European cities; • to describe the processes relating to health promotion activities in communities and to identify the optimum conditions for best practice; • to achieve a positive change in dietary behaviour, and attitudes to food and health; • to decrease differences in nutritional status between higher and lower socio-economic groups within the Study population; and • to develop more sustainable nutrition promotion in communities by incorporating activities initiated by local projects into organisational structures. According to project reports, in the period 1989–95, the approach remained focussed on nutrition education and disseminating information. Since the introduction of the lay food workers, the approach in Liverpool

					has become much broader, focusing more on health promotion and less on nutrition education. A major strength, and possibly the most important outcome, of the project in Liverpool was the process of reorientation experienced by participating health professionals and organizations. Experience demonstrated, however, that community involvement or community participation was much more difficult to achieve in practice. Local people were involved in the data collection process, but because they were excluded from planning what questions to ask they were provided with no real sense of ownership. It is essential that communities share responsibility for the rapid appraisal and help identify local needs in order to develop a sustainable programme of activities. Vaandrager describes the key elements of the approach used to promote healthy eating in Liverpool (Vaandrager, 1989): • participation in the Health Education Authority's (HEA) ‘Look after your heart’ programme – nutrition education campaign; • the main activity in 1988 was the ‘lifestyle fair’ – a 3-day health fair; • Liverpool Health Authority signed up to the HEA ‘Look after your heart’ Workplace Charter – incorporating activities to promote healthier eating amongst employees; • establishment of a Local Authority Food Policy Network. Illing (1992) describes three activities developed for the Croxteth area for the 14-month intervention period • school recipe competition; • nutrition open days in health clinic – information stalls, posters, leaflets; • a Nutrition in Action Group established (1991) to help develop nutrition strategy for Liverpool and to examine issues re: school meals (Illing, 1992). In 1993 more comprehensive but similar activities were organised over 4–14 months. Supermarkets: • monthly promotional activities and healthy eating themes:

					– ‘enjoy your food with less fat’ (poster) – ‘the importance of fruit and vegetables’ – ‘enjoy your food with less sugar’ – ‘a varied diet a healthy diet’; • a dietitian held a stall in the foyer of local supermarket offering promotional literature, such as information leaflets, posters or display boards, and to answer customer questions. Schools: • dietitian gives talks on healthy eating themes; • competition – pupils to design healthy eating leaflet; • posters and leaflets distributed; • school meals– healthier menu items highlighted for a limited period (every fourth week); • parent support group – practical demonstration sessions: healthier cooking. Community group: • healthy eating talks and practical demonstrations with mums and toddler groups (Smit & Rolling, 1993); • activities for the period 1995–97: – increased involvement in the work of the West Everton Community Health Forum; – Liverpool Food and Health Strategy Development Group established to represent wider agenda (1999); – introduction of lay nutrition workers – community food workers (1996); – food workers use an outreach work approach and consult communities to develop responses to help local people address barriers to healthy eating; – practical advice on ‘how-to’ implement healthy eating messages is provided for small community groups; – represent community members on health forums or committees to place local food issues (e.g. lack of shops) on the agenda; – offer referrals to people requiring help with non-nutrition problems (e.g. debt). (Sources: Judd & Jones, 1995; Heeson, 1996.)

French, 2000	Survey	Women aged 25–45 years, enrolled in Pound of Prevention Study (USA)	To examine demographic, behavioural and dietary correlates of frequency of fast food restaurant use in a community-based sample of 891 adult women.	3 years	Twenty-one percent of the sample reported eating three or more fast food meals per week. Frequency of fast food restaurant use was higher among younger women, those with lower income, non-White ethnicity, greater body weight, lower dietary restraint, fewer low-fat eating behaviours, and greater television viewing. Intake of several other foods, including fruits and vegetables, did not differ by frequency of fast food restaurant use.
Women's Health Initiative Study Group, 2004 Women's Health Initiative Dietary Modification Trial	FFQ as part of RCT	Postmenopausal women (USA)	To assess adherence to a low-fat diet.	5 years	This paper describes adherence to a low-fat dietary pattern (less than 20% energy from fat, five or more fruit/vegetable and six or more grain servings daily) in years 1 and 5 of the Women's Health Initiative Dietary Modification Trial, which was designed to examine the effects of a low-fat dietary pattern on risk of breast and colorectal cancers and other chronic diseases in postmenopausal women. Participants were randomly assigned to a low-fat dietary intervention arm (40%, *n* = 19,542) or a usual-diet control arm (60%, *n* = 29,294). Women in the intervention arm completed 18 group sessions during the first year, followed by quarterly annual maintenance sessions. Adherence was assessed as control minus intervention (C – I) group differences in percent total energy from fat as estimated by a food frequency questionnaire. Based on these self-reported dietary data, mean C – I was 10.9 percentage points of energy from fat at year 1, decreasing to 9.0 at year 5. Factors associated with poorer adherence were being older, being African American or Hispanic (compared with White), having low income, and being obese. Group session attendance was strongly associated with better dietary adherence.

EVIDENCE SUMMARY TABLE 3a: INTERVENTIONS TO PREVENT WEIGHT GAIN, IMPROVE BEHAVIOURS ASSOCIATED WITH THE MAINTENANCE OF A HEALTHY WEIGHT, IMPROVE DIET AND INCREASE ACTIVITY LEVELS IN INDIVIDUALS AT VULNERABLE LIFE-STAGES (MENOPAUSE)

SUMMARY

One systematic review of 18 RCTs assessed the effect of exercise (walking, other aerobic training, resistance training, strength training with weights machines or combinations) in postmenopausal women. One RCT was included that aimed to prevent excessive weight gain during the menopause, with the full anthropometric results at 54 months published in 2003. The study was conducted in Pittsburgh and followed women from pre-menopause for 54 months when 35% of the women had become postmenopausal. The aim of the intervention was to provide modest weight loss to keep the women at their baseline weight by the end of the study. The study reported changes in weight, BMI, % body fat, % fat-free mass, PA and energy intake. The intervention included 1300 kcal (5.44 MJ)/day (25% of energy from total fat, 7% of energy from saturated fat and 100 mg cholesterol), PA expenditure of 1000–1500 kcal (4.19–6.28 MJ)/week (mainly through increasing walking and lifestyle activities) other lipid-lowering dietary strategies, i.e. increasing soya protein, fruits and vegetables and fibre if necessary; provided in a cognitive-behavioural programme and compared with an assessment-only control.

In the study, women were predominantly White, college-educated and employed full-time. 53.6% were of normal weight at baseline and all women were healthy with average risk factor levels. Mean age was 47 years and mean BMI was 25 kg/m^2. Women (*n* = 535) were randomised and the study was adequately powered to detect statistically significant differences in outcomes, with only 5% dropout and an ITT analysis.

Evidence of efficacy for weight management/reduction

In the systematic review, weight and body fat were studied in 18 studies with 1804 subjects. Body composition was improved in nine studies and most studies showed a small loss of body weight and fat. The effect seemed to be optimal when combining exercise with a weight-reducing diet. The most effective results were accomplished in three studies with overweight participants who used weight-reducing diets in combination with exercise training. The mean weight loss ranged was 2–10 kg in 12 weeks to 1 year.

At 54 months 55% of the intervention women were at or below their baseline weight compared with 26% in the control.

Mean weight change (kg) at 54 months was also significant between groups (–0.1 [SD 5.2] intervention vs. +2.4 [SD 4.9] control. There was a significant reduction in waist circumference (cm) at 54 months compared with control (–2.9 [SD 5.3] vs. –0.5 [SD 5.6], $p < 0.001$). There was a significant reduction in BMI (kg/m^2) in intervention women compared with control at 54 months (0.05 [SD 2.0] vs. 0.96 [SD 1.8], $p < 0.001$). Change in % body fat was also significantly reduced in the intervention group compared with control at 54 months (–0.5 [SD 4.1] vs. 1.1 [SD 3.9], $p < 0.01$). Fat-free mass (kg) was also significantly reduced in the intervention group compared with control at 54 months (0.0 [SD 1.9] vs. 0.5 [SD 2.1], $p < 0.05$).

Evidence of efficacy for diet/physical activity outcomes

In the systematic review the most effective exercise prescription for losing body fat was 30–60 min of walking or other aerobic training at 45–75% VO_{2max} on 3–5 days per week for 15 weeks to 1 year, or strength training with weight machines, five exercises with 80% of one repetition maximum with eight repetitions and three sets twice a week for 1 year.

Energy intake (kcal/day) was significantly reduced in the intervention group compared with control at 54 months (–160 [SD 465] vs. –25 [SD 560] [–0.67 {SD 1.95} vs. –0.10 {SD 2.34} MJ/day], $p < 0.01$). The intervention group reported eating significantly less dietary fat and cholesterol than controls.

There was a significant increase in the amount of energy expended through physical exercise (kcal/day) in the intervention group compared with controls at 54 months (275 [SD 1173] vs. –113 [SD 1261] [1.15 {SD 4.91} vs. –0.447 {SD 5.28} MJ/day], $p < 0.001$) (blocks walked (***no further details reported)*** (kcal/ 188 [SD 615] vs. –83 [SD 611] kcal/day [0.79 {SD 2.57} vs. –0.35 {SD 2.56} MJ/day], $p < 0.001$). There was no significant difference between the groups in terms of energy expended through sport and recreational activity (kcal/day) (intervention vs. control): 57 (SD 1023) vs. –47 (SD 1104) (0.24 [SD 4.28] vs. –0.20 [SD 4.62] MJ/day). There was a significant increase in the intervention group (counts/hour of activity) when measured with the activity monitor at 54 months compared with control (2.3 [SD 9.1] vs. –0.26 [SD 7.8], $p < 0.01$).

Evidence of corroboration in the UK
Evidence of corroboration was limited. Although none of the identified RCTs focussing on pregnancy, menopause or smoking cessation were UK-based, it is likely that the findings are applicable to the UK population.

Cost-effectiveness data
No cost-effectiveness data were reported.

Asikainen et al. (2004) Systematic Review (RCTs with >25 subjects and <35% attrition) 1++	All the subjects used in the studies were postmenopausal women aged 50–65 years. If a study had younger or older women then it was accepted providing the mean age was in the range of 50–65 years. Subjects had either been selected either on a voluntary basis or from a population-based sample. All subjects were sedentary at baseline or had some leisure PA that was kept constant during the study. Healthy women were accepted as well as subjects with diseases or risk factors such as dyslipidaemia, hypertension, obesity or osteoporosis. Hormone replacement therapy (HRT) and other medications were allowed.	To evaluate data from RCTs on exercise training studies with special reference to improving health in early postmenopausal women. Walking, other aerobic training, resistance training, strength training with weights machines or combinations of these were used. Exercise could be in addition to diet. Minimum 8 weeks. No further details on length of follow-up	Weight and body fat were studied in 18 studies with 1804 subjects. Body composition was improved in nine studies. Most studies showed a small loss of body weight and fat. The effect seems to be optimal when combining exercise with a weight reducing diet. The most effective results were accomplished in three studies with overweight participants who used weight-reducing diets in combination with exercise training. The mean weight loss ranged from 2 to 10 kg in 12 weeks to 1 year. The most effective exercise prescription for losing body fat was 30–60 min of walking or other aerobic training at 45–75% VO_{2max} on 3–5 days per week for 15 weeks to 1 year, or strength training with weight machines, five exercises with 80% of one repetition maximum with eight repetitions and three sets twice per week for 1 year.	Training programmes were relatively short in duration. VO_{2max} and muscular strength also reported in paper but not extracted for this review.

Evidence for implementation – Will it work in the UK?

EVIDENCE SUMMARY TABLE 3b: INTERVENTIONS TO PREVENT WEIGHT GAIN, IMPROVE BEHAVIOURS ASSOCIATED WITH THE MAINTENANCE OF A HEALTHY WEIGHT, IMPROVE DIET AND INCREASE ACTIVITY LEVELS IN INDIVIDUALS AT VULNERABLE LIFE-STAGES (PREGNANCY)

SUMMARY

Two studies (one RCT and one CBA) were included that aimed to prevent excessive weight gain during pregnancy and were published in 2001 and 2002. One further CCT was included that aimed to test the hypothesis that continuing a regular regimen of recreational exercise alters the time specific rate of maternal weight gain and subcutaneous fat deposition during pregnancy. The CBA study was conducted in New York and followed women from early pregnancy to 1-year postpartum (Olson 2004). The RCT was conducted in Pittsburgh and followed women from prior to 20-weeks gestation to 8-weeks postpartum (Polley 2002). The CCT was conducted in Cleveland and followed women from pre-pregnancy to 37-weeks gestation (Clapp 1995). All of the studies reported weight change; one reported dietary and PA outcomes (Polley 2002). The CBA study included an intervention group that had their gestational weights monitored and received education about appropriate weight gain during pregnancy and healthy eating and exercise advice, compared with a historical control group. The RCT included an intervention group that received advice about weight gain during pregnancy and a diet substituting high-fat ‘fast foods’ with fruit and vegetables and increasing moderate exercise (walking). This intervention was a stepped care approach where women received additional sessions and behavioural goals were increasingly structured should she exceed recommended levels of weight gain at any time during the pregnancy, compared with standard nutritional counselling. The CCT compared participants who continued with the same regular exercise as before pregnancy to those who voluntarily stopped regular exercise. Most of the intervention participants continued to exercise at least three times per week for 30 min or more at an intensity >50% VO_{2max} throughout pregnancy to 37th week.

A Cochrane systematic review of diet in pregnancy reports that the limited evidence available suggests that protein/energy restriction of pregnant women who are overweight or exhibit high weight gain is unlikely to be beneficial and may be harmful to the developing fetus. Only three studies were included, two in Scotland that were both published prior to 1990, one in obese women and the other in women with high gestational weight gain between weeks 20–30.

In the CBA study, 94% were aged between 20–40 years, 75% were of normal pre-pregnancy BMI, 41% were having first baby and 40% had household incomes below 185% federal poverty line. In the RCT, mean age was 25.5 years, 47% were first pregnancies, 57% were unemployed (setting was an obesity clinic for low-income women) just under half of both the control and intervention group women were classed as overweight (BMI 31–34 kg/m^2). One hundred and twenty women were randomised in the RCT and 179 participants in the intervention group of the CBA study were compared with 381 women in the historical control group. In the CCT participants mean age was 31 years, parity ranged from 0 to 2; participants were well educated with family incomes at or above 75th percentile for their state of origin, they were non-smoking White females. There were significantly more homemakers and/or part-time workers in intervention group (31 vs. 14%, $p < 0.05$) and the percentage of women with jobs known to require moderate PA was significantly higher in the control group (39 vs. 23%. $p < 0.05$). Forty-four women in the exercise intervention group and 35 women were in the control group. Baseline body mass (before pregnancy) was 58.1 kg in the intervention group and 60.2 kg in the control group. Mean weekly duration of exercise was 172 min and mean exercise intensity was 66% VO_{2max} for all participants at baseline.

Evidence of efficacy for weight management/reduction
All three studies reported weight change. The CBA study demonstrated that the diet and exercise intervention reduced the risk of excessive gestational weight gain in the low-income subgroup only. Low-income women who received the intervention had a significantly reduced risk of excessive gestational weight gain (OR 0.41, 95% CI 0.20, 0.81); overweight women within this subgroup were at significantly reduced risk of retaining more than 2.27 kg at 1-year postpartum (OR 0.24, 95% CI 0.07, 0.89).

The RCT of diet and exercise using a stepped care approach was effective in reducing the frequency of excessive weight gain in normal weight women (33% intervention vs. 58% control), with the intervention having no significant effect among overweight women but a trend in the opposite direction. The CCT demonstrated that continuing a regular exercise regimen throughout pregnancy resulted in significantly less total weight gain (13.0 [SD 0.5] vs. 16.3 [SD 0.7] kg, $p < 0.0001$). Increases in the sum of skinfold thicknesses were 22 ± 2 and 31 ± 2 mm intervention vs. control at 37 weeks. The intervention did not influence the rate of early pregnancy weight gain or subcutaneous fat deposition but decreases both in late pregnancy. However, overall pregnancy weight gain remains well within the normal range.

Within the Cochrane systematic review (Kramer 2003) of diet during pregnancy, three trials involving 384 women were included. Both Campbell trials (UK) reported that energy/protein restriction was associated with a significant reduction in weekly maternal weight gain, although the magnitude of the reduction was much larger in the 1975 trial (random effects weighted mean difference [WMD] –254.81 [95% CI –436.56, –73.06] g/week). The two trials reporting on birth weight (Campbell 1983; Badrwai 1993) yielded highly (and statistically significantly) heterogeneous results, with Campbell 1983 reporting virtually no effect of the intervention (WMD 6.00 [95% CI –121.55, +133.55] g) but Badrwai (1993) finding a large significant adverse effect (WMD –450.00 [95% CI –624.72, 275.28] g). Postpartum weight retention was not reported.

Evidence of efficacy for diet/physical activity outcomes
The RCT reported a lack of significant effect of the intervention on changes in intake of high-fat foods and changes in exercise level from recruitment to 30 weeks were not related to treatment condition or BMI.

Evidence of corroboration in the UK
Although none of the individual studies was conducted with the UK, the interventions could be implemented in the UK. Two studies published in 1975 and 1983 and included in the review of diet in pregnancy (Kramer 2003) were conducted in Scotland.

EVIDENCE TABLE 3b. INTERVENTIONS TO PREVENT WEIGHT GAIN IN INDIVIDUALS AT VULNERABLE LIFE-STAGES (PREGNANCY)

First author, study design, research type, quality	**Study population**	**Intervention details and length of follow-up**	**Results**	**Confounders/comments**
Kramer 2003 Cochrane systematic review 1+	Pregnant women	Energy and protein intake in pregnancy. Review of the effects of advice to increase or reduce energy or protein intake, or of actual energy or protein supplementation or restriction during pregnancy on energy and protein intakes, gestational weight gain and the outcome of pregnancy. Various follow-up Campbell 1975 intervention included 1200 kcal (5.02 MJ)/day low-carbohydrate diet from 30 weeks gestation compared with normal diet. Campbell 1983 intervention involved 1250 kcal (5.23 MJ)/day diet in obese women compared with control. Badrwai intervention involved 1500–2000 kcal	Three trials involving 384 women were included. Both Campbell trials reported that energy/protein restriction was associated with a significant reduction in weekly maternal weight gain, although the magnitude of the reduction was much larger in the 1975 trial (random effects WMD –254.81 [95% CI –436.56, –73.06] g/week). Energy/protein restriction had no effect on either (proteinuric) pre-eclampsia or pregnancy-induced hypertension (with or without proteinuria), although the small number of trials and participants provides inadequate statistical power to exclude a small effect. The two trials reporting on birth weight (Campbell 1983; Badrwai 1993) yielded highly (and statistically significantly) heterogeneous results, with Campbell 1983 reporting virtually no effect of the intervention (WMD 6.00 [95% CI –121.55, +133.55] g) but Badrwai (1993) finding a large significant adverse effect (WMD –450.00 [95% CI –624.72, –275.28] g).	This review just focuses on one element of the Cochrane review: evaluation of low-energy diets in pregnant women who are obese or have high gestational weight gain. Two Campbell studies were conducted in Scotland, one in obese women and the other in women with high gestational weight gain between weeks 20–30. Both were conducted prior to 1990.

First author, study design, research type, quality	Study population	Intervention details and length of follow-up	Results	Confounders/comments
		(6.28–8.37 MJ)/day diet in obese Egyptian women compared with normal WHO-recommended diet;	These large differences in results could reflect either differences in study samples (Scotland vs. Egypt) or differences in the degree of energy/protein restriction achieved. Only Campbell (1983) reported results bearing on gestational duration; the results appear to exclude an important adverse effect of dietary restriction (WMD in mean gestational age +0.25 (95% CI –0.17 to +0.67) weeks). Other outcomes, including fetal/infant mortality and other measures of maternal morbidity (e.g. Caesarean section) or postpartum weight retention, have not been reported. The limited evidence available suggests that protein/energy restriction of pregnant women who are overweight or have high weight gain is unlikely to be beneficial and may be harmful to the developing fetus.	
Olson et al. 2004 CBA (historical control) 2++ **Aim:**	**Eligibility criteria:** Women with normal (19.8–26.0 kg/m^2) and high (26.1–29.0 kg/m^2) BMI entered prenatal care before third trimester, ≥18 years old at delivery, no medical condition	**Intervention:** Graphic design of the Institute of Medicine gestational weight gain grid, separate colour-coded grid was developed for of the four pre-pregnancy BMI	**Lost to follow-up:** Not reported; 21 excluded from intervention group and 22 excluded from control group. Details of the historical control group and recruitment details are described elsewhere in studies by Kendall et al. (2001) and Hinton & Olson	Twelve women who participated in historical control group also participated in prospective intervention group. Bias was detected in the historical control self-reported pre-pregnancy

	Obstetric clinic, Cleveland, OH, USA. Age 31 (SD 0.3) years, parity ranged from 0 to 2; well educated (mean 17.3 years), family incomes at or above 75th percentile for their state of origin, non-smoking White; significantly more homemakers and/or part-time workers in intervention group (31 vs. 14%, $p < 0.05$); percentage of women with jobs known to require moderate PA was significantly higher in control group (39 vs. 23%, $p < 0.05$); **Sample size:** Intervention: $n = 44$ Control: $n = 35$ **Baseline body mass: (prior to pregnancy):** Intervention: 58.1 (SD 1.0) kg Control: 60.2 (SD 1.2) kg Mean height for all participants 166.7 (SD 0.6) cm **Mean weekly duration of exercise:** All participants: 172 ± 6 min **Mean exercise intensity:**	exercise regimen because of concern that it would have negative effects on pregnancy, $n = 31$ or reduced it below baseline fitness levels in very early pregnancy, $n = 4$). All participants consumed a balanced diet, reported energy intake rose consistently during pregnancy with no significant differences between the two groups; however, 12 aerobics instructors who were intervention participants had significantly greater energy intake. **Follow-up:** 37 weeks	significantly ($p < 0.001$) less than the controls (0.31 vs. 0.47 kg/week). As a result total weight gain was significantly ($p < 0.0001$) less in the intervention group (13.0 [SD 0.5] vs. 16.3 [SD 0.7] kg). Increases in the sum of skinfold thicknesses were 22 ± 2 mm and 31 ± 2 mm intervention vs. control at 37 weeks. Authors conclude that continuing a regular exercise regimen throughout pregnancy does not influence the rate of early pregnancy weight gain or subcutaneous fat deposition but decreases both in late pregnancy. However, overall pregnancy weight gain remains well within the normal range.	

First author, study design, research type, quality	Study population	Intervention details and length of follow-up	Results	Confounders/comments
	All participants: 66 ± 1% VO_{2max}. **Significant differences at baseline:** Sum of five skinfold thicknesses greater in control group, also subjects who continued to exercise (intervention group) spent 44% ($p < 0.01$) exercising each week than those subjects who stopped (control group) representing average difference in energy expenditure of 600 kcal (2.51 MJ)/week.			

Evidence of corroboration (external validity)

Evidence of salience from studies conducted in the UK

First author	Study population	Research question	Length of follow-up	Main results	Confounders/comments

Evidence for implementation – Will it work in the UK?

