

Non-Hodgkin's lymphoma: diagnosis and management

Appendix G: Evidence review

Final version, July 2016

This guideline was developed by the National Guideline Alliance, hosted by the Royal College of Obstetricians and Gynaecologists

Disclaimer

Healthcare professionals are expected to take NICE clinical guidelines fully into account when exercising their clinical judgement. However, the guidance does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of each patient, in consultation with the patient and/or their guardian or carer.

CONTENTS

2: Diagnosis	7
2.1: Type of Biopsy	7
2.1.1: Review Question: Is core biopsy an acceptable alternative to excision biopsy for the accurate diagnosis of suspected non-Hodgkin's lymphoma at first presentation?	7
Evidence Quality	7
Evidence Statements	8
Excluded Studies	9
2.2: Genetic Testing	26
2.2.1: What is the most effective genomic/phenotypic testing strategy to diagnose the subtypes of aggressive b-cell non-Hodgkin's lymphoma?	26
Evidence Quality	28
Evidence Summary	32
Evidence Statements	46
References	48
Excluded Studies	51
Evidence Tables	67
2.2.2: Review question: What is the most effective genomic/phenotypic testing strategy to determine therapeutic stratification and prognostic subtypes of aggressive b-cell non-Hodgkin's lymphoma?	116
Evidence Quality	117
Summary Tables: characteristics, results and limitations of included studies	120
Evidence Statements	161
References	163
Excluded Studies	168
Evidence Tables	262
3. Staging	321
3.1.1: Review question E1: What is the staging value of pre-treatment functional imaging with PET-CT compared with other initial assessments for people with different subtypes of non-Hodgkin's lymphoma?	321
Evidence Quality	322
Summary Tables	324
Evidence statements	332
3.1.2: Review question: What is the prognostic value of an interim assessment using functional imaging with PET-CT during the treatment of diffuse large B-cell non-Hodgkin's lymphoma?	334
Evidence Quality	335
Summary Tables	338
Evidence Statements	339
3.1.3: Review question E3: What is the prognostic value of functional imaging with PET-CT performed after the various types of treatment for non-Hodgkin's lymphoma are completed?	340
Evidence Quality	341
Summary Tables	343
Evidence Statements	351
References	358
Excluded Studies	362
Evidence tables for staging, interim and post treatment FDG-PET/CT	384
4: Management	481
4.1 Follicular Lymphoma	481

Non Hodgkin's lymphoma: diagnosis and management	
4.1.1 Review question: What is the most effective first-line treatment for people with stage IIa follicular lymphoma?	481
Evidence Quality	482
Evidence Statements	485
GRADE Tables	487
References	497
Excluded Studies	498
Evidence Tables	512
4.1.2: Review question: Is autologous transplantation, allogeneic transplantation or no transplantation the most effective treatment for people with follicular lymphoma at various time points?	522
Summary Tables	523
Evidence Statements	532
GRADE Tables	537
References	561
Excluded studies	563
Evidence Tables	578
4.1.3 Review question: Is immediate treatment or deferred chemotherapy (watch and wait) the more effective treatment for people with advanced asymptomatic follicular lymphoma?	635
Summary Tables	636
Evidence Statements	638
GRADE Tables	639
References	646
Excluded Studies	647
Evidence Tables	659
Economic evidence	669
4.1.4: Review question: What is the effectiveness of first-line consolidation with high-dose therapy with autologous or allogeneic transplantation in people with histological transformation of follicular lymphoma to diffuse large B-cell lymphoma or concurrent presentation with follicular lymphoma & diffuse large B-cell lymphomas, compared with other strategies?	678
Summary Tables	679
Evidence Statements	685
GRADE Tables	690
References	698
Excluded Studies	699
Evidence Tables	704
4.2: Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT) Lymphoma	729
4.2.1: Review question: What is the most effective first-line treatment for people with MALT lymphoma?	729
Summary Tables	730
Evidence Statements	738
GRADE Tables	742
References	766
Excluded Studies	768
Evidence Tables	771
4.3: Mantle Cell Lymphoma	820
4.3.1: Review question: What is the most effective first-line treatment for people with mantle-cell lymphoma?	820
Summary Tables	821
Evidence Statements	827

Non Hodgkin's lymphoma: diagnosis and management	
GRADE Tables	831
References	859
Excluded Studies	862
Evidence Tables	869
4.3.2: Review question What is the effectiveness of first-line consolidation of high-dose therapy with autologous or allogeneic transplantation in people with mantle-cell lymphoma?	909
Summary Tables	910
Evidence Statements	914
GRADE Tables	916
References	922
Excluded Studies	924
Evidence Tables	936
4.3.3: Review question: What is the effectiveness of first-line maintenance strategies compared with observation for people with mantle-cell lymphoma?	958
Summary Tables	959
Evidence Statements	963
GRADE Tables	965
References	971
Excluded Studies	972
Evidence Tables	982
4.4: Diffuse Large B-Cell Lymphoma (DLBCL)	994
4.4.1: Review question: What is the effectiveness of consolidation radiotherapy when given following immuno-chemotherapy as first-line treatment for people with advanced stage diffuse large B-cell lymphoma?	994
Summary Tables	995
Evidence Statements	1000
GRADE Tables	1001
References	1002
Evidence Tables	1003
4.4.2: Review question: What are the risk factors associated with central nervous system (CNS) relapse in patients with diffuse large B-cell lymphoma?	1012
Study Quality	1013
Summary Tables	1016
Evidence Statements	1022
References	1023
Excluded Studies	1024
Evidence Tables	1033
436.

ni, P. L. & Piccaluga, P. P. (2011) Primary mediastinal DLBCL: evolving biologic understanding and therapeutic strategies. [Review]. <i>Current Oncology Reports</i> , 13: 407-415.	1077
4.4.3: Review question: What is the efficacy of central nervous system prophylaxis for people with diffuse large B-cell lymphoma?	1078
Summary Tables	1079
Evidence Statements	1098
GRADE Tables	1100
References	1108
Excluded Studies	1110
Evidence Tables	1118

Non Hodgkin's lymphoma: diagnosis and management	
4.4.4: Review question: What is the most appropriate salvage strategy for people with relapsed/refractory diffuse large B-cell lymphoma?	1165
Summary Tables	1166
Evidence Statements	1168
GRADE Tables	1170
References	1177
Excluded Studies	1181
Evidence Tables	1191
4.5 Burkitt Lymphoma	1207
4.5.1: Review question: What is the most effective first-line treatment for people with Burkitt lymphoma?	1207
Summary Tables	1208
Evidence Statements	1218
GRADE Tables	1220
References	1225
Excluded studies	1226
Evidence tables	1229
4.6: T-Cell Lymphoma	1247
4.6.1: Review question: What is the most effective first-line treatment for people with peripheral T-cell lymphoma?	1247
Summary Tables	1249
Evidence Statements	1253
GRADE Tables	1255
References	1260
Excluded Studies	1261
Evidence Tables	1265
4.6.2: Review question: What is the effectiveness of high-dose consolidation of first-line therapy with autologous or allogeneic transplantation in people with peripheral T-cell lymphoma?	1282
Summary Tables	1283
Evidence Statements	1288
GRADE Tables	1290
References	1298
Excluded Studies	1299
Evidence Tables	1303
5: Patient Information Needs	1321
5.1 Review question: What are the information and support needs of patients with a diagnosis of non-Hodgkin's lymphoma and their carers?	1321
Evidence Statements	1331
References	1337
Excluded Studies	1340
Evidence Tables	1344
6: Follow-up	1418
6.1: Review question: In patients in remission after treatment with curative intent for non-Hodgkin's lymphoma, what are the optimal method(s), frequency and duration of follow-up?	1418
Summary Tables	1420
Evidence Statements	1422
GRADE Tables	1423
References	1425
Excluded Studies	1425

Non Hodgkin's lymphoma: diagnosis and management	
Evidence Tables	1431
7: Survivorship	1436
7.1: Review question: What is the effectiveness of surveillance protocols for late adverse effects of treatment in people with non-Hodgkin's lymphoma?	1436
Summary Tables	1437
Evidence Statements	1439
GRADE Tables	1440
References	1442
Excluded Studies	1442
Evidence Tables	1454

2: Diagnosis

2.1: Type of Biopsy

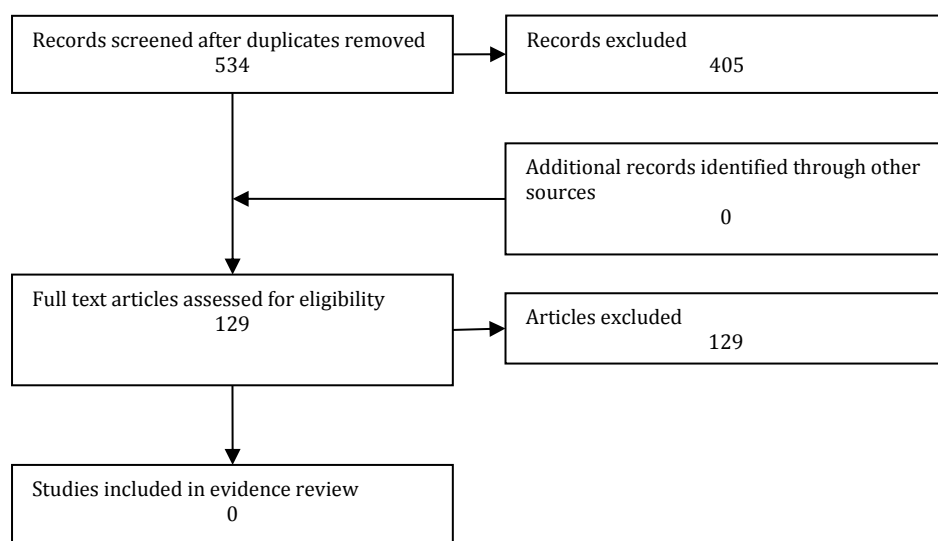

2.1.1: Review Question: Is core biopsy an acceptable alternative to excision biopsy for the accurate diagnosis of suspected non-Hodgkin’s lymphoma at first presentation?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) presenting with suspected lymphoma (at initial presentation)	Core biopsy Image Needle Trucut	Excision biopsy Surgical Lymph node biopsy	Diagnostic accuracy Health-related quality of life Patient preference Patient satisfaction Accuracy of classification of NHL Speed of diagnosis Sample adequacy Diagnostic yield Morbidity due to test
Additional Comments on PICO			
Present outcomes by type of NHL malignancy subtypes included in scope Level of confidence in diagnosis might be an outcome Exclude: Fine needle aspiration biopsy alone			

Evidence Quality

Figure 1: Study flow diagram

Evidence Statements

The evidence review identified no evidence that met the inclusion criteria of the review.

Excluded Studies

2.2: Genetic Testing

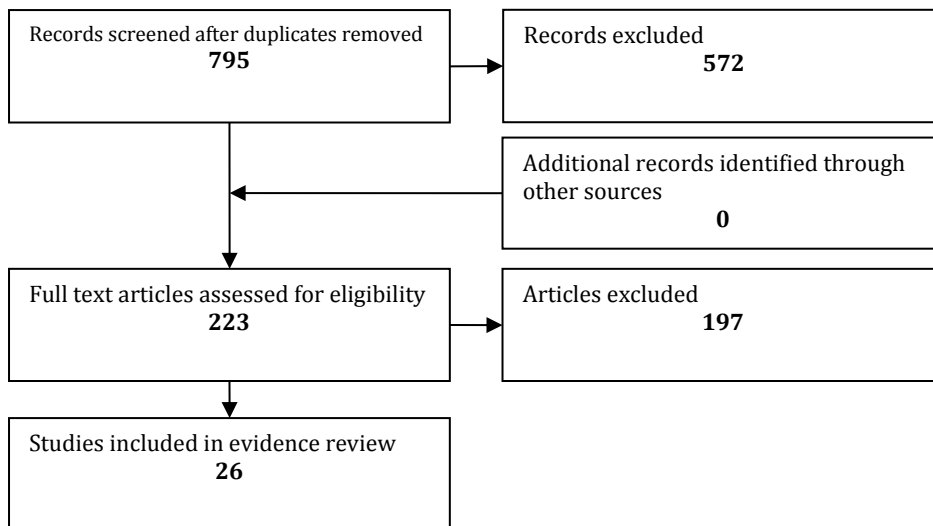

2.2.1: What is the most effective genomic/phenotypic testing strategy to diagnose the subtypes of aggressive b-cell non-Hodgkin’s lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) presenting with new aggressive b-cell non-Hodgkin’s lymphoma.	Gene expression profiling Patterns of genes/genes in list form Fluorescence in situ hybridisation (FISH) Realtime PCR DNA sequencing Immunohistochemistry	Where reported: gene expression as the reference standard For aggressive b-cell lymphoma have a comparison of each other	Diagnostic accuracy Reproducibility Turnaround time for test
Additional Comments on PICO			
Present outcomes by aggressive b-cell NHL malignancy subtypes included in scope Make note of different platforms used in the gene expression (Illumina, Affymetrix, Agilent)

NPV: Negative predictive value. *Proportion of tests with a correct result

Evidence Statements

Twenty six studies provided information on diagnostic tests. All were retrospective cross sectional studies using retrospectively collected data.

Diagnostic accuracy of testing strategies for sub-typing aggressive non-Hodgkin's lymphomas (NHL)

Burkitt lymphoma (BL) versus diffuse large B-cell lymphoma (DLBCL)

Four studies (Barrans *et al.*, 2013; Gormley *et al.*, 2005; Soldini *et al.*, 2013 and Iqbal *et al.*, 2015) including 796 patients assessed testing strategies to differentiate between BL and DLBCL. Low quality evidence from one study (Soldini *et al.*, 2013) indicated all patients were accurately classified to their original diagnosis when using FISH. Low quality evidence from two studies (Barrans *et al.*, 2013 and Iqbal *et al.*, 2015) indicated that classic diagnostic methods can accurately diagnose BL and DLBCL compared to gene expression profiling at rates of 93.59-95.4%. Finally, one study (Gormley *et al.*, 2005) provided low quality evidence that immunohistochemistry (IHC) can accurately diagnose patients into BL/DLBCL and GC/ABC subtypes compared to morphology at a rate of 85.5%.

Burkitt lymphoma (BL) versus other NHL subtypes

Two studies (Dave *et al.*, 2006 and Hummel *et al.*, 2006) including 291 patients assessed testing strategies to differentiate between BL and other NHL subtypes. Low quality evidence from one study (Dave *et al.*, 2006) indicated that pathological review provides more diagnostic accuracy (87.3%) compared to classic diagnostic methods (73.2%) when diagnosing Burkitt lymphoma. One study (Hummel *et al.*, 2006) provided low quality evidence that morphology can accurately diagnose patients into BL versus other NHL subtypes at a rate of 83.6%.

Primary mediastinal B-cell lymphoma (PMBL) versus diffuse large B-cell lymphoma (DLBCL)

One study (Votavova *et al.*, 2010) including 82 patients assessed the use of histopathological and clinical review compared to gene expression profiling in the diagnosis of PMBL reporting low quality evidence of a diagnostic accuracy rate of 85.4%.

Diffuse large B-cell lymphoma (DLBCL) versus other NHL subtypes

One study reporting low quality evidence (Deffenbacher *et al.*, 2010) including 17 patients assessed the use of pathological review compared to gene expression profiling in the diagnosis of DLBCL, with a diagnostic accuracy rate of 64.7%.

Diagnostic accuracy of testing strategies for sub-typing diffuse large B-cell lymphoma (DLBCL)

Sub-typing diffuse large B-cell lymphoma into germinal centre B-cell (GCB) and activated B-cell (ABC)-like lymphomas

Five studies (Barrans *et al.* 2012; Malik *et al.*, 2010; Booman *et al.*, 2006; Scott *et al.*, 2013 and Choi *et al.* 2009) including 472 patients provided low quality evidence comparing various immunohistochemistry (IHC) algorithms to gene expression profiling (GEP). The highest rates of diagnostic accuracy (>90%) were reported when using IHC (93.4%; Malik *et al.* 2010), IHC Hans (91.5%; Scott *et al.*, 2013), IHC Tally (93.6%; Scott *et al.*, 2013) and IHC Choi algorithms (training set: 92.9%, validation set: 93.7%; Choi *et al.*, 2009) and the lowest rate of diagnostic accuracy using IHC reported by Booman *et al.* (2006; 70%). Rimsza *et al.* (2009) assessed the use of qNPA at two thresholds (>0.8 and >0.9) compared to GEP reporting low quality accuracy rates of 92.3% (threshold >0.9) and 100% (threshold >0.8). Su *et al.*, (2013) assessed the value of a bivariate mixture model reporting the a diagnostic accuracy rate when using a two-species analysis (human and canine) of 89.7% compared to 89.1% when using a human species alone analysis (89.1%). Finally, Williams *et al.* (2010) providing low quality evidence on the use of formalin-fixed paraffin embedded tissue when sub-typing DLBCL, reported a 97.7% accuracy rate compared to the use of fresh

Non Hodgkin's lymphoma: diagnosis and management

frozen tissues, and Mareschal *et al.* (2015) also providing low quality evidence found that GEP using a RT-MLPA assay accurately subtyped patients at a rate of 100% compared to GEP Affymetrix.

Sub-typing diffuse large B-cell lymphoma into Germinal centre B-cell (GCB) and non-GCB-like lymphomas

Four studies (Poulsen *et al.*, 2005; Gutierrez-Garcia *et al.*, 2011; Haarer *et al.*, 2006 and Visco *et al.* 2012) including 569 patients provided low quality evidence comparing various immunohistochemistry (IHC) algorithms to gene expression profiling (GEP). The highest rates of diagnostic accuracy (>90%) were reported when using IHC (92.7%; Poulsen *et al.*, 2005) and a 3-marker algorithm (92.6%) or 4-marker algorithm (92.8%; Visco *et al.*, 2012) and the lowest rate of diagnostic accuracy was reported when using the IHC Choi algorithm (59.1%; Gutierrez-Garcia *et al.*, 2011). When assessing studies that had reported using the same IHC algorithms (Hans and Choi) there was wide variation between the reported diagnostic accuracy of these algorithms (59.1% compared to 90% for the Choi algorithm and 65.3% and 87.2%).

Comparison of testing strategies for the identification of genes in non-Hodgkin's lymphomas.

One study (Chang *et al.*, 2010) assessed the use of FISH compared to polymerase chain reaction in the detection of t(14;18) in 227 patients with NHL reporting low quality evidence of a 70.5% accuracy rate. One study (Dunphy *et al.*, 2008) assessed the use of FISH compared to PCR in the detection of BCL2 in 22 patients with primary mediastinal B-cell lymphoma reporting low quality evidence of a 95.5% accuracy rate. One study (Lynnhtun *et al.*, 2014) assessed the use of FISH compared to immunohistochemistry plus FISH in the detection of MYC in 41 patients with high-grade B-cell lymphomas reporting low quality evidence of accuracy rates of 58.5% with a $\geq 40\%$ IHC-FISH threshold and 87.8% at $\geq 70\%$ and $\geq 80\%$ IHC-FISH threshold. One study (Mationg-Kalaw *et al.*, 2012) reported the use of pathological review compared to immunohistochemistry plus FISH in the detection of Ki67 in 432 patients with diffuse large B-cell lymphoma reporting low quality evidence of a 38.4% accuracy rate at $>70\%$ threshold and a 61.6% accuracy rate at $>90\%$ threshold. Finally, one study (Zeppa *et al.*, 2012) assessed the use of flow cytometry, immunohistochemistry-FISH and polymerase chain reaction compared to histology and follow-up in the detection of immunoglobulin heavy-chain (IGH) signals in 48 patients with non-Hodgkin's lymphoma, reactive hyperplasia and small lymphocytic lymphoma/chronic lymphocytic leukemia reporting low quality evidence of accuracy rates of 95.8%, 86.4% and 80% (respectively).

Evidence Tables

Table 5. Evidence tables for diagnostic accuracy of testing strategies for sub-typing aggressive non-Hodgkin's lymphomas.

Barrans, S et al. "Development of a cross platform, 2-way gene expression classifier to distinguish Burkitt Lymphoma from DLBCL, and assessment of the potential impact of its use in treatment decision making". Blood (2013) 122: 21.										
Pub year: 2013		Patient selection		Index test		Reference standard		Flow and timing		
Country	Not reported	Inclusion criteria: Algorithm was applied to Illumina Whole-Genome DASL data from 558 aggressive B-cell lymphoma samples (original diagnoses reported). Exclusion criteria: Not reported		Retrospective dataset with original diagnosis		Gene expression profiling (GEP)		97% (n=544) samples where GEP data were of sufficient quality for analysis. No information provided regarding the time between index test(s) and reference standard.		
Design, period	Retrospective review Time period not reported	Was a consecutive or random sample of patients enrolled?	Unclear	Were the index test results interpreted without knowledge of the results of the reference standard?	Unclear	Is the reference standard likely to correctly classify the target condition?	Yes	Was there an appropriate interval between index test(s) and reference standard?	Unclear	
N	544/558 Illumina whole-Genome DASL data aggressive B-cell lymphoma sample	Was a case-control design avoided?	Yes	If a threshold was used, was it pre-specified?	Unclear	Were the reference results interpreted without knowledge of the results of the index test?	Yes	Did all patients receive a reference standard?	Yes	
Follow-up	Not reported	Did the study avoid inappropriate exclusions?	Unclear					Did all patients receive the same reference standard?	Unclear	
		Could the selection of patients have introduced bias?	Unclear	Could the conduct or interpretation of the index test have introduced bias?	Unclear	Could the reference standard, its conduct, or its interpretation have introduced bias?	Low	Were all patients included in the analysis?	No (3% did not have sufficient quality data for GEP to be included)	
Funding source	Not reported	Are there concerns that the included patients do not match the review question?	Low	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low	Are there concerns that the target condition as defined by the reference standard does not match the review question?	Low	Could the patient flow have introduced bias?	Low	
Results	Table 1. Diagnostic accuracy of original diagnosis compared to gene expression profiling									
			GEP		Total N	Sensitivity	Specificity	PPV	NPV	Accuracy
			BL	DLBCL	544	88.0	96.2	69.8	98.8	95.4
	Original diagnosis	BL	44	19						
	DLBCL	6	475							
Authors note that had the 2-way classification been used to determine treatment, only 1% of patients currently regarded as DLBCL would have received intensive chemo, but 30% of patients diagnosed with BL using current diagnostic methods may have been undertreated. However, data shows that there is significant biological heterogeneity.										

Non Hodgkin's lymphoma: diagnosis and management

Non Hodgkin's lymphoma: diagnosis and management

Scott, DW et al. "Determining cell-of-origin subtypes in diffuse large b-cell lymphoma using gene expression profiling on formalin-fixed paraffin-embedded tissue-an LLLMPP project". Blood (2013) 122(21)									
Pub year: 2013		Patient selection		Index test		Reference standard		Flow and timing	
Country	Not reported	Training cohort consisted of 51 cases comprising: <ul style="list-style-type: none"> – 20 GCB – 19 ABC – 12 Unclassifiable cases Independent validation cohort (drawn from the validation cohort of Lenz et al., 2008), consisting of 68 cases: <ul style="list-style-type: none"> – 28 GCB – 30ABC – 10 U 		IHC Tissue microarrays were made using 0.6mm duplicate cores from 60/68 validation cohort cases, and stained for CD10, BCL6, MUM1, FOXP1, GCET1 and LMO2 Two hematopathologists independently assessed the proportion of tumour cells stained, with consensus on discordant cases reached with a third hematopathologist.		Centrally reviewed DLBCL FFPET biopsies using cases that had "gold standard" COO assigned by frozen-GEP using Affymetrix U133 plus 2.0 microarrays. Digital gene expression was performed on 200ng of RNA using NanoString technology (Seattle, WA). All FFPET GEP studies were performed in parallel at two independent sites.		For the validation studies, those producing and analyzing the GEP and IHC data were blinded to the "gold standard" cell of origin.	
Design, period	Retrospective review No time period reported	<i>Was a consecutive or random sample of patients enrolled?</i>	No	<i>Were the index test results interpreted without knowledge of the results of the reference standard?</i>	Yes	<i>Is the reference standard likely to correctly classify the target condition?</i>	Yes	<i>Was there an appropriate interval between index test(s) and reference standard?</i>	Unclear
N	64/68	<i>Was a case-control design avoided?</i>	Yes	<i>If a threshold was used, was it pre-specified?</i>	Yes	<i>Were the reference results interpreted without knowledge of the results of the index test?</i>	Yes	<i>Did all patients receive a reference standard?</i>	No Despite the age of the FFPET blocks (6-32 years old), 95% (49/51) of the training samples gave gene expression data of sufficient quality.
Follow-up	Not reported	<i>Did the study avoid inappropriate exclusions?</i>	Unclear						<i>Did all patients receive the same reference standard?</i>
		<i>Could the selection of patients have introduced bias?</i>	Unclear					<i>Could the conduct or interpretation of the index test have introduced bias?</i>	Low

Non Hodgkin's lymphoma: diagnosis and management

Funding source	Not reported	<i>Are there concerns that the included patients do not match the review question?</i>	Low	<i>Are there concerns that the index test, its conduct, or interpretation differ from the review question?</i>	Low	<i>Are there concerns that the target condition as defined by the reference standard does not match the review question?</i>	Low	<i>Could the patient flow have introduced bias?</i>	Low		
Results	All 119 FFPET yielded sufficient RNA. A pilot study using the training cohort identified 20 genes (15 genes of interest and 5 housekeeping genes) whose expression measured using NanoString, would allow accurate replication of the COO assignment model of Lenz et al. (2008).

Non Hodgkin's lymphoma: diagnosis and management

Table 8. Evidence tables for diagnostic accuracy of testing strategies for identification of genes in non-Hodgkin's lymphomas.

Chang, CM et al. "Non-Hodgkin lymphoma (NHL) subtypes defined by common translocations: utility of fluorescence in situ hybridization (FISH) in a case controlled study" Leukemia Research (2010) 34; 190-195				
Pub year: 2010	Patient selection	Index test	Reference standard	Flow and timing
Country	USA	<p>t(14;18)-FISH Commercially available FISH IGH and t(14;18) assays were run on 5-µm sections archived from FARM study tumour blocks (Vysis/Abbot Molecular, Des Plaines, IL)</p> <p>Assays were run according to the manufacturer's instructions (Abbot Molecular/Vysis, Des Plaines, IL) with minor modifications</p> <p>Criteria for scoring were established before performing FISH assays. The samples in this study had fewer readable cells, thus the cutoff was more conservative. Cases were classified as translocation-positive if more than 30% of cells showed abnormal signal patterns. For each sample, a minimum of 25 non-overlapping lymphocytes with complete FISH signals were scored; samples with fewer than 25 readable cells were not classified. A complete FISH signal was defined as one that included the full set of orange, green or fusion signals expected in a positive or negative cell. Samples in which the quality of the sample or the strength of the FISH signals were inadequate to reliably identify positive cells (i.e. samples that did not include at least 25 cells that could be scored) were classified as unreadable for the assay.</p> <p>Assays were scored by two investigators. Concordance between the independent scores was 72% (121/169), including 9 cases that were classified as unreadable by both scorers. Discordant cases included sections that were classified as</p>	<p>t(14;18)-PCR Assays were performed on DNA extracted from 10-µm sections cut from archival tumour blocks. Negative samples were subjected to a second PCR reaction with the IGH consensus primer and a second BCL2 primer 360 base pairs upstream of the MBR primer.</p> <p>57 samples that were HBB-negative were classified as inadequate for PCR.</p>	<p>No information was provided concerning when each test was conducted.</p>

Non Hodgkin's lymphoma: diagnosis and management

				unreadable by only one scorer (26 cases). Discordant cases were subsequently reviewed and assigned a consensus score when possible, resulting in 152 successfully classified cases							
Design, period	Retrospective review 1980-1983	<i>Was a consecutive or random sample of patients enrolled?</i>	No	<i>Were the index test results interpreted without knowledge of the results of the reference standard?</i>	Unclear	<i>Is the reference standard likely to correctly classify the target condition?</i>	Yes	<i>Was there an appropriate interval between index test(s) and reference standard?</i>	Unclear		
N	227/248	<i>Was a case-control design avoided?</i>	Yes	<i>If a threshold was used, was it pre-specified?</i>	Yes	<i>Were the reference results interpreted without knowledge of the results of the index test?</i>	Unclear	<i>Did all patients receive a reference standard?</i>	No 57 samples that were HBB-negative were classified as inadequate for PCR.		
Follow-up	Not reported	<i>Did the study avoid inappropriate exclusions?</i>	Unclear					<i>Did all patients receive the same reference standard?</i>	Yes

Non Hodgkin's lymphoma: diagnosis and management

Lynnhtun, K et al. "Detection of MYC rearrangement in high grade B cell lymphomas: correlation of MYC immunohistochemistry and FISH analysis". Pathology (2014) 46(3): 211-215									
Pub year: 2014		Patient selection		Index test		Reference standard		Flow and timing	
Country	Australia	<p><i>Inclusion criteria:</i> All patients with sufficient materials for both immunohistochemical staining and FISH testing in the same block.</p> <p>37/41 came from archives of the Anatomical Pathology Department, ICPMR, Westmead hospital, Sydney, Australia</p> <p>4/41 referral cases</p> <p>Age range: 29-90 years</p> <p>WHO 2008 diagnostic criteria</p>		<p>FISH</p> <p>MYC rearrangement in 25 cases during diagnostic work-up. Remaining 16 cases sent to another lab. Using 4µm sections from the formalin fixed paraffin embedded (FFPE) tissue blocks, each case was analysed by FOSH using commercial dual-coloured MYC break apart rearrangement, IGH@-MYC dual-coloured dual fusion translocation and IGH/Bcl-2 dual-coloured dual fusion translocation probes (Abbott Molecular, USA) according to the manufacturer's instructions.</p>		<p>IHC</p> <p>Sections 4µm thick were prepared from FFPE blocks for each case, IHC for MYC protein was performed using a fully automated BenchMark Ultra immunostainer (Ventana Medical Systems, USA). Individual cases were stained as routine diagnostic cases following the manufacturer's protocol. The same image of each case was evaluated by two observers independently who were blinded to all the clinical histological, immunohistochemical and FISH results</p>		Index test and reference standard conducted independently	
Design, period	Retrospective review No time period reported	<i>Was a consecutive or random sample of patients enrolled?</i>	No	<i>Were the index test results interpreted without knowledge of the results of the reference standard?</i>	Yes	<i>Is the reference standard likely to correctly classify the target condition?</i>	Yes	<i>Was there an appropriate interval between index test(s) and reference standard?</i>	Yes
N	41	<i>Was a case-control design avoided?</i>	Yes	<i>If a threshold was used, was it pre-specified?</i>	Yes	<i>Were the reference results interpreted without knowledge of the results of the index test?</i>	Yes	<i>Did all patients receive a reference standard?</i>	Yes
Follow-up	Not reported	<i>Did the study avoid inappropriate exclusions?</i>	Unclear					<i>Did all patients receive the same reference standard?</i>	Yes
		<i>Could the selection of patients have introduced bias?</i>	Unclear	<i>Could the conduct or interpretation of the index test have introduced bias?</i>	Low	<i>Were all patients included in the analysis?</i>	Yes		
Funding source	Financial support of staff specialist private practice trust fund. No conflicts of interest.	<i>Are there concerns that the included patients do not match the review question?</i>	Low	<i>Are there concerns that the index test, its conduct, or interpretation differ from the review question?</i>	Low	<i>Are there concerns that the target condition as defined by the reference standard does not match the review question?</i>	Low	<i>Could the patient flow have introduced bias?</i>	Low
Results	The two independent observers were concordant in MYC immunohistochemical staining in all 41 cases, although they were initially discrepant scores in four cases, three of which became concordant in recounting and one of which required simultaneous review of both observers. These four cases had 40% or less MYC positivity.

Non Hodgkin's lymphoma: diagnosis and management

Mationg-Kalaw, E et al. "Does the proliferation fraction help identify mature B cell lymphomas with double and triple-hit translocations?" Histopathology (2012) 61:1214-1218.											
Pub year: 2012		Patient selection			Index test		Reference standard		Flow and timing		
Country	Singapore	<i>Inclusion criteria:</i> MYC+ double/triple-hit lymphomas Sample: 492 cases of DLBCL, grey-zone lymphomas and BL taken from archives at Singapore General hospital – 40 cases of BL identified, of which sufficient material was available in 28 cases for both immunohistochemistry and complete FISH analysis. All cases tested displayed a high proliferation fraction of >95% and possessed C-MYC translocation to an immunoglobulin gene. – Of all cases of DLBCL, 46 showed double or triple translocations in addition to IGH. 28/46 showed C-MYC translocations			Pathological review		Ki67 Immunohistochemistry and FISH		To assess the degree of inter- and intraobserver error, Ki67 staining in 121 cases was graded independently by two pathologists. To assess the degree of intraobserver agreement, the same cases were re-assessed by the study pathologist more than 3 months apart, blinded to results of the previous assessment.		
Design, period	Retrospective review 2004-2011	<i>Was a consecutive or random sample of patients enrolled?</i>	No	<i>Were the index test results interpreted without knowledge of the results of the reference standard?</i>	Yes	<i>Is the reference standard likely to correctly classify the target condition?</i>	Yes	<i>Was there an appropriate interval between index test(s) and reference standard?</i>	Yes		
N	28/40	<i>Was a case-control design avoided?</i>	Yes	<i>If a threshold was used, was it pre-specified?</i>	Yes	<i>Were the reference results interpreted without knowledge of the results of the index test?</i>	Yes	<i>Did all patients receive a reference standard?</i>	No 40 cases of BL, sufficient material available in 28 cases for both immunohistochemistry and FISH		
Follow-up	Not reported	<i>Did the study avoid inappropriate exclusions?</i>	Unclear					<i>Did all patients receive the same reference standard?</i>	Yes		
		<i>Could the selection of patients have introduced bias?</i>	Unclear	<i>Could the conduct or interpretation of the index test have introduced bias?</i>	Low	<i>Could the reference standard, its conduct, or its interpretation have introduced bias?</i>	Low	<i>Were all patients included in the analysis?</i>	Unclear. 121/492 underwent the observer agreement check		
Funding source	National MRC of Singapore & the Major John Long Trust Fund & the Chew Woon Poh Trust Fund	<i>Are there concerns that the included patients do not match the review question?</i>	Low	<i>Are there concerns that the index test, its conduct, or interpretation differ from the review question?</i>	Low	<i>Are there concerns that the target condition as defined by the reference standard does not match the review question?</i>	Low	<i>Could the patient flow have introduced bias?</i>	Unclear		
Results	Table 1.										
	Total N			Sensitivity		Specificity					
	Proliferation fraction cut-off >75% to predict MYC+ double/hit lymphomas			77		36					
	Proliferation fraction cut-off >90% to predict MYC+ double/hit lymphomas			62		54					
	Interobserver agreement was 90.5% with a weighted kappa value of 0.677, indicating good agreement (according to author). The percentage of intraobserver agreement was 83.26% with a weighted kappa statistic of 0.386.										
Table 2. Creation of 2x2 table from data provided in the article.

Non Hodgkin's lymphoma: diagnosis and management

Comments	Notes

Non Hodgkin's lymphoma: diagnosis and management

Zeppa, P et al. "Immunoglobulin heavy-chain fluorescence in situ hybridization-chromogenic in situ hybridization DNA probe split signal in the clonality assessment of lymphoproliferative processes on cytological samples". *Cancer Cytopathology* (2012) 25:390-400.

Pub year: 2012		Patient selection		Index test		Reference standard		Flow and timing			
Country	Italy	Consecutive cytological samples of lymphoproliferative processes were collected from the university of Naples during a 10 month period. The series included mainly specimens of lymph nodes and extranodal lymphoproliferative processes. Obtained by FNC, as well as effusions suspected to be lymphoproliferative processes. In 30 cases (in which it was possible) an additional pass was performed and suspended in RNAlater to be used for PCR <i>Exclusion:</i> 3 cases of HL and 2 cases of PTCL excluded. 25 men 23 women Age range: 23-86		FISH – According to the manufacturer's indications, cases in which >10% of the counted nuclei demonstrated split signals were considered to be positive CISH – Signal was scored according to the guidelines provided with the IGH FISH-CISH DNA probe PCR – Defined PCR result as positive when 2 of 3 framework-amplified regions demonstrated a monoclonal pattern		Histology and follow-up were checked at the time of the study by reviewing the former and subsequent histological diagnoses, which were all confirmed by 2 authors		The study did not influence patient management because all the necessary tests were performed routinely			
Design, period	2010-2011	<i>Was a consecutive or random sample of patients enrolled?</i>	Yes	<i>Were the index test results interpreted without knowledge of the results of the reference standard?</i>	Unclear	<i>Is the reference standard likely to correctly classify the target condition?</i>	Yes	<i>Was there an appropriate interval between index test(s) and reference standard?</i>	Yes		
N	50 cases from 48 patients	<i>Was a case-control design avoided?</i>	Yes	<i>If a threshold was used, was it pre-specified?</i>	Yes	<i>Were the reference results interpreted without knowledge of the results of the index test?</i>	Yes	<i>Did all patients receive a reference standard?</i>	Yes

2.2.2: Review question: What is the most effective genomic/phenotypic testing strategy to determine therapeutic stratification and prognostic subtypes of aggressive b-cell non-Hodgkin's lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) presenting with new diffuse large b-cell lymphoma.	Gene expression profiling Patterns of genes/genes in list form Flourescence in situ hybridisation (FISH) Realtime PCR DNA sequencing Immunohistochemistry	Standard procedure (International Prognostic Index [IPI], stage, age)	Prediction of survival (Overall/progression-free survival) Health-related quality of life Turnaround time for test

Additional Comments on PICO

Present outcomes by aggressive b-cell NHL malignancy subtypes included in scope
 Make note of different platforms used in the gene expression (illumina, affymetrix, agilent)
 GDG6: 06.11.14
 Following on from the discussions and draft recommendations made for topic D1, the GDG proposed to the following additional inclusion criteria to be applied during sifting to ensure that the evidence appraised is appropriate to the proposed question:
 Patients with diffuse large B-cell lymphoma
 Sample size ≥100 (chosen for practical reasons due to the large volume of small observational studies)
 Conference abstracts ≤3 years since publication (GDG reasoned that most abstracts who make to full publication will have done so within by 3 years)
 Reported patient characteristics need to include the component parts of the International Prognostic Index (IPI)
 Subgroup email communication December 2014:
 Following on from screening the search, MSH confirmed with the subgroup that the target comparisons are GCB v non-GCB; GCb v ABC v Type 3; MYC translocation v MYC no translocation; BCL2 translocation v BCL2 no translocation; BCL6 translocation v BCL6 no translocation, and that this is limited to patients who have been treated with rituximab (phone conversation with AJ on 8/12/14). That means that gene (protein) expression results are not included and neither are results on double-hit lymphomas.
 It was not feasible to undertake any meta-analyses due to the between-study variation in terms of which covariates the reported multivariate estimates were adjusted for.
 Following discussion at the GDG meeting, 26.01.2015, it was decided to also look at the following comparisons:
 - patients with MYC translocation versus patients with a MYC translocation AND a BCL2/T(14,18)/18q21 translocation (Double hit)

- patients with MYC translocation versus patients with a MYC translocation AND a BCL6/3q27 translocation (Double hit)
- patients with MYC translocation versus patients with a MYC translocation AND a BCL2/T(14,18)/18q21 translocation AND a BCL6/3q27 translocation (Triple hit)

Evidence Quality

Figure 1. Study flow diagram

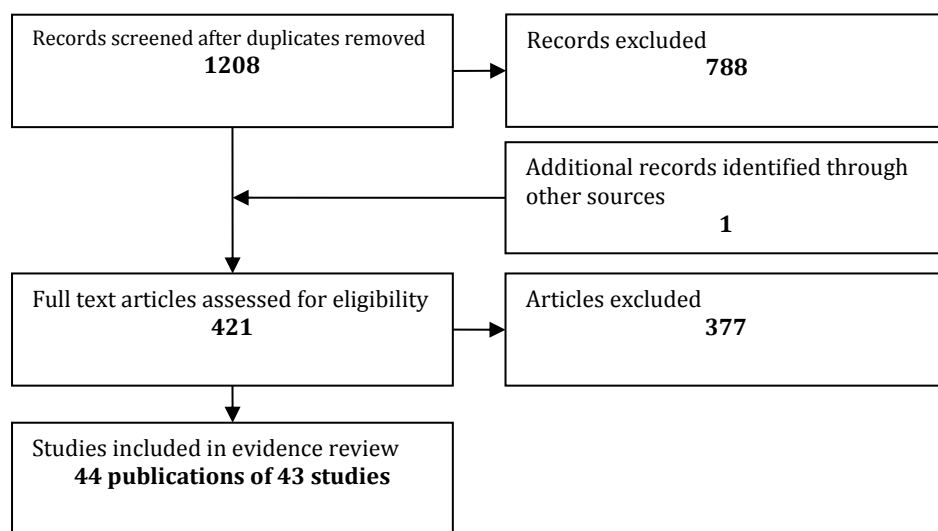

Table 17 lists the risk of bias associated with each of the included studies. The main challenges to the validity of the evidence as a whole concerned (1) missing data and the risk that these were not missing at random in a number of the studies, (2) the failure to control for age by including it as a separate covariate rather than just incorporated into the IPI risk scores in a number of the studies that performed multivariate analyses, and (3) the fact that a number of the studies appeared to be subject to commercial funding. All these three factors may influence the result in a number of ways that are difficult to predict, other than, conceivably, that the absence of age as a covariate may inflate the estimated influence of the variables under investigation, although even this is only a hypothesis.

Evidence Statements

43 studies provided evidence about the prognostic value of molecular diagnostics in people with high grade B-cell lymphoma.

GCB versus non-GCB: IHC (Hans)

Moderate quality evidence from 22 studies (n=5065 patients) reported overall survival does not differ between patients with GCB and non-GCB DLBCL subtype, although two additional studies suggest that overall survival may be inferior in patients with non-GCB (Molina, 2012, 2013; Mitrovic, 2013; n = 776; reported HRs ranged from 1.9-2; low quality). Progression-free survival (17 studies; n = 3177; moderate quality) does not differ between patients with GCB and non-GCB DLBCL subtype, although one additional study suggest that progression-free survival may be inferior in patients with non-GCB (Molina, 2012, 2013; n = 640; HR = 1.9; low quality).

GCB versus non-GCB/ABC: IHC (Choi)

Moderate quality evidence from 12 studies (n=1804 patients) reported overall survival does not differ between patients with GCB and non-GCB DLBCL subtype, although low quality evidence from one additional study suggest that overall survival may be inferior in patients with non-GCB (Perry, 2014 validation set; n = 215; reported HRs ranged from 2.07-2.14).

Moderate quality evidence from 9 studies (n=1396 patients) reported similar progression/event-free survival is either similar between patients with GCB and non-GCB/ABC DLBCL while low to moderate quality evidence from 3 studies (n=592 patients) reported lower progression/event free survival in patients with the non-GCB/ABC DLBCL subtype (HRs ranged from 2-2.27).

GCB versus non-GCB: IHC (Visco-Young)

Five studies (n=1127 patients) provided low quality evidence that overall survival is either similar between patients with GCB and non-GCB DLBCL (4 studies; n = 652) or inferior in patients with the non-GCB DLBCL subtype (1 study; n = 475; HR = 0.56). Four studies (n=1187 patients) provided low quality evidence that progression-free survival is either similar between patients with GCB and non-GCB DLBCL (3 studies; n = 475) or inferior in patients with the non-GCB DLBCL subtype (1 study; n = 712; HRs ranged from 0.59-0.63).

GCB versus non-GCB: IHC (other algorithms than Hans, Choi and Visco-Young)

Twelve studies (n=2051 patients) provided low-moderate quality evidence that overall survival does not differ between patients with GCB and non-GCB/ABC DLBCL.

Eight studies (n=1173 patients) provided low to moderate quality evidence that progression-free survival does not differ between patients with GCB and non-GCB/ABC DLBCL.

GCB versus ABC/non-GCB: GEP with/without IHC

Low to moderate quality evidence from 6 studies (n=1573 patients) reported that overall survival is similar between patients with GCB and non-GCB/ABC DLBCL while five studies (n=1768 patients) provided low to moderate quality evidence that overall survival was inferior in patients with the non-GCB/ABC DLBCL subtype (reported HRs ranged from 0.53-2.1 [these span 0 as different reference groups are used]). There was large patient overlap between these studies. Progression-free survival is either similar between patients with GCB and non-GCB/ABC DLBCL (4 studies; n = 1488; low-moderate quality) or inferior in patients with the ABC DLBCL subtype (4 studies; n = 1577; HRs ranged from 0.63-2.6 [these span 0 as different reference groups are used]; low-moderate quality).

MYC translocation

Seven studies (n=1821 patients) provided low to moderate quality evidence that overall survival is either similar between patients with and without *MYC* translocation while 4 studies (n=1066) provided low to

moderate quality evidence that overall survival was inferior in patients with *MYC* translocation (reported HRs ranged from 1.68-4.87). Progression-free survival (9 studies; n = 1967; low-moderate quality) does not differ between patients with and without *MYC* translocation (as assessed by FISH), although one additional study found inferior progression-free survival in patients with *MYC* translocation (Kojima, 2013; n = 100; HR = 2.717; unclear quality).

No evidence was found for the following comparisons:

patients with *MYC* translocation versus patients with a *MYC* translocation AND a *BCL2/T(14,18)/18q21* translocation (Double hit)

patients with *MYC* translocation versus patients with a *MYC* translocation AND a *BCL6/3q27* translocation (Double hit)

patients with *MYC* translocation versus patients with a *MYC* translocation AND a *BCL2/T(14,18)/18q21* translocation AND a *BCL6/3q27* translocation (Triple hit)

***BCL2* translocation**

Low to moderate quality evidence from nine studies (n=2139 patients) reported no difference in overall survival and from eight studies (n=1771 patients) reported no difference in progression-free survival between patients with and without *BCL2* translocation (as assessed by FISH), although one additional study may have found inferior overall survival in patients with *BCL2* translocation (Horn, Ziepert, Bart *et al.*, 2013; n = 112; unclear quality).

***BCL6* translocation**

Low to moderate quality evidence from seven studies (n=1982 patients) showed no difference in overall survival while low to moderate quality evidence from four studies (n=1247 patients) showed no difference in progression-free survival between patients with and without *BCL6* translocation (as assessed by FISH).

Turnaround time of the test

One study reported that the turnaround time of the GEP testing strategy employed was less than 1 day and repeated testing of up to 40 patients in parallel was possible (Rumimy, 2013; n = 141; unclear quality).

Health-related quality of life

No studies were identified that reported health-related quality of life.