Pregnancy Anderson 1995	CCT	Maternity hospital in Aberdeen.	To assess the effect of dietary advice education intervention on nutrient intake during pregnancy.	From booking to 26 weeks gestation.	Intervention participants received information packs on nutrition at time of booking and at 26-weeks gestation, all participants received general pregnancy health guide. Results showed that knowledge about nutrition was significantly higher in the intervention group (magnitude unlikely to make difference in practice), but no significant differences were noted on attitude variables or nutrient intake (fat, energy).

EVIDENCE SUMMARY TABLE 3c: INTERVENTIONS TO PREVENT WEIGHT GAIN, OR IMPROVE BEHAVIOURS ASSOCIATED WITH THE MAINTENANCE OF A HEALTHY WEIGHT, IMPROVED DIET AND INCREASED ACTIVITY LEVELS, IN INDIVIDUALS AT VULNERABLE LIFE-STAGES (SMOKING CESSATION)

(METHODOLOGY: Report continuous abstinence [no smoking since quitting] rather than point prevalence abstinence [no smoking in past 7 days], report weight gain by quitters in each treatment group only, report latest follow-up point only.)

SUMMARY

Seven smoking cessation studies (six RCTs and one CBA) were included that aimed to prevent excessive weight gain when stopping smoking. Five of the RCTs only included women. Five of the studies were published between 1999 and 2004 and two studies were published in 1992 (Hall 1992; Pirie 1992). Five studies were conducted in North America, one in Sweden (Danielsson, 1999) and one in Iceland (Jonsdottir, 2001). All studies had at least 12-months follow-up from when participants quit smoking. All of the studies reported % rates of continuous abstinence and weight change; none reported dietary or PA outcomes. All the studies included a smoking cessation intervention, three RCTs focussed on dietary interventions including energy reduction, food replacements, and early and late introduction of diet. Two RCTs focussed on diet and exercise intervention (Hall 1992; Pirie 1992; both arms had identical exercise) and two studies focussed on an exercise only intervention (Marcus 1999; Jonsdottir 2001).

Participants mean age within the studies ranged from 39 to 47 years, BMI ranged from 24 to 28 kg/m^2 at baseline. Numbers of cigarettes smoked per day ranged from 19 to 32 cigarettes and where reported years of smoking ranged from 22 (Marcus 1999) to 30 years (Hall 1992; Danielsson 1999). Numbers of participants in each arm ranged from 33 (Jonsdottir 2001) to 150 (Danielsson 1999). The majority of studies only included women who wanted to stop smoking and control their weight and were therefore a motivated population.

Evidence of efficacy for weight management/reduction

All seven studies reported weight change; only weight change in women who remained continuously abstinent is reported here.

One RCT (Spring 2004) compared a low-energy (150 kcal [630 kJ]/day deficit) diet given in the initial 8 weeks alongside exercise and smoking cessation programme with diet given in the later 8 weeks of the 16-week treatment period, with both compared with a control which consisted of the smoking cessation programme only. Nine-month abstinence did not differ between the groups (weight control did not undermine smoking cessation) with 18.2% in the control, 21.4% early diet and 19.5% in the late diet group. Nine-month weight change also did not differ between the groups (6.20 kg in control, 7.57 kg in early diet, 4.88 kg in late diet).

In one CBA study (Jonsdottir 2001) of an exercise intervention in a convenience sample of self-referred participants, the addition of exercise in a gym did not significantly improve abstinence rates (20.6 vs. 39.4%, $p = 0.16$) or prevent weight gain (3.0 vs. 5.0 kg, $p = 0.37$) compared with control in a healthcare centre, despite the exercise group having paid more money to take part (all participants received option of nicotine replacement therapy [NRT] and received health education and both individual and group behavioural modification).

One study (Perkins 2001) demonstrated that cognitive behavioural therapy (CBT) for weight concerns (to promote acceptance of and reduce concerns about modest weight gain when stopping smoking) significantly attenuated weight gain (2.5 vs. 7.7 kg) and significantly increased rates of abstinence (21 vs. 9%), compared with standard smoking cessation counselling in weight concerned women (13% abstinence in weight control group, no significant weight control vs. CBT for weight concerns). The third arm of the intervention included a 500 kcal (2.10 MJ)/day deficit, but there was no significant difference in weight change between this weight control arm and the standard intervention arm (5.4 vs. 7.7 kg).

One exercise intervention (Marcus 1999) in sedentary women significantly improved smoking abstinence compared with control (11.9 vs. 5.4% $p = 0.05$), but there was no significant difference in weight gain (8.92 vs. 5.76 kg respectively) at 60 weeks post-quit.

One intervention (Danielsson 1999) included a very-low-energy (6.7 MJ/day) food replacement supplied to female participants for three 2-week periods; this was in addition to nicotine gum, which all participants could use. At 12 months the food replacement group had 28% abstinence compared with 16% abstinence within the control group ($p = 0.02$). There was, however, no significant difference between the groups regarding weight gain (2.5 kg in intervention vs. 3.8 kg in control, $p = 0.61$).

One study (Hall 1992) included a low energy, low-fat diet if participants gained 2 lb (0.90 kg) or more, plus aerobic exercise, this intervention had three arms: specific (individualised diet and exercise plan); non-specific (not individualised) diet and exercise; and a standard control group. At 12 months both active interventions (specific and non-specific diet and aerobic exercise) had a greater risk of smoking than the control group (specific intervention 21%, non-specific intervention 22%, control 35% continuous abstinence). The authors reported no significant difference between the three groups regarding weight change (0.86 kg specific intervention, 3.35 kg non-specific intervention, 3.61 kg control).

One RCT (Pirie 1992) included four arms all including smoking cessation treatment with weight control added in one arm, nicotine gum in another arm and both nicotine gum plus weight control in another arm. The two arms that included weight control element also included a walking element. At 12-months post-treatment, the arm that included smoking cessation plus nicotine gum and the highest rate of abstinence and there was no significant difference between the intervention arms regarding weight change (ranged from 9.77 to 14.15 lb [4.43 to 6.42 kg]).

Evidence of efficacy for diet/physical activity outcomes
None of the studies reported diet or PA outcomes relevant to this review.

Evidence of corroboration in the UK
Although none of the studies were conducted with the UK, many of the interventions cited within the included studies could be implemented in the UK.

EVIDENCE TABLE 3C. INTERVENTIONS TO PREVENT WEIGHT GAIN IN INDIVIDUALS AT VULNERABLE LIFE-STAGES (SMOKING CESSATION)

First author, study design, research type, quality	**Study population**	**Intervention details and length of follow-up**	**Results**	**Confounders/comments**
Perkins et al. 2001 Cluster RCT 1+ **Aim:** To identify most effective approach to addressing weight gain concerns in women quitting smoking.	**Eligibility criteria:** Women, 18–65 years old, smoking at least ten cigarettes per day, free of any major health problem or illicit drug use, significantly interested in quitting smoking, endorsing concerns about weight gain after quitting. **Exclusion:** Women trying to become pregnant or following medically prescribed diet were excluded. **Setting:** Allegheny County, Pennsylvania. **Sample size:** Total *n* = 219 Weight control group:	**All:** CBT smoking cessation counselling (ACS Fresh Start program). Therapists were women with master's degrees in clinical or counselling psychology that received intensive didactic training and weekly supervision. Participants received ten × 90 min group sessions (ten to twelve participants) over 7 weeks, two sessions per week during first 3 weeks and one session per week in last 4 weeks. Participants instructed to quit smoking after group's fourth session and before fifth session, follow-up at 3, 6 and 12 months post-quit; asked not to use NRT **Weight control intervention:** Subjects were given daily energy goals (typically less than 500 kcal [2.09 MJ] less than would be required to maintain baseline weight if still smoking) and were instructed to self-monitor daily food intake in a	**Lost to follow-up:** By the end of the 7 weeks of treatment (4 weeks post-quit) was 19% for CBT group, 10% for the weight control group and 21% for the control/standard group. Also the difference between weight control and standard was significant ($p < 0.05$). Mean attendance at the three follow-up sessions was 62% and did not differ between the three groups. **12-month continuous abstinence: (assumed dropouts resumed smoking):** Weight control: 13% CBT for weight concerns: 21% Standard: 9% (Not significant between weight control vs. CBT for weight concerns, but significant between CBT for weight concerns vs. standard.) **Weight gain (only in abstinent women):**	Significantly more participants in CBT for weight concerns vs. weight control had dieted in last 12 months at baseline Outcome results not changed when analyses were repeated excluding participants who used nicotine replacement therapy. Pre-quit BMI predicted cessation outcome at 1 year Self-reported abstinence verified by exposed air carbon monoxide readings Randomisation was by cluster and

	n = 72, mean BMI 25.6 kg/m^2 CBT: *n* = 72, mean BMI 25.8 kg/m^2 Standard: *n* = 75, mean BMI 25.5 kg/m^2 **Age:** Weight control: 45.7 (SD 10.4) CBT: 44.3 (SD 9.5) Standard: 43.6 (SD 10.0) **College graduate:** Weight control: 51.4% CBT: 43.0% Standard: 46.7% **Smoking rate (years):** Weight control: 27.4 (SD 10.4) CBT: 24.7 (SD 10.9) Standard: 24.9 (SD 10.1) **Baseline BMI (kg/m^2):** Weight control: 25.6 (SD 5.4) CBT: 25.8 (SD 4.7) Standard: 25.5 (SD 4.7)	diary, which was reviewed weekly by the group therapist. Subjects also graphed their weight on a chart containing a solid horizontal line across time at their pre-quit baseline weight. Participants encouraged to practice self-monitoring and stimulus control particularly to reduce between-meal snacking. **Cognitive beviourial therapy for weight concerns:** Promote acceptance of and reduce concerns about modest weight gain, self-monitor negative thoughts, promote health benefits of quitting smoking superseding health risks of weight gain, reducing dietary restraint, improving body image, discourage dieting and encourage moderate consumption of healthy foods during between-meal snacking. **Control (standard advice):** Non-specific social support, discussed other aspects of quitting, discussion of weight gain concerns was discouraged. **Follow-up:** 12-months post-quit.	Weight control: 5.4 (SD 3.3) kg CBT for weight concerns: 2.5 (SD 4.2) kg Standard: 7.7 (SD 4.7) (Significant between CBT for weight concerns vs. standard but not significant between weight control vs. standard or CBT vs. weight control.) **Diet:** Not reported. **Physical activity:** Not reported. **Author's conclusion:** CBT to reduce weight concerns but not weight control, improved smoking abstinence in weight concerned women beyond that produced by standard cessation counselling; weight control group attenuated post-cessation weight gain, unexpectedly, weight gain in the CBT group was also less than weight gain in the standard group but not different from that in the weight control group.	analysis was by individual, which may limit reliability of the results. It is not clear if the study was sufficiently powered to detect a significant effect with intervention when compared with control.

Marcus et al. 1999 Commit to quit RCT 1+ **Aim:** To determine if regular, vigorous exercise, a healthful alternative to smoking, enhances the achievement and maintenance of smoking cessation and reduces weight gain among sedentary female smokers.	**Eligibility criteria:** Inclusion: Healthy sedentary women aged 18–65 years, regularly smoked ten or more cigarettes per day for at least 3 years, exercised less than twice per week for at least 6 months. Exclusion: Current or planned use of NRT, medical problems or use of medications that would make compliance difficult, current psychiatric illness, alcohol or substance abuse, were excluded. **Setting:** The Miriam Hospital, Providence, RI, USA. **Sample size:** Exercise: *n* = 134 Control: *n* = 147 **Age (years):** Exercise: 40.7 (SD 9.1) Control: 39.7 (SD 8.8)	**All:** 12-week group- (approximately 15 participants) based smoking cessation programme, quit at week 4, then 8-week treatment programme. **Exercise intervention:** Resting heart rate plus 60–85% heart rate reserve, started 3 weeks before quit date, three exericse sessions per week for 12 weeks, 5-min warm up, 30–40 min aerobic activity, 5-min cool-down with stretching, supervised by exercise specialist. Providers of the intervention included an exercise specialist and staff from the Miriam Hospital and Brown University School of Medicine in Providence, Rhode Island. **Control:** 12-week wellness programme started 3 weeks before quit date, three × 45–60 min supervised sessions per week, advised not to adopt exercise. **Follow-up:** 60 weeks post quit.	**Lost to follow-up:** At 12 months: Exercise 44% Control 49.7% (not significant). ITT analysis on all 281 participants (lost to follow-up assumed to have relapsed). **60-weeks continuous abstinence:** Exercise: 11.9% (*n* = 16) Control: 5.4% (*n* = 8) *p* = 0.05 **Weight:** Only in abstinent women –among quitters, exercise participants gained significantly less weight at 8 weeks but difference was not significant at 20 and at 60 weeks. **60 weeks weight:** Exercise: 8.92 (SD 8.9) kg, *n* = 15 Control: 5.76 (SD 12.6) kg, *n* = 6 **Diet:** Not reported. **Physical activity:** Not reported (only VO_{2max}). **Authors' conclusion:** Vigorous exercise as part of CBT for smoking cessation leads to improved rates of continuous abstinence in young to middle-aged	Significantly higher BMI and body weight in exercise group at baseline compared with control. Exercise participants exercised at 83% maximum heart rate. Self-reported abstinence verified by exposed air carbon monoxide readings A total sample size of 150 at 12-months was projected to provide a power of 80% (alpha=0.05) and to detect a 21% net difference in smoking rates between intervention and control.

	Education (years): Exercise: 13.8 (SD 2.1) Control: 13.8 (SD 2.1) **Smoking rate, cigarettes per day:** More than 20. Exercise: 22.9 (SD 9.7) Control: 21.8 (SD 9.0) **Smoking (years):** Exercise: 22.6 (SD 8.8) Control: 22.2 (SD 9.0) **Baseline BMI (kg/m^2):** Exercise: 26.1 (SD 5.2) Control: 24.8 (SD 4.7)		female smokers who averaged more than one pack of cigarettes per day for more than 20 years, maintained at 12 months, CBT to attenuate weight gain was only effective during treatment period (when participated in exercise).	
Danielsson et al. 1999 RCT 1++ **Aim:** To determine whether intermittent use of very-low-energy diet	**Eligibility criteria:** Inclusion: Female smokers aged 30–60 years who wanted to stop smoking and maintain their body weight, BMI 23–31 kg/m^2, smoke at least ten cigarettes per day for at least 3 years, have made at least one serious	**All:** Eleven sessions over 16 weeks including three group sessions with a dietitian and standardised written information, each session 45 min in groups of 10–15 women, follow-up at 21, 26,3 9 and 52 weeks. 2 mg nicotine gum (Nicorette) (could switch to 4 mg if consumed more than 20 pieces per day), free gum for 3 months then advised to	**Lost to follow-up:** At 12 months Intervention: *n* = 35 women Control: *n* = 51 women ITT analysis. **52 weeks complete and continuous abstinence:** Intervention: 28% (*n* = 38) Control: 16% (*n* = 24) *p* = 0.02	96 of 201 women at 12 month follow-up were still using NRT Significantly more women reported headaches in VLED compared with control. Self-reported abstinence verified by

(VLED) to improve weight control affected the success of a smoking cessation programme.	attempt to stop and restarted because of weight gain. Exclusions: Cardiovascular disease, participation in another clinical study in previous 6 months, clinical important renal or hepatic disease, pregnancy or lactation, lactose intolerance, alcohol or drug abuse, use of smokeless tobacco or NRT, gout, acute porphyria, insulin-dependent diabetes mellitus, vegetarian diet, any serious metabolic or malignant disease likely to interfere with compliance. **Setting:** Obesity Unit, University Hospital, Sweden. **Sample size:** Intervention *n* = 137 Control *n* = 150	taper consumption, on request gum supplied up to 12 months; standardised balanced diet of 6.7 MJ/day, behaviour modification sessions for stopping smoking and providing support for weight control. **Intervention:** Nutrilett 1.76 MJ/day (420 kcal total food replacement given free of charge for three × 2-week periods (weeks 1 and 2, 7 and 8, 13 and 14). Compliance with the VLED was based on self-reported adherence and verified through ketone body analysis in urine, sampled by the women at home. Women with missing samples were asked to provide a urine sample after the VLED period. **Follow-up:** 52 weeks	**Weight (abstainers):** 52 weeks weight loss: Intervention: 2.5 (95% CI 0.78–4.3) kg Control: 3.8 (95% CI 2.5–5.1) kg, *p* = 0.61 **Diet:** Not reported- not known reported if the subjects actually used the meal replacement product. **Physical activity:** Not reported. **Authors' conclusion:** Smoking can be stopped for up to 1 year with acceptable weight control in women selected for their previous weight control problems when attempting to quit. (Significant difference in quitting in favour of VLED but no differences in weight gain at 12 months.)	exposed air carbon monoxide readings. This study had power to detect an effect size of intervention of 80% compared with control, at a significance level of alpha 0.05.

	Age (years): Intervention: 46.9 (SD 7.0) Control: 46.8 (SD 6.9) **Mean number of cigarettes smoked per day:** Intervention: 20.0 (SD 6.3) Control: 19.1 (SD 6.2) **Smoking (years):** Intervention: 29.6 (SD 6.9) Control: 28.1 (SD 7.4) 210 of 287 women had used NRT before. **Baseline BMI (mean, kg/m^2):** Intervention: 26.7 (SD 2.2) Control: 26.9 (SD 2.3)			
Hall et al. 1992 RCT 1+ **Aim:** To evaluate an innovative weight gain prevention programme to reduce smoking	**Eligibility criteria:** Inclusion: Smoke at least ten cigarettes per day in past week or be at least 10% above ideal weight. Exclusions: Cardiovascular or pulmonary disease,	**All:** Smoking treatment programme of Seven × 90 min group sessions (five to eight participants) of aversive smoking and relapse prevention skill training in initial two weeks, assessed at weeks 2, 6, 12, 26 and 52; four female therapists (one master's level social worker and one doctoral level	**Lost to follow-up:** Not reported, participants with missing data were coded as smoking. **52 weeks abstinence:** Tailored intervention: 21% (*n* = 11) Non-tailored intervention: 22% (*n* = 11) Standard control: 35% (*n* = 19) Two active interventions had	Standard intervention smoked significantly more cigarettes per day pre-treatment, innovative intervention had significantly greater variance in cigarettes smoked and pre-treatment body weight.

relapse risk.	diabetes, hospitalisation for major mental illness in previous year, any chronic condition that would influence eating or activity levels. **Setting:** San Francisco. **Sample size:** Intervention, *n* = 53 Control, *n* = 51 Standard treatment control, *n* = 54 **Age (years):** Tailored intervention, 40.68 (SD 8.71) Control, 41.22 (SD 8.96) Standard treatment control, 39.24 (SD 8.92) **Female:** Tailored intervention: 77% Control: 67% Standard treatment control: 74% **Smoking rate, cigarettes per day:** Innovative	psychologist treated 88% of participants), two female dietitians and a male exercise consultant also participated. **Tailored intervention:** Weight-gain prevention sessions weeks 3–6, daily monitoring. Eat what liked unless gained 2 lb (0.91 kg) or more then encouraged to use low calorie low fat diet designed to lose 2 lb (0.91 kg) per week individualized exercise plan of aerobic exercise three or more times per week, behavioural self-management of eating. **Non-tailored intervention**: Weight gain prevention sessions weeks 3–6, no attempt to individualize diet or exercise or behavioural components **Control:** Standard (?) assessment at week 6 only, information pack on good nutrition and exercise at last smoking treatment session not targeted at smoking-cessation induced weight gain. **Follow-up:** 52 weeks. Providers of the intervention	greater risk of smoking compared with control. **Weight (non smokers):** 52 weeks weight: Tailored intervention: 0.86 (3.95) kg, *n* = 10 Non-tailored intervention: 3.35 (2.38) kg, *n* = 7 Standard control: 3.61 (3.99) kg, *n* = 14 **Diet:** Only reported on subgroup of 68 (75%) of the original sub-sample that completed dietary recalls at every assessment. These subjects did not differ from either the whole sample or the sample of 91 on whom the researchers attempted to collect data on cigarettes smoked or body weight. **Physical activity:** Only reported on subgroup. **Authors' conclusion:** Because there was no significant difference between abstinent and smoking subjects in the tailored intervention condition suggests that the condition prevented weight gain, particularly when this lack of difference is compared with the significant differences found between abstinent and smoking	Self-reported abstinence verified by exposed air carbon monoxide readings. It is not clear if the study was sufficiently powered to detect a significant effect of intervention when compared with control.

	intervention: 25.65 (SD 12.56) Control: 24.91 (SD 10.80) Standard treatment control: 31.59 (SD 11.74) **Baseline mean body weight (kg):** Innovative intervention: 72.68 (SD 17.72) kg Non-specific control: 69.23 (SD 12.38) kg Standard treatment control: 67.65 (SD 12.51) kg	included four female therapists, two female registered dietitians and a male exercise consultant.	subjects in the non-specific intervention. Differences in the control group also failed to reach significance, which meant interpretation of results was difficult. In the tailored intervention there was evidence of early compliance with dietary instruction, especially among women and abstinent subjects. Higher smoking rates in two active interventions is troubling, complicated interventions may have detracted from non-smoking	
Pirie et al. 1992 RCT 1++ **Aim:** To evaluate a weight control programme in addition to nicotine gum to enhance smoking cessation	**Eligibility criteria:** Inclusion: Women aged 20–64 years who wanted to quit smoking and maintain weight. whether adding behavioural weight control to cessation treatment suppresses weight gain but undermines abstinence and to determine whether outcomes differ depending on whether weight control intervention begins concurrently or after smoking cessation treatment.	pre-packaged meal plan and PA programme, be willing to accept random assignment. Exclusions: Current substance abusers, pregnant, lactating, current using of NRT, appetitive suppressants, beta-blockers, history of diabetes, hypoglycaemia, eating disorder, psychosis, surgery for obesity, currently dieting, strong biases against or prior experience with Nutri/System meal plan. **Setting:** Three centres: University of Illinois, Chicago; Finch University of Health Sciences-Chicago Medical School; and the Hines Veterans Affairs Medical Center.	traditional behavioural techniques taught including contract for quit date. **Early diet intervention:** Diet and exercise during first 8 weeks cessation treatment; 150 kcal (630 kJ) per day decrease, pre-packaged three meals per day plus two high-carbohydrate low-fat snacks per day to be consumed late afternoon/evening, received meals each week during 16 weeks, supplemented by fresh fruits and vegetables, final transition week with 4 days low-fat grocery store meals plus 3 days meal plans; encouraged to do 30 min moderate intensity activity at least 5 days per week, trained in self-monitoring heart rate and led on 30 min group walks at end of initial 8 weeks treatment. **Late diet intervention:** Received identical exercise at same time as early diet group and received identical diet during final 8 weeks cessation treatment. **Control:** Focused on smoking cessation and received weight loss counselling at week 16 **Follow-up:**	asked to attend follow-up). ITT analysis. **9-months post-treatment continuous abstinence** (measured from week 7 which was 2 weeks after quit date, missing data coded as smoking): Early diet: 21.4% Late diet: 19.5% Control: 18.2% No significant difference between early diet versus control and late diet vs. control on smoking cessation at 12 months. **Weight change** (continuous abstainers, measured change from week 7): 9 months post-quit weight change (mean): Early diet: 7.57 (SD 8.24) lb (3.43 [SD 3.74] kg) Late diet: 4.88 (SD 7.06) lb (2.21 [SD 3.20] kg) Control: 6.20 (SD 6.65) lb (2.81 [SD 3.02] kg No significant difference in weight gain between late diet and control at 9 months. **Diet:** Not reported.	least 1 occasion Statistical power was low for weight change outcome because 9-month data were available for only 37% of the sample. This study was not sufficiently powered to detect a significant effect of intervention compared with control.