Evidence Tables

<p>Study, country: Akyurek (2012), Turkey</p>
<p>Study type, study period: Observational retrospective study, 2001-2009</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): N = 145 (69 males / 76 females) patients diagnosed according to the WHO (2008) criteria who had been uniformly treated with R-CHOP and had FISH< clinical and follow-up data available.</p> <p>IPI characteristics: - Age: Median (range) = 56 (17-95) years; < 60 years: N = 87; ≥ 60 years: N = 58. - Performance status: Not reported - Stage: I-II: N = 53; III-IV: N = 67; Not known: N = 20 - LDH: Not reported - Extra-nodal status: Nodal: N = 88; Extranodal: N = 57 IPI score: 0-2: N = 64; 3-5: N = 35; Not known: N = 46 Treatment: R-CHOP Exclusions: Burkitt lymphoma.</p>
<p>Prognostic variables, including methods of classification: - IHC; Hans algorithm; GCB (N = 68) versus non-GCC (N = 77); - FISH; MYC normal (N = 134) versus rearranged (N = 11); - FISH; BCL2 normal (N = 121) versus rearranged (N = 24) - FISH; BCL6 normal (N = 103) versus rearranged (N = 42)</p>
<p>Results: Overall survival: Not reported Progression-free survival: Not reported Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: Not reported - OS: GCB = non-GCB, p = 0.3 - PFS: GCB = non-GCB, p = 0.1 - OS: MYC normal > rearranged, p = 0.01 - PFS: MYC normal = rearranged, p = 0.1 - OS: BCL2 normal = rearranged, p = 0.2 - PFS: BCL2 normal = rearranged, p = 0.4 - OS: BCL6 normal > rearranged, p = 0.04 - PFS: BCL normal = rearranged, p = 0.1 Multivariate analysis (controlling for IPI and stage, and inputting MYC, and BCL6 too): - OS: MYC normal > rearranged, p < 0.02 favouring normal. IPI also significant. - OS: BCL6 normal = rearranged; not significant.</p>
<p>Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N - age not separated out from IPI in multivariate analyses - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y</p>
<p>Additional comments (including funding): It is unclear if study subject to commercial funding</p>

<p>Study, country: Barrans (2010), UK</p>
<p>Study type, study period: Observational retrospective study, 2003-2006</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): N = 303 (156 males / 147 females) previously untreated patients diagnosed according to the WHO (2008) criteria (FFPE biopsies obtained from a population-based cohort of subsequently R-CHOP-treated DLBCL patients).</p> <p>IPI characteristics:</p> <ul style="list-style-type: none"> - Age: Median (range) = 71.1 (23.6-96.3) years. - Performance status: Not reported - Stage: I: N = 64; II: N = 62; III: N = 51; IV: N = 91; Not known: N = 36 - LDH: Not reported - Extra-nodal status: Not reported <p>IPI score: Low (0, 1): N = 74; Intermediate (2, 3): N = 155; High (4): N = 47; Not known: N = 27</p> <p>Treatment: R-CHOP</p> <p>Exclusions: Burkitt lymphoma, those with underlying indolent lymphoma, human immunodeficiency virus, primary central nervous system disease, or cases with insufficient tissue.</p>
<p>Prognostic variables, including methods of classification:</p> <ul style="list-style-type: none"> - IHC; Hans algorithm; GCB (N = 126) versus non-GCC (N = 141; not known: N = 36)*; - FISH; MYC normal (N = 210) versus rearranged (N = 35; not known: N = 58); - FISH; T(14;18)/BCL2 normal (N = 183) versus rearranged (N = 81; not known: N = 39)* - FISH; BCL6 normal (N = 188) versus rearranged (N = 74; not known: N = 41) <p>*Please note: "In order to eliminate the problem of collinear covariates, the GC and t(14;18) were combined into a single variable, TGC, which was defined as = 2 for patients with a t(14;18)[translocated]; 1 in subjects for whom GC = 0[non-GC] and t(14;18) = 0[normal]; and 0 where GC = 1[GC] and t(14;18) = 0."</p>
<p>Results:</p> <p>Overall survival: 3-year = 49% (95% CI 42%-56%)</p> <p>Progression-free survival: Not reported in multivariate analysis.</p> <p>Health-related quality of life: Outcome not reported</p> <p>Turnaround time for the test: Outcome not reported</p> <p>Univariate analysis: Not reported</p> <p>Multivariate analysis (controlling for age, sex, IPI with age removed, BCL2 expression, FOXP1 expression, TP53 status):</p> <p><i>Two analyses were conducted to examine the effect of missing data, one analysis based on the complete data records and a second analysis based on multiple imputation of the missing data (using the technique of multiple imputation by chained equations with a logarithmic transform of the survival time):</i></p> <p><u>Complete data:</u></p> <ul style="list-style-type: none"> - OS: MYC translocation (relative to normal): HR = 2.03 (95% CI 1.15-3.58; significant) favouring normal. Age and age-removed IPI were also significant. BCL6 normal/translocation and the 'GCB/non-GCB-T(14;18) normal/translocated' combined variable were not significant. Please note, this latter result is only summarized in the table listing the results for overall survival for studies of IHC using the Hans algorithm (Table 1) and not in the table listing the BCL2 results for overall survival to avoid double counting these data (Table 13). <p><u>Multiple imputation data:</u></p> <ul style="list-style-type: none"> - OS: MYC translocation (relative to normal): HR = 1.68 (95% CI 1.05-2.69; significant) favouring normal. Age and age-removed IPI were also significant. BCL6 normal/translocation and the 'GCB/non-GCB-T(14;18) normal/translocated' combined variable were not significant. Please note, this latter result is only summarized in the table listing the results for overall survival for studies of IHC using the Hans algorithm (Table 1) and not in the table listing the BCL2 results for overall survival to avoid double counting these data (Table 13).

Risks of bias (answer yes [Y], no [N] or unclear to each question):

- The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y
- Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y
- The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? Y (age separated out from IPI in multivariate analyses)
- The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Additional comments (including funding): Data from 140/303 also included in Barrans (2012)

Funded by: Leukaemia Research Fund.

<p>Study, country: Barrans (2012), UK</p>
<p>Study type, study period: Observational retrospective study, study years not reported</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): N = 140 (88 males / 52 females) previously untreated patients diagnosed according to the WHO (2008) criteria: 303 FFPE biopsies obtained from a population-based cohort of R-CHOP-treated DLBCL (Barrans, 2010); 206/303 had sufficient tissue remaining for further studies; 187/206 yielded sufficient RNA for GEP analysis; 172/187 satisfied quality control criteria; 140/172 were treated with R-CHOP with curative intent and included here.</p> <p>IPI characteristics:</p> <ul style="list-style-type: none"> - Age: Mean (range) = 66.8 (23.6-91) years. - Performance status: Not reported - Stage: I: N = 31; II: N = 25; III: N = 31; IV: N = 39 - LDH: Not reported - Extra-nodal status: Not reported <p>IPI score: Low (1): N = 40; Intermediate (2, 3): N = 67; High (4): N = 20; Not known: N = 13</p> <p>Treatment: R-CHOP with curative intent (at least 6 courses, with CNS prophylaxis and radiotherapy as clinically indicated)</p> <p>Exclusions: Burkitt lymphoma, mediastinal large B-cell lymphomas, those with underlying indolent lymphoma, human immunodeficiency virus, or primary central nervous system disease.</p>
<p>Prognostic variables, including methods of classification: Gene Expression Profiling</p> <p>Illumina WG-DASL assay, performed according to Illumina protocols using 200ng total RNA, and HumanRef-8 V3 arrays. Arrays were scanned on a BeadArray reader, data processed using GenomeStudio (Illumina United Kingdom). The DLBCL Automatic Classifier (DAC) was used. "Using the Weka package, four decision-tree machine-learning tools (LMT, J48 and RandomForest with 100/200 trees) were trained on the LLMPP data and combined into the DAC using the Vote scheme with average probabilities..... Three classes were assigned (ABC, GCB or Type-III) along with corresponding confidence values for each class, for each sample. The confidence values for each class were generated as fractions, together totaling 1, and a high confidence dataset was generated by selecting all cases in which the selected class predictions had a value of >0.5 (n = 145)."</p> <p>- GCB (N = 82) versus ABC (N = 53) versus Type 3 (N = 37, <i>Please note these numbers includes the 172 patients for whom GEP could be undertaken, however, the results reported below only includes the 140/172 patients who received rituximab with curative intent</i>)</p>
<p>Results:</p> <p>Overall survival: Median = 4.7 years (<i>please note these numbers includes the 172 patients for whom GEP could be undertaken, however, the results reported below only includes the 140/172 patients who received rituximab with curative intent</i>)</p> <p>Progression-free survival: Not reported in multivariate analysis.</p> <p>Health-related quality of life: Outcome not reported</p> <p>Turnaround time for the test: Outcome not reported</p> <p>Univariate analysis:</p> <ul style="list-style-type: none"> - OS: HR for GCB relative to ABC = 0.57 (95% CI 0.33-0.99; p = 0.044) favouring GCB - OS: HR for Type III relative to ABC = 0.31 (95% CI 0.14-0.69; p = 0.0041) favouring Type III <p>Multivariate analysis (controlling for age, sex, and IPI with age removed):</p> <p><u>Full data:</u></p> <ul style="list-style-type: none"> - OS: GCB (relative to ABC): HR = 0.58 (95% CI 0.34-0.99; p = 0.047) favouring GCB - OS: Type III (relative to ABC): HR = 0.35 (95% CI 0.16-0.78; p = 0.011) favouring Type III. Study, country: Copie-Bergman (2012), France
Study type, study period: Observational retrospective study, study years not reported
Patients, number and characteristics (including diagnostic criteria, if reported): 576 (gender not reported) patients with de novo CD20+ DLBCL (diagnostic criteria not reported) enrolled in the randomized GELA trials (LNH-03-1B, -2B, -3B, -39B, -6B, -7B, -5B) who had been treated with rituximab-chemotherapy. IPI characteristics: - Age: Not reported - Performance status: Not reported - Stage: Not reported - LDH: Not reported - Extra-nodal status: Not reported IPI score: Not reported Treatment: R-CHOP/R-miniCHOP, R-ACVBP Exclusions: Not reported.
Prognostic variables, including methods of classification: - FISH; MYC normal versus translocation (N = 53/576) – Of these N = 53, 21 had simple-hit MYC translocations (MYC-SH) and 32 had double or triple –hit translocations with concurrent BCL2 and/or BCL6 rearrangements (MYC-DH) - FISH; BCL2 normal versus translocation (N = 82/515) - FISH; BCL6 normal versus translocation (N = 129/541)
Results: Overall survival: Not reported Progression-free survival: Not reported Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: - OS 5-year: MYC normal (73.7%) > rearranged (57.7%), significant - OS 5-year, R-CHOP treated patients only: MYC normal > rearranged, p = 0.04 --- When separating MYC-SH and MYC-DH, MYC-SH < normal, whereas MYC-DH = normal; both in all patients and in R-CHOP treated patients only. - PFS, EFS: Not reported for MYC normal/rearranged - OS, PFS, EFS: BCL2 normal = rearranged, non-significant - OS, PFS, EFS: BCL6 normal = rearranged, non-significant Multivariate analysis (controlling at least for IPI [unclear whether “IPI” means IPI score or the constituent parts of IPI, but probably IPI score] and possibly also MYC simple/double hit [unclear if this has been added to the same analyses as MYC normal/rearrangement overall]): - “In multivariate analysis, the prognostic impact of the IPI, MYC-R+ [rearrangement] and MYC-SH [simple hit] breakpoint remained significant” No further details reported.
Risks of bias (answer yes [tytY], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Unclear why data only available for 515-576/766 patients. - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? Unclear - age does not appear to be separated out from IPI in multivariate analyses. - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
Additional comments (including funding): Unclear if study is subject to commercial funding. Published as abstract only. Patients appear to be the same as those included in Molina (2012, 2013) and Jardin (2012).

Multivariate analysis (controlling for IPI and IHC algorithms predictive in univariate analyses [as detailed above]):

- OS: Significant effect of IPI, but not of Hans, Hans* or Muris algorithms.
- PFS: Significant effect of IPI, but not of Hans, Hans*, Muris, Choi, Choi* or Tally algorithms.

Risks of bias (answer yes [Y], no [N] or unclear to each question):

- The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y
- Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y
- The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N, age not separated out from IPI in multivariate analyses
- The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Additional comments (including funding): It is unclear if study is subject to commercial funding.

<p>Study, country: Cunningham (2013), UK</p>
<p>Study type, study period: Observational prospective study, 2005-208</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): 1080 (582 males / 498 females) patients with previously untreated, histologically confirmed, Ann Arbor bulky stage 1A (tumour mass diameter > 10 cm) or stage 1B-IV, DLBCL (according to WHO classification) aged ≥ 18 years a good performance status (WHO grade 0-2), adequate cardiac, renal, hepatic, and haematological function (initial neutrophil count >1.5 × 10⁹ per L, initial platelet count >100 × 10⁹ per L unless the abnormality was caused by lymphoma rather than another disease in which case the patient was eligible), and who were treated with R-CHOP with curative intent. Patients with previously undiagnosed concurrent small-cell infiltration in bone marrow or lymph node were eligible.</p> <p>IPI characteristics:</p> <ul style="list-style-type: none"> - Age: Median (range) = 61 (19-88) years - Performance status (WHO): 0: N = 544; 1: N = 392; 2: N = 144 - Stage: Bulky IA: N = 46; IB: N = 33; II: N = 323; III: N = 317; IV: N = 355 - LDH: Elevated: N = 701 - Extra-nodal: Not reported <p>IPI score: 0: N = 83; 1: N = 233; 2: N = 306; 3: N = 279; 4: N = 154; 5: N = 25.</p> <p>Treatment: R-CHOP with curative intent.</p> <p>Exclusions: Patients with T-cell lymphomas, transformed follicular lymphoma, a history of indolent lymphoma, CNS involvement, positive serology for HIV, hepatitis B or hepatitis C virus, a history of heart failure or uncontrolled angina pectoris, active malignancy in the preceding 10 years, or other illnesses precluding administration of study treatment.</p>
<p>Prognostic variables, including methods of classification:</p> <ul style="list-style-type: none"> - IHC; Hans algorithm; GCB (N = 289) versus non-GCB-like (N = 271) - FISH; BCL2 normal (N = 278) versus rearrangement (N = 90) - FISH; BCL6 normal (N = 285) versus rearrangement (N = 76) - FISH; MYC normal (N = 323) versus rearrangement (N = 36) – 16 patients had double-hit mutations defined as both MYC and BCL2 rearrangements.
<p>Results:</p> <p>Overall survival: 2-year = 80.8% (77.5-84.2) – 82.7% (79.5-85.9)</p> <p>Progression-free survival: Outcome not reported</p> <p>Health-related quality of life: Outcome not reported</p> <p>Turnaround time for the test: Outcome not reported</p> <p>Univariate analysis:</p> <ul style="list-style-type: none"> - OS: Hans; GCB = non-GCB-like - OS: BCL2; normal = rearrangement - OS: BCL6; normal = rearrangement - OS: MYC; normal (85%, 95% CI 80.7-88.6) > rearrangement (75%; 95% CI 60.7-89); HR = 2.08 (95% CI 1.15-3.78), p = 0.016. - OS: double-hit MYC/BCL2 (63%, 95% CI 38.8-86.1) = non-double-hit (84%; 95% CI 80.5-88.3); HR = 2.24 (95% CI 0.98-5.17), p = 0.0575. <p>Multivariate analysis (controlling for age, sex, stage, B symptoms, bulky disease, performance status, LDH):</p> <ul style="list-style-type: none"> - OS: MYC; normal = rearrangement; HR = 1.71 (95% CI 0.92-3.18), p = 0.0875. - OS: Double-hit MYC/BCL; double-hit = non-double-hit; HR = 2.03 (95% CI 0.87-4.73), p = 0.1023.
<p>Risks of bias (answer yes [Y], no [N] or unclear to each question):</p> <ul style="list-style-type: none"> - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Unclear why data only available for 359-560/1080 patients - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? Y, age separated out from IPI in multivariate analyses - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
<p>Additional comments (including funding): The study is subject to commercial funding, but the funder had no part in any of the study aspects.</p>

<p>Additional comments (including funding): Study published in abstract only. Unclear if study is subject to commercial funding.</p>

<p>Study, country: Hu (2013), various countries</p>
<p>Study type, study period: Observational retrospective? study, study years not reported</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): 461 (270 males / 191 females) patients with de novo DLBCL (diagnosed according to WHO [year not reported] criteria, organised as part of the International DLBCL Rituximab-CHOP Consortium program study.</p> <p>IPI characteristics (not all data available for all patients):</p> <ul style="list-style-type: none"> - Age: Median (range) = 64 (16-92) years; ≤ 60 years: N = 188; > 60 years: N = 273 - Performance status (ECOG): < 2: N = 344; ≥ 2: N = 51 - Stage: I-II: N = 207; III-IV: N = 236 - LDH: Normal: N = 160; Elevated: N = 253 - Extra-nodal status: < 2 sites: N = 341; ≥ 2 sites: N = 96 <p>IPI risk group: 0-2: N = 263; 3-5: N = 148</p> <p>Treatment: R-CHOP.</p> <p>Exclusions: History of low-grade B-cell lymphoma, HIV/AIDS infection, primary cutaneous DLBCL, primary CNS DLBCL, primary mediastinal b-cell lymphoma and Epstein-Barr virus-positive DLBCL. Cases with unknown CD30 expression status (owing to tissue exhaustion in the TMA, N = 11) were also excluded.</p>
<p>Prognostic variables, including methods of classification: GEP + IHC, with GEP results considered gold standard.</p> <p>- GEP: "For data analysis and classification, the microarray DQN signals were generated and normalized to the quantiles of β distribution. DQN is an ideal expression algorithm used for expression microarray analysis and represents the non-central trimmed mean of differences between perfect match and mismatch intensities with quantile normalization. A Bayesian model was also used to determine the classification probability [Wright et al., 2003, Proc Natl Acad Sci USA, 100 (17): 9991-9996]. The methodology developed in this study has been validated with the Lymphoma Leukaemia Molecular Profiling Program dataset in the Gene Expression Omnibus Genomic Spatial Event database #10846, which has 181 CHOP-treated and 233 R-CHOP-treated DLBCL patients. We obtained an 80% concordance rate of classification for all classes (GCB, ABC, and unclassified) and a 97% rate for 2 classes (GCB and ABC), if excluding the unclassified. We required a percentage call rate ≥ 12% for the project with a failure rate of 10.64%. The 445 cases with GEP in this study were part of a larger data set on which profiling was successfully performed and validated" (p 2716).</p> <p>- GEP performed in 445/461 patients and classified 407 as GCB or ABC with 38/445 unclassifiable; the GEP classifications for the 407 patients were retained and the 38 unclassifiable cases by GEP as well as the remaining 16 cases for whom GEP was not performed were classified using IHC according to the Visco-Young algorithm; GCB (N = 235) versus ABC (N = 223), the cell of origin was unknown for 3 patients for whom GEP was not done and IHC was not successful due to TMA tissue exhaustion.</p>
<p>Results:</p> <p>Overall survival: Not reported</p> <p>Progression-free survival: Not reported</p> <p>Health-related quality of life: Outcome not reported</p> <p>Turnaround time for the test: Outcome not reported</p> <p>Univariate analysis: None reported</p> <p>Multivariate analysis (controlling for IPI risk group, tumour size [≥ 6 cm], B symptoms, TP53 mutation, and CD30 IHC):</p> <ul style="list-style-type: none"> - OS: HR for ABC (relative to GCB) = 1.56 (95% CI 1.08-2.24), p = 0.0165, favouring GCB. IPI risk score, CD30 IHC and TP53 mutation were also significant. - PFS: HR for ABC (relative to GCB) = 1.54 (95% CI 1.08-2.18), p = 0.0157, favouring GCB. IPI risk score, CD30 IHC and TP53 mutation were also significant.

Risks of bias (answer yes [Y], no [N] or unclear to each question):

- The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y
- Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y
- The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N - age not separated out from IPI in multivariate analyses
- The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Additional comments (including funding): The patients included in this study seem to overlap almost completely with those in Hu, Xu-Monette, Tzankov et al. (2013), Kim (2014), Tzankov (2014), Xu-Monette (2012) and Visco (2012) – they are all part of the the International DLBCL Rituximab-CHOP Consortium program study. Study appears to be subject to some commercial funding.

<p>Study, country: Hu, Xu-Monette, Tzankov, et al (2013), various countries</p>
<p>Study type, study period: Observational retrospective? study, study years not reported</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): 466 (272 males / 194 females) patients with de novo DLBCL (diagnosed according to WHO [year not reported] criteria, organised as part of the International DLBCL Rituximab-CHOP Consortium program study. Only cases with successful MYC and BCL2 staining were included.</p> <p>IPI characteristics (not all data available for all patients):</p> <ul style="list-style-type: none"> - Age: ≤ 60 years: N = 194; > 60 years: N = 272 - Performance status (ECOG): < 2: N = 350; ≥ 2: N = 50 - Stage: I-II: N = 219; III-IV: N = 228 - LDH: Normal: N = 168; Elevated: N = 252 - Extra-nodal status: < 2 sites: N = 346; ≥ 2 sites: N = 96 <p>IPI risk group: 0-2: N = 263; 3-5: N = 148</p> <p>Treatment: R-CHOP.</p> <p>Exclusions: History of low-grade B-cell lymphoma, HIV/AIDS infection, primary cutaneous DLBCL, primary CNS DLBCL, and Epstein-Barr virus-positive DLBCL.</p>
<p>Prognostic variables, including methods of classification: GEP + IHC, with GEP results considered gold standard.</p> <p>- GEP: "For data analysis and classification, the microarray DQN signals were generated and normalized to the quantiles of β distribution with parameters $P = 1.2$ and $q = 3$. DQN is an ideal expression algorithm used for expression microarray analysis and represents the non-central trimmed mean of differences between perfect match and mismatch intensities with quantile normalization. A Bayesian model was also used to determine the classification probability [Wright et al., 2003, Proc Natl Acad Sci USA, 100 (17): 9991-9996]. The GEP classification method developed from this study was validated with an independent Lymphoma Leukaemia Molecular Profiling Program dataset in the Gene Expression Omnibus Genomic Spatial Event database GSE10846.....with 181 CHOP-treated and 233 R-CHOP-treated DLBCL patients and achieved over 97% concordance rate for the classification of 2 subtypes (GCB and ABC)." (p 4024-5).</p> <p>- GEP performed in 451/466 patients and classified 411 as GCB or ABC with 40/411 unclassifiable; the GEP classifications for the 411 patients were retained and the 40 unclassifiable cases by GEP as well as the remaining 15 cases for whom GEP was not performed were classified using IHC according to both the Visco-Young and Choi algorithms; GCB (N = 241) versus ABC (N = 225)</p>
<p>Results:</p> <p>Overall survival: Not reported</p> <p>Progression-free survival: Not reported</p> <p>Health-related quality of life: Outcome not reported</p> <p>Turnaround time for the test: Outcome not reported</p> <p>Univariate analysis:</p> <ul style="list-style-type: none"> - OS: GCB (N = 241) > ABC (N = 225), $p = 0.008$. - PFS: GCB (N = 241) > ABC (N = 225), $p = 0.0075$. <p>Multivariate analysis (controlling for IPI risk group, tumour size [≥ 7.5 cm], B symptoms, TP53 mutation, and MYC/BCL2 coexpression):</p> <ul style="list-style-type: none"> - OS: HR for ABC (relative to GCB) = 1.17 (95% CI 0.79-1.72), $p = 0.4329$. IPI risk score, B symptoms, TP53 mutation and MYC/BCL2 coexpression were significant. - PFS: HR for ABC (relative to GCB) = 1.18 (95% CI 0.82-1.71), $p = 0.375$. IPI risk score, B symptoms, TP53 mutation and MYC/BCL2 coexpression were significant.

Risks of bias (answer yes [Y], no [N] or unclear to each question):

- The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y
- Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y
- The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N - age not separated out from IPI in multivariate analyses
- The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Additional comments (including funding): The patients included in this study seem to overlap almost completely with those in Hu (2013), Tzankov (2014), Xu-Monette (2012), Kim (2014) and Visco (2012) - they are all part of the the International DLBCL Rituximab-CHOP Consortium program study. Study appears to be subject to some commercial funding.

Results:

Overall survival: 5-year: Training set = 64%; validation set = 62%

Progression-free survival: Not reported

Health-related quality of life: Outcome not reported

Turnaround time for the test: Outcome not reported

Univariate analysis:

Training set:

- OS: HR ABC (relative to GCB) = 2.6 (95% CI 1.5-4.6), $p < 0.001$

- PFS: HR ABC (relative to GCB) = 3.1 (95% CI 1.8-5.2), $p < 0.001$

- OS: MYC normal = translocation, $p = 0.07$

- PFS: MYC normal = translocation, $p = 0.06$

- OS: BCL2 normal = translocation, $p = 0.89$

- PFS: BCL2 normal = translocation, $p = 0.74$

Validation set:

- OS: GCB = ABC, $p = 0.18$

- PFS: GCB = ABC, $p = 0.06$

- OS: MYC normal = translocation, $p = 0.19$

- PFS: MYC normal = translocation, $p = 0.19$

- OS: BCL2 normal = translocation, $p = 0.17$

- PFS: BCL2 normal = translocation, $p = 0.07$

Combined population:

- OS: Translocation of MYC and BCL2 (DH): DH (N = 14; 5-year OS = 27%) < 'no double hit and no concurrent MYC and BCL2 protein expression' (N = 236; 5-year OS = 71%); $p < 0.001$; HR = 3.95 (95% CI 2-7.7), $p < 0.004$.

- PFS: Translocation of MYC and BCL2 (DH): DH (N = 14; 5-year PFS = 18%) < 'no double hit and no concurrent MYC and BCL2 protein expression' (N = 236; 5-year PFS = 65%); $p < 0.001$; HR = 4.1 (95% CI 2.1-7.8), $p < 0.004$.

Multivariate analysis (controlling for IPI risk group and MYC/BCL2 expression [MYC-/BCL2- relative to MYC-/BCL2+, MYC+/BCL2-, and MYC+/BCL2+]):

Training set:

- OS: HR for ABC (relative to GCB) = 1.9 (95% CI 1-3.5), $p = 0.04$, favouring GCB. IPI risk score, and MYC+/BCL+ were also significant.

- PFS: HR for ABC (relative to GCB) = 2.2 (95% CI 1.3-4), $p = 0.005$, favouring GCB. IPI risk score was also significant.

Validation set:

- OS: HR for ABC (relative to GCB) = 1 (95% CI 0.9-1.1), $p = 0.66$. IPI risk score was significant.

- PFS: HR for ABC (relative to GCB) = 1 (95% CI 0.9-1.1), $p = 0.62$. IPI risk score was significant.

Multivariate analysis (controlling for IPI risk group and MYC/BCL2 expression [dichotomized into MYC+/BCL2+ coexpression versus all other cases]):

Training set:

- OS: HR for ABC (relative to GCB) = 2.1 (95% CI 1.1-3.8), $p = 0.017$, favouring GCB. IPI risk score, and MYC+/BCL+ were also significant.

- PFS: HR for ABC (relative to GCB) = 2.6 (95% CI 1.5-4.5), $p = 0.001$, favouring GCB. IPI risk score was also significant.

Validation set:

- OS: HR for ABC (relative to GCB) = 1 (95% CI 0.9-1.1), $p = 0.67$. IPI risk score and MYC+/BCL2+ were significant.

- PFS: HR for ABC (relative to GCB) = 1 (95% CI 0.9-1.1), $p = 0.62$. IPI risk score was significant.

Multivariate analysis (controlling for IPI risk group and GCB/ABC subtype):

Combined population:

- OS: Translocation of MYC and BCL2 (DH): DH (N = 14; 5-year OS = 27%) < 'no double hit and no concurrent MYC and BCL2 protein expression' (N = 236; 5-year OS = 71%); HR = 2.7 (95% CI 1.3-5.3), $p < 0.01$.

- PFS: Translocation of MYC and BCL2 (DH): DH (N = 14; 5-year PFS = 18%) < 'no double hit and no concurrent MYC and BCL2 protein expression' (N = 236; 5-year PFS = 65%); HR = 2.8 (95% CI 1.4-5.3), $p < 0.02$.

Risks of bias (answer yes [Y], no [N] or unclear to each question):

- The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y
- Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y
- The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N – age was separated out from IPI in the multivariate analyses
- The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Additional comments (including funding): Subsets of the patients included in the training set in this study are also included in Lenz (2008; N = 158) and Iqbal (2011; N = 167). Study does not appear to be subject to some commercial funding.

Study, country: Kim (2014), Korea
Study type, study period: Observational retrospective study, 2010-2012
Patients, number and characteristics (including diagnostic criteria, if reported): 175 (99 males / 76 females) patients with newly diagnosed DLBCL (according to WHO criteria [year not reported]) without HIV who had been treated with R-CHOP IPI characteristics: - Age: Median (range) = 61 (23-86) years; ≤ 60 years: N = 85; > 60 years: N = 90 - Performance status (ECOG): < 2: N = 147; ≥ 2: N = 28 - Stage: I-II: N = 86; III-IV: N = 89 - LDH: Normal: N = 78; Elevated: N = 97 - Extra-nodal status: < 2 sites: N = 116; ≥ 2 sites: N = 59 IPI score: Low: N = 75; low-intermediate: N = 28; high-intermediate: N = 36; high: N = 36. Treatment: R-CHOP. Exclusions: Primary mediastinal (thymic) DLBCL, primary DLBCL of the CNS, post-transplantation lymphoproliferative disorders and primary cutaneous DLBCL.
Prognostic variables, including methods of classification: - IHC; Hans algorithm; GCB (N = 34) versus non-GCB (N = 96); N = 130/175 evaluable patients
Results: Overall survival: 2-year = 79% Progression-free survival: 2-year = 71.6% Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: - OS: HR for non-GCB (relative to GCB) = 4.97 (95% CI 1.18-20.97), p = 0.029, favouring GCB [I think] - EFS: HR for non-GCB (relative to GCB) = 2.06 (95% CI 0.85-4.94), p = 0.105. Multivariate analysis (controlling for at least IPI score and free light chain): It is unclear which covariates have been entered into these analyses apart from IPI score and free light chain, which were both significant. It is therefore unknown whether GCB/non-GCB was entered, but not significant, or not entered at all, for both OS and EFS.
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Unclear why data only available for 130/175 patients - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? Unclear- see comment above in results section, also unclear whether age was separated out from IPI in multivariate analyses, but probably not. - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
Additional comments (including funding): The patients included in this study seem to overlap almost completely with those in Hu (2013), Xu-Monette (2012), Hu, Xu-Monette, Tzankov et al. (2013), Tzankov (2014), Visco (2012) – they are all part of the the International DLBCL Rituximab-CHOP Consortium program study. The remaining analyses reported in this paper are not included here as they are not adjusted for IPI. Study does not appear to be subject to commercial funding.

Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? Unclear which variables entered into the multivariate analyses, age does not appear to be separated out from IPI in the multivariate analyses - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
<p>Additional comments (including funding): It is unclear whether the study is subject to commercial funding.</p>

Study, country: Li (2012), China
Study type, study period: Observational retrospective study, 2003-2007
Patients, number and characteristics (including diagnostic criteria, if reported): 118 (75 males / 43 females) patients aged > 18 years with histologically proven diagnosis of DLBCL (according to WHO 2008 criteria), which is previously untreated and CD20+. The patients had to have availability of paraffin-embedded tumor specimens before treatment, no previous neoplasm or no second primary malignancy, no severe coincident diseases; and available clinical information and follow-up data. All patients were treated with R-CHOP. IPI characteristics (not all data available for all patients): - Age: Median (range) = 53 (21-83) years; ≤ 60 years: N = 70; > 60 years: N = 48 - Performance status (ECOG): < 2: N = 114; ≥ 2: N = 4 - Stage: I-II: N = 70; III-IV: N = 48 - LDH: > 245 IU/L: N = 63 - Extra-nodal status: < 2 sites: N = 109; ≥ 2 sites: N = 9 IPI risk group: 0-1: N = 74; 2-5: N = 44 Treatment: R-CHOP. Exclusions: HIV infection, primary CNS lymphomas, primary mediastinal lymphoma, and DLBCL secondary to low-grade lymphoma
Prognostic variables, including methods of classification: IHC; Hans algorithm; GCB (N = 54) versus non-GCB (N = 64)
Results: Overall survival: 3-year = 73.9% Progression-free survival: 3-year = 65.3% Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: - OS: GCB = non-GCB, p = 0.33 - PFS: GCB = non-GCB, p = 0.287
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? Y - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
Additional comments (including funding): Study does not appear to be subject to commercial funding.

Study, country: Lopez (2011), country not reported
Study type, study period: Observational retrospective? study, study years not reported
Patients, number and characteristics (including diagnostic criteria, if reported): 166 (gender not reported) patients with de novo DLBCL (diagnostic criteria not reported), all treated with rituximab-chemotherapy. IPI characteristics: - Age: Not reported - Performance status: Not reported - Stage: Not reported - LDH: Not reported - Extra-nodal status: Not reported IPI score: Not reported Treatment: R-CHOP or R-CHOP-like Exclusions: Not reported.
Prognostic variables, including methods of classification: - FISH; MYC normal versus rearranged (N = 15/166) - IHC; Choi (at al, Cancer Research, 2009) algorithm; GCB (N = 74) versus ABC (N = 82)
Results: Overall survival: Not reported Progression-free survival: Not reported Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Multivariate analysis (controlling at least for IPI score; unclear how many analyses have been conducted): - "Clinical outcome", probably PFS, but may also be OS: ABC (relative to GCB): HR = 2.16 (95% CI 1.1-4.21), p = 0.0182. - "Clinical outcome", probably PFS, but may also be OS: MYC normal = rearranged, not significant. IPI was also significant.
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Unclear why data only available for 166/241 for FISH and 156/166 for IHC - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N, very little information, age is not separated out from the IPI status. - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
Additional comments (including funding): Unclear if study is subject to commercial funding. Published as abstract only.

Study, country: Madida (2012), various countries
Study type, study period: Observational retrospective? study, study years not reported
Patients, number and characteristics (including diagnostic criteria, if reported): 251 (58.6% males) patients diagnosed with DLBCL (diagnostic criteria not reported) who had extranodal involvement and been treated with R-CHOP. IPI characteristics: - Age: Median (range) = 63 (12-88) years - Performance status (ECOG?): < 2: N = 86; ≥ 2: N = 14 - Stage: III-IV: 63.2% - LDH: Elevated: 66.8% - Extra-nodal status: ≥ 1 sites: 100% IPI score: 3-5: 48.5%. Treatment: R-CHOP Exclusions: Not reported
Prognostic variables, including methods of classification: GEP + IHC with GEP as gold standard (no further GEP information reported); no algorithm reported; GCB (47%) versus non-GCB (53%)
Results: Overall survival: Not reported Progression-free survival: Not reported Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: Not reported Multivariate analysis (controlling for IPI score and double-hit score [MYC/BCL2 expression]): - OS: HR for non-GCB (relative to GCB) = 1.05 (95% CI 0.71-1.52, p = 0.817. IPI score and double-hit score were significant. - PFS: HR for non-GCB (relative to GCB) = 1.07 (95% CI 0.75-1.5, p = 0.704. IPI score and double-hit score were significant.
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y, but all patients had extranodal involvement - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N age not separated out from IPI in the multivariate analyses - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
Additional comments (including funding): It is unclear whether the study is subject to commercial funding. Published as abstract only.

Study, country: Maeshima (2012), Japan
Study type, study period: Observational retrospective study, 2003-2010
Patients, number and characteristics (including diagnostic criteria, if reported): 285 (148 males / 137 females) consecutive patients with de novo DLBCL (diagnostic criteria not reported) who had been treated with rituximab. IPI characteristics: - Age: Median (range) = 55 (17-88) years; ≤ 60: N = 158; > 60: N = 127 - Performance status (ECOG?): < 2: N = 249; 2-4: N = 36 - Stage: I-II: N = 198; III-IV: N = 87 - LDH: Normal: N = 144; Elevated: N = 141 - Extra-nodal status: < 2 sites: N = 236; ≥ 2 sites: N = 49 IPI score: 0Lo/low-intermediate: N = 218; high-intermediate/high: N = 67 Treatment: Rituximab-containing immunochemotherapy. Exclusions: DLBCL preceded by low-grade b-cell lymphoma or DLBCL with co-existing low-grade b-cell lymphoma; necrosis and starry sky patterns.
Prognostic variables, including methods of classification: IHC; Hans algorithm; GCB (N = 100) versus non-GCB (N = 132), data appear to be missing for 53/285
Results: Overall survival: 5-year = 91% Progression-free survival: 5-year = 72% Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: - 5-year OS: GCB (93%) = non-GCB (89%), non-significant - 5-year PFS: GCB (73%) = non-GCB (71%), non-significant Multivariate analysis: NA
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Unclear – it is unclear why data appear to be missing for 53/285 - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? Y - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
Additional comments (including funding): Study is subject to commercial funding.

Study, country: Mitrovic (2013), various
Study type, study period: Observational retrospective study, 1997-2008
Patients, number and characteristics (including diagnostic criteria, if reported): 140 (79 males / 61 females) patients with de novo DLBCL (diagnostic criteria not reported) who were treated with rituximab-chemotherapy. IPI characteristics: - Age: Median (range) = 59 (18-89) years; > 60 years: N = 70 - Performance status (ECOG): > 1: N = 15 - Stage: III-IV: N = 68 - LDH: Elevated: N = 63 - Extra-nodal status: > 1 site: N = 30 IPI score: 0-2: N = 93; 3-5: N = 39 Treatment: R-CHOP (N = 105), R-CNOP (N = 34), or intensified protocol with rituximab (N = 1). Exclusions: Not reported.
Prognostic variables, including methods of classification: - IHC; Hans algorithm; GCB (N = 75) versus non-GCB (N = 61); unevaluable: N = 4
Results: Overall survival: 3-year = 71% Progression-free survival: 3-year = 59% Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: - OS: GCB > non-GCB, p = 0.002 Multivariate analysis (controlling for IPI and CD43 expression): - OS: GCB > non-GCB, HR = 1.9 (95% CI 1-3.3), p = 0.042, favouring GCB. IPI was (also) significant.
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y. - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N age not separated out from IPI score in multivariate analyses - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
Additional comments (including funding): Study does not appear to be subject to commercial funding.

Study type, study period: Observational retrospective study, study years not reported
Patients, number and characteristics (including diagnostic criteria, if reported): 506 (268 males / 238 females) patients aged > 60 years with CD20+ DLBCL (according to WHO 2008 diagnostic criteria) who were enrolled in the ROOVER-60 trial, treated with CHOP ± rituximab and who had immunohistochemical data. <i>Please note, in the analyses only the analyses conducted on the R-CHOP treated patients are reported.</i> IPI characteristics (these data includes patients who did not receive R-CHOP; only data from 171/506 patients are included): <ul style="list-style-type: none"> - Age: Median (range) = 68 (61-80) years - Performance status (ECOG): > 1: N = 62 - Stage: III-IV: N = 222 - LDH: Elevated: N = 231 - Extra-nodal status: > 1 site: N = 73 IPI score: 1: N = 181; 2: N = 141; 3: N = 118; 4-5: N = 66 Treatment: R-CHOP or R-CHOP-like. Exclusions: Not reported.
Prognostic variables, including methods of classification: - IHC; Hans algorithm; GCB (N = 82) versus non-GCB (N = 91)
Results: Overall survival: Not reported Progression-free survival: Not reported Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: - OS: GCB = non-GCB, p = 0.691. Multivariate analysis (controlling for IPI factors): - OS: GCB = non-GCB, HR = 1 (95% CI 0.5-1.8), p = 0.901. - PFS: GCB = non-GCB, HR = 1.3 (95% CI 0.8-2.2), p = 0.299.
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Unclear why data from only 171/506 patients could be included, although the data missing from about 250 patients is probably due to the absence of rituximab in their treatment, assuming a 1:1 randomisation schedule. - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? Y it appears age is separated out from IPI score in multivariate analyses - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Results:

Overall survival: Not reported

Progression-free survival: Not reported

Health-related quality of life: Outcome not reported

Turnaround time for the test: Outcome not reported

Training set:

Univariate analysis:

- OS: GCB > non-GCB, $p = 0.018$

- EFS: GCB > non-GCB, $p = 0.0098$

Multivariate analysis (controlling for IPI and BCL2>30%/MYC>50% protein expression):

- OS: HR for non-GCB (relative to GCB) = 1.92 (95% CI 0.98-3.78, $p = 0.059$). IPI and BCL2/MYC protein expression were significant.

- EFS: HR for non-GCB (relative to GCB) = 2.15 (95% CI 1.2-3.83, $p = 0.01$) favouring GCB over non-GCB. BCL2/MYC protein expression, but not IPI, was also significant.

Validation set:

Multivariate analysis (controlling for IPI and BCL2>70%/MYC>40% protein expression):

- OS: HR for non-GCB (relative to GCB) = 2.14 (95% CI 1.08-4.21, $p = 0.028$) favouring GCB over non-GCB. IPI and BCL2/MYC protein expression ($p = 0.05$) were also significant.

- EFS: HR for non-GCB (relative to GCB) = 2.23 (95% CI 1.25-3.98, $p = 0.007$) favouring GCB over non-GCB. BCL2/MYC protein expression, but not IPI, was also significant.

Multivariate analysis (controlling for IPI and BCL2≥70%/MYC≥40% protein expression):

- OS: HR for non-GCB (relative to GCB) = 2.07 (95% CI 1.05-4.06, $p = 0.035$) favouring GCB over non-GCB. IPI was also significant.

- EFS: HR for non-GCB (relative to GCB) = 2.27 (95% CI 1.27-4.05, $p = 0.006$) favouring GCB over non-GCB. BCL2/MYC protein expression, but not IPI, was also significant.

Risks of bias (answer yes [Y], no [N] or unclear to each question):

- The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y

- Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Unclear

- The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y

- The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y

- Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N, age not separated out from IPI in multivariate analyses

- The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Additional comments (including funding): Unclear if study is subject to commercial funding.

Study, country: Ruminy (2013), France
Study type, study period: Observational retrospective? study, 2001-2011
Patients, number and characteristics (including diagnostic criteria, if reported): 141 (gender not reported) patients with DLBCL (diagnostic criteria not reported), all treated between 2001 and 2011 with rituximab-chemotherapy. IPI characteristics: - Age: Not reported - Performance status: Not reported - Stage: Not reported - LDH: Not reported - Extra-nodal status: Not reported IPI score: Not reported Treatment: R-chemotherapy Exclusions: Not reported.
Prognostic variables, including methods of classification: GEP: "we established a 10 genes expression signature which discriminates ABC from GCB cases (ABC: IRF4, FOXP1, IGHM, TNFRSF13B, CCND2; GCB: LMO2, MYBL1, BCL6, NEK6, TNFRSF9). These genes were incorporated into a Reverse Transcriptase Multiplex Ligation-dependant Probe Amplification assay (RT-MLPA), together with cMYC and BCL2, whose co-expression was recently shown to be prognostic in these diseases, and the CCND1 and MS4A1 (encoding CD20) genes used as controls..... We next applied this assay on a training series of 50 cases previously identified as belonging to ABC or GCB subtypes by gene expression profiling using the Wright's algorithm to construct a Bayesian predictor" (no further information reported); GCB (N = 49) versus ABC (N = 64); N = 28 remained unclassified
Results: Overall survival: Not reported Progression-free survival: Not reported Health-related quality of life: Outcome not reported Turnaround time for the test: < 1 day, repeated testing of up to 40 patients in parallel Univariate analysis: - OS: GCB = ABC, p = 0.06
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? <p>Study type, study period: Observational retrospective study, 2002-2007</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): 219 (125 males / 94 females) consecutive patients with de novo DLBCL that had been diagnosed according to WHO [year not reported] criteria who had been treated with rituximab-chemotherapy.</p> <p>IPI characteristics (not all data available from all patients):</p> <ul style="list-style-type: none"> - Age: Median (range) = 61 (19-91) years; ≥ 60 years: N = 123 - Performance status: Not reported - Stage: III-IV: N = 122 - LDH: Elevated: N = 95 - Extra-nodal status: Extranodal involvement: N = 82 <p>IPI score: Low: N = 69; Low-intermediate: N = 40; High-intermediate: N = 45; High: N = 46. Treatment: R-CHOP (N = 185), R-high dose-CHOP/R-ESHAP (N = 11). Exclusions: Previous indolent lymphoma, immunodeficiency-associated lymphomas, post-transplant lymphoproliferative disorders, intravascular, CNS, primary effusion lymphomas and primary mediastinal lymphomas, Burkitts lymphoma.</p>
<p>Prognostic variables, including methods of classification:</p> <ul style="list-style-type: none"> - FISH; MYC not rearranged (N = 164/176) versus rearranged (N = 12/176)
<p>Results:</p> <p>Overall survival: 5-year = 60% (95% CI 53-67%)</p> <p>Progression-free survival: Median = 7.5 years</p> <p>Health-related quality of life: Outcome not reported</p> <p>Turnaround time for the test: Outcome not reported</p> <p>Univariate analysis (includes 196 patients treated with curative intent):</p> <ul style="list-style-type: none"> - 5-year OS: MYC no alterations (69%) versus gains (59%) versus rearrangements (31%), p = 0.021 - 5-year PFS: MYC no alterations (65%) versus gains (41%) versus rearrangements (15%), p = 0.003 <p>Multivariate analysis (controlling for at least IPI score and MYC protein expression at cut-offs of 10%, 25% and 40%; N = 141):</p> <ul style="list-style-type: none"> - 5-year OS: MYC no alterations = gains = rearrangements, not significant (all MYC protein expression cut-offs). IPI and MYC protein expression (at cut-off 10%, but not 25% or 40%) were significant. - 5-year PFS: MYC no alterations = gains = rearrangements, not significant (all MYC protein expression cut-offs). IPI was significant.
<p>Risks of bias (answer yes [Y], no [N] or unclear to each question):</p> <ul style="list-style-type: none"> - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Unclear why data only available from 141/196 patients - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N – age is not separated out from the IPI in the multivariate analyses. - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y
<p>Additional comments (including funding): Study does not appear to be subject to commercial funding.</p>

<p>Study, country: Visco (2012), country not reported</p>
<p>Study type, study period: Observational retrospective? study, 2002-2009</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): 475 (273 males / 202 females) patients with de novo adult DLBCL that had been diagnosed according to WHO criteria (year not reported) as part of the international DLBCL rituximab-CHOP consortium program study who had available GEP results and clinical data and who had been treated with R-CHOP</p> <p>IPI characteristics: - Age: Median = 62 years; < 60: N = 186; ≥ 60: N = 289 - Performance status (ECOG?): < 2: N = 378; ≥ 2: N = 97 - Stage: I-II: N = 224; III-IV: N = 251 - LDH: Normal: N = 149; Elevated: N = 280 - Extra-nodal status: < 2 sites: N = 366; ≥ 2 sites: N = 109 IPI score: 0-1: N = 172; 2-3: N = 198; 4-5: N = 59. Treatment: R-CHOP. Exclusions: Not reported.</p>
<p>Prognostic variables, including methods of classification: - IHC; 3-marker Visco-Young algorithm; GCB (N = 252) versus non-GCB (N = 223)</p>
<p>Results: Overall survival: 5-year = 62% Progression-free survival: 5-year = 60% Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis: - 5-year OS: GCB (71%) > non-GCB (51%), p = 0.003. - 5-year PFS: GCB (64%) > non-GCB (48%), p = 0.002. Multivariate analysis (controlling for IPI score and achievement of a complete response <u>at least, and possibly also gender, B symptoms, bulky mass and c-MYC breaks, which all appear to be non-significant if they were entered into the model</u>): - OS: Significant effect of GCB/non-GCB: HR = 0.56 (95% CI 0.4-0.77, p = 0.0004) favouring GCB IPI score and achievement of a complete response were also significant. - PFS: Significant effect of GCB/non-GCB: HR = 0.59 (95% CI 0.43-0.81, p = 0.001) favouring GCB IPI score and achievement of a complete response were also significant.</p> <p>The authors applied the 3-marker algorithm to a validation set consisting of 237 archival DLBCL patients who had been treated with R-CHOP and were selected according to the same criteria as the original patients, whom they did not differ significantly from in terms of gender, LDH, stage, presence of B symptoms, or IPI. The validation set patients were however significantly younger (median age = 58 years) than the original patients (p < 0.007). Multivariate analyses conducted in the validation set showed the following results: - PFS: Significant effect of GCB/non-GCB: HR = 0.63 (95% CI 0.42-0.96, p = 0.03) favouring GCB IPI score, but apparently not achievement of a complete response, was also significant (also in this case is it possible that the analysis included adjustment for gender, B symptoms, bulky mass and c-MYC breaks, which all appear to be non-significant <u>if</u> they were entered into the model). No results reported for OS.</p>
<p>Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N - age not separated out from IPI in multivariate analyses - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y</p>

Additional comments (including funding): The patients included in this study seem to overlap almost completely with those in Hu (2013), Kim (2014), Tzankov (2014), Xu-Monette (2012) and Hu, Xu-Monette, Tzankov et al. (2013) – they are all part of the the International DLBCL Rituximab-CHOP Consortium program study. The remaining analyses reported in this paper are not included here as they are not adjusted for IPI. Study does not appear to be subject to commercial funding.

<p>Study, country: Wong (2014), Denmark</p>
<p>Study type, study period: Observational retrospective study, 2001-2008</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): 159 (89 males / 70 females) patients with previously untreated DLBCL (diagnosed according to WHO 2001, 2008; as detailed in Green, 2012) who were treated with R-CHOP with curative intent.</p> <p>IPI characteristics:</p> <ul style="list-style-type: none"> - Age: Median (range) = 67 (20-91) years - Performance status (ECOG?): < 2: N = 136; ≥ 2: N = 23 - Stage: I-II: N = 87; III-IV: N = 72 - LDH: Normal: N = 94; Elevated: N = 65 - Extra-nodal status: < 2 sites: N = 134; ≥ 2 sites: N = 25 <p>IPI score: 0-2: N = 112; 3-5: N = 47.</p> <p>Treatment: R-CHOP with curative intent.</p> <p>Exclusions: Patients with primary CNS involvement or who were HIV positive (as detailed in Green, 2012).</p>
<p>Prognostic variables, including methods of classification:</p> <ul style="list-style-type: none"> - IHC; Choi algorithm; GCB (N = 95) versus non-GCB (N = 60); N = 4 could not be classified. - IHC; Hans algorithm; GCB versus non-GCB, numbers not reported.

Risks of bias (answer yes [Y], no [N] or unclear to each question):

- The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y
- Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y
- The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y
- Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N, age not separated out from IPI in multivariate analyses
- The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Additional comments (including funding): The patients in Green (2012) are from the same populations as the patients included in this study. Study does not appear to be subject to commercial funding.