	Sample size: Early diet: *n* = 104 Late diet: *n* = 104 Control: *n* = 107 66% White, 31% African American, 3% other; middle-aged, mildly depressed, moderately overweight, mildly weight concerned women who were moderately heavy smokers and mildly to moderately nicotine dependent. **Mean age (years):** Early diet: 41.45 (SD 9.80) Late diet: 43.20 (SD 9.81) Control: 43.39 (SD 11.28) **Smoking rate, cigarettes per day:** Early diet: 20.24 (SD 8.64) Late diet: 21.02 (SD 510.90) Control: 19.75 (SD 8.88) **Baseline BMI**	9 months post-quit.	**Physical activity:** Not reported. **Authors' conclusion:** For post-cessation weight control, the findings suggest superiority for a sequential approach that addresses smoking cessation before initiating weight control treatment.	

	(mean, kg/m^2): Early diet: 27.23 (SD 4.99) Late diet: 28.26 (SD 5.95) Control: 26.80 (SD 5.44)			
Jonsdottir & Jonsdottir, 2001 CBA 2++ **Aim:** To examine whether adding exercise to a multi-component smoking cessation programme will increase smoking cessation and suppress weight gain.	**Eligibility criteria:** Participants self-referred. **Setting:** One health centre and one health club in Reykjavik, Iceland **Sample size:** Intervention 1: *n* = 34 Intervention 2: *n* = 33 **Female:** Intervention 1: 61.8%, *n* = 21 Intervention 2: 36.4%, *n* = 12 **Mean age (years):** Intervention 1: 43.5 (SD 11.9) Intervention 2: 39.3 (SD 9.0) Participants had smoked 1 to 40 years. Not significant between groups	**Intervention 1 (usual intervention/control):** NRT (nicotine medication, gum and spray adjusted to individual needs), health education, behavioural modification and individual and group counselling all provided by one nurse (author of study). Group counselling for 1 month with five sessions and individual counselling for 1 year, contacted four times by telephone 3 weeks after last group session, 6 weeks, 3 months and 6 months later (12 months after first smoke-free day); second day after the first group session was defined as the quitting day**.** **Intervention 2:** Same as intervention 1 except the group counselling lasted for 2 months with seven meetings and the four telephone contacts started one month after last session with 3-month intervals until 12 months after first smoke-free day; in addition an exercise specialist supervised physical exercise	**Lost to follow-up:** Zero (NB: convenience sample) **12 months lapse-free abstinence (%):** Intervention 1: 20.6% (*n* = 7) Intervention 2: 39.4% (*n* = 13), *p* = 0.16 **Weight (abstainers):** 12 months post-quit weight gain (mean, kg): Intervention 1: 3.0 (SD 3.9) (*n* = 5) Intervention 2: 5.0 (SD 3.8) (*n* = 11), *p* = 0.37 **Diet:** Not reported. **Physical activity:** Not reported. **Author's conclusion:** A non-significant difference in abstinence at one year and weight gain was demonstrated between the two interventions, further studies with a larger sample size are needed.	Participants self-referred and paid for the intervention. Intervention 2 was more expensive as subjects paid more for their intervention and they had more often attempted to quit smoking, which may indicate that they were more motivated to quit than the participants in intervention 1/control. Self-reported abstinence verified by exposed air carbon monoxide readings. Weight measured at baseline and mainly self-reported at 1 year, 20 participants in intervention 1 and seven participants in

	on years smoked or smoked cigarettes per day. Baseline BMI not reported.	programme three times per week (increasing from 40 to 80 min) during 2 months of group counselling and the following 4 months participants continued without exercise specialist and at their own time schedule; aerobic training, 40% consisting of treadmills and stationary biking, weight lifting (40%) and stretching exercises (20%). Providers of the intervention were one nurse from the health care centre, plus staff from the University of Iceland. **Follow-up:** 265 days (8 months) post-quit.		intervention 2 were not willing to be weighed at follow-up. Difference in frequency and timing of contacts varied between groups. Intervention 2 participants had more often attempted to quit (may have therefore been more motivated) Convenience sample. Only 15.8% (*n* = 8) participants used nicotine medication by end of intervention, no statistical difference between smokers and abstainers regarding use of NRT. This study was not sufficiently powered to detect a significant effect of intervention compared with control.

Perkins 1997	Review	Weight concerned women who want to stop smoking (USA).	To assess rationales for three different treatment approaches.	Various.	Three approaches: more effective weight control; direct reduction in weight concerns by CBT; and smoking cessation only. Although weight concern is a serious obstacle to quitting smoking, particularly for women, it is not clear how best to address these concerns in the context of smoking cessation. The authors conclude that a more logical approach may be to assist weight-concerned smoker in attitudes to weight in relation to health risks of continuing smoking.
Ussher 2003 Smoking cessation	RCT	UK adults	To examine whether exercise counselling increases smoking abstinence and reduces tobacco withdrawal and gains in weight and body fat.	6 weeks	Male and female smokers (*n* = 299) were assigned randomly to a 7-week smoking cessation programme, including nicotine replacement therapy plus either: (1) exercise counselling; or (2) health education advice with equal contact time as for the exercise counselling condition. There was no significant difference in smoking abstinence between the exercise group (*n* = 154) and the controls (*n* = 145) at 6 weeks (39.6 vs. 38.6%), nor was there any difference in gains in weight or body fat, although those in the exercise group increased their exercise levels. Exercise participants reported less tension, anxiety and stress than the controls during the first week of smoking abstinence (p = 0.03, 0.01 and 0.04, respectively), less irritability throughout 2 weeks of abstinence (p = 0.03) and less

					restlessness throughout 3 weeks of abstinence (*p* = 0.04). Adding brief exercise counselling to a smoking cessation programme did not increase smoking abstinence or reduce gains in weight or body fat significantly, although exercise levels were raised and there were some beneficial effects on psychological symptoms.

A second search was then developed with CPHE to ensure that no potentially relevant references had been overlooked. This search was run in Medline only and did not produce any additional references to those identified in previous rapid reviews. Search terms included terms for Black and minority ethnic groups, vulnerable groups and vulnerable life-stages.

The Cochrane database was also double checked for relevant RCTs – as the agreed review parameters. Bibliographies of included studies were also searched, as were key reports and systematic reviews with these topic areas (Bush 1997, Ciliska 2004, Fox 2004, Hunter 2004, Thomas 2004, Summerbell 2005) and a database of references identified for the ongoing systematic review funded by the World Cancer Research Fund at Teesside.

Appendix 12

TREATMENT OF OVERWEIGHT AND OBESITY IN NON-CLINICAL SETTINGS

EVIDENCE SUMMARY TABLES

CONTENTS

EVIDENCE TABLE 1a: EVIDENCE OF EFFICACY (INTERNAL VALIDITY) FOR THE MANAGEMENT OF OVERWEIGHT AND OBESITY IN ADULTS

All summary data are mean values unless otherwise stated.
Studies are grouped by intervention.
Within each intervention category, studies are listed by study type in the following order: systematic review; randomised trial (RCT); controlled non-randomised trial (CCT), controlled before and after study (CBA), interrupted time series (ITS); other study type.
Within each study type, studies are listed in alphabetical order.

First author, country, study design, research type, quality	**Study population**	**Research aim/question**	**Intervention details, length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for the management of overweight and obesity in adults					
Commercial weight-loss programmes					
Ahrens 2003 [3037] USA RCT Individual 1–	**Setting:** A pharmacy in Iowa, USA. **Meal replacement (MR):** *n* = 45 BMI (kg/m^2): 29.5 (SD 2.2) Weight (kg): 81.9 (SD 11.1) Waist circumference (cm): 89.1 (SD 8.5) Age (years): 47.6 (SD 7.9) **Conventional reduced-energy diet (RED):** *n* = 43 BMI (kg/m^2): 29.0 (SD 2.6) Weight (kg): 78.3 (SD 10.1) Waist circumference (cm): 87.0 (SD 8.2)	To compare a meal replacement programme with a conventional RED for weight management using the pharmacy as the setting and the pharmacist as the point of contact for dietary advice.	**MR:** Participants received free liquid meal replacement shakes (Slim-Fast) and were instructed to use these to replace two main meals per day for the first 12 weeks, and one main meal a day for the following 10 weeks. They were also given dietary advice involving instruction on healthy eating, the prescription of a daily energy intake in the first 12 weeks and assistance in self-selecting the rest of their diet. Participants were given physical activity (PA) advice at their initial visit. They returned to the pharmacy every 2 weeks	**Loss to follow-up**: 12-week intervention: *n* = 27/95 (28%) Weight maintenance: *n* = 40/95 (42%) Not reported for individual groups. **Weight (kg):** Over the 12-week intervention period, weight decreased significantly ($p < 0.001$) in both MR (–4.9 [SE 0.3]) and RED (–4.3 [SE 0.3]) groups. There was no significant difference between the two groups. During the weight maintenance phase, from week 12 to week 22, there was a significant ($p = 0.02$) further loss in the RCD group (–0.9 [SE 0.4]). The change in the MR group (–0.7 [SE 0.4]) was not	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20%. No ITT. Funded by Slim-Fast Nutrition Institute.

	Age (years): 47.8 (SD 9.5) **Other relevant information:** Ninety-five participants (12.6% male) were randomised but data are only provided for participants who remained in the programme at week 2. Participants were required to be free of specific medical conditions and have a BMI of 25–32 kg/m^2.		for a 15 min review to discuss progress and to collect their shakes. **Delivered by:** A registered dietitian reviewed diet plans and was consulted as needed. Two pharmacists provided all other support. The pharmacists received no special training. **RED:** Participants were given dietary advice involving instruction on healthy eating, the prescription of a daily energy intake and assistance in self-selecting their diet using diabetic exchange lists. After 12 weeks they were instructed to return to a healthy diet of their choice. Participants were given the same PA advice and support as the intervention group. **Delivered by:** As intervention group. **Length of follow-up:** 12 and 22 weeks. **Other agencies involved:** None reported. **Other information related to**	statistically significant. There was no significant difference between the two groups. **Waist circumference (% change):** Significant reductions were reported in the intervention group at 12 weeks (–5.31%) and 22 weeks (–8.08%) and in the control group at 12 weeks (–6.10%) and 22 weeks (–7.82%). There was no significant difference between the groups.	

			delivery: None.		
Heshka 2003 [36] USA Individual RCT 1++	**Setting:** Home based. **Self-help:** *n* = 212 BMI (kg/m^2): 33.6 (SD 3.7) Weight (kg): 93.1 (SD 14.4) Waist (cm): 99 (SD 12) Age (years): 44.0 (SD 10) Gender: 13% male **Weight Watchers programme:** *n* = 211 BMI (kg/m^2): 33.8 (SD 3.4) Weight (kg):94.2 (SD 13.1) Waist (cm): 101 (SD 12) Age (years): 45 (SD 10) Gender: 18% male **Other relevant information:** Participants were recruited from clinic records or advertisement. Individuals with a BMI of 27–40, aged 18–65, including persons with health problems for which weight reduction is a medically accepted therapy, were eligible. Potential participants were excluded if already involved	To compare weight loss and health benefits achieved and maintained through self-help weight loss vs. weight loss with a structured commercial programme.	**Self-help:** Participants received a 20 min consultation with a dietitian at baseline and week 12 visits. Participants were given publicly available printed material encouraging dietary principles and exercise guidelines for safe weight loss. Other information resources were brought to their attention (e.g. websites). Two-year intervention. **Delivered by:** Dietitian. **Weight Watchers:** Participants were given vouchers for free attendance at sessions of Weight Watchers. The locations of this programme were reviewed with participants. The programme consists of a food plan, an activity plan, and a behaviour modification plan. There were weekly 1-hour group meetings led by successful programme graduates. They conduct the weekly weigh-in, act as role models, and provide written educational materials and social support.	**Loss to follow-up (at 2 years):** Self-help: *n* = 53 (25%) Weight Watchers: *n* = 61 (28.9%) **BMI (kg/m^2):** Self-help: –0.5 (SD 0.2), Year 1 –0.2 (SD 0.2), Year 2 (from baseline) Weight Watchers: –1.6 (SD 0.2), Year 1 –1.1 (SD 0.2), Year 2 (from baseline) A greater reduction in BMI from baseline was shown in the commercial programme than the self-help programme at year 1 ($p < 0.001$), and at year 2 ($p < 0.001$). The Weight Watchers group demonstrated significant mean change from baseline to follow-up at year 1 ($p < 0.001$), and at year 2 ($p < 0.001$). The self-help group demonstrated significant mean change from baseline to year 1 follow-up ($p < 0.01$), but not at year 2. **Weight (kg)** Self-help: –1.3 (SD 0.4), Year 1 –0.2 (SD 0.4), Year 2 (from baseline)	Randomisation well covered. Adequate allocation concealment. No mention of blinding. Loss to follow-up >20%. ITT analysis performed. Missing values were imputed by last-observation-carried-forward or linear interpolation and participants who made no follow-up visits were assumed to remain at baseline value. Results from ITT, modified ITT and completers only were similar. In the self-help group, 20 participants reported using weight loss medication (including herbal products); ten reported enrolling in some form of structured weight loss programme (including Weight Watchers);

	in a weight loss programme or if they had taken prescription weight loss medications in the previous 90 days.		2-year intervention. **Delivered by:** Weight Watchers programme graduates. **Length of follow-up:** 2 years. **Other agencies involved:** None reported. **Other information related to delivery:** None.	Weight Watchers: –4.3 (SD 0.4), Year 1 –2.9 (SD 0.5), Year 2 (from baseline) Weight loss of participants from baseline in the Weight Watchers programme was significantly greater than that in the self-help programme at year 1 (*p* < 0.001) and at year 2 (*p* < 0.001). The Weight Watchers group demonstrated a significant change from baseline (*p* < 0.001) at year 1 and at year 2. The self-help group demonstrated a significant change from baseline at year 1 (*p* < 0.01), but not at year 2. There was no significant difference between Weight Watchers and self-help groups in the percentage of participants who had lost between 5 and 10% of their original weight at year 1 (17 vs. 11%) or year 2 (18 vs. 15%). Significantly more Weight Watchers participants than self-help participants had lost more than 10% of their original weight at year 1 (21 vs. 9%; *p* = 0.002) and year 2 (16 vs. 6%; *p* = 0.005). **Waist circumference (cm):** Self-help: –1.6 (SD 0.6), Year 1 –0.6 (SD 0.6), Year 2	and nine reported following an alternative diet plan (e.g. Atkins, The Zone) at some point during the 2-year study. Funded by Weight Watchers International.

				Weight Watchers: –4.1 (SD 0.6), Year 1 –2.4 (SD 0.6), Year 2 A greater reduction in waist circumference from baseline was found in the Weight Watchers programme compared with the self-help programme at year 1 ($p = 0.003$) and at year 2 ($p = 0.02$). The Weight Watchers programme demonstrated a significant change from baseline at year 1 ($p < 0.01$) and at year 2 ($p < 0.04$). The self-help programme demonstrated a significant change from baseline at year 1 ($p < 0.02$) but not at year 2. **Other outcomes:** Participants who dropped out of the study were younger, had higher BMI, greater percentage body fat, were more likely to be smokers and reported lower income than completers ($p < 0.05$ for all comparisons). Dropout characteristics did not differ by treatment group. There was no statistically significant difference between men and women in weight loss. There were no statistically significant differences between the groups in the amount of improvement on quality of life	

				scales (Short-Form 36 Health Survey, Impact of Weight on Quality of Life Questionnaire)	
Rippe 1998 [12522] USA RCT Individual 1–	**Setting**: Weight Watchers, Jericho, New York, USA **Intervention:** *n* = 40 Baseline data reported for completers only (*n* = 30) Weight (kg): 81.2 (SD 7.6) % Body fat: 36.8 (SD 2.6) Height (cm): 161.6 (SD 6.7) Age (years): 37.4 (SD 7.9) Gender: 0% male **Control:** *n* = 40 Baseline data reported for completers only (*n* = 14): Weight (kg): 82.1 (SD 5.3) % Body fat: 36.2 (SD 2.7) Height (cm): 167.6 (SD 5.4) Age (years): 35.6 (SD 5.9) Gender: 0% male **Other relevant information:** Women aged 20–49 years who were 20–50% over desirable weight for height (Metropolitan Life Insurance Table 1983) were eligible provided they had not participated in a weight loss/exercise programme in	**Aim:** To assess the effects of a 12-week weight loss strategy in moderately overweight women.	**Intervention:** Subjects were enrolled in a 12-week nationally available weight loss programme (Weight Watchers International). **Nutrition:** Self-selected, hypoenergetic diet with an energy range of 33,258 to 41,462 kJ. **Exercise:** Self-selected exercise plan expending ≥6279 kJ/week by fourth week. **Behaviour:** Education regarding behaviour modification techniques, as well as problem solving and coping skills for weight loss challenges. **Group support:** Weekly meetings. **Delivered by:** Facilitated by a trained lay leader who has lost weight on the programme. **Control**: Subjects were asked to maintain their baseline	**Loss to follow-up:** Intervention: *n* = 10 (25%) Control: *n* = 26 (65%) **Weight (kg):** The intervention group lost significantly more weight than the control group (–6.07 [SD 4.01] and +1.31 [SD 1.28] respectively; $p < 0.001$). **% Body fat:** The intervention group lost significantly more body fat than the controls (–4.3%, and –0.2% respectively; $p < 0.001$). **Other outcomes:** Quality of Life was assessed using SF-36 Health Survey. Intervention group participants achieved significant improvements ($p < 0.006$) in their perception of their physical function, vitality and mental health after the 12-week period. Changes in control group participants were not statistically significant.	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20%. No ITT. Controls were taller and more physically active at baseline ($p < 0.05$). Funding from Weight Watchers International.

	the previous 3 months.		nutritional and PA practices for 12 weeks. **Delivered by:** N/a **Length of follow-up:** 12 weeks. **Other agencies involved:** None reported. **Other information related to delivery:** Unclear whether enrolment to the Weight Watchers programme was free.		
Rothacker 2000 [3952] USA CBA 2–	**Setting**: Intervention: Two rural neighbouring villages, Wisconsin. Control: Residency within a 50-mile (80-km) radius of the study centre. **Intervention:** *n* = 158 Although 158 participants were recruited to the weight loss programme, data for 134 participants (50 men and 84 women) were presented at baseline. **BMI (kg/m^2):** Men 32.5 (SD 4.4)	**Aim**: To assess 5-year weight changes after a self-managed meal-replacement weight loss programme.	**Intervention**: A self-managed meal replacement weight control programme. Participants were instructed to follow the label instructions of a 200–220 kcal (840–920 kJ), fortified, milk-based meal replacement diet (shake). This product replaced two meals each day for the first 3 months, and then 1–2 meals each day thereafter until their ideal weight was achieved. For maintenance participants replaced one meal each day with a shake or monitored their	**Loss to follow-up:** Intervention: *n* = 24 (16%) Control: *n* = ? (unclear) **BMI (kg/m^2):** Intervention: A significant decrease in BMI was found for both males (–1.8, SD 1.8) and females (–1.6, SD 2.6). Control: BMI increased significantly for both males (2.2, SD 3.5) and females (2.5, SD 4.1) The authors do not present *p* values. **Weight (kg):** Intervention:	The authors did not state process for selecting controls. The authors investigated change within groups. They did not assess whether there was a between group difference in the extent of change. Funded by Slim-Fast Nutrition Institute

	Women 30.7 (SD 5.6) **Weight (kg):** Men 102.9 (SD 15.3) Women 81.2 (14.7) **Age (years):** Men 40.3 (SD 10.3) Women 41.4 (SD 10.6) **Gender:** 37.3% Male **Control:** From an unclear number of initial participants, data were provided for *n* = 389 (142 men and 247 women) **BMI (kg/m^2):** Men 31.7 (SD 4.9) Women 30.2 (SD 5.6) **Weight (kg):** Men 96.3 (SD 15.2) Women 80.6 (SD 15.8) **Age (years):** Men 40.3 (SD 10.0) Women 42.0 (SD 10.5) **Gender:** 37% Male		weight daily. If participants gained more than 1–2 kg, they were instructed to return to regular use of the meal replacement product. No medical intervention was provided. Participants were asked to weigh-in each week at the local village centre during the first 3 months, and then twice per year. Meal replacement products were provided free of charge from the local grocers. **Delivered by:** Unclear. **Control:** Control weight data were obtained from three medical clinics within 50 miles (80 km) of the study centre. Self-report weight data was used for baseline for 28% of the participants. Controls were weighed at follow-up. Three controls were selected for each participant and were matched for gender, BMI (within 2 kg/m^2), and age (within 5 years).	A significant decrease in weight was found in both male (–5.8, SD 5.4; $p < 0.001$) and female (–4.2, SD 6.9; $p < 0.001$) participants. Control: A significant increase in weight was shown for both male (6.7, SD 10.2; $p < 0.001$)) and female (6.5, SD 10.7; $p < 0.001$) subjects.	

			Length of follow-up: 5 years **Other agencies involved:** None stated. **Other information related to delivery:** **None.**		
Interventions using computers					
Agras 1990 [11342] USA RCT Individual 1+	**Setting:** Hand-held computer-assisted therapy, California. **Computer alone:** *n* = 30 Weight (kg): 76.9 **Computer plus support:** *n* = 30 Weight (kg): 78.7 **Behaviour therapy:** *n* = 30 Weight (kg): 78.5 **Other relevant information:** Ninety mild to moderately overweight women (BMI 25–35 kg/m^2) were admitted to the study. Age (years): 45.2 (SD 12.4) BMI (kg/m^2): 29.7 (SD 4.3)	To compare the efficacy of hand-held computer therapy alone, computer therapy with support, and therapist-conducted weight loss programmes.	12-week weight loss programme. All three groups aimed to reduce energy intake (not >1200 kcal [5.02 MJ]) so that weight loss occurred and participants exercised 20–45 min, at least three times per week. **Computer alone:** At a 90-min introductory group session participants were given a hand-held computer to use for the duration of the programme. Participants received an oral presentation, and an operational manual, describing the computer and weight loss programme, in addition to a book of energy values. Participants were requested to set daily energy intake and exercise goals and enter these on the computer. Energy intake	**Loss to follow-up (12 months):** Computer alone: *n* = 1 (3.3%) Computer plus support: *n* = 1 (3.3%) Behaviour therapy: *n* = 0 (0%) **Weight (kg):** Computer alone: Post-treatment: 74.6 6 months: 75.5 12 months: 76.6 Computer plus support: Post-treatment: 76.1 6 months: 76.6 12 months: 76.8 Behaviour therapy: Post-treatment: 76.7 6 months: 75.8 12 months: 77.5 Weight loss, from pre- to post-treatment, for all participants combined was 2.19 kg ($p < 0.001$). The authors report that no significant differences	Randomisation well covered. No mention of allocation concealment or blinding. Loss to follow-up <20%. Unclear if ITT used. Supported by National Institute of Arthritis, Diabetes, and Digestive Kidney Diseases.