<p>Study, country: Xu-Monette (2012), various countries</p>
<p>Study type, study period: Observational retrospective? study, 1998-2008</p>
<p>Patients, number and characteristics (including diagnostic criteria, if reported): 506 (296 males / 210 females) patients with de novo DLBCL (diagnosed according to WHO [year not reported] criteria, organised as part of the International DLBCL Rituximab-CHOP Consortium program study.</p> <p>IPI characteristics (not all data available for all patients):</p> <ul style="list-style-type: none"> - Age: < 60 years: N = 206; ≥ 60 years: N = 300 - Performance status (ECOG): < 2: N = 378; ≥ 2: N = 57 - Stage: I-II: N = 237; III-IV: N = 249 - LDH: Normal: N = 156; Elevated: N = 299 - Extra-nodal status: < 2 sites: N = 386; ≥ 2 sites: N = 96 <p>IPI risk group: 0-2: N = 291; 3-5: N = 158</p> <p>Treatment: R-CHOP.</p> <p>Exclusions: History of low-grade B-cell lymphoma with transformation to DLBCL, HIV/AIDS infection, primary cutaneous DLBCL, primary CNS DLBCL, and primary mediastinal b-cell lymphoma.</p>
<p>Prognostic variables, including methods of classification: GEP + IHC,</p> <ul style="list-style-type: none"> - GEP: For data analysis and classification, the microarray DQN (trimmed mean of differences of perfect match and mismatch intensities with quantile normalization...) signals were generated and normalized to the quantiles of beta distribution with parameters P = 1.2 and q = 3. A Bayesian model was also used to determine the classification probability [Wright et al., 2003, Proc Natl Acad Sci USA, 100 (17): 9991-9996]. The classification model was built on the 47 paired formalin-fixed, paraffin-embedded tissue-fresh frozen sample data set previously generated with confidence of 90-100% for both fresh frozen tissue and FFPE tissue [Williams et al., 2010, J Mol Diagn, 12: 680-686]. The same methodology developed during this pilot study has been validated and demonstrated to be applicable by using the LLMPP data set in the Gene Expression Omnibus Genomic Spatial Event database GSE# 10846 that have 181 CHOP-treated and 233 R-CHOP-treated DLBCL patients with FF samples" (Visco 2012, p 2104). <p>"Most patients were able to be classified into GCB- and ABC-DLBCL subtypes according to the GEP data (n = 441), supplemented by IHC assessment (n = 499)" (p 3989) according to the Visco-Young algorithm; GCB (N = 258) versus ABC (N = 241).</p>
<p>Results:</p> <p>Overall survival: Not reported</p> <p>Progression-free survival: Not reported</p> <p>Health-related quality of life: Outcome not reported</p> <p>Turnaround time for the test: Outcome not reported</p> <p>Univariate analysis:</p> <ul style="list-style-type: none"> - OS: GCB > ABC, p = 0.0009 - PFS: GCB > ABC, p = 0.0019. <p>Multivariate analysis (controlling for at least IPI risk group, B symptoms, and TP53 mutation):</p> <ul style="list-style-type: none"> - OS: HR for ABC (relative to GCB) = 1.62 (95% CI 1.15-2.28), p = 0.0062, favouring GCB. IPI risk score, B symptoms and TP53 mutation were also significant. - PFS: HR for ABC (relative to GCB) = 1.6 (95% CI 1.15-2.24), p = 0.0052, favouring GCB. IPI risk score, B symptoms and TP53 mutation were also significant.
<p>Risks of bias (answer yes [Y], no [N] or unclear to each question):</p> <ul style="list-style-type: none"> - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Y - Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias? Y - The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias? Y - The outcome of interest is adequately measured in study participants, sufficient to limit potential bias? Y - Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest? N – the multivariate analyses only report significant covariates. It is unclear whether any other covariates were included, age does not appear to be separated out from IPI in these multivariate analyses - The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results? Y

Additional comments (including funding): The patients included in this study seem to overlap almost completely with those in Hu (2013), Hu, Xu-Monette, Tzankov et al. (2013), Tzankov (2014), Kim (2014) and Visco (2012) – they are all part of the the International DLBCL Rituximab-CHOP Consortium program study. Study appears to be subject to some commercial funding.

Study, country: Yan (2014), China
Study type, study period: Observational retrospective study, 2000-2012
Patients, number and characteristics (including diagnostic criteria, if reported): 125 (gender not reported for these patients) patients with de novo DLBCL that had been diagnosed according to WHO 2008 criteria who had been treated with 6-8 cycles of CHOP with 8 applications of rituximab and who had available baseline clinical and outcome data and sufficient formalin-fixed paraffin-embedded tissue from the pre-treatment biopsy sample for TMA representation. IPI characteristics (include data from 211 patients treated with CHOP): <ul style="list-style-type: none"> - Age: Median (range) = 57 (7-87) years - Performance status (ECOG): ≥ 2: N = 51 - Stage: III-IV: N = 156 - LDH: Elevated: N = 129 - Extra-nodal status: ≥ 2 sites: N = 57 IPI score: 0-1: N = 170; 2: N = 83; 3: N = 59; ; 4-5: N = 24. Treatment: R-CHOP. Exclusions: Not reported.
Prognostic variables, including methods of classification: - IHC; Hans algorithm; GCB (N = 90) versus non-GCB (N = 231); N = 15 in the CD+ subgroup (includes 211 patients treated with CHOP).
Results: Overall survival: 5-year = 66% (includes 211 patients treated with CHOP) Progression-free survival: 5-year = 47% (includes 211 patients treated with CHOP) Health-related quality of life: Outcome not reported Turnaround time for the test: Outcome not reported Univariate analysis (includes 118/125 patients): - 5-year OS: GCB = non-GCB, HR = 1.67 (95% CI 0.69-4.06), p = 0.259. - 5-year PFS: GCB = non-GCB, HR = 1.97 (95% CI 0.96-4.03), p = 0.064. Multivariate analysis: NA
Risks of bias (answer yes [Y], no [N] or unclear to each question): - The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results? Additional comments (including funding): Study does not appear to be subject to commercial funding.

3. Staging

3.1.1: Review question E1: What is the staging value of pre-treatment functional imaging with PET-CT compared with other initial assessments for people with different subtypes of non-Hodgkin's lymphoma?

PICO Table

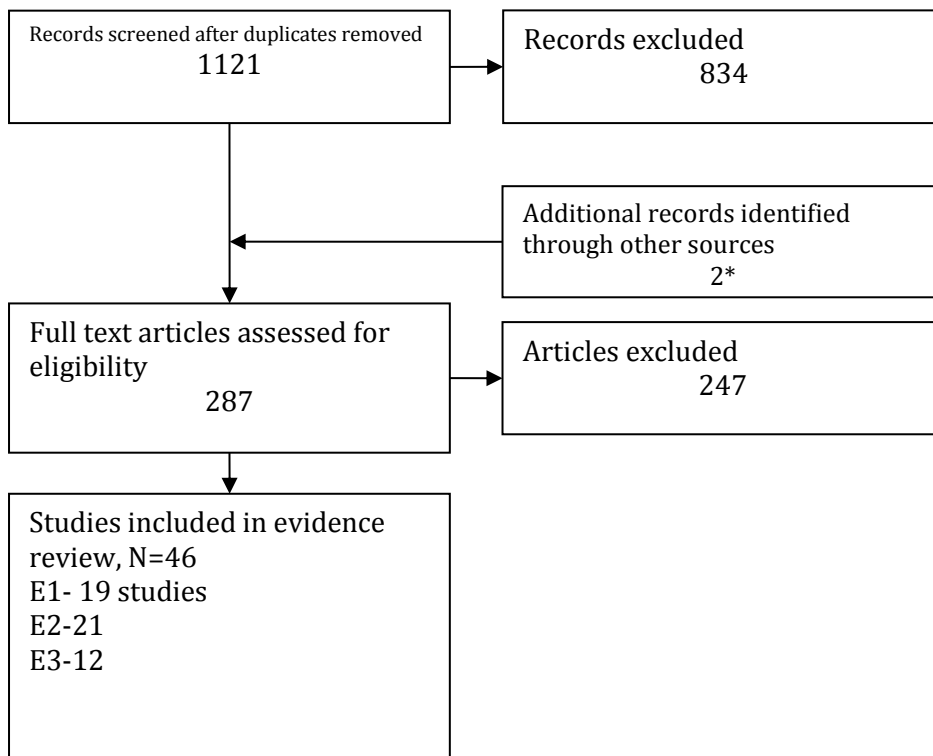

Population	Index test	Reference standard	Outcomes
Adults and young people (16 years and older) presenting with newly diagnosed non-Hodgkin's lymphoma.	Functional imaging with FDG PET-CT enhanced Functional imaging with FDG PET-CT not-enhanced Contrast enhanced CT	Standard staging CT Bone marrow biopsy Positive test on imaging results: Histopathological examination Bone marrow biopsy Positive CT but Pet negative Negative test on imaging results: Clinical and radiological follow-up	Diagnostic accuracy for • Bone marrow involvement • Staging (Upstaging and Down-staging) Test-related morbidity Health-related quality of life Treatment management change

Additional Comments on PICO

present information by subtypes included in scope.
Papers may include Hodgkin's lymphoma.
Please note the different criteria used when scoring a positive and negative PET-CT scan (e.g. IWG 2007; Deauville, International harmonisation project)
If PET-CT enhanced the paper will state this, if just PET-CT then it is not enhanced.
Sifting update (July 2015): search produced 1028 hits, 294 potentially relevant articles from title and abstract sift so conference abstracts (decision made at GDG 06.06.14) and articles with <40 participants were not ordered (n=136/294) due to the large number of small low-powered studies.
Sifting update (July 2015): Full text articles with <40 participants were not appraised due to low frequency of outcome events (i.e. positive PET/CT scan)

Evidence Quality

Figure 2. Meta-analysis of sensitivity and specificity of PET-CT and bone marrow biopsy for the detection of bone marrow involvement in diffuse large B-cell lymphoma.

Pooled sensitivity and specificity*	Sensitivity (95% C.I.)	Specificity (95% C.I.)
PET-CT	79.5% (69.8% to 86.6%)	96% (93.1% to 97.7%)
Bone marrow biopsy of iliac crest	55.8% (43.2% to 67.7%)	99.3% (98.5% to 99.7%)

* Bivariate diagnostic random-effects meta-analysis

Table 4. Staging and treatment changes following PET/CT

Study, country	NHL subtype	N	Mean age (yr)	Positivity criteria	Interpreters	Staging change	Treatment Change
Casulo 2013 USA	TCL, NKL	95	54	FDG uptake greater than liver background activity with a corresponding structural abnormality on CT scan	Not reported	FDG-PET would have altered the clinical stage in 5.2% of patients (5/95) as compared to CT. Two patients were up-staged (stage I increased to stage III; stage II increased to stage IV), while three patients were down-staged.	Change in stage resulted in no changes in treatment (combination chemo used regardless of stage).
Khan 2013 UK	DLBCL	130	59	FDG uptake in the bone marrow higher than in the liver, with no anatomical changes to suggest alternative benign pathology	2 nuclear medicine physicians or radiologists	PET-CT identification of BMD increased the number of stage IV patients in the cohort by 25%. (9/59 clinical stage I-II upstaged to IV on PET)	Not reported
Le Dortz 2010 France	FL	45	60	Cheson criteria	2 nuclear medicine specialists	5 patients with localized stage following standard evaluation found to have advanced stage. Three patients with stage I or III were considered stage IV after PET/CT	Not reported directly, although 50% (5/10) of patients with limited disease were upstaged by PET-CT to stage III/IV – with implications for involved field-RT.
Luminari 2013 Italy	FL	142	57	PET analysis was based on a qualitative assessment of PET results	Not reported	PET-CT scan increased the proportion of patients with Ann Arbor stage III-IV disease when compared to CT-scan.	Not reported directly, although 62.5% (15/24) of patients with limited disease were upstaged by PET-CT to stage III/IV – with implications for involved field-RT.
Papajik 2011 Czech Rep.	NHL	122	59	Focal or diffuse accumulation of F-DG higher than the mediastinal blood pool background	Not reported	PET-CT scan changed stage in 11/122 (9%) patients: increased in 5/11 and decreased in 6/11.	Therapy was changed in 3/11 patients following their staging change (a stage I→III FL; stage I→III DLBCL; mycosis fungoides stage IV→I)
Pelosi 2011 Italy	NHL, HD	337	Not reported	FDG uptake in the bone marrow higher than in the liver	2 nuclear medicine physicians	PET-CT identified BMD in 35 patients with negative BMB. 25/35 were upstaged to stage IV (originally 1 stage I, 10 stage II, 14 stage III)	Not reported
Raanani 2005 Israel	NHL	68	52	Any site of increased uptake not due to physiological or benign uptake was a possible lymphoma site.	Team of specialists by consensus	Compared to CT-scan stage, disease was upstaged by PET/CT in 31% of patients and down staged in 1%.	The suggested treatment strategy (based on CT scan) was changed following PET/CT in 17/68 patients (25%)
Yi 2010 Korea	DLBCL, MALT	42	Md55.5	FDG uptake present if it was higher than the hepatic uptake	Experienced nuclear medicine physicians	DLBCL: Downstaging: 6, Upstaging: 7 MALT: Upstaging: 2	Not reported.

Non Hodgkin's Lymphoma: diagnosis and management

Abbreviations; BMD, bone marrow disease; BMI, bone marrow involvement; DLBCL, diffuse large B-cell lymphoma; FL, follicular lymphoma; HD, Hodgkins Lymphoma; MALT, mucosa-associated lymphoid tissue lymphoma; RT, radiotherapy. TCL, T-cell lymphoma;

Evidence statements

The evidence included 27 cross-sectional studies (21 using retrospectively collected data) of FDG-PET-CT for staging and 16 cohort studies (seven prospective) reporting the use of both pre and post treatment FDG-PET-CT.

FDG-PET-CT and bone marrow biopsy for the detection of bone marrow involvement (BMI)

Moderate quality evidence from 14 studies including 1737 patients suggests FDG-PET-CT has a sensitivity of 79.5% (95% CI 69.8% to 86.6%) and a specificity of 96% (95%CI 93.1% to 97.7%) for the detection of bone marrow involvement in patients with newly diagnosed DLBCL. If prevalence of BMI is assumed to be 15% then FDG-PET-CT has a positive predictive value of 80% and a negative predictive value of 96% for bone marrow involvement.

Moderate quality evidence from 12 studies including 1603 patients suggests bone marrow biopsy of the iliac crest has a sensitivity of 55.8% (95%CI 43.2% to 67.7%) and a specificity of 100% for the detection of bone marrow involvement in patients with newly diagnosed DLBCL. If prevalence of BMI is assumed to be 15% then bone marrow biopsy has a positive predictive value of 100% and a negative predictive value of 92% for bone marrow involvement.

FDG-PET-CT for the detection of lymph node involvement

Three studies including 289 patients (Morimoto *et al* 2008; Pinilla *et al* 2010; Papajik *et al* 2010) provided low quality evidence on the sensitivity and specificity of FDG-PET-CT for the detection of lymph node involvement in NHL. One study (Morimoto *et al*, 2008; n=66), limited to retroperitoneal and pelvic lymph nodes, reported FDG-PET-CT sensitivity ranging from 75% to 100% (PPV 60% to 98%) and specificity from 81% to 92% (NPV 71% to 100%), depending on the location of the lymph node. Pinilla *et al* (2010) and Papajik *et al* (2010) reported FDG-PET-CT diagnostic accuracy for any lymph nodal involvement, sensitivity ranged from 97% to 100% with specificity 94% to 96%.

FDG-PET-CT for the detection of extranodal organ involvement

Two studies including 223 patients (Papajik *et al* 2011; Pinilla *et al* 2010) provided low quality evidence on the sensitivity and specificity of FDG-PET-CT for the detection of extranodal organ involvement in NHL. The sensitivity ranged from 94% to 96% and specificity from 81% to 92%, but insufficient detail was provided to calculate predictive values.

FDG-PET-CT and change in stage and treatment

FDG-PET-CT changed the allocated stage of patients with localised follicular lymphoma to stage III/IV in most cases. 5/10 (50%) of patients with stage I-II follicular lymphoma in Le Dortz *et al* (2010) were upstaged to stage III or IV and 15/24 (63%) in Luminari *et al* (2013). Although the impact of this change on treatment was not reported it could have implications for the use of limited-field radiotherapy in this population.

Staging with FDG-PET-CT increased the number of patients with stage IV DLBCL by as much as 25% when compared to staging using bone marrow biopsy (Khan *et al* 2013; Pelosi *et al* 2010) but it was not reported whether treatment was also changed.

Raanani *et al* (2005) reported that compared to CT-scan stage, disease was upstaged by FDG-PET-CT in 31% and down staged in 1% in a cohort of 68 patients with NHL. The suggested treatment strategy (based on CT scan) was changed following FDG-PET-CT in 17/68 patients (25%). Papajik *et al* (2011) reported that treatment strategy (based on CT-scan stage) was changed following FDG-PET-CT in 3/122 patients (2%).

Use of pretreatment FDG-PET-CT to evaluate end of treatment response Sixteen studies observational did baseline FDG-PET-CT as well as interim or end of treatment FDG-PET-CT. Although some used baseline

Non Hodgkin's Lymphoma: diagnosis and management

FDG-PET-CT to evaluate the quality of interim treatment response, none reported the use of baseline FDG-PET-CT in evaluating end of treatment response

3.1.2: Review question: What is the prognostic value of an interim assessment using functional imaging with PET-CT during the treatment of diffuse large B-cell non-Hodgkin's lymphoma?

Pico Table

Population	Index test	Outcomes
<p>Adults and young people (16 years and older) currently undergoing first-line treatment for Diffuse Large B-cell non-Hodgkin's lymphoma.</p> <p>Subgroups: Stages: Early stage nodal disease Advanced Time point of scan When during the interval of treatment is the scan conducted Treatment use (esp. Rituximab)</p>	<p>Functional imaging with FDG PET-CT enhanced PET+ PET-</p> <p>Functional imaging with FDG PET-CT not-enhanced PET+ PET-</p> <p>No functional imaging with PET-CT scan Alternative scanning: CT scan</p>	<p>Overall survival Progression-free survival Health-related quality of life Treatment management change</p>

Additional Comments on PICO

When reviewing papers please note whether PET-CT scan data was blinded.

Please note the different criteria used when scoring a positive and negative PET-CT scan (e.g. IWG 2007; Deauville, International harmonisation project)

Make a note of treatment type prior to scan

Query – Should we note treatment type due to the variable results since use of Rituximab because not all patients will be receiving Rituximab under the recommendations of the TA65 (localised only as part of ongoing or new clinical studies). – Not a problem as all patients will receive rituximab now as the TA was for a specific stage which is rarely diagnosed.

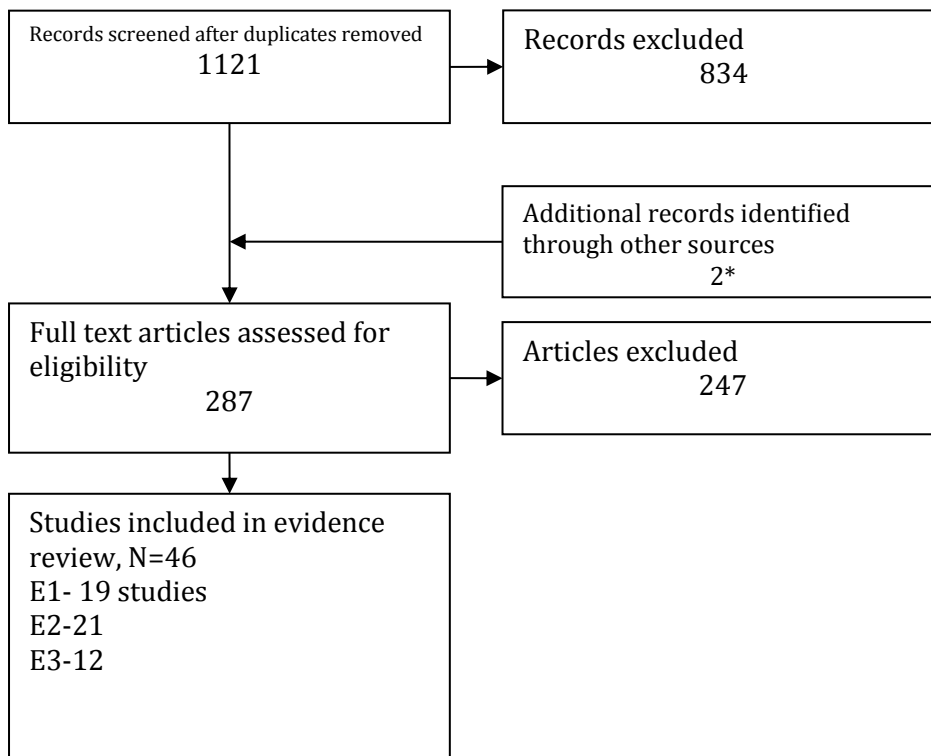

Sifting update (July 2015): search produced 1028 hits, 294 potentially relevant articles from title and abstract sift so conference abstracts (decision made at GDG 06.06.14) and articles with <40 participants were not ordered (n=136/294).

Sifting update (July 2015): Full text articles with <40 participants were not appraised due to low frequency of outcome events (i.e. positive PET/CT scan)

Multivariate analysis should include IPI and its sub components.

Evidence Quality

Evidence Statements

Interim assessment of DLBCL – Table 6

Moderate quality evidence came from seventeen cohort studies including 2326 patients compared survival outcomes according to FDG-PET-CT scan during RCHOP or RCHOP-like chemotherapy for DLBCL. The interim FDG-PET-CT was typically done following cycle 2 and across studies the mean proportion with a positive interim FDG-PET-CT scan was 35% (range 20% to 60%). Survival outcomes were consistently poorer in those with positive interim FDG-PET-CT. Progression free survival at three years was between 18% and 78% (median 32%) lower in patients with positive interim FDG-PET-CT. Overall survival at three years was between 0% and 48% (median 26%) lower and event free survival between 22% and 59% (median 41%) lower in those with positive interim FDG-PET-CT.

In multivariate analysis (taking other prognostic variables such as IPI and its components and post treatment FDG-PET-CT into account) interim FDG-PET-CT (negative versus positive) was not always an independent prognostic factor for outcome. In four studies reporting multivariate analyses of overall survival in patients with DLBCL (Cox *et al* 2012, Lanic *et al* 2011, Mamot *et al* 2015 and Mylam 2014), interim FDG-PET-CT (negative versus positive) was a significant independent prognostic factor for survival in all studies except for Mamot *et al* (2015).

There was uncertainty about the usefulness of interim FDG-PET-CT as an independent predictor of progression free survival (Cox *et al*, 2012; Lanic *et al*, 2011; Mylam *et al*, 2014, Pregno *et al* 2012) and event free survival (Carr *et al*, 2012; Mamot *et al* 2015 and Gonzalez-Barca *et al* 2013) when other prognostic variables such as interim CT and post-treatment FDG-PET-CT are taken into account.

3.1.3: Review question E3: What is the prognostic value of functional imaging with PET-CT performed after the various types of treatment for non-Hodgkin’s lymphoma are completed?

Pico Table

Population	Index test	Outcomes
<p>Adults and young people (16 years and older) with non-Hodgkin’s lymphoma who have completed planned first-line treatment (RCHOP, rituximab plus any chemo, any radiotherapy).</p> <p>Subgroups: Stages: Early Advanced Residual mass on CT Time interval of scan (current practice in the UK 4 weeks after chemo, 3 months after radiotherapy) Treatment type</p>	<p>Functional imaging with FDG PET-CT enhanced PET+ PET-</p> <p>Functional imaging with FDG PET-CT not-enhanced PET+ PET-</p> <p>No functional imaging with PET-CT scan Alternative scanning: CT scan</p>	<p>Diagnostic accuracy (accuracy often based on PFS) Overall survival Progression-free survival Health-related quality of life Treatment management change</p>

Additional Comments on PICO

Present outcomes by NHL subtypes included in scope.
Please note the different criteria used when scoring a positive and negative PET-CT scan (e.g. IWG 2007; Deauville, International harmonisation project)
Sifting update (July 2015): search produced 1028 hits, 294 potentially relevant articles from title and abstract sift so conference abstracts (decision made at GDG 06.06.14) and articles with <40 participants were not ordered (n=136/294).
Sifting update (July 2015): Full text articles with <40 participants were not appraised due to low frequency of outcome events (i.e. positive PET/CT scan)
Multivariate analysis should include IPI and its sub components.

Evidence Statements

Post treatment scanning – Tables 9, 10 and 11

Moderate quality evidence about the post treatment FDG-PET-CT scan results and outcomes came from ten retrospective cohort studies including 915 patients. Five concerned DLBCL (Abo-Sheisha *et al* 2014; Mylam *et al* 2014; Gonzalez-Barca *et al* 2013; Pregno *et al* 2012; Cashen *et al*, 2011), three follicular lymphoma (Trotman *et al*, 2014; Tychyj-Pinel, 2014; Le Dortz *et al*, 2010) and one each mantle cell (Mato, 2012) and primary mediastinal B-cell lymphoma (Martelli *et al*, 2014).

The usefulness of post treatment FDG-PET-CT as a predictor of outcome was examined in multivariate analyses of survival (Cox *et al*, 2012; Mylam *et al*, 2014 and Mato *et al* 2012), progression free survival (Cox *et al*, 2012; Mylam *et al*, 2014, Pregno *et al* 2012 and Mato *et al* 2012) and event free survival (Carr *et al*, 2012 and Gonzalez-Barca *et al* 2013). In all of the DLBCL studies (Carr *et al*, 2012; Cox *et al*, 2012; Gonzalez-Barca *et al* 2013; Pregno *et al* 2012 and Mylam *et al*, 2014) post-treatment FDG-PET-CT was an independent prognostic factor for each outcome survival examined. In Mato *et al* (2012) post-treatment FDG-PET-CT was an independent prognostic factor for progression-free survival but not for overall survival in patients with Mantle cell lymphoma.

Evidence from two retrospective studies including 167 patients (The PRIMA study [Trotman *et al*, 2010 and Tychyj-Pinel *et al*, 2014] and Le Dortz *et al*, 2010) suggests that FDG-PET-CT post-induction therapy predicts progression free survival and overall survival in patients with follicular lymphoma. Patients with positive FDG-PET-CT (interpreted by local physicians) following induction therapy had progression free survival of 33% at 3.5 years compared with 71% for those with negative FDG-PET-CT (Trotman *et al* 2010). Overall survival at 3.5 years was 79% versus 97% for patients with positive versus negative post-induction FDG-PET-CT respectively (Trotman *et al* 2010). Subsequent analysis of the PRIMA FDG-PET-CT data by Tychyj-Pinel *et al* (2014) suggests that the difference is less clear when FDG-PET-CT scans are reviewed centrally using standardised criteria – 3 year progression free survival was 41% versus 59% for FDG-PET-CT positive and negative patients in this analysis (HR 1.9 [95% C.I. 0.8 to 4.6]).

<p>Adams, HJA et al. "FDG PET/CT for the detection of bone marrow involvement in diffuse large B-cell lymphoma: a systematic review and meta-analysis". <i>Eur J Nucl Med Mol Imaging</i> 41; 565-574.</p> <p>Systematic review aim: assess the diagnostic performance of FDG PET/CT in detecting bone marrow involvement in patients with newly diagnosed DLBCL</p> <p>Search strategy: PubMed/MEDLINE, Embase; bibliographies of articles which finally remained after the selection processes were screened. Review articles, meta-analyses, conference abstracts, editorials or letters, case reports, guidelines for management, studies performed on animals and ex vivo studies were excluded. Studies that did not provide sufficient data to construct a 2x2 contingency table to calculate sensitivity and specificity for detecting lymphomatous bone marrow involvement were excluded</p> <p>Search date limits: No start date limited use and updated to 13th June 2013</p> <p>Literature search results: 980 articles (after duplicates removed) and screened. 37 articles reviewed in full text. 7 articles included</p>										
Pub year: 2014		Patient selection			Index test			Reference standard		Flow and timing
Country	UK Spain France Korea Italy Singapore France	Studies written in English, Spanish, French, Italian, German or Dutch. Population >10 patients <i>Exclusion:</i> Studies that did not allow separate extraction of data relating to previously treated patients with newly diagnosed DLBCL from previously treated patients with DLBCL or other NHL subtypes			FDG PET-CT Only studies that used a state-of-the-art integrated PET/CT system were included; studies that used a stand-alone PET system (i.e. without CT-based attenuation correction of PET data) were excluded. Studies in which the FDG PET/CT field of view included less than the area from the base of the skull to the pubic symphysis were excluded			BMB and follow-up Studies had to include bone marrow biopsy (BMB) as part of the reference standard otherwise they were excluded. BMB alone was planned as an exclusion criteria as it can miss focal bone marrow involvement and not suitable alone, but authors include 1 study with BMB only reference standard		Not reported in systematic review per included study

Table 3. FDG PET/CT parameters, methods of image interpretation and reference standard of included studies

	FDG dose	Time between FDG administration and scanning	Criteria for positivity	Interpreters	Reference standard
Khan	370 MBq	90	FDG uptake in the bone marrow higher than in the liver, with no anatomical changes to suggest alternative benign pathology ^a	2 nuclear medicine physicians or radiologists	Unilateral BMB, follow-up FDG PET-CT
Cortes-Romera	3.7 MBq/kg	60-120	FDG uptake in the bone marrow higher than in the liver ^a	NR	Unilateral BMB, follow-up FDG PET-CT
Berthet	3-5 MBq/kg	60	Uni- or multifocal bone marrow FDG uptake that could not be explained by benign findings on the underlying CT image or history ^b	Experienced reader	Unilateral BMB, follow-up FDG PET-CT, image-guided BMB, targeted MRI
Hong	370-555 MBq	60	FDG uptake in the bone marrow higher than in the liver ^a	3 nuclear medicine physicians	Bilateral BMB, follow-up FDG PET-CT
Pelosi	222-370 MBq	60	FDG uptake in the bone marrow higher than in the liver ^a	2 nuclear medicine physicians	Bilateral BMB, follow-up FDG PET/CT, image-guided biopsy, MRI
Ngeow	NR	NR	NR ^c	NR	Unilateral BMB
Ribrag	367-866 MBq	46-184	NR ^c	2 nuclear medicine physicians	Unilateral BMB, follow-up FDG PET-CT, whole-body MRI

Note. NR: Not reported. ^aDiffusely/homogeneously increased bone marrow FDG uptake was regarded as positive for bone marrow involvement. ^bDiffusely/homogeneously increased bone marrow FDG uptake was not regarded as positive for bone marrow involvement. ^cNot mentioned whether diffusely/homogeneously increased bone marrow FDG uptake was regarded as positive or negative for bone marrow involvement.

Table 4. Diagnostic performance of six of seven included studies in which calculation of sensitivity and specificity was allowed

Study	Sensitivity (%)		Specificity (%)	
	Value	95% CI	Value	95% CI
Khan	94.3	80.8-99.3	100	96.2-100
Cortes-Romera	95.8	78.9-99.9	100	93.9-100
Berthet	93.9	79.8-99.3	99.0	94.6-100
Hong	70.8	48.9-87.4	100	94.5-100
Pelosi	84.0	63.9-95.5	100	96.2-100
Ribrag	88.9	51.8-99.7	100	89.7-100
Pooled estimate	88.7	82.5-93.3	99.8	98.8-100
Area under the sROC curve	0.9983			
DORs	I²=0.0%			

Note. The diagnostic odds ratios (DORs) were homogeneous across individual studies so no further subgroup analyses were performed. Heterogeneity was defined as I²>50%, if no heterogeneity was identified, no further subgroup analyses were performed.

The proportions of FDG PET/CT negative patients with positive BMB findings among all patients were homogeneous across the 6 studies that could be used ($I^2=41.1$) but the proportions of FDG PET/CT positive patients with negative BMB findings among all patients were inhomogeneous across the studies ($I^2=58.1$)

Table 5. Results of included studies that allowed separate calculation of sensitivity and specific when only focal bone marrow FDG uptake was regarded as positive for bone marrow involvement and when both focal and diffuse bone marrow FDG uptake were regarded as positive for bone marrow involvement.

Study	Only focal bone marrow FDG uptake regarded as positive				Both focal and diffuse bone marrow FDG uptake regarded as positive			
	Sensitivity	(%)	Specificity	(%)	Sensitivity	(%)	Specificity	(%)
	Value	95% CI	Value	95% CI	Value	95% CI	Value	95% CI
Khan	88.6	73.3-96.8	100	96.2-100	94.3	80.8-99.3	100	96.2-100
Cortes-Romera	79.2	57.8-92.9	100	93.9-100	95.8	78.9-99.9	100	93.9-100
Berthet	93.9	79.8-99.3	99.0	94.6-100	NR	NR	NR	NR
Hong	41.7	22.1-63.4	100	94.5-100	70.8	48.9-87.4	100	94.5-100
Pelosi	NR	NR	NR	NR	84.0	63.9-95.5	100	96.2-100
Ribrag	NR	NR	NR	NR	NR	NR	NR	NR
Pooled estimate	78.4	69.9-85.5	99.7	98.3-100	87.0	79.2-92.7	100	98.8-100

The weighted summary proportion (fixed effects model) of FDG PET/CT-negative patients with positive BMB findings was 3.1% (95% CI: 1.8-5.0%)

The weighted summary proportion (random effects model) of FDG PET/CT-positive patients with negative BMB findings among all patients was 12.5% (95% CI: 8.4-17.3%)

Treatment planning:

- Khan et al. reported that 6.9% of all patients (9/130) were upstaged to stage IV because of positive FDG PET/CT findings while BMB was negative. No patient was classified as stage IV based on BMB alone. Therapeutic consequences were not reported
- Berthet et al. reported that 8.3% of all patients (11/133) were upstaged to stage IV because of positive FDG PET/CT findings while BMB was negative. 4/11 patients with initial stage I or II (3% of all patients) benefited from a change in consolidation treatment consisting of additional cycles of standard immunochemotherapy in two and intensified chemotherapy followed by autologous stem cell transplantation in the other two. Of the 2 patients with negative FDG PET/CT findings and positive BMB findings, one had an IPI score of 4 and the other had an IPI score of 5; the 2 were assigned to stage IV without consideration of bone marrow FDG uptake.

Comments

E1-DLBCL

Adams, HJA et al. "Bone marrow ¹⁸ F-flouro-2-deoxy-D-glucose positron emission tomography/computed tomography cannot replace bone marrow biopsy in diffuse large B-cell lymphoma". American Journal of Hematology 89(7); 726-731.					
Pub year: 2014		Patient selection	Index test	Reference standard	Flow and timing
Country	Netherlands	<p>All patients aged 18 years and older with newly diagnosed DLBCL who routinely underwent pretreatment FDG PET-CT and bone marrow biopsy (BMB) were retrospectively identified through a search of the hospital's database between September 2007 and July 2013.</p> <p><i>Exclusion:</i> primary mediastinal DLBCL, previously treated/relapsed lymphoma, transformed lymphoma, co-existence of another lymphoma subtype in the diagnostic biopsy, another previous malignancy within the past 5 years, interval between FDG-PET/CT and BMB >30 days, non-diagnostic BMB, and start of therapy (chemotherapy or radiation therapy) and/or hematopoietic growth factor injections before FDG PET/CT or BMB</p> <p>117 underwent PET-CT 39 excluded:</p> <ul style="list-style-type: none"> - 6 no BMB - 2 primary mediastinal DLBCL - 4 suffered from relapsed/previously treated lymphoma 	<p>FDG PET-CT</p> <p>Whole-body PET/CT images were obtained with an integrated 40-detector row PET/CT scanner</p> <p>60 minutes after FDG injection, image acquisition was performed</p> <p>58/78 patients had full-dose contrast-enhanced CT of the neck, chest, abdomen and pelvis with oral contrast agents</p> <p>An experienced reader, who was blinded to BMB, other imaging modalities, clinical parameters and patient outcome, evaluated all PET-CT images for the presence or absence of bone marrow involvement</p> <p>Bone marrow FDG uptake higher than liver FDG uptake was considered positive for bone marrow involvement</p> <p>Bone marrow involvement, if present, was classified as univocal, multifocal, diffuse, or focal and diffuse. Diffusely increased bone marrow FDG uptake was also considered positive for lymphomatous bone marrow infiltration.</p> <p>Quantitative FDG PET/CT analysis: Same observer used the ROVER software package</p>	<p>Bone marrow biopsy (BMB) and follow-up</p> <p>Unilateral BMB of the posterior iliac crest was performed by different hematologists and interpreted by different hematopathologists as part of routine clinical care. A positive BMB confirms bone marrow involvement, but a negative BMB cannot rule out bone marrow disease because of the possibility of sampling errors. Therefore, specificity of FDG PET/CT could not be determined, and only the patient-based sensitivity was calculated.</p> <p>Considered positive in the presence of either large-cell or small-cell lymphoma involvement</p> <p>Positive biopsies were reevaluated by an experienced hematopathologists who assessed the percentage of tumour involvement in the biopsy and classified bone marrow involvement as either concordant or discordant</p> <p>Flow cytometry of bone marrow aspirates was not used for the diagnosis of bone marrow involvement</p> <p>Follow-up: Follow-up PET/CT studies were used in all patients to determine if and when relapsed or progressive disease had occurred during follow-up, according to the revised response criteria for malignant lymphoma. The date on which a patient was last known to be alive or, in case a patient was deceased, the date of death was recorded. Post-treatment scans with PET/CT were not used as a reference standard because both lymphomatous and benign/inflammatory bone marrow lesions may demonstrate decrease in FDG uptake at follow-up.</p>	<p>Interval between FDG-PET/CT and BMB ≤30 days</p>

Comments

Sample includes patients less than 16 years of age (range: 15-83 years).

E1-NHL

Mittal, BR et al. (2011). Can fluorodeoxyglucose positron emission tomography/computed tomography avoid negative iliac crest biopsies in evaluation of marrow involvement by lymphoma at time of initial staging? <i>Leukemia & Lymphoma</i> , 52(11); 2111-2116									
Pub year: 2011		Patient selection		Index test		Reference standard		Flow and timing	
Country	India	All newly diagnosed patients with lymphoma who underwent F-18FDG PET/CT and ILBMB for initial staging between 2009 and 2010		PET/CT – Discovery STE-16 PET/CT scanner (GE Healthcare) – 60 minutes after injection image acquisition – All patients fasted for at least 6 hours before injection – Fasting blood glucose level of less than 150 mg/dL was a standard requirement for imaging in all patients Interpretation – All images were reviewed jointly by two nuclear medicine physicians, who had details of the patients' clinical history but were blinded to the ILBMB results – Uptake more than the liver background visually localised to the marrow on CT considered to be positive for BMI – Morphological changes such as lysis and sclerosis on CT, if present along with FDG uptake, were also interpreted as positive – FDG uptake classified into 3 patterns: (1) diffuse homogeneous uptake in the entire skeleton (2) isolated focal involvement and (3) heterogenous multifocal involvement/diffuse marrow involvement with a few sites of intense focal involvement – In patients with positive bone marrow uptake on FDG PET/CT, maximum standardised uptake value (SUVmax) normalised to body weight was measured in the most intense area. In patients with no abnormal uptake of FDG in the bone marrow, a reference bone marrow SUVmax was measured from regions of interest drawn on the posterior superior iliac spine on both sides and the mean of the two values was considered for analysis		ILBMB – Bone marrow examination from iliac crests performed in all patients, under local anesthesia – Bone marrow aspirate (BMA) and bilateral BM trephine biopsies (BMTBs) were obtained			
		97 patients (65 male, 32 female) 77: NHL (60/77 had aggressive lymphomas) 20: Hodgkin lymphoma

- True positive (TP) in the case of visualisation of diffuse or focal FDG along with positive ILBMB
- In the case of focal uptake on PET and negative ILBMB, PET considered TP when the uptake was associated with CT changes or when focal uptake decreased on follow-up
- No marrow uptake of F-18FDG on PET/CT and a negative ILBMB was considered as true negative (TN)
- A negative ILBMB with diffuse marrow uptake of FDG was considered as false positive (FP)
- No marrow uptake of FDG on PET/CT with positive ILBMB was interpreted as false negative (FN)

Table 1. F-18FDG PET/CT and ILBMB diagnostic accuracy

	Final positive N=38		Final negative N=59		Compared to final diagnosis (%)			
	True positive	False negative	True negative	False positive	Sensitivity	Specificity	Positive predictive value	Negative predictive value
All patients n=97								
F-18FDG PET/CT	34	4	55	4	89	93	89	93
ILBMB	29	9	59	-	76	-	-	86
NHL (n=77)								
F-18FDG PET/CT	29	4	42	2	88	95	93	100
ILBMB	27	6	44	-	82	-	-	91.3
Aggressive NHL (n=60)								
F-18FDG PET/CT	25	0	33	2	100	94	93	100
ILBMB	19	6	35	-	76	-	-	85.3
Indolent NHL (n=17)								
F-18FDG PET/CT	4	4	9	0	50	100	100	70
ILBMB	8	0	9	-	100	-	-	100

Note. False positive findings not expected for ILBMB, therefore false positives, specificities and positive predictive values were not defined for ILBMB.

Mean SUVmax in patients with positive BMI on ILBMB: 5.1±1.1 (range: 3.9-10.7)

Mean SUVmax in patients with negative ILBMB: 2.1±0.7 (range: 1.5-3.4)

SUVmax was significantly higher (p=0.001) in patients with positive ILBMB when compared with patients with negative ILBMB

	Paracaval lymph node	100	3/3	95	61/63	60	3/5	100	61/61	95	64/66	n.s.
	Lymph node	Sensitivity		Specificity		b. Non-Contrast-enhanced PET/CT				Accuracy		
		%	N	%	N	PPV %	N	NPV %	N	%	N	
	External iliac lymph node	98	44/45	52	11/21	81	44/54	92	11/12	83	55/66	
	Internal iliac lymph node	78	40/51	53	8/15	85	40/47	42	8/19	72	48/66	
	Common iliac lymph node	80	41/51	40	6/15	82	41/50	38	6/16	71	47/66	
Paraortic lymph node	90	45/50	94	15/16	98	45/46	75	15/20	91	60/66		
Aortocaval lymph node	88	7/8	95	55/58	70	7/10	98	55/56	94	62/66		
Paracaval lymph node	100	3/3	95	61/63	60	3/5	100	61/61	95	64/66		
	Note. PPV: positive predictive value; NPV: negative predictive value											
	Per-patient analysis: nodal stage of pelvic and retroperitoneal lymphatic pathways was correctly determined in 47 patients (71%) on non-contrasted PET/CT whereas determination of lymph node involvement based on contrast-enhanced PET/CT was correctly staged in 52 patients (79%). Difference in the accuracy of nodal status of pelvic and retroperitoneal lymphatic pathways between non-contrasted PET/CT and contrast-enhanced PET/CT was significant (p=0.0048)											
	Non-contrasted PET/CT revealed 6 over staged patients (9%) and 7 understaged patients (11%)											
	Contrast-enhanced PET/CT showed 2 over staged patients (4%)											
	Contrast-enhanced PET/CT enabled more accurate staging in 11 (17%) patients compared with non-contrasted PET/CT											
	The therapeutic plan was consequently altered in 3 patients											
	Contrast-enhanced PET/CT depicted intravascular extension of tumour that was not diagnosed with non-contrasted PET/CT											
Comments	Includes 16 patients with Hodgkin disease Author notes that unchanged lymph nodes after treatment were present in 9 patients (14%), and these nodes were excluded from study analysis, it is unclear what the justification for this and the implications for the results.

Results	- Significant differences between staging based on CT versus PET/CT (p=0.0001)								

Non Hodgkin's Lymphoma: diagnosis and management

- Discordant staging by diagnostic CT and by PET/CT was found in 22 patients (32%)
- Disease was upstaged by PET/CT in 31% of patients and downstage in 1%
- Upstaging by PET/CT was mainly for the early stages I and II
- Lesions diagnosed on PET/CT and overlooked on CT, included increased FDG uptake in a small-sized lymph nodes or extranodal involvement in the liver, spleen, bones or skin
- Significant differences found between staging based on CT alone and staging based on CT and PET/CT ($p=0.0001$) (data not presented)
- 29 cases (42%) were discordant
- Disease was upstaged by CT plus PET/CT in 41% of patients and downstage only in 1%
- Although difference between staging algorithms based on PET/CT alone versus CT and PET/CT reached statistical significance ($p=0.005$), discordance was found in only 8 patients (12%). All were upstaged by the addition of CT to PET/CT (data not presented)
- Suggested treatment strategy based on CT versus PET/CT was different in 17 patients (25%)
- Suggested treatment strategy based on CT versus CT plus PET/CT was different in 18 patients (26%)
- Suggested treatment strategy based on PET/CT versus CT plus PET/CT was different in 6/68 patients (9%)

Luminari, S., Biasoli, I., Arcaini, L., Versari, A., Rusconi, C., Merli, F., . . . Federico, M. (2013). The use of FDG-PET in the initial staging of 142 patients with follicular lymphoma: a retrospective study from the FOLL05 randomized trial of the Fondazione Italiana Linfomi. *Annals of Oncology*, 24(8), 2108-2112.

Pub year:		Patient selection	Index test	Reference standard	Flow and timing	
Country	Italy	Patients stage II to IV follicular lymphoma from FOLL05 randomised trial were included. Median age was 57 years (range 33–74).	Total body PET/CT scan (machine not reported) CT scan with iodine contrast medium for neck, thorac and abdomen	For each examination, nodal sites were classified and counted accordingly to the Follicular Lymphoma International Prognostic Index (FLIPI) schema. Nodal sites were considered positive if their maximum transverse diameters were >1.5 cm at CT or if they were positive at PET scan. Extra-nodal sites were considered positive at CT in the case of nodular involvement or case of organ enlargement not otherwise justified. EN involvement at PET scan was considered for sites showing avidity for FDG. EN sites were counted on an organ basis. BM involvement was established on the basis of the local pathology report of BM biopsy.	Baseline PET/CT amd CT were done before the start of treatment

Non Hodgkin's Lymphoma: diagnosis and management

E1-NHL

Papajik, T et al. (2011). Determining the extent and stage of disease in patients with newly diagnosed non-Hodgkin's lymphoma using F-FDG-PET/CT. Neoplasma, 58(4); 291-297									
Pub year: 2011		Patient selection		Index test		Reference standard		Flow and timing	
Country	Czech	Between September 2007 and March 2009, total of 122 patients with newly diagnosed and untreated NHL were indicated for initial 18F-FDG PET/CT examination. Lymphoma diagnosed on basis of two readings of cancer tissue biopsy specimens by 2 independent pathologists		18F-FDG PET/CT		– Blood count with differential and bone marrow tests		– Not reported	
		Median age: 59 years (range: 26-79 years) Male/female: 67/55		– Siemens Biograph 16 HI-REZ scanner		– Samples were analysed histopathologically and immunohistochemically from tissue sampled by trephine biopsy from the iliac blade or immunocytologically (by flow cytometry) from bone marrow aspirate			
		117/122 defined as 18F-FDG –avid and included in analyses		– Patients fasted for at least 6 hours		– Basic imaging method for determining the size and extend of unclear findings on PET/CT scans or unclear clinical or laboratory findings, the attending physician referred the patient for additional adequate investigations (endoscopy, ultrasound or MRI), complemented with biopsy of unclear lesions if necessary			
				– 60 minutes after injection image acquisition started		– Disease was staged by the attending haematologist based on the summary of all available data on the extent and behaviour of the patient's tumour			
				– Blood glucose levels measured and did not exceed 10 mmol/l					
				PET CT Interpretation:					
				– Independently assessed by a radiologist and a nuclear medicine physician					
				– An abnormal lymph node seen on a CT scan was defined as that with either the long axis exceeding 15mm or the long axis of 11-15 mm and the short axis exceeding 10mm; in the case of an extranodal organ, changes in its pathological and anatomical properties					
				– A PET-positive finding was defined as a visually evaluated lesion with focal or diffuse accumulation of 18F-FDG higher than that in the background or structures of mediastinal blood pool, respectively					
Design, period	Prospective multicentre observational study 2007-2009	Was a consecutive or random sample of patients enrolled?	Yes	Were the index test results interpreted without knowledge of the results of the reference standard?	Unclear	Is the reference standard likely to correctly classify the target condition? Adams, H. J., Kwee, T. C., Vermoolen, M. A., de, K. B., de Klerk, J. M., Adam, J. A., . . . Nievelstein, R. A. (2013). Whole-body MRI for the detection of bone marrow involvement in lymphoma: prospective study in 116 patients and comparison with FDG-PET. *European Radiology*, 23(8), 2271-2278.