	% Overweight: 125.3 (SD 21.1) Marital status: 15% single, 64% married, 21% divorced/separated. Of the participants in the two computer-based groups, 69% had experience with computers at work, 46% had access to a home computer and 33% used a home computer on a weekly basis. Individuals meeting DSM-IV criteria for bulimia, major depression, alcohol or drug dependence, or psychosis were excluded.		information was added to the computer throughout the course of the day. Meals could be planned on the computer; other options included a trainer to promote slow eating, and messages aimed at motivating or reminding the participant of distorted cognitions related to eating. Reinforcing statements depending on individual progress were also provided Longer-term feedback on energy intake, exercise and weight (based on a 14-day period) could be examined, from which participants were encouraged to set new goals and change behaviour. **Delivered by:** Unclear. **Computer plus support:** In addition to the programme described above, participants attended four group sessions in weeks 2, 4, 6 and 8. Sessions were therapist led. Brief education on weight loss, including diet and exercise, discussed by the group. Any problems regarding the use of the computer were also discussed at these sessions.	between groups were shown at any point from post-treatment to 1-year follow-up (data not presented). **Eating behaviour:** (Assessed using Eating Patterns Questionnaire) Significant changes were seen in eating patterns at both 12 weeks and 12 months, but there were no between-group differences. **Cost-effectiveness** (kg lost/US$100): Computer alone: Post-treatment: 4.12 6 months: 3.02 12 months: 0.52 Computer plus support: Post-treatment: 1.57 6 months: 1.29 12 months: 1.1 Behaviour therapy: Post-treatment: 0.68 6 months: 1.11 12 months: 0.43 A significant post-treatment difference between groups was shown ($p < 0.01$), with the computer alone group demonstrating greater cost-effectiveness than either computer with support ($p < 0.05$) or behaviour therapy (BT) ($p < 0.05$) groups.	

			Delivered by: Therapist. **Behaviour therapy:** Ten sessions over a 12-week period. A treatment manual from the Stanford Eating Disorders Clinic was followed. The programme included education on the problem and treatment of overweight, principles of behaviour change, and enhancement of self-control. Participants were requested to monitor their food intake and the circumstances surrounding that intake as well as activity levels during treatment. **Delivered by:** Psychologist. **Length of follow-up:** 1 year. **Other agencies involved:** None reported. **Other information related to delivery:** Participants were asked to deposit US$75 at the start; US$25 was returned at each of three post-treatment assessments.	**Programme adherence:** (During last week of treatment) Computer alone: 29% Computer plus support: 70% BT: 29% The authors report that this difference was not significant (data not presented). **Other outcomes:** All three groups were equally confident in the treatment group to which they had been assigned, felt that treatment made sense and would recommend their treatment to friend. There was a significant decrease from baseline in the Beck Depression Inventory score in all three groups at both 12 weeks and 12 months, with no between group differences. There were decreases in the number of participants engaging in binge eating and increases in participant satisfaction with weight in all three groups at 12 months, with no between group differences.	

Jones 2002 [3986] USA RCT Individual 1–	**Setting:** University classroom or home, Mesa, AZ, USA**.** **Classroom:** *n* = 24 BMI (kg/m^2): 28.8 (SD 4.3) Weight (lb): 172.9 (SD 28.4) (78.4 [SD 12.9] kg) Waist-to-hip ratio: 0.77 (SD 0.06) **Computer:** *n* = 25 BMI (kg/m^2): 29.4 (SD 5.6) Weight (lb): 171.9 (SD 32.3) (78.0 [SD 14.6] kg Waist-to-hip ratio: 0.77 (SD 0.08) **Textbook:** *n* = 25 BMI (kg/m^2): 29.8 (SD 4.4) Weight (lb): 173.0 (SD 28.9) (78.5 [SD 13.1] kg) Waist/hip ratio: 0.76 (SD 0.05) **Other relevant information:** All participants were female, with an average age of 42 years (range 22–	To compare the effectiveness of three methods for delivering a weight loss education programme for women.	Three active interventions, all based on the textbook, The LEARN Program for Weight Control by Kelly Brownell (1994). All groups had identical weekly written assignments on which feedback was provided. **Classroom:** 1-hour weekly classes consisting of lectures, group activities, discussion, and assessment, for an unstated number of weeks. **Delivered by:** Not stated. **Computer:** Participants collected a new program disk containing a single lesson each week for an unstated number of weeks. Lessons contained knowledge, tests and feedback on results. Participants were encouraged to communicate with the instructor by phone or email with any questions or problems. **Delivered by:** Not stated. **Textbook:** Participants collected a new reading assignment each week	**Loss to follow-up**: *n* = 19 (26%). Not reported for each group separately. **BMI (kg/m^2):** (At 12-week follow-up) Classroom: 28.2 (SD 4.2) Computer: 28.7 (SD 5.5) Textbook: 29.2 (SD 4.8) All groups: Baseline 29.4 (SD 4.8), 6 weeks 28.6 (SD 4.5), 12 weeks 28.7 (SD 4.8) There was a statistically significant reduction in BMI from baseline to follow-up across all groups ($p < 0.001$). There was no statistically significant difference between groups in the extent of change. **Weight (lb):** At 12 week follow-up: Classroom: 170.5 (SD 28.7) (77.3 [SD 13.0] kg) Computer: 166.6 (SD 30.4) (75.6 [SD 13.8 kg) Textbook: 169.1 (SD 31.1) (76.7 [SD 14.1 kg) All groups: Baseline 172.6 (SD 29.5) (78.3 [SD 13.4] kg) 6 weeks 168.0 (SD 26.8) (76.2 [SD 12.2] kg) 12 weeks 168.9 (SD 29.5) (76.7 [SD 13.4] kg)	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20%. Although there were statistically significant decreases in weight outcomes, the actual changes were small. There were two follow-up points but the authors do not report when the significant change occurred.

	76). Fifty-eight participants were university staff members, five were students, two were faculty members and eight were recruited from the surrounding area. 82% were White. Participants were required to be at least 10 lb (4.5 kg) over ideal weight based on Metropolitan Life tables, be able to attend a class once per week, and have computer access.		for an unstated number of weeks. They were encouraged to communicate with the instructor by phone or email with any questions or problems. **Delivered by:** Not stated. **Length of follow-up:** 12 weeks. **Other agencies involved:** None reported. **Other information related to delivery:** Participants paid US$25 deposit, which was returned along with an additional US$25 upon completion of the course.	There was a statistically significant reduction in weight from baseline to follow-up across all groups (*p* < 0.01). There was no statistically significant difference between groups in the extent of change. **Waist-to-hip ratio:** At 12 week follow-up: Classroom: 0.75 (SD 0.05) Computer: 0.72 (SD 0.05) Textbook: 0.76 (SD 0.08) All groups: Baseline 0.77 (SD 0.06) 6 weeks 0.75 (SD 0.06) 12 weeks 0.75 (SD 0.07) There was a statistically significant reduction in BMI from baseline to follow-up across all groups (*p* < 0.05). There was no statistically significant difference between groups in the extent of change. **Other:** There were no significant differences between groups on weekly attendance.

1+	Weight (kg): 89.4 (SD 12.6) Waist circumference (cm): 111 (SD 11.7) Age (years): 47.3 (SD 9.5) Gender: 11% male Ethnicity: 89% White Education: 48% college degree or higher Web/email experience (months): 80 (SD 58) Weekly Internet use (hours): 3.8 (SD 4.9) **Internet + behavioural e-counselling:** *n* = 46 BMI (kg/m^2): 32.5 (SD 3.8) Weight (kg): 86.2 (SD 14.3) Waist circumference (cm): 108 (SD 12.4) Age (years): 49.8 (SD 9.3) Gender: 9% male Ethnicity: 89% White Education: 52% college degree or higher Web/email experience (months): 87 (SD 71) Weekly Internet use (hours): 5.1 (SD 5.5) **Other relevant information:** Participants were required to have computer access and to have one or more other risk factors for type 2	email provided for 1 year to individuals at risk of type 2 diabetes.	encouraged to self-monitor these daily. They were also given access to a secure study website and a demonstration of its use. The website provided a tutorial on weight loss, a new tip and link each week, a directory of weight loss resources and a message board. Participants were required to submit their weight weekly for which they received email reminders. The total duration of the intervention was 12 months. **Delivered by:** Unclear who gave introductory meeting. **+ Behavioural e-counselling:** Participants attended the same introductory meeting with the Internet-only group and were given access to the same website but a different message board. They were also able to communicate via email with a counsellor. During the first month, the counsellor emailed participants five times per week, providing feedback, recommendations for change, answers to questions and general support. For the remaining 11 months emails were sent weekly. The total	counselling group (–1.6 [SD 2.2]) and the Internet only group (–0.8 [SD 2.1]). **Weight (kg):** There was a significant difference ($p = 0.04$) at 12 months between change in the behavioural e-counselling group (–4.4 [SD 6.2]) and the Internet only group (–2.0 [SD 5.7]). There was also a significant difference ($p = 0.03$) in the percentage of initial body weight lost by the behavioural e-counselling group (4.8%) and the Internet-only group (2.2%) at 12 months. **Waist circumference (cm):** There was a significant difference ($p = 0.05$) at 12 months between change in the behavioural e-counselling group (–7.2 [SD 7.5]) and the Internet-only group (–4.4 [SD 5.7]). **Log-in frequency:** There were significantly ($p < 0.05$) more log-ins to the website by the behavioural e-counselling group than the Internet-only group at all timepoints.	Weight outcomes were analysed using ITT. For those with missing data, change from baseline was assumed to be zero. Funded by American Diabetes Association.

	diabetes as well as being overweight (BMI 27–40 kg/m^2). Individuals with major health problems or recent weight loss ≥4.5 kg were excluded.		duration of the intervention was 12 months. **Delivered by:** Unclear who gave introductory meeting. Counsellors had masters or doctoral degrees in education, nutrition or psychology. **Length of follow-up:** 12 months. **Other agencies involved:** None reported. **Other information related to delivery:** Participants were seen at baseline, 3, 6 and 12 months for measurements, and were paid US$10–25 for attendance.		
Tate 2001 [3942] USA RCT Individual 1+	**Setting:** Participants were employees of a large network of hospitals. The study website was accessible on the organisation's Intranet. **Internet behaviour therapy:** *n* = 46 BMI (kg/m^2): 29.1 (SD 3.0) Weight (kg): 77.4 (SD 9.4) Waist circumference (cm):	To determine whether a structured Internet behavioural weight loss programme produces greater initial weight loss and changes in waist circumference than a weight loss education	**Internet behaviour therapy:** Participants were treated as the comparison group (described below) but they were also instructed to use an electronic diary on the website to record weekly self-monitoring information and to contact a therapist if required. They also received weekly behavioural weight loss lessons and personalised feedback via email, and they had access to a group electronic bulletin board.	**Loss to follow-up**: Behaviour therapy: *n* = 13 (28%) for weight and waist circumference, *n* = 14 (30%) for diet and activity. Education: *n* = 13 (29%) for weight and waist circumference, *n* = 15 (33%) for diet. *n* = 17 (38%) for activity. **Weight (kg):** There was a significant change over time ($p < 0.001$) in both groups. The	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20%. ITT for weight and waist circumference outcomes (using baseline data carried forward) but not for diet and activity

	98.5 (SD 9.4) Age (years): 41.1 (SD 11.6) Gender: 11% male Ethnicity: 89% White Education: 63% college degree or higher Web or email experience (months): 60.9 (SD 47.4) **Internet education:** *n* = 45 BMI (kg/m^2): 28.9 (SD 3.1) Weight (kg): 78.8 (SD 11.6) Waist circumference (cm): 98.4 (SD 10.2) Age (years): 40.6 (SD 9.7) Gender: 11% male Ethnicity: 78% White Education: 55% college degree or higher Web or email experience (months): 60.8 (SD 43.7) **Other relevant information:** Participants were recruited via email and a worksite webpage advertisement. Participants were required to be healthy with a BMI of 25–36 kg/m^2 and to agree not to seek additional weight loss treatment for 1 year.	website.	Participants who did not send a log in were contacted by email. **Delivered by:** A doctoral-level clinical psychologist gave introductory and follow-up meetings. A doctoral-level therapist provided individualised emailed feedback. **Internet education:** Participants were given access to a website providing basic information related to weight loss and a directory of resources about diet, exercise, self-monitoring, and behavioural topics for 24 weeks. They received an introductory 1-hour group lesson on behavioural weight control where they were advised on energy and fat intake and PA and were encouraged to use the self-monitoring web resources. They attended 15 min individual meetings with a clinical psychologist at 3 and 6 months. **Delivered by:** A doctoral-level clinical psychologist gave introductory and follow-up meetings.	weight change from baseline in the BT group was –3.2 (SD 2.9) at 3 months and –2.9 (SD 4.4) at 6 months. In the education group the change from baseline was –1.0 (SD 2.4) at 3 months and –1.3 (SD 3.0) at 6 months. Weight loss was significantly greater in the BT group than the education group at both 3 months ($p < 0.001$) and 6 months ($p = 0.04$). The goal of 5% weight loss was achieved by significantly ($p = 0.07$) more participants in the BT group (35%) than in the education group (18%). **Waist circumference (cm):** There was a significant change over time in both groups ($p = 0.004$). The waist change from baseline in the BT group was –5.3 (SD 4.9) at 3 months and –4.6 (SD 5.5) at 6 months. In the education group the change from baseline was –2.1 (SD 3.9) at 3 months and –2.3 (SD 3.9) at 6 months. The decrease in waist circumference was significantly greater in the BT group than the education group at both 3 months ($p = 0.001$) and 6 months ($p = 0.02$). **Website log-in frequency:** Participants in the BT group logged-on more often than those in the education group. Log-in frequency decreased in	outcomes. Diet and PA were self-reported. Funding was provided by a research division of Knoll Pharmaceutical.

			Length of follow-up: 6 months. **Other agencies involved:** None reported. **Other information related to delivery:** All participants received instruction on login procedures and website navigation. Participants were paid US$10 and US$25 for attending the 3- and 6-month follow-up appointments respectively.	both groups over time.	
Taylor 1991 [11346] USA RCT Individual 1–	**Setting:** Hand-held computer-based. **Computer-assisted therapy (CAT):** *n* = 28 Weight (kg): 78.8 Gender: 0% male **Frozen Foods First (FFF) + CAT:** *n* = 27 Weight (kg): 74.5 Gender: 0% male **Other relevant information:** Female participants with BMI between 25 and 35 were recruited via newspaper advertisements.	To investigate factors that might produce greater weight loss using CAT.	**CAT:** For a 12-week period participants were given a hand-held computer onto which they were encouraged to enter details of their diet on a daily basis, as well as exercise after every episode and their weight each week. They were encouraged to enter targets for weight loss and energy intake. The computer provided feedback on progress and a 12-week exercise programme. Participants who were not attaining their weight loss goals were encouraged to use a guided weight loss programme. This programme prescribed frozen meals to provide 1200 kcal (5.02 MJ) per day.	**Loss to follow-up:** At 12 weeks: CAT: *n* = 4 (14%) FFF + CAT: *n* = 1 (4%) At 38 weeks: CAT: *n* = 7 (25%) FFF + CAT: *n* = 2 (7%) **Weight (kg):** At 12 weeks there was a significant difference ($p < 0.001$) between weight change in the CAT group (–3.1 [SD 2.2]) and the FFF + CAT group (–5.3 [SD 2.2]). At 38 weeks the weight loss from baseline was still significantly different ($p < 0.0001$) between the two groups; CAT group –0.9 (SD 3.6), FFF + CAT group –3.8 (SD 2.7). **Adherence:**	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20% in one arm. No intention to treat (ITT) analysis. Analysis of those participants lost to follow-up found them to be significantly heavier and less confident of success than subjects remaining in the study.

	The mean age of all participants was 43.7 (SD 1.1) years.		Participants also attended four 1.5-hour group meetings to introduce them to the computer and then to discuss problems with the programme. **Delivered by:** Not stated. **FFF + CAT:** For a 12-week period participants were given a hand-held computer but were instructed to follow the guided weight loss programme (described above) and only use the computer to record weight and exercise. After they had lost 8–10 lb (3.6–4.5 kg) or after the fifth week of the programme, they proceeded as the CAT group. **Delivered by:** Not stated. **Length of follow-up:** 38 weeks. **Other agencies involved:** None reported. **Other information related to delivery:** All participants were required to give a deposit of US$100,	At week 12, the average number of computer entries per week was not significantly different between the two groups, 3.2 in the FFF + CAT group and 3.6 in the CAT group. This was about 50% of the recommended entries. **Other outcomes:** Participants had positive attitudes about computer-use, which did not change over the course of treatment. The FFF + CAT group found the computer less interesting than the CAT group at the end of the programme. Assuming that dropouts lost no weight, the mean weight loss for participants with BMI (kg/m^2) <31 (*n* = 43) was 4.3 kg compared with 2.7 kg for those with BMI >31 (*n* = 14). The difference between the groups was significant ($p < 0.05$).	Baseline weight was taken into consideration in the analysis of weight outcomes.

			which was returned after completion of follow-up assessments.		
Womble 2004 [57] USA RCT Individual 1+	**Setting:** Recruited by University of Pennsylvania. Setting was wherever participants accessed the Internet. **eDiets:** *n* = 23 BMI (kg/m^2): 33.9 (SD 3.2) Weight (kg): 93.4 (SD 12.6) Age (years): 44.2 (SD 9.3) Gender: 0% male **Weight loss manual:** *n* = 24 BMI (kg/m^2): 33.0 (SD 3.0) Weight (kg): 87.9 (SD 10.8) Age (years): 43.3 (SD 11.1) Gender: 0% male **Other relevant information:** Participants were required to have daily access to the Internet. Participants had to be free of specific physical conditions (reported in paper).	To assess the efficacy of eDiets.com (a commercial weight loss programme) in improving weight, cardiovascular health, and quality of life.	**eDiets:** Participants were given free 1-year membership of eDiets.com. They were encouraged to log-on to the programme daily, and met with a psychologist at weeks 8, 16, 26 and 52 for 20 min to review progress. There were also brief assessment visits every 4 weeks to obtain weight and blood pressure. The eDiets.com programme includes a virtual visit with a dietitian, individualised diet prescription and grocery lists, an animated fitness instructor and PA recommendations tailored to participants' self-reported fitness, access to online meetings and bulletin board support groups, a 24-hour helpdesk, email reminders and bi-weekly newsletters. **Delivered by:** Baseline and follow-up meetings were with a psychologist (one of the researchers). Research assistants conducted the assessment visits.	**Loss to follow-up**: eDiets: *n* = 8 (35%) Weight loss manual: *n* = 8 (33%) (One lost participant in the weight loss manual group developed diabetes and was excluded from all analyses.) **Weight (kg):** At week 16, the eDiets group had lost 0.7 (SD 2.7) and the weight loss manual group 3.0 (SD 3.1) and at week 52 the losses were 0.8 (SD 3.6) and 4.0 (5.1) respectively. There was a significant (p = 0.02) weight loss over time for both groups, and the weight loss manual group showed greater weight loss than the eDiets group at both week 16 (p = 0.01) and week 52 (p = 0.04). **Eating-related behaviour:** (Assessed by Eating Inventory; included treatment completers only) There were no statistically significant differences between the groups in self-reported eating restraint, disinhibition and hunger. **Attendance:** Attendance at scheduled visits did not differ significantly between groups. **Other outcomes:** Mood was assessed using the Beck	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20%. Analysis of weight outcomes was performed using last observation carried forward. Analysis using baseline carried forward or completers only gave similar results but differences between groups did not reach statistical significance. Analysis of eating-related behaviour and other outcomes included treatment completers only. Funded by North American Association for the Study of Obesity and National Intitutes of Health.

			Weight loss manual: Participants were given a copy of the weight loss manual 'LEARN Program for Weight Management 2000' and after 16 weeks were given a maintenance guide. They received the same schedule of progress meetings with the psychologist and assessment visits as the intervention group. **Delivered by:** Same as the intervention group. **Length of follow-up:** 1 year (outcomes reported at weeks 16 and 52). **Other agencies involved:** None reported **Other information related to delivery:** Participants were paid US$50 for completing the 52-week assessment.	Depression Inventory-II. At week 52 treatment completers reported significantly ($p < 0.004$) fewer symptoms of depression than at baseline. There were differences between the groups. Quality of Life was evaluated using the Short Form-36 Health Survey. At week 52 treatment completers reported significant improvements in physical functioning ($p < 0.05$) and vitality ($p < 0.003$) compared with baseline. There were no differences between the groups.	
Dennison 1996 [11287] USA CBA 2–	**Setting:** Two sites of a large car-manufacturing firm, New York. **Intervention:** Ninety-three participants enrolled, but data are for completers only.	To determine whether a computer-assisted instruction nutrition program would assist employees in maintaining	**Computer instruction program:** Eight weekly classes of 'Weigh To Go' computer-based program, consisting of nutrition information and computerised food intake and activity analysis, delivered in a worksite computer laboratory.	**Loss to follow-up**: Weight outcome: Intervention (both groups): $n = 71$ (76%) Control: $n = 32$ (80%) Diet outcomes: Intervention (both groups): $n = 76$ (82%) Control: $n = 33$ (83%)	Data reported for completers only.

	Computer instruction program: *n* = 11 Weight (lb): 238.8 (108.3 kg) **Non-computer instruction programme:** *n* = 11 Weight (lb): 203.6 (92.4 kg) **Control:** Forty participants enrolled from the second factory site, but data are for completers only (*n* = 8). Weight (lb): 233.5 (105.9 kg) **Other relevant information:** The 30 completers (all groups combined) had the following characteristics: Mean age (years): 47 Gender: 90% male Ethnicity: 90% White They were described as being mainly blue collar workers. Participants were required to be between 20–35% above their desirable	weight loss and dietary intake improvements for a 1-year period.	Additionally, activities such as power walking and cycling were conducted (no details provided). **Non-computer instruction programme:** Eight weekly classes with the same content as the computer instruction intervention but participants had no computer interaction. Additionally, activities such as power walking and cycling were conducted (no details provided). **Delivered by:** The intervention team consisted of a certified health educator, a registered dietitian and an exercise technician. **Control:** No intervention. **Delivered by:** N/a **Length of follow-up:** 1 year **Other agencies involved:** None reported. **Other information related to delivery:**	**Weight (lb):** Change at follow-up: Computer instruction program: –20.2 (–9.2 kg) Non-computer instruction programme:–2.7 (–1.2 kg) Control: +2.0 (+0.9 kg) There was no statistically significant difference between the three groups, nor between intervention groups combined and control.	

	weight using standard weight tables.		The Activated Health Education model was used as the basis of the intervention.		
Interventions in a work-based setting					
Dennis 1999 [4011] USA RCT Individual 1–	**Setting:** Onboard a US Navy aircraft carrier, the participants' place of work for a 6-month period. **Intervention:** Twenty-seven were randomised to the group, but data are for completers only (*n* = 21). BMI (kg/m^2): 33.9 (SD 2.7) Weight (kg): 108.1 (SD 10.2) Waist circumference (cm): 111.5 (SD 4.8) Age (years): 31.9 (SD 7.1) Gender: 100% male Previous weight loss attempts (*n*): 5.4 (SD 6.0) **Control:** Twenty were randomised to the group but data are for completers only (*n* = 18). BMI (kg/m^2): 33.0 (SD 2.9) Weight (kg): 106.7 (SD 12.0) Waist circumference (cm): 111.3 (SD 6.8) Age (years): 30.4 (SD 5.7)	To determine whether a multi-faceted approach to weight loss and physical readiness could be implemented onboard a deployed US Navy ship.	**Intervention:** Participants attended weekly 1-hour lecture and discussion sessions in small groups (7–12 individuals) for 16 weeks. They were given food exchange lists from which to make dietary choices falling within NCEP Step I (Heart Healthy) guidelines and they were taught behaviour modification techniques. They also took part in the standard Navy exercise programme consisting of 1 hour of exercise 4 days per week. **Delivered by:** Weekly sessions were conducted by a Navy dietitian. **Control:** Participants were provided with nutrition fact sheets and brochures if requested, but no other assistance for weight management. They also took part in the same standard Navy exercise programme as the intervention group. **Delivered by:**	**Loss to follow-up**: Intervention: *n* = 6/27 (22%) Control: *n* = 2/20 (10%) **BMI (kg/m^2):** Intervention: 31.3 (SD 3.3) Control: 31.2 (SD 3.0) There was a significant ($p < 0.001$) reduction in BMI in both groups over time and the reduction was significantly greater ($p < 0.05$) in the intervention group than control. **Weight (kg):** Intervention: 99.6 (SD 9.7) Control: 101.1 (SD 12.5) There was a significant ($p < 0.001$) reduction in weight in both groups over time and the reduction was significantly greater ($p < 0.05$) in the intervention group than control. **Waist circumference (cm):** Intervention: 100.1 (SD 5.6) Control: 102.7 (SD 7.8) There was a significant ($p < 0.001$) reduction in waist circumference in both groups over time, but no statistically	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20% in one arm. No ITT. The authors state that the publication of articles about the treatment programme in onboard newspapers may have contaminated the control group and led to competition between the two groups.

	Gender: 100% male Previous weight loss attempts (*n*): 2.1 (SD 2.4) **Other relevant information:** All service members stationed on the ship who were classified as not meeting body composition standards (*n* = 47) were invited to take part in the study. All consented and were randomised. However data are only presented for those who completed the study (*n* = 39).		N/a **Length of follow-up:** 16 weeks **Other agencies involved:** None reported. **Other information related to delivery:** **None.**	significant difference between the groups. **Other outcomes:** There were no significant differences between the groups in self-esteem (The Cooper Self-Esteem Inventory) and mood (Profile of Mood State). There was an improvement in depression (Center of Epidemiologic Studies Depression Scale) for the treated group versus the controls. There were significant differences between the groups at baseline on the eating behaviour measures (Binge Eating Scale, Eating Behaviour Inventory and Eating Self-Efficacy Scale) with the intervention group scoring more poorly. The intervention group improved on these measures so that following the intervention they were similar to the control group.	
Follick 1984 [11709] USA RCT Individual 1–	**Setting:** The participants' worksite, a general hospital. **Incentive:** *n* = 24 % Overweight: 31.6 **Control:** *n* = 24 % Overweight: 28.9% **Other relevant**	To examine the effects of an incentive procedure designed to decrease attrition in a behavioural worksite weight-loss intervention.	**Incentive:** Participants attended 14 30-min group behavioural weight-loss sessions. The first ten sessions were held weekly and focussed on losing weight, and the final four sessions were held fortnightly and focussed on the maintenance of weight loss. Before the programme started participants were required to give a US$5 deposit for each session. One US$5 deposit was	**Loss to follow-up:** Non-completers were defined as those attending fewer than 11 sessions and/or not completing all required assignments: Incentive: *n* = 10 (42%) Control: *n* = 19 (79%) **% Overweight:** (completers only) Repeated measures analysis of variance (ANOVA) showed that both groups lost weight over the course of	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20%. No ITT. Outcome data was only reported for participants defined as completers.

	information: All participants (*n* = 48): Age (years): range 20 to 69 Gender: 15% male % Overweight: range 10–113		returned at each session provided the subject attended (three 'excused absences' were allowed provided all other requirements were fulfilled), submitted completed daily food and energy intake records, and weighed in. At the end of the programme forfeited deposit money was divided between participants who attended at least 11 sessions and met all other requirements. **Delivered by:** Two psychologists led the sessions. **Control:** Participants followed the same behavioural weight-loss programme as the incentive group, and were required to give the same pre-programme deposits. The deposits were returned to the participants at the first session. **Delivered by:** Two psychologists led the sessions. **Length of follow-up:** 6 months. **Other agencies involved:**	the intervention but there was no significant difference between the groups. The incentive group were 23.60 (SD 12.00)% overweight at baseline, 17.57 (SD 12.97)% overweight after the 18 week programme and 22.30 (SD 16.91)% overweight at 6 month follow-up. The control group were 27.64 (SD 13.12)% overweight at baseline, 22.70 (SD 10.32)% overweight after the 18 week programme and 28.20 (SD 14.96)% overweight at 6 month follow-up. **Attendance:** There was a significant difference ($p < 0.01$) in the number of sessions attended by the incentive group (9.42 [SD 4.04]) and the control group (6.04 [SD 2.68]).	

			None reported. **Other information related to delivery:** **None.**		
Leslie 2002 [3977] UK RCT Individual 1–	**Setting:** Large petrochemical worksite (BP Grangemouth), Scotland. **Energy-deficient diet (ED):** *n* = 61 BMI (kg/m^2): 31.5 (SD 3.7) Weight (kg): 98.2 (SD 13.9) Waist (cm): 108.4 (SD 9.3) Age (years): 41.3 (SD 8.1) Gender: 100% male **Generalised low-energy diet (GLE):** *n* = 61 BMI (kg/m^2): 30.4 (SD 3.7) Weight (kg): 94.6 (SD 13.3) Waist (cm): 105.9 (SD 9.3) Age (years): 42.1 (SD 7.8) Gender: 100% male **Control:** Forty-four of the above 122 participants were randomised to an initial control period prior to receiving dietary advice. The baseline characteristics of this subgroup, and non-	To compare the effectiveness of a 600 kcal (2.51 MJ) daily deficit diet and a generalised low calorie (1500 kcal [6.28 MJ]) diet for weight loss, and to compare the inclusion and exclusion of meat in the weight loss diets.	Randomisation was to four different groups, the two diets each with or without meat. However, data are only presented separately for the two diet groups. **ED (meat):** Participants received individualised daily energy prescriptions of 600 kcal (2.51 MJ) less than their estimated daily energy requirement to maintain their initial weight (prescriptions ranged from 1700 to 2600 kcal [7.11 to 10.89 MJ]). They were given eating plans to match their prescriptions based on a food exchange system. They were advised to consume lean cuts of red meat at least five times per week. The initial dietetic consultation took a minimum of 60 min. Participants received individual 15–20 min consultations every 2 weeks for the first 12 weeks. After this, participants' individualised energy prescriptions were recalculated	**Loss to follow-up:** At 12 weeks: ED: *n* = 12 (20%) GLC: *n* = 19 (31%) At 24 weeks: ED: *n* = 16 (26%) GLC: *n* = 21 (34%) **Weight (kg):** An analysis of participants in the control group for the first 12 weeks (*n* = 44) vs. ED (*n* = 40) vs. GLE (*n* = 38) found that there were statistically significant ($p < 0.0001$) weight changes with ED (–4.6 [SD 3.4]) and with GLE (–5.6 [SD 3.7]) but not in the control group (+0.5 [SD 2.2]). There was no significant difference between weight loss in ED and GLE groups, but both diet groups were significantly different ($p < 0.0001$) from the control group. Analysis (including control participants within their allocated diet groups) of completers only found significant increases in weight between weeks 12 and 24 (to levels significantly lower than baseline) in both ED (+0.9 [SD 2.0]) and GLE (+1.4 [SD 1.6]) groups. There was no significant difference between the	No description of randomisation method. Allocation concealment adequately addressed. No mention of blinding. Loss to follow-up >20%. ITT reported for 12-week analysis but not at 24 weeks. Zero weight loss was assumed where only the baseline measure was available. Baseline data and loss to follow-up are not reported for the control vs. intervention groups comparison. Funded by the Meat and Livestock Commission.

	control subgroups, are not provided. **Other relevant information:** Participants were recruited via workplace email. Participants were required to have a BMI >25 kg/m^2. Exclusion criteria included intentional weight loss >3 kg in the previous 3 months.		for weight maintenance and contact was via email every 2 weeks for 12 weeks. **ED (no meat):** Participants received the same intervention as ED (meat) but red meat was not included in their food plans; alternatives included fish, eggs and cheese. **Delivered by:** Not stated. **GLE (meat):** Participants received a 1500 kcal (6.28 MJ) eating plan based on a food exchange system. They were advised to consume lean cuts of red meat at least five times per week. Participants received individual 15–20 min consultations every 2 weeks for the first 12 weeks. Then healthy eating advice was reviewed for weight maintenance and contact was via email every 2 weeks for a further 12 weeks. **GLE (no meat):** Participants received the same intervention as GLE (meat) but red meat was not included in their food plans; alternatives included fish, eggs and cheese.	groups. Inclusion/exclusion of meat had no significant effect on weight loss.	

			Delivered by: Not stated. **Control:** Before receiving dietary advice and starting their assigned diet programme, participants underwent a 12-week control period. No further details were provided. **Delivered by:** Not stated. **Length of follow-up:** 24 weeks. **Other agencies involved:** None reported. **Other information related to delivery:** During the maintenance period, face-to-face consultations were discouraged.		
Muto 2001 [3967] Japan RCT Individual 1–	**Setting**: Building maintenance company, Japan. Health promotion programme. **Intervention:** *n* = 163 total participants, *n* = 70 overweight BMI (kg/m^2): 27.2 (SD 1.5)	**Aim:** To assess the long-term effectiveness of a multi-component worksite health promotion programme targeting cardiovascular	**Intervention:** The main programme was conducted over 4 days at a hot springs resort. Participants were given lectures, practical sessions, individual counselling, and group discussions on nutrition, PA, stress and cardiovascular disease risk factors. The main focus was on	**Loss to follow-up:** (whole group) Intervention: *n* = 11 (6.7%) Control: *n* = 13 (7.9%) The authors do not report loss to follow-up for the overweight sub-group. **BMI (kg/m^2):** Mean change at 6 months follow-up	Randomisation poorly addressed. No mention of allocation concealment or blinding. Loss to follow-up <20% for whole group, unclear for subgroup of interest.

	Weight (kg): 77.2 (SD 6.8) **Control:** *n* = 163 total participants, *n* = 60 overweight BMI (kg/m^2): 27.4 (2.0) Weight (kg): 79.3 (SD 7.9) **Other relevant information:** The authors state that approximately 80% of participants in each group were blue collar workers and 20% were white collar workers. Male employees were recruited from a national company, across its seven branches. Participants were required to have at least one abnormality in BMI (≥25 kg/m^2), blood pressure, cholesterol or blood glucose. All participants were recruited from those who had attended one of six health promotion seminars conducted twice per year over a 3-year period.	disease risk factors.	nutrition and PA. At the end of the programme participants were required to define goals on diet, PA, and other health goals. Self-evaluation of these goals at 3-month intervals for 1 year after the programme was required. Comments on this evaluation were provided by the participants' supervisor and spouse/family member. **Delivered by:** Physician, dietitian, exercise trainer and the programme co-ordinators, who were outside the occupational health service. **Control:** Received an annual health examination in compliance with Industrial Safety and Health Law. If cardiovascular risk factors were identified they were written to by physician or nurse and advised to make changes in their lifestyle. **Length of follow-up:** 18 months. **Other agencies involved:** None reported. **Other information related to delivery:**	Intervention: –0.8 (SD 0.9) Control: –0.1 (SD 0.6) Mean change (from baseline) at 18 months follow-up Intervention: –0.6 (SD 1.1) Control: 0.1 (SD 0.7) The intervention group demonstrated significantly greater BMI reduction compared with the control group at 6 months ($p < 0.001$), and at 18 months ($p < 0.001$). **Weight (kg):** Mean change at 6 months follow-up: Intervention: –2.5 (SD 2.7) Control: –0.1 (SD 1.8) Mean change at 18 months follow-up: Intervention: –1.9 (SD 3.3) Control: +0.2 (SD 2.1) The intervention group demonstrated significantly greater weight loss compared with the control group at 6 months ($p < 0.001$), and at 18 months ($p < 0.001$).	No ITT analysis.

			None.		
Peterson 1985 [11331] USA RCT Individual 1-	**Setting:** Blue-collar company, Texas Instruments Inc, MA, USA. **Professionally led:** *n* = 30 Weight (kg): 82.9 **Volunteer led:** *n* = 33 Weight (kg): 81.6 **Other relevant information:** Participants were at least 10% over their ideal body weight (IBW). **Baseline data for all participants grouped together (*n* = 63):** Age (years): 46.2 (range 22 to 65) Gender: 24% male % Overweight (according to Metropolitan Life Insurance (1959): 36.6%	**Aim:** To determine the effectiveness of a professionally led, and a volunteer-led, self-help worksite weight loss programme.	**Professionally led:** The weight loss programme ‘Learn to be Lean‘ was used. The programme consisted of 12 1-hour group meetings held weekly for the first 8 weeks and then bi-weekly for the next 8 weeks (focussing on maintenance). Workbooks were provided to all participants. Each session consisted of one learning module. Topics included: energy balance, group support skills, self-control skills, choosing a lean cuisine, eating and inactivity triggers, getting other to help, losing weight through aerobic exercise, etc. Maintenance strategies dealt with relapse and lifestyle transition. The programme built on problem solving skills and the use of social support systems at work (buddy system) and at home. **Delivered by:** Pawtucket Heart Health Programme health professionals: one physiologist, and one nutritionist. These health professionals were trained and supervised by two clinical psychologists.	**Loss to follow-up:** Professional-led: Post-intervention (16 weeks) *n* = 12 (40%); 8-month follow-up *n* = 23 (77%) Volunteer-led: Post-intervention (16 weeks): *n* = 7 (21%); 8-month follow-up *n* = 16 (48%). **Weight (kg):** Professional-led: 77.1, post-intervention; 72.1, 8-month follow-up. Volunteer-led: 75.3, post-intervention; 74.0, 8-month follow-up. **Mean Weight Reduction Quotient (WRQ):** (Takes into account baseline weight and ideal weight) Professional-led: Post-intervention 46.6, 8-month follow-up 69.7 Volunteer-led: Post-intervention 20.2, 8-month follow-up 40.6 The authors report that participants in both conditions lost weight over time ($p < 0.01$) but there was no difference between the groups. **Cost-effectiveness:**	Randomisation adequately addressed. No mention of allocation concealment or blinding. Loss to follow-up > 20%. ITT analysis used baseline data for lost participants. Analysis with completers only gave the same results as ITT.

			Volunteer-led: The same protocol and treatment manual as in the professionally led condition was followed. Elected volunteers facilitated the meetings. Volunteer leaders were selected on a 'double endorsement system'. **Delivered by:** Temporarily (meetings 1 and 2) led by health professionals. After which, elected volunteers facilitated the programme. **Length of follow-up:** 8 months. **Other agencies involved:** None reported. **Other information related to delivery:** Volunteer training consisted of a 1 hour weekly session for 5 weeks.	(Based on cost per kg-lost index) Professional-led: Post-intervention US$7.88, 8-month follow-up US$12.55 Volunteer-led: Post-intervention US$4.38, 8-month follow-up US$5.56 (No further details provided.)	
Pritchard 1997 [3959] Pritchard 2002 [3958] Australia RCT	**Setting:** Worksite of a national business corporation. **Diet:** *n* = 22 randomised, data only reported for completers (*n* = 18)	To compare the effects of weight loss through diet with weight loss through exercise on changes in fat and lean tissue in a long-term	**Diet:** Participants were instructed to follow a personalised low-fat diet, and were provided with the Australian Heart Foundation booklet, 'The Weight Loss Guide'.	**Loss to follow-up:** Diet: *n* = 4/22 (18.2%) Exercise: *n* = 1/22 (4.5%) Control: *n* = 1/20 (5.0%) **BMI (kg/m^2):** Percentage change in BMI was significantly different ($p < 0.05$) in both	Some inconsistency between tables in the two papers. Randomisation poorly addressed. No mention of allocation concealment or

Individual 1+ Note: both papers report randomised data on the same participants. All the extracted data was taken from Pritchard 1997, and some additional information was from Pritchard 2002.	BMI (kg/m^2): 29.0 (SD 2.8) Weight (kg): 88.1 (SD 10.5) Age (years): 43.6 (SD 6.0) Gender: 100% male **Exercise:** n = 22 randomised, data only reported for completers (n = 21). Data were only provided for completers (n = 58).	worksite programme.	**Delivered by:** Not stated. **Exercise:** Participants were instructed to avoid changing their diet, but to follow an aerobic exercise regimen in their leisure time; at least three 30-min sessions per week. They were prescribed a personal heart rate target (65–75% maximum heart rate) but could select the type of exercise (walking, cycling, swimming, jogging, gym). **Delivered by:** Not stated. **Control:** Participants were instructed to follow their usual pattern of activity and to avoid changes in diet. They were told they would move on to a weight-loss programme on completion of 12 months. **Delivered by:** Not stated. **Length of follow-up:** 12 months **Other agencies involved:** None reported.	diet (–8.2% [SD 0.9%]) and exercise (–4.4% [SD 0.7%]) groups compared with control (+1.0% [SD 0.7%]). **Weight (kg):** Percentage change in weight was significantly different ($p < 0.05$) in both diet (–7.2 [SD 0.9]) and exercise (–3.0 [SD 0.8]) groups compared with control (+1.03 [SD 0.6]). **Total fat mass (kg):** Percentage change from baseline was significantly different ($p < 0.05$) in the diet (–19.4 [SD 2.3] from 19.6 [SD 4.3]) and exercise (–11.0 [SD 2.6] from 18.8 [SD 5.0]) groups compared with control (–0.4% [SD 1.6] from 19.2 [SD 3.5]). **Total lean mass (kg):** Percentage change from baseline was significantly different ($p < 0.05$) in the diet (–3.9% [SD 0.5] from 66.7 [SD 6.7]) and exercise (–1.0% [SD 0.5] from 66.3 [SD 7.8]) groups compared with control (+0.2 [SD 0.4] from 64.9 [SD 7.7]).	blinding. Loss to follow-up <20%. No ITT analysis.

			Other information related to delivery: All participants were invited to attend bimonthly motivational group breakfast or lunch meetings at which diet, exercise and health information was delivered by guest speakers or video films. All participants completed 24-hour food recall records at monthly sessions and provided 3-day food diaries at 6 and 12 months. The diet and control group completed activity logs at monthly sessions and the exercise group completed daily activity records.		
Furuki 1999 [8838] Japan CBA 2–	**Setting**: Automobile parts manufacturer, Kyoto Prefecture and other worksite settings. **Intervention:** Whole group *n* = 507, overweight subgroup *n* = 60 BMI (kg/m^2): men 26.3 (SD 1.4), women 26.3 (SD 1.0) Gender: 90% male. **Control:** Whole group *n* = 507; overweight subgroup *n* = 81	**Aim:** To evaluate the effect of a work-based health promotion programme on BMI.	**Intervention:** Four-year (June 1992 – June 1996) THP programme, sponsored by Japan's ministry of Labour. Workers were screened and individuals identified as 'at risk' based on elevated BMI (≥25 kg/m^2), blood pressure, cholesterol or oxygen uptake received health guidance (no further details provided). **Delivered by:** Unclear. **Control:**	**Loss to follow-up:** Not reported. **BMI (kg/m^2):** Change at follow-up: Men Intervention: +0.25 (SD 1.24) Control: +0.02 (SD 1.34), $p < 0.01$ Women Intervention: –1.28 (SD 1.87) Control: +0.45 (SD 1.60) No statistically significant significance between intervention and control group was shown.	Control group selected from those who completed all annual health checks. Unclear how comparable control and intervention groups were at baseline other than BMI.

	BMI (kg/m^2): men 26.8 (SD 1.9); women, 26.2 (SD 1.2) Gender: 79% male Workers in an automobile parts company were offered the 'Total Health Promotion Plan' (THP). In total, 507 employees, aged between 26 and 55 years old entered the programme. Control subjects were matched by gender and age. Control subjects were selected from 20,000 employees in companies across the same region not employing the THP health programme. A subgroup of overweight participants (BMI ≥25 kg/m^2) was identified at the start of the study in both groups. Although the paper provides results for all participants, it is this overweight subgroup that forms the basis of the results presented here. Individuals undergoing medical treatment were excluded from the study.		Participants attended health checks over the study period. **Length of follow up:** 4 years. **Other agencies involved:** None reported. **Other information related to delivery:** None.		

Other non-clinical settings					
Jason 1991 [11310] USA RCT Individual 1–	**Setting**: Television-based programme. All pre-programme and follow-up interviews and/or measurements completed at DePaul University, Chicago, IL, USA. **Support group:** *n* = 38 Scale weight (lb): 208.03 (SD 55.91) (94.7 [SD 25.4] kg) Gender: 14% Male, 76% Female Ethnicity: 86.5% White, 13.5% Black. Socio-economic status (SES)*: 43.00 (SD 10.99) **Non support group:** *n* = 36 Scale Weight (lb) = 199.92 (SD 44.51) Gender: 19% male, 81% female Ethnicity: 83.8% White, 10.8% Black, 2.7% Hispanic, 2.7% other. SES*: 47.91 (SD 9.81) *Using the Hollingshead Scale.	**Aim:** To evaluate the effect of a media-based weight-loss and nutrition programme with, and without, group support.	**Support group:** Weight-loss and nutrition television programme, self-help book and self-help group. Each participant was assigned a 'buddy' (research assistant), to help find appropriate self-help groups. Participants also received telephone support; once a week during the programme. This decreased in frequency after the first few months. **Delivered by:** News-reader, research assistant and support groups. **Non-support group:** Weight loss and nutrition television programme, and self-help booklet. **Programme:** A well-known news-reporter provided step-by-step instructions on how to lose weight and improve nutrition during fifteen 2–4 min broadcasts. Broadcasts were aired Monday–Friday, during the mid-day and evening (9 pm) news programme, for 3 weeks	**Loss to follow-up:** (3-month follow-up) Support group: *n* = 8 (21%). Non-support group: *n* = 8 (22%) **Weight (self reported weight, lb):** Support group: Baseline 204.95 (SD 52.84) (93.0 [SD 24.0] kg) Follow-up 192.96 (SD 54.05) (87.5 [SD 24.5] kg) Non-support group: Baseline 199.00 (SD 42.91) (90.3 [SD 19.5] kg) Follow-up 189.80 (SD 40.05) (86.1 [SD 18.2] kg) A decrease from baseline was found for the non-support group on self-reported measures of weight ($p < 0.05$). **Other outcomes:** 83.8% of the support group attended a self-help group during the intervention compared with none of the comparison group. 97.3% of support group members and 88.9% of non-support group members said they would recommend the programme to others (not statistically significant).	No description of randomisation method. No mention of allocation concealment. Loss to follow-up >20%. No ITT. Measures of weight, nutrition and exercise were based on self-reported data at 3 months. The non-support group had a slightly higher protein intake at baseline than the support group ($p < 0.05$).