Pub year:		Patient selection		Index test		Reference standard		Flow and timing	
Country	The Netherlands	Age > 7 years, newly diagnosed, Hodgkin (N=20) or non-Hodgkin lymphoma (N=96), before start of treatment, Exclusion criteria: contraindications for MRI, prior malignancy, pregnancy, treatment already started		FDG-PET was performed with four different PET systems (Biograph 40 TruePoint PET-CT, Siemens Healthcare; Biograph mCT, Siemens Healthcare; Philips Gemini TOF PET-CT, Philips Healthcare; or Allegro; Philips Healthcare). Classified as positive or negative for bone marrow involvement: focally increased FDG uptake relative to the surrounding bone marrow was considered positive for bone marrow involvement. Whole-body MRI was performed at 1.5 T (Achieva, Philips Healthcare, Best, The Netherlands or Magnetom Avanto, Siemens Healthcare, Erlangen, Germany).		Unilateral BMB of the posterior iliac crest was performed by different haematologists as part of routine clinical care. Biopsies were interpreted by different experienced haematopathologists who were blinded to whole-body MRI, FDG-PET and other imaging findings.		Whole-body MRI was done before the start of treatment. All patients also underwent blind BMB of the posterior iliac crest as part of standard clinical care before the start of treatment. Pretreatment FDG-PET was also performed as part of standard clinical care in some patients (N=80), at the request of the treating haematologists, this decision was not influenced by whole-body MRI or BMB findings. The mean time interval between FDG-PET and BMB was 10.8 days (SD: 9.9 days, range: 0–45 days). In 35 out of 80 patients, FDG-PET was performed after BMB.	
Design, period	Prospective observational study	<i>Was a consecutive or random sample of patients enrolled?</i>	unclear risk	<i>Were the index test results interpreted without knowledge of the results of the reference standard?</i>	low risk	<i>Is the reference standard likely to correctly classify the target condition?</i>	unclear risk (BMB of iliac crest only – can miss bone marrow involvement – but patients were also followed up with other tests)	<i>Was there an appropriate interval between index test(s) and reference standard?</i>	low risk
N	116 (PET-CT done in 80)	<i>Was a case-control design avoided?</i>	low risk	<i>If a threshold was used, was it pre-specified?</i>	low risk	<i>Were the reference results interpreted without knowledge of the results of the index test?</i>	low risk	<i>Did all patients receive a reference standard?</i>	low risk
Follow-up		<i>Did the study avoid inappropriate exclusions?</i>	low risk					<i>Did all patients receive the same reference standard?</i>	low risk
		<i>Could the selection of patients have introduced bias?</i>	low risk	<i>Could the conduct or interpretation of the index test have introduced bias?</i>	low risk	<i>Could the reference standard, its conduct, or its interpretation have introduced bias?</i>	unclear risk – BMB was done before PET in 30 cases and could have caused a signal change	<i>Were all patients included in the analysis?</i>	low risk

Non Hodgkin's Lymphoma: diagnosis and management

Funding source		<i>Are there concerns that the included patients do not match the review question?</i>	unclear risk – HD included	<i>Are there concerns that the index test, its conduct, or interpretation differ from the review question?</i>	low concern	<i>Are there concerns that the target condition as defined by the reference standard does not match the review question?</i>	low concern	<i>Could the patient flow have introduced bias?</i>	low concern

FDG-PET -	7	10	FDG-PET -	1	27																															
Bone marrow involvement for intermediate grade (mantle cell) NHL	BMB +	BMB -																																		
FDG-PET +	0	0																																		
FDG-PET -	6	0																																		
Comments	No true reference standard. Authors note that Post-hoc analysis revealed that seven out of eight whole-body MRI-positive/FDG-PET-positive/BMB-negative cases were true positive for lymphomatous bone marrow involvement.																																			

Non Hodgkin's Lymphoma: diagnosis and management

E1 TCL

Casulo, C., Schoder, H., Feeney, J., Lim, R., Maragulia, J., Zelenetz, A. D., & Horwitz, S. (2013). 18F-fluorodeoxyglucose positron emission tomography in the staging and prognosis of T cell lymphoma. <i>Leukemia and Lymphoma</i> , 54(10), 2163-2167.									
Pub year:		Patient selection		Index tests		Reference standard		Flow and timing	
Country	USA	Patients with histologically proven mature T-cell or natural killer (NK) lymphomas who underwent FDG-PET as part of initial staging or staging at relapse. 61% male, 39% female. Patients with primary cutaneous T-cell lymphomas were excluded.		Staging FDG-PET scans were done on state of the art PET/CT systems before the start of treatment at initial diagnosis or relapse. Patients were staged based on the Ann Arbor system, using helical computed tomography (CT) scan of the chest, abdomen and pelvis, physical examination and bone marrow biopsy. CT scans of the neck were not routinely performed.		No reference standard		Not reported	
Design, period	Retrospective observational study, 2001-2010	Was a consecutive or random sample of patients enrolled?	Unclear risk	Were the index test results interpreted without knowledge of the results of the reference standard?	Low risk	Is the reference standard likely to correctly classify the target condition?	High risk	Was there an appropriate interval between index test(s) and reference standard?	Unclear risk
N	95	Was a case-control design avoided?	Low risk	If a threshold was used, was it pre-specified?	Unclear risk	Were the reference results interpreted without knowledge of the results of the index test?	High risk	Did all patients receive a reference standard?	Unclear risk
Follow-up	Not reported	Did the study avoid inappropriate exclusions?	Low risk					Did all patients receive the same reference standard?	Unclear risk
		Could the selection of patients have introduced bias?	Low risk	Could the conduct or interpretation of the index test have introduced bias?	Low risk	Could the reference standard, its conduct, or its interpretation have introduced bias?	High risk	Were all patients included in the analysis?	Unclear risk
Funding source	Not reported	Are there concerns that the included patients do not match the review question?	Unclear concern – some restaging not new diagnosis	Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Low concern	Are there concerns that the target condition as defined by the reference standard does not match the review question?	High concern	Could the patient flow have introduced bias?	Unclear concern
Results	Initial staging and new sites of disease FDG-PET was positive at initial staging in 96% (91/95) of patients. New nodal and extranodal disease sites were identified in 50% (47/95) of patients. Since FDG-PET scan routinely images from the base of the skull, sites in the neck and supraclavicular regions were included in the imaging. Since CT of the neck was not routinely used in staging (clinical evaluation was done), the most frequently found additional nodal sites were in the neck (11/95) and supraclavicular area (4/95)								

Non Hodgkin's Lymphoma: diagnosis and management

	<p>Alteration of stageFDG-PET would have altered the clinical stage in 5.2% of patients (5/95) as compared to CT. Two patients were up-staged (stage I increased to stage III; stage II increased to stage IV), while three patients were down-staged. The change in stage did not result in any treatment alterations, largely due to the use of combination chemotherapy regardless of stage, and short course chemotherapy was not performed</p>	
	<p>Change in stage based on FDG-PET.</p>	
	Stage change	Reason
	Upstage	
	1. Stage I → III	Axillary, inguinal lymph nodes detected
	2. Stage II → IV	Nasopharynx, tonsil lesions detected
	Downstage	
	1. Stage IV → III	Lung lesions not detected by FDG-PET
	2. Stage IV → III	Lung lesions not detected by FDG-PET
3. Stage III → 0	No FDG uptake in neoplastic lesions	
Comments		

Non Hodgkin's Lymphoma: diagnosis and management

E1 DLBCL

Cerci, J. J., Gyorke, T., Fanti, S., Paez, D., Meneghetti, J. C., Redondo, F., Carr, R. (2014). Combined PET and biopsy evidence of marrow involvement improves prognostic prediction in diffuse large B-cell lymphoma. *Journal of Nuclear Medicine*, 55(10), 1591-1597.

Pub year:		Patient selection		Index test		Reference standard		Flow and timing	
Country	Brazil, Chile, Hungary, India, Italy, Korea, Phillipines and Thailand	Sequential cases of DLBCL, with patients aged 16 y or older, provided that informed consent could be obtained before chemotherapy. Exclusions were central nervous system involvement, cancer within preceding 5 y, and steroid therapy before staging scan. Diagnosis of DLBCL was based on histology with standard immunohistochemistry to include, at minimum, CD20, CD3, and either Ki-67 or MiB1.		PET/CT (n =217) or separate PET and CT (Italy, Brazil; n =110). Marrow involvement on the staging PET or PET/CT scan was classified as: <ul style="list-style-type: none"> Negative Positive, focal (1 or more circumscribed areas of high 18F-FDG uptake within the skeleton). Positive, diffuse (uniform increased 18F-FDG uptake throughout the bone marrow space). Diffuse 18F-FDG uptake was not considered to represent lymphoma involvement unless supported by positive biopsy histology. 		Patients were considered to have bone marrow involvement by lymphoma if they had either histologic DLBCL in the marrow biopsy or focal PET-positive (PET+) marrow involvement irrespective of iliac crest biopsy histology. So by definition "PET positive, focal" was considered marrow involved by lymphoma.		All tests were done before start of treatment – but exact timings are not reported.	
Design, period	Prospective consecutive series, 2008-2011	<i>Was a consecutive or random sample of patients enrolled?</i>	consecutive	<i>Were the index test results interpreted without knowledge of the results of the reference standard?</i>	low risk	<i>Is the reference standard likely to correctly classify the target condition?</i>	Unclear risk	<i>Was there an appropriate interval between index test(s) and reference standard?</i>	unclear risk
N	327	<i>Was a case-control design avoided?</i>	low risk	<i>If a threshold was used, was it pre-specified?</i>	low risk	<i>Were the reference results interpreted without knowledge of the results of the index test?</i>	Unclear risk	<i>Did all patients receive a reference standard?</i>	low risk
Follow-up	Median 35 months	<i>Did the study avoid inappropriate exclusions?</i>	low risk					<i>Did all patients receive the same reference standard?</i>	low risk

Non Hodgkin's Lymphoma: diagnosis and management

E1 -NHL

Akkas, B. E., & Vural, G. U. (2013). The incidence of secondary central nervous system involvement in patients with non-Hodgkin's lymphoma as detected by F-18-FDG PET/CT. <i>Nuclear Medicine Communications</i> , 34(1), 50-56.									
Pub year:		Patient selection		Index test		Reference standard		Flow and timing	
Country	Turkey	<p>Patients with biopsy-proven NHL who had FDG-PET-CT (n=123 patients,58 men, 65 women) PET/CT was indicated for initial staging in 68 patients and for restaging of recurrent disease in 55 patients. Mean age 56.5±19.2 (range: 6–93) years. Clinical Ann Arbor stages were: stage I – 10 patients; stage II – 44 patients; stage III – 32 patients; and stage IV – 37 patients. The subtypes of NHL were: DLBCL 72 patients, B-cell lymphoma with features intermediate between DLBCL and Burkitt lymphoma in two patients, B-cell lymphoma with features intermediate between DLBCL and Hodgkin's lymphoma in 17 patients, Burkitt lymphoma in two patients, follicular lymphoma in five patients, MALT lymphoma in three,mantle cell lymphoma in eight, T-cell lymphoma in three,small lymphocytic lymphoma in eight, and lymphoplas-macytic lymphoma in three patients.</p>		<p>PET/CT imaging using an integrated PET/CT scanner (Siemens Biograph 6 – True Point PET/CT systems; Siemens, Chicago, Illinois, USA). Images were analyzed visually and quantitatively by two reviewers experienced in interpreting PET/CT scans. Findings were recorded by consensus.</p>		<p>Leptomeningeal and parenchymal involvements were considered as CNS involvement. Parenchymal involvement was diagnosed when a mass lesion was detected in the brain on PET/CTand confirmed by MRI and cerebrospinal fluid (CSF) cytology. Leptomeningeal involvement was confirmed when malignant cells were detected in the CSF cytological study conducted after PET/CT. MRI for the brain and spine was not routinely performed for all patients. However, patients with pathological findings on 18F-FDG PETand patients with neurological symptoms underwent MRI imaging for the brain and spine when necessary.</p>		<p>Flow and timing is unclear. The paper indicates that MRI and CSF cytology were done following PET-CT – but only if PET-CT was positive. There is no indication of the timings of the tests.</p>

Non Hodgkin's Lymphoma: diagnosis and management

E1

Cetin, G., Cikrikcioglu, M. A., Ozkan, T., Karatoprak, C., Ar, M. C., Eskazan, A. E., . . . Cermik, T. F. (2015). Can positron emission tomography and computed tomography be a substitute for bone marrow biopsy in detection of bone marrow involvement in patients with Hodgkin's or Non-Hodgkin's lymphoma? Turkish Journal of Hematology, 32(3), 04. doi:http://dx.doi.org/10.4274/tjh.2013.0336

Pub year:		Patient selection		Index test		Reference standard		Flow and timing	
Country	Turkey	<p>The medical files of a total of 297 patients diagnosed with HL or aNHL and followed at the hematology clinics of 3 hospitals were screened. Patients with classical HL (N=61) or aggressive NHL (N=100) were included.</p> <p>Exclusion criteria: indolent aNHL, chronic lymphocytic leukemia/small lymphocytic lymphoma, or nodular lymphocyte-predominant HL and those with secondary malignancies.</p>		<p>PET/CT imaging was performed using a Siemens Biograph LSO HI-REZ integrated PET/CT camera (Biograph 6, Siemens Medical Solutions, Chicago, IL, USA). PET/CT scans were obtained 60-80 min after the administration of 5.4 MBq/kg 18F-fluorodeoxyglucose (FDG). The patients fasted for at least 6 h and serum glucose levels were below 120 mg/dL in all patients. All PET/CT images were visually assessed for BMI by 2 experienced nuclear medicine physicians without the results of the BMBs. The uptake of FDG in the bone marrow was visually classified into 3 categories: (1) diffusely intense FDG uptake in the bone marrow, which represents diffuse involvement; (2) lesions with focal intense FDG uptake, which were suggestive of focal involvement of bone marrow; (3) no focal or diffuse increased FDG uptake in bone marrow, which represents normal bone marrow functions.</p>		<p>Unilateral BMB samples – obtained from the dorsal iliac crest and reviewed by haematopathologist. Discordant cases (BMB negative, PET-CT positive) were considered focal disease and treated with chemotherapy because bone marrow infiltration could not be excluded.</p>		Not reported

Chen-Liang, T. H., Martin-Santos, T., Jerez, A., Senent, L., Orero, M. T., Remigia, M. J., Ortuno, F. J. (2015). The role of bone marrow biopsy and FDG-PET/CT in identifying bone marrow infiltration in the initial diagnosis of high grade non-Hodgkin B-cell lymphoma and Hodgkin lymphoma. accuracy in a multicenter series of 372 patients. American Journal of Hematology, 90(8), 686-690.									
Pub year:		Patient selection		Index test		Reference standard		Flow and timing	
Country	Spain	Patients of 18 years old or older were included if both BMB and PET/CT were performed simultaneously as part of the routine pre-therapy staging for newly diagnosed HL or HG-B NHL. Patients had not received either chemotherapy or corticosteroids, and no concomitant malignancy was known to be present at the time of both procedures.		FDG PET/CT scans were performed as whole-body scans (from the base of the skull to mid thigh) after a 6-hr fast. PET/CT studies were obtained on the following PET/CT devices: Gemini TF64 (Philips), Gemini GXL (Philips), Gemini TF16 (Philips), Discovery LS (GE Healthcare), and BiographTP16 (Siemens).		Unilateral posterior iliac crest trephine biopsy and marrow aspirate routinely formalin-fixed and paraffin embedded and subsequently evaluated morphologically on the basis of hematoxylin-eosin and Giemsa stains. PET-CT was also part of the reference standard		Time between BMB and PET-CT was 30 days or less.	
Design, period	Retrospective, 2009-2014	Was a consecutive or random sample of patients enrolled? Cho, S. F., Chang, C. C., Liu, Y. C., Chang, C. S., Hsiao, H. H., Liu, T. C., . . . Lin, S. F. (2015). Utilization of 18F-FDG PET/CT as a staging tool in patients with newly diagnosed lymphoma. Kaohsiung Journal of Medical Sciences, 31(3), 130-137.

Pub year:		Patient selection		Index test		Reference standard		Flow and timing	
Country	Taiwan	The inclusion criteria were recent diagnosis and histology- proven Hodgkin's lymphoma (HL) or non-Hodgkin's lymphoma (NHL). The patients had to be 20 years old or older and free of other previous or concurrent malignant disease. 109 had aggressive NHL, and 47 indolent NHL.		Patients underwent whole-body imaging with a dual-modality PET/CT system (Discovery ST 16, GE Medical System, Waukesha, Wisconsin, USA). The determination of bone marrow involvement was made by a nuclear medicine physician blinded to the pathological diagnoses from the bone marrow biopsy. A positive bone marrow involvement result was defined by focally increased FDG uptake in the bone marrow or diffusely increased bone marrow uptake with an intensity greater than that of the liver. A negative result was recorded when no abnormal FDG uptake was observed. Bone marrow involvement was classified as focal only, diffuse only, or both focal and diffuse.		Bone marrow examination, including aspiration and trephine biopsy, was performed via the right iliac crest (one site bone marrow biopsy) by an experienced hematologist after the procedures had been thoroughly explained to the patients. The bone marrow specimen was > 2 cm in each case, and the pathology of each biopsy was peer-reviewed by experienced pathologists. Immunohistochemical studies were also incorporated in cases of suspected marrow involvement.		All patients underwent PET/CT and bone marrow biopsy as part of a staging work-up. Exact timings not reported.	
Design, period	Retrospective, 2009	Was a consecutive or random sample of patients enrolled?	Low risk (likely consecutive)	Were the index test results interpreted without knowledge of the results of the reference standard?	Low risk	Is the reference standard likely to correctly classify the target condition?	Unclear risk (focal involvement)	Was there an appropriate interval between index test(s) and reference standard? Pub year:		Patient selection			Index test		Reference standard		Flow and timing	
Country	Korea	Patients identified from medical records of one institution. Included 86 patients with NHL			FDG PET-CT in line system (Discovery ST, General Electronic Medical Systems, Milwaukee, WI). Qualitative PET data were collected from retrospectively reviewed medical records, which were reported based on visual comparison of uptakes between the lesion and normal background by a nuclear medicine physician. All detected FDG-avid lesions in the iliac crest were objectively analyzed by measurement of the calculated maximum standardized uptake value (SUVmax), and the cut-off value for positivity was 2.0 g/mL.		BM biopsy was conducted on one side of the dorsal iliac crest and BM biopsy samples were analyzed following standard procedures, including formalin fixing and paraffin embedding and staining with hematoxylin and eosin. Additional immunohistochemical study was performed when necessary.		Not reported

Pub year:		Patient selection			Index test		Reference standard		Flow and timing	
Country	Hong Kong	Consecutive patients who received staging PET/CT for indolent lymphoma (N=46) were included.			PET-CT was done using a GE AFW4.3 scanner. Scans were classified qualitatively by consensus of 2 radiologists blinded to BM results. Scans were categorized as normal, diffuse or focal uptake patterns in comparison to the liver.		Bilateral BMA and BMB were done and morphological assessment, flow-cytometry and immunohistochemical studies were done to the WHO 2008 system. In patients with focal uptake on PET/CT serial PET/CT was the reference standard – including assessment of lesion response to treatment.		The mean interval between PET/CT was 4 days (S.D. 9 days).	
Design, period	Retrospective, 2007-2014	Was a consecutive or random sample of patients enrolled? Non Hodgkin's Lymphoma: diagnosis and management

González-Barca E., et al. (2013). Predictive value of interim 18F-FDG-PET/CT for event free survival in patients with diffuse large B-cell lymphoma homogenously treated in a phase II trial with 6 cycles of R-CHOP-14 plus pegfilgrastim as first-line treatment.

Table 2. Event free survival according to PET/CT

I-PET/CT	Event free survival %	P value	Median event free survival	Negative predictive value %	Positive predictive value	Sensitivity	Specificity
Negative I-PET	86.1	0.036	Not reached	82.9	-	NR	NR
Positive I-PET	64.3		Not reached	-	32.4	NR	NR
F-PET/CT							
Negative F-PET	85.2	<0.0001	Not reached	86.0	75.0	52.9	94.2
Positive F-PET	25		4.5 months				

Note. NR: Not reported

In multivariate analysis, F-PET/CT was the only significant variable in the model (p<0.0005)

	YES	NO	UNCLEAR
The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results?	X		
Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias?	X		
The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias?		X Not all patients had a scan Not all patients had the same scan No information on type of scanner. No information on criteria for positive and negative scans. Variation in timing of the scan (60-90 minutes)	
The outcome of interest is adequately measured in study participants, sufficient to limit potential bias?	X		
Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest?	X		
The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results?	X

E2 and E3 - DLBCL

Pregno P., et al. (2012). Interim 18-FDG-PET/CT failed to predict the outcome in diffuse large B-cell lymphoma patients treated at the diagnosis with rituximab-CHOP. *Blood*, 119(9); 2066-2073.

Pub year: 2012		Patient Characteristics	Intervention	Outcome
Country	Italy	88 newly diagnosed patients with DLBCL 5 hematology departments	18 F-FDG PET/CT – Philips Gemini, General Elctric Discovery ST, General Electric Discovery LS and Siemens Biograph 16 HI-REZ. – All patients fasted for at least 6 hours – Glucose levels between 90 and 160 mg/dL – Scans done within a range of 60-90 after injection (82/88 patients had the scan at 60 minutes)	Progression free survival – Time from the start of treatment to death/progression as a result of any cause, patients still alive were censored at the date of last contact
Design, period	Retrospective review 2004-2009	Baseline scan: at diagnosis I-PET: after 2 (n=58), 3 (n=9) or 4 (n=21) cycles of chemotherapy F-PET: approximately 1 month after the end of chemoimmunotherapy with or without radiotherapy	Interpretation: – All scans centrally reviewed at Turin University Centre – δ SUVmax calculated with a cut-off value of 66% (Lin et al. 2007) – Interim results interpreted as positive or negative by visual dichotomous response criteria according to the 5-point score system defined at the First Consensus Conference in Deauville 2009: – 1: no uptake – 2: uptake equal or less than mediastinum – 3: uptake more than mediastinum but less than liver – 4: uptake moderately increased compared with the liver at any site – 5: uptake markedly increased compared with the liver at any site or/and new sites of disease – Cut-off value at grade 4 of the 5 point score – When appreciation of difference on a visual basis was difficult, a SUVmax-based analysis (liver vs. lesion) was performed – All final scans evaluated using Juweid criteria using mediastinal blood pool as reference background for visual evaluation of residual activity in masses equal to or greater than 2cm	Overall survival – Time from start of treatment to death as a result of any cause; patients still alive censored at the date of last contact
N	88			
Follow-up	Median: 26.2 months Range: 8-67 months	Median time to perform I-PET from the previous course: 13 days (range: 4-27 days) Median time to perform F-PET: 36 days (range: 12-210 days)		
Funding source	Supported in part by Ministero della Salute, Dipartimento dell'Innovazione-Direzione Generale Ricerca Scientifica e Tecnologica One author: advisory committee of Roche Italy and lecture fee from Roche. All other authors declared no competing financial interests	Median age: 55 years (range: 18-80) 41 males 47 females Stage I or II: 29 Stage III or IV: 53 Treatment: R-CHOP Involved field radiotherapy to areas of bulky disease: n=14

E2 - DLBCL

Yang DH., et al. (2009). The combined evaluation of interim contrast-enhanced computerized tomography (CT) and FDG-PET/CT predicts the clinical outcomes and may impact on the therapeutic plans in patients with aggressive non-Hodgkin's lymphoma. *Ann Hematol* 88:425-432

Pub year: 2009		Patient Characteristics	Intervention	Outcome
Country	Korea	106 newly diagnosed patients with aggressive NHL enrolled between August 2004 and June 2008 at Chonnam National University Hwasun Hospital	PET/CT and CT – International Workshop Criteria (Cheson, 1999) – Classified patients based on three mid-response criteria of PET/CT using the semi-quantitative assessment of the maximal standardised uptake value (SUVmax): – Complete metabolic response (CMR): complete resolution of former PET findings and/or SUV of all former lesions <3.5 were classified – Partial metabolic response (PMR): SUV decrease greater than 50% of the maximum pathologic FDG uptake between the diagnosis and interim scan classified but still positive at the previously involved site – No metabolic response (NMR): Decrease less than 50% of the max SUV or increased uptake at prior pathological lesions or newly developed pathological lesions between successive PET scans	Event free survival – Calculated from the treatment start time to the first recording of disease progression or death from any cause. Patients whose disease did not progress were censored using the date at which they were last known to show no progress Overall survival – Period from treatment start time to the date of last follow-up or death from any cause. Patients who were subjected to high-dose chemotherapy followed by autologous stem cell transplantation were censored at the time of transplantation
Design, period	Prospective observational study 2004-2008	Interim CT and PET/CT after the third or fourth primary PET/CT and performed a day prior to a scheduled chemotherapy		
N	116	Final CT and PET/CT assessed with a month of completing chemotherapy		
Follow-up	Median: 24.3 months Range: 5.8-52.9 months	Treatment: patients with localized lymphoma were treated with 3-4 cycles of chemotherapy followed by involved field radiation therapy. Patients with advanced stage were treated with eight cycles of chemotherapy		
Funding source	Not reported	Patients aged greater than 60 were treated with six cycles of primary chemotherapy if they achieved a complete response (CR) for the interim PET/CT Median interval from the moment of diagnosis to interim response time was 95 days (range: 34-281 days) Median age: 59 years (range: 17-85 years) 90 (84.9%) patients had diffuse large B-cell lymphoma 16 (15.1%) patients had peripheral T-cell lymphoma Stage I-II: 59 Stage III-IV: 47