	Other relevant information: Study participants were recruited from the respondents to two television announcements, aired on Channel 9, asking for volunteers. Individuals selected to participate in the study met the following inclusion criteria: overweight (at least 50% over IBW); no history of intestinal problems; not currently taking psychoactive drugs.		in November 1986. Manuals were provided to all study participants before the start of the programme. All study participants were encouraged to watch the programme. **Length of follow-up:** 3 months. **Other agencies involved:** None reported. **Other information related to delivery:** **None.**	Based on the Master Questionnaire, from baseline to follow-up, the amount of hopelessness experienced by the support group decreased ($p < 0.05$) and their motivation increased ($p < 0.05$). Stimulus control increased in both groups ($p < 0.05$). It is not reported whether there were statistically significant differences between the groups.	
Kennedy 2005 [259 update] USA RCT 1–	**Setting:** African American church in Baton Rouge, LA, USA. **Group intervention:** $n = 20$ BMI (kg/m^2): 37.5 (SD 6) Weight (kg): 103.7 (SD 17.5) Body fat (%): 47.4 (SD 8.1) Fat free mass (kg): 54 (SD 9.3) Age (years): 44 (SD 10) **Individual intervention:** $n = 20$ BMI (kg/m^2): 39.3 (SD 7.8) Weight (kg): 103.4 (SD 24)	To evaluate a church-based weight loss programme.	**Group intervention:** Nutrition education was delivered during six, monthly group meetings, which involved group discussion. The importance of increasing PA was emphasised. **Individual intervention:** Nutrition education was delivered during 15 one-to-one sessions over 6 months. The first six sessions covered the same topics as the group intervention. There were then additional sessions on diet activity and self-monitoring and assessment. Participants were	**Loss to follow-up**: Group intervention: $n = 4$, 10% Individual intervention: $n = 0$, 0% **BMI, mean change (kg/m^2)** Group intervention: –1.0 (SD 1) Individual intervention: –1.3 (SD 1.3) **Weight (kg)** Group intervention: –3.1 (SD 3.5) Individual intervention: –3.4 (3.5) **Body fat (%) (assessed using dual-emission X-ray absorptiometry [DEXA])** Group intervention: –0.4 (SD 1.1) Individual intervention: –0.5 (SD 1.6)	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up <20%. No ITT analysis. Baseline data provided only on participants who completed the study.

	Body fat (%): 48.8 (SD 6.6) Fat free mass: 52 (SD 9.5) Age (years): 44 (10) **Other relevant information:** There were three male participants across both groups. Participants were recruited using posters, flyers and personal communication from church leaders and members. African American individuals >19 years, who were overweight or obese but otherwise healthy, were eligible.		encouraged to keep a 7-day food diary each month and there was basic dietary assessment using a computer programme. The importance of increasing PA was emphasised. **Delivered by:** Two church members with some background in nutrition and/or health education. They received two days training and were provided with education material. **Length of follow-up:** 24 weeks. **Other agencies involved:** Training was provided by the investigators at a biomedical research centre. **Other information related to delivery:** Each educator worked with ten participants from each intervention group. Participants were paid US$100 for taking part in the study.	**Fat free mass (kg)** Group intervention: –1.2 (SD 1.3) Individual intervention: –1.4 (SD 1.8) There were no statistically significant differences between the two groups in change from baseline to follow-up. There was a statistically significant weight loss (kg), body fat (kg) and fat free mass (kg) from baseline to follow-up in both groups ($p < 0.05$).	
McNabb 1997 [3972] USA	**Setting:** Three urban African American churches **Intervention:**	To test the effectiveness of PATHWAYS, a weight loss programme	**Intervention:** Weekly 1.5-hour facilitator-led group sessions for 14 weeks held in each of the churches. The programme involved	**Loss to follow-up**: Intervention: $n = 4$ (21%) Control: $n = 2$ (10%) (For waist circumference, diet, exercise and behaviour outcomes loss to follow	No description of randomisation method. RCT Individual 1+	$n = 19$ BMI (completers only) (kg/m^2): $n = 15$, 33.9 (SD 5.07) Weight (lb, completers only $n = 15$): 199.0 (90.3 kg) Waist circumference (inches, completers only $n = 12$): 38.2 (SD 3.62) (92.0 [SD 9.2] cm) Age (years): 56.5 (SD 14.5) 0% male 42% unemployed 11% education less than high school **Control:** $n = 20$ BMI (kg/m^2) (completers only, $n = 18$): 33.1 (SD 3.70) Weight (lb, completers only $n = 18$): 196.9 (89.3 kg) Waist circumference (inches, completers only $n = 16$): 37.7 (SD 3.75) (95.9 [SD 9.5] cm) Age (years): 56.6 (SD 13.0) 0% male 50% unemployed 15% education less than high school **Other relevant information:** Participants were required	designed specifically for urban African American women, administered in urban churches by trained lay facilitators	assisting participants in eating and behaviour change goal-setting, discussion of progress, problem-solving techniques and instruction in at-home exercise such as walking. **Control:** On waiting list to receive intervention. **Delivered by:** Site co-ordinator and two lay facilitators for each church. The lay facilitators had some health education experience. They had 9 hours of training and ongoing training and feedback from the researchers who attended each session. **Length of follow-up:** 15 weeks. **Other agencies involved:** None reported. **Other information related to delivery:** None reported.	up was: intervention $n = 7$ [37%]; control $n = 4$ [20%]) **BMI (kg/m^2):** Intervention: 32.5 (SD 5.41) Control: 33.7 (SD 4.07) There was a significant reduction ($p < 0.0001$) in BMI (kg/m^2) with the intervention (–1.4 [SD 1.61]) compared with control (+0.6 [SD 0.73]). **Weight (lb):** Intervention: 189.0 (SD 27.69) (85.7 [SD 12.56] kg) Control: 198.8 (SD 27.32) (90.2 [SD 12.39] kg) There was a significant ($p < 0.0001$) reduction in weight with the intervention (–10.0 [SD 10.28]) (–4.5 [SD 4.66] kg) compared with control (+1.9 [SD 4.25]) (+0.86 [SD 1.93] kg). There was no statistically significant difference between the weight loss of high attendees (attended <75% sessions) and low attendees. **Waist circumference (inches):** At follow-up: Intervention: 35.7 (SD 4.46) (90.7 [SD 11.3] cm) Control: 37.3 (SD 3.68) (94.7 [SD 9.3] cm) Waist circumference decreased significantly ($p < 0.02$) with the	allocation. Loss to follow-up >20% in one arm. ITT analysis for weight outcomes only. Eating and exercise behaviours were self-reported.

	to be African American female church members with BMI between 30 and 45 kg/m^2.			intervention (–2.5 [SD 2.39] inches [–6.3 {SD 6.1} cm]) compared with control (–0.4 [SD 1.84] inches [–1.0 {SD 4.7} cm]). **Behaviour and attitude:** (Assessed using the PATHWAYS Weight Loss Behaviour Index) There was a significant ($p < 0.001$) increase in positive eating behaviours and significant ($p < 0.002$) decrease in negative eating behaviours in intervention compared with control. **Attendance:** 75% of participants attended nine or more sessions.	
Perri 1997 [3961] USA RCT Individual 1+	**Setting:** A clinic (for group intervention) or participants' homes, Florida. **Group-based exercise:** *n* = 25 BMI (kg/m^2): 34.04 (SD 4.54) Weight (kg): 89.81 (SD 11.71) Age (years): 48.72 (SD 6.18) **Home-based exercise:** Twenty-four participants were randomised, but baseline data provided for *n* = 23	To compare group- vs. home-based exercise for the treatment of obese women undergoing behavioural weight loss therapy.	**Group-based exercise:** Participants attended weekly 2-hour group BT sessions (12–14 members per group) for 26 weeks, involving behavioural weight management techniques. They were also instructed to follow a 1200 kcal (5.02 MJ)/day diet. For the next 26 weeks they attended biweekly sessions focussing on the maintenance of changes in behaviours. Participants were given individual exercise prescriptions (target level 60–70% maximum heart rate) with a target of exercising 30 min per day 5	**Loss to follow-up:** Group: *n* = 7/25 (28%) Home: *n* = 2/24 (8%) One of the participants lost from the home group was excluded from all analyses. **Weight (kg):** There were significant ($p < 0.0001$) changes over time in both groups. Change from baseline to 6 months was –9.35 (SD 5.24) with group-based exercise and –10.40 (SD 6.29) with home-based exercise. At 15 months the weight change from baseline with home-based exercise (–11.65 [SD 8.99]) was significantly greater than with group-based exercise (–7.01 [SD 8.23]). This analysis took pre-	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20% in one arm. Weight and activity analyses included all participants except one from the home-based exercise group. Missing data were imputed using last observation carried forward or self-reported data

	BMI (kg/m^2): 33.10 (SD 2.85) Weight (kg): 87.14 (SD 10.91) Age (years): 48.91 (SD 4.97) **Other relevant information:** Participants were required to be female, aged between 40 and 60 years, have BMI between 27 and 45 kg/m^2, and were not engaged in a regular routine of aerobic exercise.		days per week. They were instructed to complete three group exercise (walking) sessions per week for the first 26 weeks and two sessions per week for weeks 27–52. Participants were encouraged to exercise in groups of two to seven individuals. Treadmill sessions could be taken at a clinic facility on weekdays between 4 pm and 7 pm. Supervised sessions were scheduled for immediately before the behavioural sessions. Equivalent outdoor walking was also allowed. **Delivered by:** Behavioural sessions were conducted by pairs of clinical psychology graduate students with no previous experience in the behavioural treatment of obesity, supervised by a researcher. The clinic exercise facility was staffed by the graduate students, supervised by an exercise physiologist. **Home-based exercise:** Participants attended the same BT sessions as the group-based exercise group	treatment weight into consideration. **Adherence to programme:** There were no differences between the groups for the first 6 months. The number of weeks of full adherence to the exercise programme was significantly greater with home-based exercise than with group-based exercise in the last 6 months of the programme. Adherence to the BT programme, measured as completion of daily self-monitoring records, was also significantly greater with home-based exercise than group-based exercise. **Therapists:** The authors report that analyses examining the effects of therapists did not show any significant effect on outcomes.	given via telephone. Analyses using completers only gave similar results.

			(described above). Participants were given individual exercise prescriptions and were instructed to complete 30 min of exercise (walking) on 5 days per week in their home (or work) environment. Exercise progress was reviewed at behavioural sessions. **Delivered by:** Behavioural sessions were delivered as described for group-based exercise. Group leaders reviewed exercise progress at these sessions. **Length of follow-up:** 15 months. **Other agencies involved:** None reported. **Other information related to delivery:** **None.**		
Harvey-Berino 1998 [3998] USA CBA 2–	**Setting:** Six television studios at sites representing a mix of rural and urban locations in Vermont and a university classroom. **Interactive television (IT):** *n* = 133	To determine if interactive video-conferencing is a feasible, acceptable, effective and cost-efficient vehicle for delivering a	**Interactive television:** Participants received a 12-week BT programme. This was delivered in weekly 1-hour group sessions held at several television studios. One group were in the same studio as the therapist and other groups at remote sites participated via	**Loss to follow-up:** IT: *n* = 30 (23%) ST: *n* = 6 (18%) **Weight (kg):** There were significant ($p < 0.001$) weight changes with both IT (–7.6 [SD 4.1]) and ST (–7.9 [SD 5.4]). There was no significant difference between	No ITT analysis. Analysis uses baseline data from all participants and follow-up data from completers only. Although participants from one of the sites

	BMI (kg/m^2): 34.5 (SD 5.4) Weight (kg): 97.7 (SD 18.4) Age (years): 45.8 (SD 8.0) Gender: 19% male Ethnicity: 97% White Education: 47% college degree or higher Previous weight loss: 70% had participated in a previous weight –loss programme. **Standard therapy (ST):** *n* = 33 BMI (kg/m^2): 35.4 (SD 5.7) Weight (kg): 102.1 (SD 18.7) Age (years): 44.4 (SD 6.6) Gender: 25% male Ethnicity: 100% White Education: 51% college degree or higher Previous weight loss: 81% had participated in a previous weight loss programme. **Other relevant information:** Recruitment was through newspaper adverts at the six locations. Participants were required to be at least 20% over IBW based on Metropolitan Life Insurance Tables (1983).	behavioural weight-control intervention.	interactive television. They could see and hear the therapist and each other at all times. The programme included behaviour modification and instruction in diet and exercise. Participants were each prescribed a target energy intake, and were required to record daily intake in a diary. They were also given exercise goals and they recorded their activity on a daily basis (The programme was similar to the LEARN programme). **Delivered by:** The behavioural programme was delivered by a trained behavioural therapist. The therapist reviewed weight and self-monitoring diaries of participants at the local site. Each remote site had a site facilitator who was not a trained behaviour therapist but who was trained in how to weigh participants and review diaries. Facilitators included Local Extension Educators and one local dietitian. **Standard therapy:** Participants received the same BT programme as the IT group, but this was delivered in person	the groups. **Cost-effectiveness:** The cost per participant of running the groups was calculated as US$34.71 for IT and US$24.65 for ST. The average price per pound of weight loss was calculated as US$2.56 for IT and US$2.00 for ST.	were randomised to IT and ST groups, randomised data were not reported separately.

			in a university campus classroom. Weight and self-monitoring diaries were monitored by the therapist. Further details are not provided. **Delivered by:** The same trained behavioural therapist as the IT programme. **Length of follow-up:** 12 weeks **Other agencies involved:** None reported. **Other information related to delivery:** **None.**		

EVIDENCE TABLE 1b: EVIDENCE OF EFFICACY (INTERNAL VALIDITY) FOR THE MANAGEMENT OF OVERWEIGHT AND OBESITY IN CHILDREN

All summary data are mean values unless otherwise stated.
Studies are grouped by intervention.
Within each intervention category, studies are listed by study type in the following order: systematic review; randomised trial (RCT); controlled non randomised trial (CCT), controlled before and after study (CBA), interrupted time series (ITS); other study type.
Within each study type, studies are listed in alphabetical order.

First author, country, study design, research type, quality	**Study population**	**Research aim/question**	**Intervention details/length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for the management of overweight and obesity in children					
School-based interventions with family involvement					
Figueroa-Colon 1996 [11292] USA RCT Cluster 1+	**Setting:** Two suburban public schools in New Orleans, serving low to middle socio-economic-level families. **Intervention:** *n* = 12 BMI (kg/m^2): 30.9 (SD 5.4) Weight (kg): 69.6 (SD 21.1) % IBW for height: 171.8 (SD 20.7) Age (years): 10.4 (SD 1.3) Gender: 58% male **Control:** *n* = 7 BMI (kg/m^2): 28.8 (SD 4.2) Weight (kg): 62.2 (SD 15.9)	To test the effectiveness of a hypoenergetic dietary intervention for superobese children in a school setting.	**Intervention:** 1.5-hour sessions held at school weekly for the first 10 weeks and then fortnightly for the following 16 weeks. At least one parent was required to attend with each child. Sessions were held after 5 pm. Sessions involved dietary and exercise instruction, discussion and monitoring, and behavioural modification. Diet for the first 10 weeks was protein-sparing modified fast (PSMF). For the following 16 weeks a hypoenergetic balanced diet was used, with gradual increase in energy content. Individual activity	**Loss to follow-up**: Intervention: *n* = 1 (8%) Control: *n* = 0 (0%) **BMI (kg/m^2):** There was a significant ($p < 0.002$) reduction in BMI in the intervention group (–3.8 [SD 3.2]). There was no significant change in control group BMI (+0.2 [SD 0.9]). **Weight (kg):** There was a significant ($p < 0.02$) reduction in weight in the intervention group (–5.6 [SD 7.1]). There was a significant ($p < 0.0001$) increase in weight in the control group (+2.8 [SD 3.1]).	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up <20%. Of those children invited to participate in the study at screening, enrolment rates were 27% for the intervention school and 37% for the control school. Baseline characteristics of those who enrolled

	% IBW: 164 (SD 20.3) Age (years): 10.8 (SD 1.2) Gender: 57% male **Other relevant information:** Of 755 children screened, 63 were defined by the authors as superobese (>140% IBW) and were invited to participate in the study.		programmes were devised, consisting of five 45-min sessions per week at school and at home. **Delivered by:** The group leaders included a paediatrician, a psychologist, a nutritionist, a physical education instructor and a nurse. **Control:** No intervention control. **Delivered by:** N/a **Length of follow-up:** 6 months. **Other agencies involved:** None reported. **Other information related to delivery:** None.	**% IBW:** There was a significant ($p < 0.002$) decrease in the intervention group (–24.3 [SD 20]). There was no significant change in the control group (–0.3 [SD 5.9]).	and those who refused were compared for each school. At the intervention school % IBW was significantly ($p < 0.002$) lower in those who refused treatment. There were no significant differences at the control school. Statistical analysis reported for within group change only.
Grey 2004 [3054] USA RCT School 1+	**Setting**: Two middle schools in the New Haven, CT, area. **Intervention group:** *n* = 22 BMI (kg/m^2): 35.8 (SD 5.8) Weight (lb): 203.3 (SD 43.1) (92.2 [SD 19.5] kg)	**Aim**: To evaluate the preliminary effects of a school-based nutrition education, PA, and coping skills training (CST) programme on	**Intervention:** Nutrition, PA and CST for 16 weeks. **Nutrition education:** Programme was designed to be family centred, culturally sensitive and interactive. It focused on slowing weight gain and improving glucose	**Loss to follow-up:** There were no dropouts from the programme. The authors report that nine participants did not complete metabolic data, and five participants did not complete psychosocial or behavioural data at 12-month follow-up. The authors do not report which group these individuals	Randomisation adequately addressed. No mention of allocation concealment. Blinding poorly addressed. Loss to follow-up <20% for weight outcomes.

	Central adiposity (inches): 44.7 (SD 6.2) (113.5 [SD 15.7] cm) Age (years): 12.4 (SD 1.2) Gender: 36.4% male Ethnicity: 11 (50%) African American; 10 (45.5%) Hispanic; 1 (4.5%) White. Income: 11 (50%) <US$19,900; 9 (41%) US$20,000–59,999; 1 (5%) ≥$60,000. **Comparison group:** *n* = 19 BMI (kg/m^2): 37.0 (SD 7.1) Weight (lb): 214.9 (SD 54.2) (97.5 [SD 24.6] kg) Central adiposity (inches): 45.0 (SD 3.9) (114.3 [SD 9.9] cm Age (years): 12.6 (SD 0.8) Gender: 36.8% Male Ethnicity: 10 (52.6%) African American, 8 (42.1%) Hispanic, 1 (5.3%) White. Income: 7 (36.8%) <US$19,900; 8 (42%) US$20,000–59,999; 1 (5%) ≥US$60,000. **Other relevant information:** Adolescents screened at	insulin resistance, self-management, and psychosocial well being among inner city youth at risk for type 2 diabetes.	metabolism. Classes were provided weekly, lasting 45 min. A 'non-diet' approach was taught, encouraging regular and nutritious meals with a reduced portion size. Parents were also invited to participate in the nutrition education programme. **Physical activity:** After-school activity of 45 min. Adolescents were included in designing the activity programme. Participants were encouraged to increase their physical activities, and decrease their sedentary behaviours, at home for an additional three days. Parents were encouraged to collaborate with the PA programme. **Coping skills training:** This was taught during nutrition classes. Training included culturally sensitive weight management materials. CST was also reinforced opportunistically during the PA sessions. There was weekly telephone support during the summer in the form of reinforcement and positive feedback.	were assigned to. **BMI (kg/m^2):** At follow-up: Intervention: 35.9 (SD 6.8) Comparison: 37.8 (SD 7.7) **Weight (lb):** At follow-up: Intervention: 214.6 (SD 49.1) (97.3 [SD 22.3] kg) Comparison: 230.3 (SD 58.8) (104.5 [SD 26.7] kg) **Central adiposity (inches):** At follow-up: Intervention: 44.5 (SD 6.7) (113.0 [SD 17.0] cm) Comparison: 46.8 (SD 7.0) (118.9 [SD 17.8] cm) There was no statistically significant difference between groups in change from baseline to 12-month follow-up.	

	school by the by the school nurse practitioner. Families of youths with a BMI ≥95th percentile and a family history of diabetes were contacted regarding the study.		**Delivered by:** Dietitian, licensed personal trainer and research assistant. **Comparison:** Participants received the education and PA programme (as described above), but not the CST for 16 weeks, and monthly telephone contact. **Length of follow-up:** 12-month follow-up. **Other agencies involved:** None reported. **Other information related to delivery:** **None.**		
Lansky 1983 [11322] USA RCT Individual 1–	**Setting:** Three junior high schools. **Intervention:** *n* = 30 Weight (kg): 68.42 % Overweight (% deviation from mean weight for height and age): 43.93 Age (years): 12.9 (SD 1.3*) Gender: 47% male **Control:** *n* = 25 Weight (kg): 71.01 % Overweight: 47.47%	To evaluate the effectiveness of a school-based intervention for adolescent obesity.	**Intervention:** Twelve weekly 45-min group meetings. Children were excused from class to attend meetings. Children were taught self-monitoring of diet and exercise, problem solving, a food-exchange plan and eating behaviour techniques. Half of the sessions involved aerobic activities and the discussion of ways to increase out-of-session exercise levels. Weight was recorded every 3 weeks and children received a lottery ticket for each 0.23 kg lost. Lottery	**Loss to follow-up:** Not stated. **Weight (kg):** There was a significant ($p < 0.01$) difference between weight change in the intervention group (+0.57 [SD 2.94*]) and the control group (+3.29 [SD 3.32*]). **Height (cm):** There was a significant ($p < 0.01$) increase in height from baseline in both groups. The intervention group increased by 1.83 (SD 1.42*) and the control group by 2.03 (SD 1.65*).	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up not stated. Data were also reported on a self-selected control group (data not extracted).

	Age (years): 13.3 (SD 1.3*) Gender: 44% male **Other relevant information:** 114 children were identified as being 10% or more overweight through screening in the schools. 55 (48%) received parental permission to participate in the trial and were randomised. *The authors do not explicitly state whether this is a standard deviation.		prizes included passes for bowling or to a local YMCA. On four different evenings 1.5 hour meetings were held for parents to attend in a group at which the instructor provided feedback and advice regarding the programme. **Delivered by:** A female physical education teacher. **Control:** No intervention (no further details provided). **Delivered by:** N/a **Length of follow-up:** 12 weeks. **Other agencies involved:** None reported. **Other information related to delivery:** **None.**	**% Overweight:** There was a significant (*p* < 0.01) difference between change in % overweight in the intervention group (–5.71 [SD 9.04*]) and the control group (+2.41% [SD 7.57*]). **Attendance:** Only one-third of parents attended a parent meeting. *The authors do not explicitly state whether this is a standard deviation	
Graf 2005 [30] Germany CBA	**Setting:** Seven primary schools randomly selected from schools in the Cologne region. **Intervention:**	**Aim:** To evaluate the effect of a school and family based intervention for overweight and obese children in	**Intervention:** A 9-month programme covering four main areas (diet, PA, parental education and family events). **Diet:**	**Loss to follow-up:** Intervention group: *n* = 81 (66.9%) Control group: *n* = 10 (6.5%) **BMI (kg/m^2):** Change at follow-up: Intervention: +0.27 (SD 0.19)	Unclear loss to follow-up for intervention group. 121 children were selected to participate but the

2+	121 children were invited to participate, but baseline data are for completers only (*n* = 40). Age (years): 8.70 (SD 1.26) BMI (kg/m^2): 22.81 (SD 3.60) Weight (kg): 43.58 (SD 10.21) **Control group:** *n* = 155 Age (years):8.47 (SD 1.27) BMI (kg/m^2): 21.77 (SD 2.66) Weight (kg): 40.84 (SD 9.62) **Other relevant information:** Participants were selected from subjects enrolled in a large study aiming to prevent overweight and obesity in primary schools (*n* = 1678). Of these children 17.7% were obese/overweight. It is from this obese/overweight group that participants for the described study were recruited.	grades 1 through 4 (STEP TWO programme).	Diet based on the OPTIMAX pyramidal programme. Specialists cooked and ate with the participants twice per week. **Physical activity:** Participants undertook 60–90 min of PA (aerobic dance, relay, soccer, etc.) after each supervised meal. **Education:** Information was given to children on healthy foods and the importance of exercise. Parents were involved in events about healthy nutrition (two evening sessions) and importance of physical exercise (one evening session). **Family events:** Two inline skating sessions for participants and their parents were organised. **Delivered by:** Nutritionists, gymnasts, psychologists and medical doctors at the selected schools. **Control:** Did not receive any intervention other than their regular school programme.	Control: +0.66 (SD 0.10) No significant difference between groups was detected at follow-up (*p* = 0.069). BMI standard deviation score (SDS) change at follow-up: Intervention: –0.15 (SD 0.04) Control: –0.05 (SD 0.02) A statistically significant difference between groups was found at follow-up (*p* = 0.028), with the intervention group demonstrating the greatest reduction. **Weight (kg):** At follow-up: Intervention: 46.90 (SD 11.44) Control: 44.66 (SD 10.32) No significant difference between groups was detected at follow-up. **Waist circumference:** The authors state that no significant difference in change of waist circumference was shown between groups (data not reported).	number who agreed to participate was not reported, therefore loss to follow-up may be over-estimated. No ITT analysis. The intervention group had a slightly higher BMI at baseline than the control group (*p* = 0.042).

			Length of follow-up: 9 months. **Other agencies involved:** None reported. **Other information related to delivery:** **None.**		
School-based interventions without specified family involvement					
Carrel 2005 [93 update] USA RCT 1–	**Setting:** Rural school in Wisconsin **Intervention:** *n* = 27 BMI (kg/m^2): 32 (SD 6) Body fat (%): 36.5 (SD 4.7) Age (years): 12.5 (SD 0.5) Gender: 48% male **Control:** *n* = 26 BMI (kg/m^2): 30 (SD 4) Body fat (%): 36.4 (SD 4.6) Age (years): 12.5 (SD 0.7) Gender: 57% male **Other relevant information:** Children with a BMI above the 95th percentile for age were eligible for inclusion.	To investigate whether a school-based fitness programme makes a difference in fitness, fatness and insulin sensitivity.	**Intervention:** Nine-month lifestyle-focused, fitness-oriented physical education classes with 14 students per class. Lifestyle activities such as walking and cycling were emphasised and competitive games de-emphasised. Emphasis was on moving rather than watching and children did not change clothes for the class. Handouts were provided on healthy eating habits. There were five classes every 2 weeks of 45 min. The typical amount of movement time in class was 42 min. **Control:** Nine-month standard physical education classes with 35 to 40 students per class. Students changed clothes for the class. There were five classes every 2 weeks of 45 min. The typical	**Loss to follow-up**: Intervention: *n* = 0 Control *n* = 3 (12%) **BMI (kg/m^2):** Mean score at follow-up Intervention: 33 (SD 10) Control: 30 (SD 5) There was no statistically significant difference between groups in change from baseline to follow-up. **Body fat (%):** (Assessed using DEXA) Mean change Intervention: –4.1% (SD 3.4) Control: –1.9% (SD 2.3) There was a statistically significant greater decrease in body fat in the intervention group compared with control (*p* = 0.04).	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up <20%. No ITT analysis. Baseline data provided only on participants who completed the study.

			amount of movement time in class was 25 min. **Delivered by:** Not stated. **Length of follow-up:** 9 months. **Other agencies involved:** Assessments were conducted at a University exercise laboratory. **Other information related to delivery:** **None.**		
Donnelly 1996 [11289] USA CBA 2–	**Setting**: Elementary schools (grades 3 to 5) from two school districts in rural Nebraska. **Intervention:** *n* = 11 BMI (kg/m^2): 20.3 (SD 4.1) Weight (kg): 91.5 (SD 23.1) % Body fat: 27.8 (SD 5.5) **Intervention school:** Ethnicity: 94.3% White Free/reduced cost lunches: 42% **Control:** *n* = 25 BMI (kg/m^2): 19.9 (SD 2.5)	**Aim**: To implement and assess the effectiveness of a nutrition and activity programme on reducing obesity and improving physical fitness in elementary school children.	**Intervention**: Multi-component programme consisting of nutrition education, modified school lunches, and increased PA. **Nutrition:** Meals were planned, with the existing kitchen staff, to reflect the ‘Lunchpower!’ programme; Lunchpower! is a reduced energy, fat and sodium lunch, developed by the National Livestock and Meat Board. Nutrition education was delivered in 18 modules, nine per year. These modules looked at basic nutrition,	**Loss to follow-up:** Intervention: *n* = unclear Control: *n* = unclear **BMI (kg/m^2):** At 2-year follow-up: Intervention: 21.6 (SD 4.5) Control: 21.3 (SD 3.4) Within-group differences were shown for both the control group and the intervention group ($p < 0.05$) from baseline to 2-year follow-up. There were no statistically significant differences between groups at either time point. **Weight (kg):** At 2-year follow-up:	Supported by the National Livestock and Meat Board, Health Management Resources, and Research Services Council.

	Weight (kg): 86.9 (SD 13.3) % Body fat: 28.8 (SD 6.6) **Control school:** Ethnicity: 93.6% White Free/reduced cost lunches: 44% **Other relevant information:** Programme was initiated across participating schools regardless of an individual's weight status. An overweight subgroup (participants with body fat ≥22%) was identified in both control and intervention schools, and the results presented related to this subgroup. Grades 3 to 5 include children aged between 8 and 11 years old.		relationship between diet and health, nutrition for healthy growth and development, healthy food choices, snack alternatives, reducing fat in the diet, and food safety. **Physical activity:** Activities were designed to promote energy expenditure and decrease time-off-task using guidelines of 'Physical Best'.* Activities were designed to use large muscle groups for 30 to 40 min, 3 days per week. Aerobic activities that could be easily incorporated into lifestyle were emphasized, such as hopping, skipping and aerobic games. *Reston (1988), American Alliance for Health, Physical Recreation and Dance. **Delivered by:** Classroom teachers, doctoral student, graduates and a registered dietitian. **Control:** Participants received usual school lunch and physical education programmes. **Length of follow-up:**	Intervention: 111.6 (SD 28.0) Control: 105.5 (SD 19.5) Within group differences were shown for both the control group and the intervention group ($p < 0.05$) from baseline to 2-year follow-up. There were no statistically significant differences between groups at either time point. **% Body fat:** At 2-year follow-up: Intervention: 25.4 (SD 8.7) Control: 26.1 (SD 7.7) There were no statistically significant within group differences from baseline to follow-up, or differences between groups.	

			2 years. **Other agencies involved:** None reported. **Other information related to delivery:** None.		
Nuutinen 1991 [11329] Finland CBA 2–	**Setting**: Group 1: Clinical setting Group 2: School healthcare setting Group 3: School-based **Intervention (Group 1):** *n* = 32 Weight (kg): 69.3 (SD 21.6) % IBW for height: 160.9 (SD 20.1) Age (years): 11.3 (SD 2.6) Gender: 23 (72%) male **Intervention (Group 2):** *n* = 16 Weight (kg): 54.3 (SD 13.5) % IBW for height: 142.1 (SD 12.8) Age (years): 11.0 (SD 2.3) Gender: 12 (75%) male **Control:** *n* = 29 Weight (kg): 39.6 (SD 14.3) % IBW for height: 100.1 (SD 7.9) Age (years): 11.4 (SD 2.9)	**Aim:** To determine the effects of dietary counselling during an intensive programme of weight control.	**Intervention (group 1):** Clinical setting. Children received BT either individually or in a group setting. These groups were combined for the analysis. **Individually treated group:** Children, accompanied by at least one parent, were seen by a physician once a month during active treatment (year 1), and twice during year 2 (observation year). Participants received five meetings with a nutritionist, each session lasting 30–60 min. Dietary counselling was based on problems identified from food records. Individual meal plans were provided (energy level between 1400 and 2200 kcal [5.86 to 9.21 MJ]). Topics discussed with parents included dietary habits within the family, purchasing of foods, and food preparation.	**Loss to follow-up:** Group 1: *n* = 4 (12.5%) Group 2: appeared to be none Group 3: *n* = 3 (9.4%) **Weight (kg):** The % IBW for height decreased by 16.2% during the treatment year in the intensive treatment group ($p < 0.001$), and at two years was 12.8% lower than baseline ($p < 0.001$). For participants in the school setting % IBW for height was 7.3% lower than baseline at 2 years (not statistically significant).	**At baseline:** The group treated in a clinical setting had proportionally more energy from protein than the normal-weight group ($p < 0.05$). Group treated in a clinical setting consumed less sucrose than either school healthcare group or the normal weight group. Group treated in a clinical setting were heavier ($p < 0.05$), had higher relative weight ($p < 0.001$), and more fat tissue ($p < 0.001$) than the school healthcare group.

	Gender: 22 (76%) male Intervention group 1 was initially divided into two groups of 16 (group 1A, individual treatment, and group 1B, behaviour modification), but subsequently aggregated. Control group comprised of normal weight children from recruited from the same school as group 2.		**Group treatment:** Children, accompanied by at least one parent, were seen by a physician once per month during year 1, and twice during year 2. Children and parents separately received seven group sessions, each lasting 1 hour. Group discussions were aimed at activating participants to make their own decisions with regard to dietary changes. Principles of the dietary counselling were similar to the individually treated group. **Delivered by:** Physician, dietitian, psychologist and psychiatrist. **Intervention (group 2):** School healthcare setting. Children visited the school nurse, without their parents, once a month during year 1, and twice in year 2. Each visit lasted 20–40 min. The nurse encouraged the participant to find their own solution to the dietary problems identified in previous discussions. Children were asked to complete a 7-day food diary before each session. The intervention was individualised according to each child’s interest in weight control.		

			Children were not persuaded to do more than they were interested in doing. **Delivered by:** School nurse. **Control**: No intervention. The control group were normal weight children from the same school. **Length of follow-up:** 2 years. **Other agencies involved:** None reported. **Other information related to delivery:** **None.**		
Home setting					
Jiang 2005 [243 update] China RCT 1–	**Setting:** Family and school setting in Beijing. **Intervention:** *n* = 36 BMI (kg/m^2): 26.6 (SD 1.7) Weight (kg): 70.1 (SD 5.7) Height (cm): 161.2 (SD 4.1 Age (years): 13.3 (SD 0.6) Gender: 61% male **Control**: *n* = 39	To evaluate the impact of a family-based behavioural treatment intervention on obese schoolchildren	**Intervention:** Two-year family-based behavioural treatment. There was individualised targeting of each child's dietary and exercise patterns based on baseline assessment. Adherence to the target behaviours was recorded by the children and monitored by the parents. PA 20–30 min per day, four days per week was advised. A detailed dietary	**Loss to follow-up**: Intervention *n* = 3 (8%) Control: *n* = 4 (10%) **Height** Mean change Intervention: +8.2 (SD 4.3) Control: +8.0 (SD 3.9) **BMI (kg/m^2):** Mean change Intervention: –2.6 (SD 1.6) Control: –0.1 (SD 1.1)	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up <20%. No ITT analysis. Baseline data provided only on participants who completed the study.

	BMI (kg/m^2): 26.1 (SD 1.5) Weight (kg): 71.2 (6.4) Height (cm): 162.7 (SD 3.4) Age (years): 13.2 (0.7) Gender: 60% male **Other relevant information:** Obese children in Grades 7–9 were eligible for inclusion. Obesity was defined as weight-for-height ≥120% of the Chinese reference.		modification plan was developed for each family. Paediatricians visited the families once per month. Daily food intake was recorded in a diary for each child. **Control:** No intervention (usual school and family life) **Delivered by:** Paediatricians. **Length of follow-up:** Two years. **Other agencies involved:** None stated. **Other information related to delivery:** There were follow-up assessments every 6 months.	**Weight (kg)** Mean change Intervention: –0.3 (SD 4.3) Control: +5.5 (SD 3.5) There was a similar increase in height in both groups. There was a statistically significant difference between groups in weight change and in BMI from baseline to follow-up at 2 years ($p < 0.001$).	
White 2004 [55] USA RCT Individual 1+	**Setting:** Geographical area is unclear. Setting was participants' homes. **Intervention (Internet-based behavioural programme):** *n* = 28 Children: BMI (kg/m^2): 35.31	To assess the process variables involved in a family-based weight loss programme presented over the Internet for African American adolescent girls.	**Intervention:** Participants were provided with a personal computer for the home and free Internet access with which to access the Health Improvements Programme for teens (HIP-Teens) intervention website. This website was only accessible to intervention participants, and the readability of its content was set at 6th grade reading level. They	**Loss to follow-up**: Intervention: *n* = 5 (18%) Comparison: *n* = 2 (7%) **BMI (kg/m^2):** Children: There was a significant difference ($p < 0.01$) between the change in the intervention group (–0.24 [SD 1.38]) and the comparison group (+0.71 [SD 1.19].	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up <20%. Missing data were imputed using mean of other participants in each group.

	(SD 7.60) % Body fat (DEXA): 45.46 (SD 8.34) Age (years): 13.14 (SD 1.59) Gender: 0% male Parents: BMI (kg/m^2): 37.90 (SD 7.62) % Body fat (DEXA): 47.68 (SD 7.07) Age (years): 43.53 (SD 6.24) **Comparison (Internet-based educational programme):** *n* = 29 Children: BMI (kg/m^2): 37.34 (SD 8.16) % Fat (DEXA): 46.22 (SD 6.45) Age (years): 13.23 (SD 1.16) Gender: 0% male Parents: BMI (kg/m^2): 39.03 (SD 6.81) % Body fat (DEXA): 48.99 (SD 5.24) Age (years): 42.87 (SD 6.18)		accessed new behavioural modification material on a weekly basis and communicated with a case manager via email, on topics including self-monitoring, goal setting, problem solving, contracting and relapse prevention. The website also featured links to recipes hobbies and activities, and chat rooms for study participants. Participants were required to submit daily food records and received automated feedback. **Delivered by:** Case manager had at least graduate-level clinical psychology training specialising in weight management. **Comparison:** Participants also received a computer and free Internet access. They accessed a control version of the HIP-Teens website and their programme was primarily educational involving basic information about nutrition and PA. **Delivered by:** Case manager was a registered dietitian.	Parents: There was a significant difference (*p* = 0.03) between the change in the intervention group (–0.90 [SD 2.01]) and the comparison group (–0.12 [SD 0.83]). **Weight (kg):** Children: There was a significant difference (*p* = 0.03) between the change in the intervention group (+0.55 [SD 3.26]) and the comparison group (+2.40 [SD 2.86]). Parents: Changes in the intervention group (–2.16 [SD 4.95]) and the comparison group (–0.52 [SD 2.55]) were not significantly different. **% Body fat (DEXA):** Children: There was a significant difference (*p* = 0.02) between the change in the intervention group (–1.04 [SD 2.00]) and the comparison group (+0.38 [SD 2.95]). This effect remained significant when a regression analysis was conducted taking into consideration baseline adiposity. Parents: Changes in the intervention group (–0.51 [SD 2.02]) and the comparison group (+0.13 [SD 1.59]) were not significantly different.	

	Other relevant information: Sixty-one participants were randomised but only 57 completed baseline assessment. Participants were required to have at least one obese parent.		**Length of follow-up:** 6 months. **Other agencies involved:** None reported. **Other information related to delivery:** The length of both programmes appeared to be 6 months.	**Website visits:** Both children and parents in the intervention group visited the website significantly more times over the 6 months than those in the control group.	
Williamson 2005 [2005 update] USA RCT 1+	**Setting:** Home-based using Internet **Intervention:** Adolescents (*n* = 28): BMI (kg/m^2): 35.3 (SD 7.6) Body fat (%): 45.5 (SD 8.3) Age (years): 13.1 (SD 1.6) Gender: 100% female Parents (*n* = 28): BMI (kg/m^2): 37.9 (SD 7.6) Body fat (%): 47.7 (SD 7.1) Age (years) 43.5 (SD 6.2) **Control:** Adolescents (*n* = 29) BMI (kg/m^2): 37.3 (SD 8.2) Body fat (%): 46.2 (SD 6.5) Age (years) 13.3 (SD 1.2) Gender: 100% female Parents (*n* = 29) BMI (kg/m^2): 39 (SD 6.8) Body fat (%): 49.0 (SD 5.2)	To assess the efficacy of an Internet-based lifestyle behaviour modification programme for weight management in African American girls.	**Intervention:** Six months of interactive BT plus nutrition education via the Internet. Lifestyle nutrition and PA habits were targeted. **Control:** Six months of passive education on nutrition and exercise delivered via the Internet. **Delivered by:** Not stated. **Length of follow-up:** Six months. **Other agencies involved:** None stated. **Other information related to delivery:** Both groups received four face-to-face therapy sessions over a	**Loss to follow-up**: Intervention: *n* = 5 (18%) Control: *n* = 2 (7%) **BMI (mean change) (kg/m^2):** Adolescents: Intervention: –0.19 (SE 0.24) Control: +0.65 (SE 0.23) There was a statistically significant difference between groups in the change from baseline to follow-up ($p < 0.05$). **BMI (mean change) (kg/m^2):** Parents: Intervention: –1.03 (SE 0.28) Control: –0.06 (SE 0.77) There was a statistically significant difference between groups in the change from baseline to follow-up ($p < 0.05$)	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up <20%. ITT analysis using baseline value carried forward. Baseline data were not reported for dietary intake. However, baseline scores were treated as covariates in the statistical analyses.

	Age (years): 42.9 (SD 6.2) **Other relevant information:** African American girls aged 11 to 15 years with a BMI >85th percentile with at least one biological parent with a BMI >30 kg/m^2 were eligible. Participants with significant co-morbidities such as diabetes were excluded. Only one overweight parent could participate. Participants had to be willing to pay US$300 towards the cost of a computer with US$700 provided by the researchers. Sixty-one participants were randomised but baseline assessments were not completed by four individuals.		12-week period. The websites for both groups were designed to be culturally specific. Parents received US$30 for completing the 6-month follow-up assessments and the adolescents received a gift worth US$10.	**% Body fat (DEXA):** Adolescents: Intervention: –1.12 (SE 0.47) Control: 0.43 (SE 0.47) There was a statistically significant difference between groups in the change from baseline to follow-up ($p < 0.05$). Parents: Intervention: 0.58 (SE 0.34) Control: +0.18 (SE 0.34) No statistically significant difference.	

EVIDENCE TABLE 2a: EVIDENCE OF EFFICACY (INTERNAL VALIDITY) FOR IMPROVED BEHAVIOURS (DIET AND ACTIVITY) IN ADULTS

All summary data are mean values unless otherwise stated.
Studies are grouped by intervention.
Within each intervention category, studies are listed by study type in the following order: systematic review; randomised trial (RCT); controlled non randomised trial (CCT), controlled before and after study (CBA), interrupted time series (ITS); other study type.
Within each study type, studies are listed in alphabetical order.

First author, country, study design, research type, quality	**Study population**	**Research aim/question**	**Intervention details/length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for improved behaviours (diet and activity) in adults					
Commercial weight loss programmes					
Rippe 1998 [12522] USA RCT Individual 1–	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet (energy intake per day):** Intervention: 1723 (SD 448) kcal (7.21 [SD 1.88] MJ) at baseline. Control: 1905 (SD 436) kcal (7.97 [SD 1.83] MJ) at baseline. The intervention group showed the greatest reduction in their daily energy intake compared with the controls (482 [SD 536] and 164 [SD 353] kcal [2.02 {SD 2.24} and 0.69 {SD 1.48} MJ]) respectively; *p* = 0.03, which did not reach prespecified significance level of *p* < 0.01). **Activity:** Activity level (using the Physical Activity Scale of Ross and Jackson, a seven-point scale where 0 represents minimal	As above in Table 1a.

				daily activity and 7 represents the equivalent of running more than 10 miles/week): Intervention: 0.8 (SD 0.5) at baseline. Control: 1.1 (SD 0.6) at baseline. The intervention group significantly increased their activity compared with controls (+4.4 [SD 2.3] and +0.7 [SD 0.3] respectively; *p* ≤ 0.0001). VO_{2max} (ml/kg per min): Intervention: 28.9 (SD 4.1) at baseline. Control: 32.2 (SD 3.3) at baseline. The intervention group significantly increased their VO_{2max} compared with the controls (+3.8 [SD 3.3] and –2.7 (SD 3.5) respectively; *p* ≤ 0.001).	
Interventions using computers					
Tate 2003 [11287] USA RCT Individual 1+	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet:** (Assessed using Block FFQ) Both groups showed significant reductions (*p* < 0.001) in energy intake at 12 months. The energy consumed from fat decreased by 1% in the Internet-only group and 4% in the behavioural e-counselling group, but there was not a statistically significant difference between the groups. **Activity:** (Assessed using Paffenbarger Activity Questionnaire) There was no significant change in	As above in Table 1a.

				exercise energy expenditure at 12 months in either group.	
Tate 2001 [3942] USA RCT Individual 1+	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet (energy intake per day):** (Assessed using Block FFQ; included only participants who completed all three assessments, *n* = 62.) There was a significant reduction in daily energy intake in both groups over time (*p* = 0.004), but no significant differences between the groups. The change in the BT group was from 1558 (SD 654) kcal (6.52 [SD 2.74] MJ) at baseline to 1062 (SD 395) (4.44 [SD 1.65] MJ) at 3 months and 1146 (SD 450) kcal (4.80 [SD 1.88] MJ) at 6 months. In the education group the change was from 1757 (SD 857) kcal (7.35 [SD 3.59] MJ) at baseline to 1256 (SD 696) kcal (5.28 [SD 2.91] MJ) at 3 months and 1286 (SD 564) kcal (5.38 [SD 2.36] MJ) at 6 months. **Activity (energy expenditure per week):** (Assessed using Paffenbarger Activity Questionnaire; included only participants who completed all three assessments, *n* = 60) There was a significant increase in PA in both groups over time (*p* = 0.03) but no significant differences between the groups.	As above in Table 1a.

				The change in the intervention group was from 1360 (SD 1415) kcal (5.69 [SD 5.92] MJ) at baseline to 1903 (SD 1757) kcal (7.97 [7.35] MJ) at 3 months and 1289 (SD 919) kcal (5.40 [3.85] MJ] at 6 months. In the control group the change was from 1031 (SD 981) kcal (4.32 [4.11] MJ) at baseline to 1500 (SD 1513) kcal (6.28 [6.33] MJ) at 3 months and 1125 (SD 1320) kcal (4.71 [5.53] MJ) at 6 months.	
Taylor 1991 [11346] USA RCT Individual 1–	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Activity (weekly min of exercise):** At 38 weeks, exercise (reported over the phone) was significantly greater in the FFF + CAT group (154 min) than the CAT group (37 min).	As above in Table 1a.
Womble 2004 [57] USA RCT Individual 1+	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Eating-related behaviour:** (Assessed by Eating Inventory; included treatment completers only) There were no statistically significant differences between the groups in self-reported eating restraint, disinhibition and hunger.	As above in Table 1a.
Dennison 1996 [11287] USA	As above in Table 1.	As above in Table 1.	As above in Table 1.	**Diet:** (Assessed using Nutrition Coordinating Centre's Nutrition Data System software package)	As above in Table 1.

CBA 2–				There was a significant ($p = 0.004$) reduction in total daily energy intake in the intervention groups combined, from 2180 kcal (9.13 MJ) at baseline to 1822 kcal (7.63 MJ) at 1 year. There was no significant change in the control group, which was 2217 kcal (9.28 MJ) at baseline and 2263 kcal (9.47 MJ) at 1 year (further details on diet outcomes are available in the paper).	
Work-based setting					
Pritchard 1997 [3959] Pritchard 2002 [3958] Australia RCT Individual 1+ Note: both papers report randomised data on the same participants. All the extracted data was taken from Pritchard 1997, and some additional information was	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet:** (Assessed from analysis of monthly 24-hour food recalls and 3-day food diaries) **Energy intake per day:** Percentage change from baseline was significantly different ($p < 0.05$) in the diet group (–30.4 [SD 3.8]% from 2594 [SD 577] kcal [10.86 {SD 2.42} MJ/]) compared with both exercise (+3.1 [SD 2.7]% from 2486 [SD 379] kcal [10.41 {SD 1.59} MJ) and control (+5.5 [SD 4.7]% from 2225 [SD 444] kcal [9.31 {SD 1.86} MJ]). **% Energy intake as fat:** Percentage change from baseline was significantly different ($p < 0.05$) in the diet group (–32.0 [SD 4.8] from 38.2 [SD 5.8]) compared with both exercise (+1.0 [SD 3.8] from 38.9 [SD 6.8]) and control (+0.4 [SD 1.0] from 38.5 [SD 6.0]).	As above in Table 1a.

from Pritchard 2002.				**Activity:** (Assessed from 24-hour activity logs and 3-day activity diaries) **Energy expenditure per day:** Percentage change from baseline was significantly greater ($p < 0.05$) in the exercise group (+14.6 [SD 2.0]% from 2570 [SD 312] kcal [10.76 {SD 1.31}] MJ]) compared with both diet (+5.9 [SD 1.9]% from 2407 [SD 161] kcal [10.08 {SD 0.67}] MJ) and control (+6.5 [SD 1.5]% from 2508 [SD 294] kcal [10.50 {SD 1.23} MJ]). **Index of activity:** Percentage change from baseline was significantly greater ($p < 0.05$) in the exercise group (+15.6 [SD 10.1]% from 1.35 [SD 0.10]) compared with both diet (+3.4 [SD 1.2]% from 1.30 [SD 0.17]) and control (+6.4 [SD 1.7]% from 1.34 [SD 0.11]).	
Furuki 1999 [8838] Japan CBA 2–	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet and activity:** Outcome data for diet and activity were reported for men in the intervention group only. No data were reported for the control group.	As above in Table 1a.
Other non-clinical settings					
Jason 1991 [11310]	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet:** (Baseline based on 3-day diaries 1–4	As above in Table 1a.

USA RCT Individual 1–				weeks before intervention.) **Mean total energy:** Support group Baseline: 1838 (SD 642) kcal (7.69 [SD 2.69] MJ) Follow-up: 1204 (SD 651) kcal (5.04 [SD 2.73] MJ) Non-support group Baseline: 1843 (SD 615) (7.71 [SD 2.57] MJ) Follow-up: 1320 (SD 544) (5.53 [SD 2.28] MJ) **Mean % energy from protein in diet:** Support group Baseline: 15.86 kcal (SD 3.03) Follow-up: 20.93 kcal (SD 6.23) Non-support group Baseline: 18.37 kcal (SD 4.71) Follow-up: 22.24 kcal (SD 7.88). **Mean % energy from carbohydrate in diet:** Support group Baseline: 47.39 kcal (SD 8.76) Follow-up: 47.72 kcal (SD 11.69) Non-support group Baseline: 45.03 (SD 9.14) Follow-up: 43.10 (SD 10.15) **Mean % energy from fat in diet:** Support group	

				Baseline: 35.25 (SD 7.22) Follow-up: 31.17 (SD 10.87) No-support group Baseline: 35.66 (SD 8.00) Follow-up: 32.38 (SD 7.05) Both support group and non-support group reduced their overall energy intake ($p < 0.05$ and $p < 0.05$), as well as increasing their % of energy as protein ($p < 0.05$ and $p < 0.05$) at follow-up. The support group were also shown to have significantly reduced the % of energy from fat ($p < 0.05$) at follow-up. **Activity:** (Baseline based on 3-day diaries 1–4 weeks prior to intervention) Aerobic exercise (mean number of min over a 3-day period) Support group Baseline: 13.63 (SD 27.93) Follow-up: 32.18 (SD 47.26) Non-support group Baseline: 15.39 (SD 29.18) Follow-up: 34.59 (SD 56.19). Non-aerobic exercise (mean number of min over a 3-day period): Support group Baseline: 55.97 (SD 58.23) Follow-up: 82.07 (SD 80.39)	

				Non-support group Baseline: 47.12 (SD 63.78) Follow-up: 48.79 (SD 74.80). Both the support group (*p* < 0.05) and the non-support group (*p* < 0.05) significantly increased their aerobic exercise from pre-testing to follow-up.	
McNabb 1997 [3972] USA RCT Individual 1+	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet:** (Assessed using Food Behaviour Checklist) The amount of high-fat foods eaten decreased significantly (*p* < 0.05) in intervention compared with control, but change in consumption of high-fibre foods was not significantly different between the two groups. **Activity (min of exercise per week):** Intervention baseline: 5.0 (SD 17.3) Control baseline: 23.8 (SD 36.7) Changes in levels of exercise were not significantly different between intervention (+36.7 [SD 42.5]) and control (+21.3 [SD 22.5]).	As above in Table 1a.
Perri 1997 [3961] USA RCT Individual 1+	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet:** (Assessed using Eating Pattern Assessment Tool (EPAT) Questionnaire; analysis was of completers only) The consumption of high-fat foods decreased significantly (*p* < 0.0001) in both groups over time, with no between group differences. With group-based	As above in Table 1a.

				exercise the change in EPAT score was from 25.94 (SD 5.32) at baseline to 17.67 (SD 3.94) at 6 months and 20.72 (SD 5.56) at 12 months. With home-based exercise the change in EPAT score was from 26.05 (SD 6.36) at baseline to 18.27 (SD 3.59) at 6 months and 20.95 (SD 5.42) at 12 months. The consumption of low-fat foods did not change significantly in either group over the 12 months. **Activity (min of exercise per week):** Activity during months 0–6 was similar in both groups: 104.4 (SD 39.5) for group-based exercise and 104.0 (SD 25.5) for home-based exercise. There were significant decreases in activity in both groups for months 7–12, but activity with home-based exercise (66.2 [SD 21.6]) was significantly higher than with group-based exercise (45.4 [SD 30.5]).	
Harvey-Berino 1998 [3998] USA CBA 2–	As above in Table 1a.	As above in Table 1a.	As above in Table 1a.	**Diet:** (Assessed from 3-day food diaries) There were significant decreases (*p* values not reported) in energy intake and fat intake (% of energy) with both IT and ST. There were no between group differences for either measure. The change in energy intake was –607 (SD 632) kcal (–2.54 [SD 2.65] MJ) from 1959 (SD 692) kcal (8.20 [SD 2.90] MJ) at baseline for IT, and –638 (SD 521) kcal (–2.67 [SD 2.18] MJ)	As above in Table 1a.

				from 2176 (SD 794) kcal (9.11 [SD 3.32] MJ) at baseline for ST. The change in fat intake (% of energy) was –3.4 (SD 7.9)% from 32.2 (SD 6.3)% at baseline for IT, and –2.1 (SD 6.6)% from 32.3 (SD 6.8)% at baseline for ST. **Activity (energy expended):** (Assessed using Paffenbarger Physical Activity Questionnaire) There were significant increases (*p* values not reported) with both IT and ST, but no between group differences. The change was +664 (SD 1346) kcal (+2.28 [SD 5.63] MJ) from 857 (SD 1174) kcal (3.59 [SD 4.91] MJ) at baseline with IT and +245 (SD 943) kcal (+1.02 [SD 3.95 MJ] from 1083 (SD 1202) kcal (4.53 [SD 5.03] MJ) at baseline with ST.	

EVIDENCE TABLE 2b: EVIDENCE OF EFFICACY (INTERNAL VALIDITY) FOR IMPROVED BEHAVIOURS (DIET AND ACTIVITY) IN CHILDREN

All summary data are mean values unless otherwise stated.
Studies are listed by study type in the following order: systematic review; randomised trial (RCT); controlled non randomised trial (CCT), controlled before and after study (CBA), interrupted time series (ITS); other study type.
Within each study type, studies are listed in alphabetical order.

First author, country, study design, research type, quality	**Study population**	**Research aim/question**	**Intervention details/length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/ Comments**
Evidence of efficacy (internal validity) for improved behaviours (diet and activity) in children					
Grey 2004 [3054] USA RCT School 1+	As above in Table 1b.	As above in Table 1b.	As above in Table 1b.	**Diet:** No statistically significant difference in terms of usual food choices, dietary knowledge, dietary self-efficacy, or intake of energy, carbohydrate and saturated fat was shown between groups at follow-up. **Physical activity:** There was no statistically significant difference between groups in change from baseline to 12-month follow-up for PA levels or activity self-efficacy.	As above in Table 1b.
Nuutinen 1991 [11329] Finland CBA 2–	As above in Table 1b.	As above in Table 1b.	As above in Table 1b.	**Food consumption:** In group 1 the consumption of edible fats ($p < 0.001$) and milk products ($p < 0.05$) was reduced after 1 year, and maintained until the end of the observation period ($p < 0.01$ and $p < 0.05$, respectively):	As above in Table 1b.

				Edible fats (butter, margarine, oil): Baseline: 43 (SD 22) g Mean change from baseline: Year 1: –10 (SD 12) g Year 2: –1 (SD 17) g **Milk and milk products:** Baseline: 818 (SD 293) g Mean change from baseline: Year 1: –192 (SD 307) g Year 2: –17 (SD 254) g **Daily nutrient intake** (using four day food record): Children in group 1 decreased their mean daily fat intake at year 1 ($p < 0.001$), and maintained this to the end of the observation period ($p < 0.001$): **Fat:** Baseline: 86 (SD 29) g Mean change from baseline: Year 1: –19 (SD 21) g Year 2: –22 (SD 28) g There was no significant change in school group. Group 1 had a lower level of sucrose consumption than group 2 at year 1 ($p < 0.05$) and at year 2 ($p < 0.001$), but there was no significant change in the	

				school group. No statistically significant changes across the study in nutrient intake were shown in the conventionally treated group.	

EVIDENCE TABLE 3: EVIDENCE OF EFFICACY (INTERNAL VALIDITY) FOR MAINTENANCE OF WEIGHT LOSS AND CONTINUATION OF IMPROVED BEHAVIOURS (DIET AND ACTIVITY)

All summary data are mean values unless otherwise stated.
Studies are listed by study type in the following order: systematic review; randomised trial (RCT); controlled non randomised trial (CCT), controlled before and after study (CBA), interrupted time series (ITS); other study type.
Within each study type, studies are listed in alphabetical order.

First author, country, study design, research type, quality	**Study population**	**Research aim/question**	**Intervention details/length of follow-up**	**Main results** (include effect size(s)/confidence intervals for each outcome if available)	**Confounders** (potential sources of bias)**/comments**
Evidence of efficacy (internal validity) for maintenance of weight loss and continuation of improved behaviours (diet and activity)					
Harvey-Berino 2004 [34] USA RCT Individual 1+	**Setting:** Internet-based intervention was wherever participants had Internet access. In person support was set in several television studios in Vermont. **Internet support:** *n* = 77 BMI (kg/m^2): 29.3 (SD 5.2) Weight (kg): 82.7 (SD 16.3) Age (years): 46.5 (SD 9.8) Gender: 19% male Education: 64% college degree or higher **Frequent in person support:** *n* = 77 BMI (kg/m^2): 28.9 (SD 3.8)	To compare the efficacy of an Internet-based weight maintenance programme with frequent and minimal in-person support programmes.	**Intervention:** 12-month weight loss maintenance programme. During this maintenance phase all participants were told to continue with the dietary and exercise prescriptions provided in the treatment phase: to reduce energy intake to 4186–10,465 kJ/d, depending on baseline weight, and to expend at least 1000 kJ/week. **Internet support:** An initial technical orientation session was provided. Participants attended pre-arranged bi-weekly maintenance meetings, held in the form of an Internet chat	**Loss to follow-up:** Internet support: *n* = 25 (32.5%) Frequent in person support: *n* = 16 (20.8%) Minimal in person support: *n* = 15 (19.2%) **Weight (kg):** There was no significant difference in weight change, relative to pre-treatment weight, between the groups: Internet support: -4.7 (SD 6.9) Frequent in-person support: -3.9 (SD 5.9) Minimal in-person support: -4.2 (SD 7.9) There was no significant difference between groups in the number of participants who were able to sustain at least a 5% weight loss (completers only):	No description of randomisation method. No mention of allocation concealment. Blinding poorly addressed. Loss to follow-up >20% in two arms. ITT was used for absolute weight change; analysis of completers only gave the same overall finding, though the actual weight loss was greater when completers only were included in the analysis.

	Weight (kg): 81.2 (SD 14.2) Age (years): 45.2 (SD 8.9) Gender: 16% male Education: 63% college degree or higher **Minimal in person support:** *n* = 78 BMI (kg/m^2): 29.0 (SD 4.3) Weight (kg): 80.5 (SD 14.4) Age (years): 46.5 (SD 7.7) Gender: 14% male Education: 65% college degree or higher **Other relevant information:** All participants received an identical 6-month behavioural weight loss programme conducted over interactive television (ITV). Only those completing the weight loss programme were randomised to a maintenance condition. There was no significant difference among the groups in the amount of weight lost during the initial treatment programme (7.8 kg [SD 5.3] kg) for all groups combined). Participants were required		session, facilitated by a therapist. Lesson topics were introduced at the start of each session by the therapist. Participants also received bi-weekly email contact with the therapist. Participants self-reported weight, dietary intake, and exercise data, on a weekly basis. Group members could contact each other by email, posting questions to the web bulletin board, or by making appointments to chat in the chat room. **Delivered by:** Researchers and therapist (dietitian). **Frequent in person support:** Participants met bi-weekly at their local ITV for 52 weeks. At each session individuals handed in their self-monitoring diaries, were weighed, and participated in group discussions facilitated by a group therapist. Topics focussed on problem solving difficult eating and exercise situations. Participants received a telephone call from the therapist on the weeks that no	Internet support: 62% Frequent in person support: 46% Minimal in person support: 49% **Programme adherence:** Subjects in the frequent in person support group attended significantly more maintenance group meetings than the Internet support group ($p = 0.02$). Subjects in the Internet support condition submitted self-monitoring diaries more frequently ($p < 0.01$), and reported more peer support contacts ($p < 0.01$) than the frequent in person group. Attendance at treatment meetings and chat sessions ($p < 0.01$), and frequency of self-monitoring ($p < 0.01$) significantly correlated with weight loss from baseline to end of maintenance phase. The minimal in person support group was not included in this analysis. **Other outcomes:** The authors report that there were no between group differences in perceived social support and working alliance. Data were not reported.	Supported by the National Institutes of Health.

	to have a computer with Internet access, and have no history of major medical problems. The majority of participants were comfortable with basic computer applications and enjoyed using computers.		meetings were held. During these weeks self-monitoring data was posted to the therapist. Subjects also participated in a social-influence peer-support programme. Each week participants could win adherence points, which were converted into lottery tickets. **Delivered by:** Therapist (dietitian) **Minimal in person support:** Participants met monthly in person at independent television studios for sessions delivered over ITV for the first 6 months. Each group support session lasted 1 hour. Participants were encouraged to continue to self-monitor, although diaries were not monitored by the therapist. Weight measurements were taken at this meeting. There was no group contact between monthly meeting or from months 7–12. **Delivered by:** Therapist (dietitian) **Length of follow-up:** 12 months		

			Other agencies involved: None reported. **Other information related to delivery:** The Internet support condition and the frequent in person support condition were based on the multi-component weight maintenance programmes developed by Perri et al. (1988).		
Harvey-Berino 2002 [3997] USA RCT Individual 1+	**Setting:** Treatment intervention and in-person support were in a clinical setting. Internet maintenance took place wherever participants had Internet access. **Internet support:** *n* = 40 BMI (kg/m^2): 32.2 (SD 4.0) Weight (kg): 89.3 (SD 15.3) Age (years): 46.3 (SD 11.1) Gender: 10% male Ethnicity: 96.9% White Education: 65.0% college degree or higher **Frequent in-person support:** *n* = 41 BMI (kg/m^2): 31.5 (SD 4.8) Weight (kg): 86.5 (SD 10.1)	To investigate the effectiveness of a weight maintenance programme conducted over the Internet.	**Internet support:** Participants attended a 24-week behavioural weight control programme. They then received a technical orientation session teaching them how to access and use the secure study website. For the next 52 weeks, participants were required to enter self-monitoring data, and bi-weekly group maintenance sessions were held online by a therapist in the study chat room. On weeks when there was no meeting, the therapist emailed the participants. Group members could contact one another using email, bulletin board or chat room. By adhering to programme goals participants earned points, which were converted into tickets for a	**Loss to follow-up:** Internet support: *n* = 10 (25%) Frequent in-person support: *n* = 9 (22%) Minimal in-person support: *n* = 13 (32%) **Weight (kg):** Over the 24-week treatment period there was no significant difference in the weight lost by the three groups: Internet support (–8.0 [SD 5]), frequent in-person support (–9.8 [SD 5.9]) and minimal in-person support (–11 [SD 6.5]). During the first 6 months of weight maintenance, weight gain was significantly greater ($p = 0.05$) in the Internet support group (+2.2 [SD 3.8]) than the frequent in-person support group (0 [SD 4]). Weight loss at 18 months from baseline was significantly smaller ($p < 0.05$) with	No description of randomisation method. No mention of allocation concealment or blinding. Loss to follow-up >20%. ITT analysis data not reported although authors state that effects with ITT analysis were the same as for completers only. Diet and activity outcomes were self-reported.

	Age (years): 49.8 (SD 8.4) Gender: 14.3% male Ethnicity: 100% White Education: 68.3% college degree or higher **Minimal in-person support:** *n* = 41 BMI (kg/m^2): 32.8 (SD 4.6) Weight (kg): 90.2 (SD 13.9) Age (years): 49.1 (SD 9.1) Gender: 19.5% male Ethnicity: 97.4% White Education: 56.1% college degree or higher **Other relevant information:** Participants were required to have a computer with Internet access, and have no history of major medical problems. The majority of participants were comfortable with basic computer applications and enjoyed using computers.		weekly lottery to win £25. **Delivered by:** Two of the researchers gave the orientation session. A therapist facilitated online meetings and email contact. **Frequent in-person support:** Participants attended the 24-week weight control programme as above. They then attended bi-weekly group maintenance sessions with a therapist for 52 weeks for review of self-monitoring diaries and group discussion. On weeks when there was no meeting, the therapist telephoned each participant. By adhering to programme goals participants earned points, which were converted into tickets for a weekly lottery to win £25. **Delivered by:** Therapist. **Minimal in-person support:** Participants attended the 24-week weight control programme as above. Then for the next 6 months participants attended a 1-hour meeting each month for weight measurement and encouragement although their	Internet support (–5.7 [SD 5.9]) than both frequent in-person support (–10.4 [SD 6.3]) and minimal in-person support (–10.4 [SD 9.3]). The percentage of participants maintaining a weight loss of 5% or more at 18 months was significantly greater ($p = 0.02$) with minimal in-person support (81.3%) or frequent in-person support (81%) than Internet support (44.4%). **Diet:** (Assessed using the Block FFQ) All groups significantly ($p < 0.001$) decreased energy intake from baseline to 6-month assessment, with no between group differences. Only the frequent in-person support group maintained a significant difference from baseline at 18 months. **Activity:** (Assessed using the Paffenbarger Physical Activity Questionnaire) All groups significantly ($p < 0.01$) increased physical activity from baseline to 6-month assessment with no between group differences. Only the frequent in-person support group maintained a significant difference from baseline at 18 months. **Attendance:** Attendance over the 1-year	

			self-monitoring diaries were not reviewed by a therapist. For the following 6 months they were not contacted. **Delivered by:** Unclear. **Length of follow-up:** 18 months (from initial treatment) **Other agencies involved:** None reported. **Other information related to delivery:** All subjects were seen for assessment measures at baseline and at 6, 12 and 18 months; attendees entered a lottery to win US$50. The frequent in person support and Internet support programmes were based on multi-component weight maintenance programmes (Perri et al. 1998).	maintenance programme was significantly ($p = 0.04$) greater in the frequent in-person support group (54%) than the Internet support group (39%). There was no difference in the submission of self-monitoring data. **Other outcomes:** At baseline acceptability of group assignment was similar in both groups. The percentage of Internet support participants who would prefer to be in the other group had increased at 6 months (from 35% to 70%). There was no change in this measure in Frequent in-person support participants at 6 months.	

Evidence of corroboration (external validity)								
No additional controlled studies conducted in a UK setting met the inclusion criteria.