Non Hodgkin's Lymphoma: diagnosis and management

Martelli M, et al. 18F Fluorodeoxyglucose positron emission tomography predicts survival after chemoimmunotherapy for primary mediastinal large B-cell lymphoma: results of the international extranodal lymphoma study group IELSG-26 study. Journal of Clinical Oncology, 32(17); 1769-1775												
Results	Table 1. PET/CT interpretation after therapy in a blind central review N=115											
	Mediastinal blood pool cutoff between 2 and 3		54 PET/CT negative (47%)				61 PET positive (53%)					
			Negative predictive value: 98%				Positive predictive value: 18%					
	Deauville score		1	2	3	4	5					
	Number of patients		12	42	27	24	10					
	Progression/relapse		0	1	0	5	6					
	Liver cutoff between 3 and 4		Negative predictive value: 99%				Positive predictive value: 32%					
			81 PET-negative (70%)				34 PET-positive (30%)					
	Table 2. Survival rates according to the Deauville cutoff points											
	Overall survival			Progression free survival			Overall survival			Progression free survival		
1-2	>2	P value	1-2	>2	P value	1-3	>3	P value	1-3	>3	P value	
100%	91%	0.0298	98%	82%	0.044	100%	83%	0.0003	99%	68%	<0.0001	
Achievement of CMR at 3 to 4 weeks after chemoimmunotherapy predicted a higher PFS (P=0.0044) with high sensitivity but poor specificity (Negative predictive value of 98% but positive predictive value of only 18%) and the difference in overall survival significantly different (p=0.0298)												
Moving the cutoff point for the definition of a CMR from the MBP uptake to liver uptake increased specificity and the PPV was 32% without loss of sensitivity. Use of liver uptake as the cutoff for PET positivity resulted in a clearer distinction between risk subgroups both in terms of PFS (p<0.001) and OS (p<0.001)

E2 - DLBCL

Carr, R., Fanti, S., Paez, D., Cerci, J., Gyorke, T., Morris, T. P., . . . Topcuoglu, P. (2014). Prospective international cohort study demonstrates inability of interim PET to predict treatment failure in diffuse large B-cell lymphoma. <i>Journal of Nuclear Medicine</i> , 55(12), 1936-1944.						
Pub year:		Patient Characteristics	Intervention	Comparison	Outcome	
Country	Brazil, Chile, Hungary, India, Italy, Philippines, South Korea, and Thailand	Patients with DLBCL (age, ≥16 y) Exclusions were cancer within the preceding 5 y, steroid therapy before the staging scan, and no 18F-FDG-avid disease on baseline PET. Diagnosis was based on biopsy with immunohistochemistry and classification by World Health Organization criteria	All patients were staged by PET/CT (N=217), or PET and CT separately (Italy & Brazil; N=110), and iliac crest marrow biopsy. Scans were done at 3 time points: before treatment, mid treatment (after 2 or 3 chemo cycles; I-PET), and end-chemotherapy (E-PET). The treatment protocol was for 6 cycles of R-CHOP at 21-d intervals (up to 8 cycles was permitted). Omission of rituximab was allowed in recognition that some eligible patients might otherwise be excluded for financial reasons. Scan results were reported to treating clinicians, but modification to planned treatment on the basis of the I-PET response was not permitted. Treatment escalation in response to a positive I-PET result was classified as treatment failure.	I-PET scan reporting was based on visual assessment and classified into 4 categories: 1. negative/CR, 2. complete response with minimal residual uptake (CR-MRU), 3. positive , 4. mixed response For outcome analysis, scans scored as CR-MRU were grouped with PET-negative; mixed response was classified as PET-positive. Mutivariate analysis was done using the following variables: I-PET, IPI, age, stage, performance status, extranodal sites, LDH , bulky disease > 5 cm, rituximab treatment, and I-PET timing [2 or 3+ cycles]	event free survival, overall survival	
	Design, period					Prospective observational study, 2008-2011
	N					361 (327 included)
	Follow-up					Median 2yr 11 mths
	Funding source					International Atomic Energy Agency.
Results	Table 1. EFS and OS according to I-PET results					
		I-PET-positive	I-PET-negative	HR (>1 favours I-PET negative)		
	2 year EFS	58% (95% CI, 48%-66%);	90% (95% CI, 85%-93%)	5.31 (3.29-8.56).		
2 year OS	72% (95% CI, 63%-80%);	93% (95% CI, 88%-96%)	HR, 3.86 (95% CI, 2.12-7.03).			
Multivariate model of EFS: I-PET status, performance status, and LDH were independent prognostic factors for EFS: positive I-PET, HR of 4.32 (2.64-7.10); performance status ≥ 2, 1.79 (1.05-3.07); and abnormal LDH, 1.66 (1.03-2.67). I-PET-negative cases with a performance status of 0-1 and normal LDH (n =110) had an exceptionally good 2-y EFS (98% [92.0%-100%]).

Comments	Unclear how many received PET/CT versus separate PET and CT.		

E2 - DLBCL

Zinzani, P. L., Gandolfi, L., Broccoli, A., Argnani, L., Fanti, S., Pellegrini, C., . . . Baccarani, M. (2011). Midtreatment 18F-fluorodeoxyglucose positron-emission tomography in aggressive non-Hodgkin lymphoma. <i>Cancer</i> , 117(5), 1010-1018.							
Pub year:		Patient Characteristics		Intervention	Comparison	Outcome	
Country	Italy	Patients with de novo aggressive NHL: histologically confirmed diagnosis of DLBCL (N=78) or primary mediastinal large B-cell lymphoma (PMLBCL; N=13) in accordance with WHO classification.		Treatment was MACOP-B (N=13), R-CHOP21 (N=65) or R-VNCOP-B (N=13) – depending on histology (DLBCL vs PMLBCL) and age. Midtreatment evaluation was performed via PET examination after 6 out of 12 cycles in patients receiving R-MACOP-B, after 4 out of 8 cycles in patients receiving R-VNCOP-B, and after 3 cycles in patients receiving R-CHOP21. PET-CT scan was done using GE Discovery. The examination was considered negative when no pathological tracer uptake was shown, or positive when areas of focal uptake were interpreted as unequivocally positive for lymphoma. Treatment does not appear to have been modified on the basis of interim PET results.	Interim PET+ vs PET-	OS,PFS

E2, E3 – DLBCL

Mamot, C., Klingbiel, D., Hitz, F., Renner, C., Pabst, T., Driessen, C., . . . Martinelli, G. (2015). Final Results of a Prospective Evaluation of the Predictive Value of Interim Positron Emission Tomography in Patients With Diffuse Large B-Cell Lymphoma Treated With R-CHOP-14 (SAKK 38/07). *J Clin Oncol*, 33(23), 2523-2529. doi: 10.1200/JCO.2014.58.9846

Pub year:		Patient Characteristics	Intervention	Comparison	Outcome
Country	Switzerland, Italy	Untreated DLBCL, with a positive PET scan and a measurable lesion of at least 15mm. Median age was 58.5 years with a WHO performance status of 0 in 56% of the patients, 1 in 36%, or 2 in 8%. Ann Arbor stage I, II, III, or IV was found in 17 (12%), 47 (34%), 32 (23%), and 42 patients (30%), respectively. An IPI score of 0 to 2 was found in 98 patients (71%) and a score of 3 to 5 was found in 39 patients (28%) with one patient score missing.	Predefined treatment consisted of six dose-dense cycles of R-CHOP every 14 days with growth factor support, followed by two cycles of rituximab. Patients with progressive disease at interim PET/CT were not eligible for further study treatment. PET/CT scans were to be performed in all patients at diagnosis, after two cycles of R-CHOP-14 (PET-2), and at the end of chemotherapy. For patients with a positive PET/CTscan after two cycles of R-CHOP-14, another PET/CT scan was performed after a total of four cycles of R-CHOP-14 (PET-4). No therapy change was made on the basis of the PET-2 or PET-4 scans unless progression was documented. PET images were evaluated locally (scored as positive/negative) and centrally (using the Deauville criteria: 1 to 3 = negative and 4 to 5 positive).	Outcomes compared according to interim PET+ and PET-. Multivariate analysis included the following variables: PET scan result after two cycles of R-CHOP-14, IPI score or its individual components, censoring after 2 years, or after refusal to continue treatment or follow-up.	Event-free survival: disease progression, death, or initiation of any nonprotocol anticancer treatment or concomitant radiotherapy were defined as events. Overall survival

E3 - DLBCL

ABO-Sheisha DM, et al. (2014). Prognostic evaluation of PET/CT in residual post-chemotherapy masses in patients with diffuse large B-cell lymphoma and its impact on survival. The Egyptian Journal of Radiology and Nuclear Medicine. 45; 921-928.

Pub year: 2014		Patient Characteristics	Intervention	Outcome
Country	Egypt	Retrospectively reviewed records of 85 patients with pathologically confirmed DLBCL according to the WHO classification (2008). Treated and followed-up in the Clinical Oncology Department of the Tanta University Hospital during the period from April 2010 to October 2013. <ul style="list-style-type: none"> 23 excluded as they had either received radiotherapy after chemotherapy; were pregnant or had diabetes. 62 patients included who were aged ≥18 years and had an Eastern Cooperative Oncology Group performance status of 0-2. Staging was done according to the Ann Arbor staging system All patients had finished chemotherapy and showed CT evidence of residual mass >1.5cm. Response assessed according to the international Workshop criteria (Cheson et al. 2007) Treatment: R-CHOP Age range: 18-73 years Mean age: 51.146 negative PET/CT; 52.357 positive PET/CT 	PET/CT Dedicated scanner (Siemens, Biograph-2) <ul style="list-style-type: none"> 6-8 weeks after completion of chemotherapy All patients fasted for at least 6 hours before FDG injection. Fasting blood glucose level of less than 150mg/dl was a requirement for all patients. Scan started 60 minutes after intravenous administration of 2.516 MBq FDG, during this period; the patient was instructed to rest without talking. CT was performed from skull base to pelvis by performing a scout view followed by a spiral CT with 80mA, 140 kVp. No oral contrast was given, and water only was used to delineate bowel. According to the criteria of the International Harmonisation Project, visual assessment was used to categorise FDG-PET scan findings as positive or negative. A PET-CT scan is defined as positive if there is abnormal FDG uptake great than background in surrounding tissue and unrelated to physiologic sites of tracer uptake, without a specific standardised uptake value (SUV) cut-off and a PET/CT scan is defined as negative if there is no 18F-FDG uptake. For residual hepatic or splenic lesion, abnormal uptake was defined as FDG accumulation greater than in the liver. 	Progression free survival <ul style="list-style-type: none"> Length of time from remission to being worse Overall survival <ul style="list-style-type: none"> Length of time from diagnosis to death Diagnostic accuracy

4: Management

4.1 Follicular Lymphoma

4.1.1 Review question: What is the most effective first-line treatment for people with stage IIa follicular lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) newly diagnosed with stage IIa follicular Non-Hodgkin's Lymphoma Subtypes: Symptomatic <i>Not 'b' symptoms but bulky disease, painful, discomfort</i> <i>Symptomatic criteria's: BNLI criteria; GELF criteria</i> Asymptomatic (including vital organ compromised) FLIPI Nodal/extra nodal Above/below diaphragm Exclude: Grade 3b All other	Radiotherapy Various dose levels Types of field radiation therapy (involved, extended) Chemotherapy Immuno-chemotherapy (Rituximab) Rituximab Radio-immuno therapy Observation/watch and wait	Each other	Overall survival Disease free survival Progression free survival Treatment related mortality Treatment related morbidity Health related quality of life Patient preference

Additional Comments on PICO

Where reported record results by subtypes included in PICO
 Query – Should we record use of PET scanning?
 Many comparative studies pre rituximab era
 06.06.14: Decision to limit population to Stage IIa only for the following reasons:
 Stage I1: These patients are generally treated with radiotherapy. GDG believe that there will be no data to answer issue of which type of therapy after surgery and that treatment within this group of patients within the UK is not an issue in current practice
 Stage IIa: Different countries are treating patients differently (US immediate radiotherapy, UK considered advanced disease: asymptomatic do nothing, symptomatic do something), uncertainty in practice so there is a need to know which treatment strategy to take.
 06.06.14: Due to potential need to include non-comparative studies a sample size limit of ≥ 40 will be applied.
 Jan 2015: excluded conference abstracts if they did not state stage information.
 Sifting update: Report data where the n of stage II patients is $>50\%$ of the entire sample when data is not reported according to disease stage II.

Evidence Quality

Figure 1. Study flow diagram

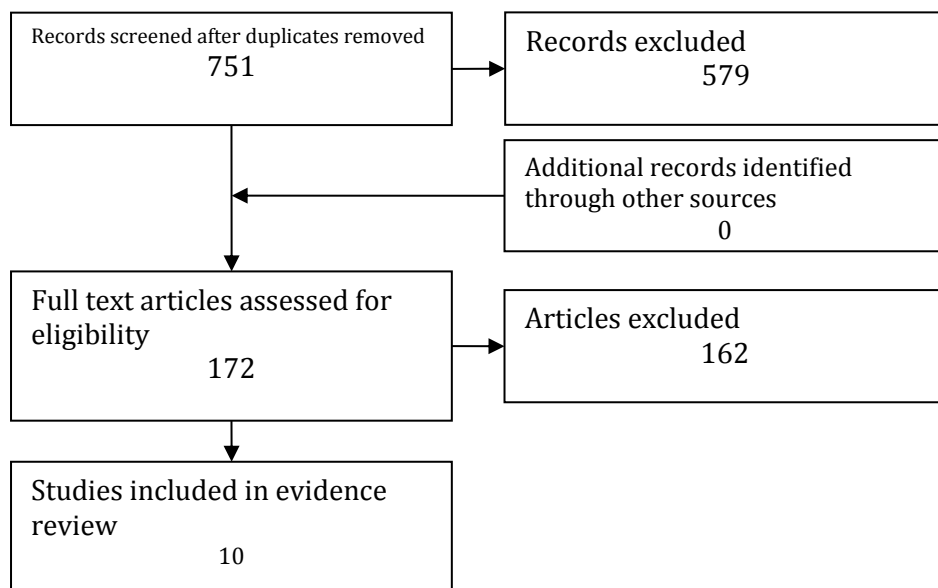

Table 1. Summary of findings. Studies were not pooled: results were reported individually

Treatment options and comparisons			Studies	N	Outcome	Study design	GRADE quality
Radiotherapy (a)	Vs.	No comparator	3	189	Overall survival: 86% (5-8years); 65% (10 years); 43% (15 years)	Observational	Very low
			2	67	Relapse free survival: 69%; 88.8% (10 years)	Observational	Very low
			1	50	Recurrence rate: 31% (5 years); 44% (7 years)	Observational	Very low
			1	102	Freedom from relapse: 45% (10 years)	Observational	Very low
			1	47	Progression free survival: 26% (15 years)	Observational	Very low
			1	47	Cancer specific survival: 54% (15 years)	Observational	Very low
	Vs.	No radiotherapy (b)	1	2140	(a) Higher disease specific survival (p=0.01) and overall survival rates (p=0.01)	Observational	Very low
Radiotherapy + chemotherapy (c)	Vs.	No comparator	1	47	Freedom from treatment failure: 70% Overall survival: 87%	Observational	Very low
	Vs.	Radiotherapy (a)	1	125	(c) Higher rate of freedom from relapse (p=0.008)	Observational	Very low
Radiotherapy + rituximab (d)	Vs.	Rituximab (e)	1	108	(d) and (e) lower relapse rates (p=0.03) higher progression free survival and longer time to next treatment (p=0.001) compared to (a)	Observational	Very low
	Vs.	Radiotherapy (a)					
	Rituximab (e)	Vs.					
Chemotherapy+ rituximab (f)	Vs.	Chemotherapy (g)	1	39	No difference between (f) and (g)	RCT	Very low
watch and wait (h)	Vs.	Chemotherapy (g)	1	36	No difference between (h) and (g)	RCT	Very

Note: The results from Barzenje et al. (2015) have not been included in Table 1, the GRADE tables or the evidence statements as although they are comparative, they are entirely descriptive with no inferential statistics presented for the target population

Evidence Statements

The evidence included ten studies: two randomised controlled trials, four retrospective cohort studies and four case series.

Radiotherapy alone

Very low quality evidence of overall survival rates came from three studies (two retrospective case series and one prospective cohort study: MacManus *et al.* 1996; Sack *et al.* 1998; Wilder *et al.* 2001) including 189 patients. These studies reported overall survival rates of 86% (5-8 years), 65% (10 years) and 43% (15 years) in patients with stage I (<50% of total sample size) and II follicular lymphoma. MacManus *et al.* (1996) and Sack *et al.* (1998) also reported relapse free survival rates between 69% and 88.8%. Recurrence rate at 5 years was 31% and at 7 years was 44% (Sack *et al.* 1998) with a 45% freedom from relapse rate at 10 years (MacManus *et al.* 1996). Wilder *et al.* (2001) reported a 15 year progression free survival rate of 26% and a cancer specific survival rate of 54%.

Radiotherapy versus no radiotherapy

One observational study (Pugh *et al.* 2010) including 2140 patients provided very low quality evidence of an overall survival benefit (higher disease specific survival: Hazard ratio [HR] 0.78, 95% confidence interval [CI] 0.65-0.94 p=0.01; higher overall survival rates: HR 0.78, 95% CI 0.65-0.94 p=0.01) in 505 patients with stage II follicular lymphoma treated with radiotherapy (external beam radiation therapy) compared to 1,635 patients treated with no radiotherapy (no information provided on type of treatments used in the comparison group).

Radiotherapy versus radiotherapy and chemotherapy

One observational study (Besa *et al.* 1995) provided very low quality evidence of a survival benefit (higher rate of freedom from relapse, p=0.008 [15 year rate]) in 80 patients with stage I (~30%) and II follicular lymphoma treated with radiotherapy and chemotherapy compared to 45 patients treated with radiotherapy alone. Overall survival (15 years) did not significantly differ according to treatment group (63% in the chemotherapy and radiotherapy group compared to 53% in the radiotherapy group) but no statistical analyses were presented to assess significant differences in relapse rates (0 at 7.5 years in the chemotherapy and radiotherapy group compared to 1 at beyond 15 years in the radiotherapy group) or the incidence of acute leukaemia (5 cases in the chemotherapy and radiotherapy group compared to 6 in the radiotherapy group).

Radiotherapy and chemotherapy alone

Very low quality evidence came from one non-comparative study (Seymour *et al.* 2003) which reported 10 year overall survival and freedom from treatment failure rates of 87% and 70% in 47 stage II follicular lymphoma patients treated with chemotherapy and involved field radiotherapy.

Radiotherapy versus rituximab versus radiotherapy and rituximab

One observational study (Mondello *et al.* 2014) provided very low quality evidence of lower relapse rates, higher progression free survival rates and longer time to next treatment in patients with stage I (47%) and II treated with either rituximab (n=38) or rituximab and radiotherapy (n=34) compared to patients treated with radiotherapy alone (n=36). Complete response rates were not significantly different according to the three treatment groups.

Chemotherapy versus chemotherapy and rituximab

Very low quality evidence came from one randomised controlled trial (RCT: Bachy *et al.* 2013) which compared rituximab plus CHVP to CHVP alone in 39 patients with stage II follicular lymphoma. This trial reported uncertainty about the relative effectiveness of the treatments in terms of event free survival (HR: 0.855 95% CI: 0.330-2.217; where HR < 1 favours chemo+rituximab).

Chemotherapy versus watch and wait

One randomised controlled trial (RCT: Ardeshta *et al.* 2014) provided low quality evidence of uncertainty about the relative median time to start of new treatment in 19 patients with stage IIA follicular lymphoma treated with rituximab compared to 17 patients with stage IIA follicular lymphoma who were randomised to a watch and wait programme (HR: 0.55 95%CI: 0.18-1.63).

GRADE Tables

Grade Profile 1: Should Rituximab induction therapy vs Watch-and-wait be used for Stage IIa Follicular lymphoma?

Settings: UK

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		
							Rituximab induction therapy	Watch-and-wait	Relative (95% CI)	Absolute	
Number of patients requiring a new treatment (follow-up median 46 months¹)											
1 N=36	randomised trials ²	no serious limitations	no serious inconsistency	no serious indirectness	very serious ^{3,4}	none	5/19 (26.3%)	8/17 (47.1%)	HR 0.55 (0.18 to 1.63)	18 fewer per 100 (from 36 fewer to 17 more)	⊕⊕○○ Low

¹ Median follow-up for all 463 patients and not provided for Stage IIa patients. Range: 38-50 months.

² Ardeshtna et al. (20124)

³ Small sample size (N=36) and low number of events. Author states that to detect an improvement in median time to start a new treatment in the Rituximab group of 18 months (30-48 months) with 5% significance level (allowing for multiple comparisons) and 90% power 192 events would be needed and 180 participants in each group.

⁴ Early closure of study arm. Study design was a three arm study comparing Rituximab induction to Rituximab maintenance to watch-and-wait. However, recruitment was stopped after 3 years in the Rituximab induction arm due to evidence showing a benefit for Rituximab maintenance over induction therapy.

Grade Profile 2: Should R-CHVP+I vs CHVP+I be used for Follicular Lymphoma Stage II?

Settings: France, Belgium

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		
							R-CHVP+I	CHVP+I	Relative (95% CI)	Absolute	
Event free survival (follow-up median 8.3 years¹)											
1 N=39	randomised trials ²	serious ³	no serious inconsistency	serious ⁴	serious ⁵	none	NR ⁶ Total N=22	NR Total N=17	HR 0.855 (0.330 to 2.217)	-	⊕○○○ Very Low

¹ Length of follow-up not reported by stage. Range: 3.3-9.6 years.

² Bachy et al. (2013)

³ Limited description of RCT methods (e.g. randomisation, blinding) to assess quality of study design.

⁴ Sample considered to be Stage II not Stage IIa because study inclusion criteria stated participants must fulfill at least any one of the criteria for high tumour burden (presence of bulk tumour, presence of B symptoms, performance status on the ECOG scale greater than 1, elevated serum levels of LDH or B2-microglobulin). No breakdown of these criteria presented by stage so unclear how many stage II participants had B symptoms.

Non Hodgkin's Lymphoma: diagnosis and management

⁵ Low sample size (N=39). No reporting of number of events in each group.

⁶ Number of events not reported by stage

Grade Profile 3: Should Chemotherapy +Radiotherapy vs Radiotherapy be used for Stage I and II Follicular Lymphoma?

Settings: USA

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		
							Chemotherapy +Radiotherapy	Radiotherapy	Relative (95% CI)	Absolute

⁵ Sample includes participants with B-symptoms so not all Stage IIa Follicular lymphoma.

⁶ Small sample size (N=72) and low number of events.

Grade Profile 9: Should Chemotherapy and Involved field radiotherapy (IF-XRT) be used for Stage II Follicular Lymphoma?

Settings: USA

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		Quality
							Chemotherapy and Involved field radiotherapy (IF-XRT)	No Control	Relative (95% CI)	Absolute	
10 year Overall survival (follow-up median 10 years¹)											
1 N=47	observational studies ²	serious ^{3,4}	no serious inconsistency	no serious indirectness	serious ⁵	none	87%	NA	-	-	⊕○○○ Very Low
10 year Freedom from treatment failure (follow-up median 10 years¹)											
1 N=47	observational studies ²	serious ^{3,4}	no serious inconsistency	no serious indirectness	serious ⁵	none	70%	NA	-	-	⊕○○○ Very Low

¹ Length of follow-up reported for whole sample and not by stage and NHL subtype. Range: 2.5-16 years

² Seymour et al. (2003)

³ No comparator

⁴ Author states that participants were allocated to two different chemotherapy regimens (COP-Bleo, CHOP-Bleo) but does not provide any information on reason for allocation and outcome by regimen for the whole sample or by stage.

⁵ Low sample size

Grade Profile 10: Should Radiotherapy vs No radiotherapy be used for Stage II and IIE Follicular Lymphoma?

Settings: USA

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		Quality
							Radiotherapy	No radiotherapy	Relative (95% CI)	Absolute	
Actuarial 10 year Disease specific survival (follow-up median 66 months¹)											
1 N=2140	observational studies ²	serious ³	no serious inconsistency	no serious indirectness	no serious imprecision	none	71%	63%	HR 0.78 (0.65 to 0.94)	71% disease specific survival with radiotherapy at 10 years compared with 63% with no radiotherapy	⊕○○○ Very Low
Actuarial 10 year Overall survival (follow-up median 66 months¹)											
1 N=2140	observational studies ²	serious ³	no serious inconsistency	no serious indirectness	no serious imprecision	none	63%	46%	HR 0.82 (0.71 to 0.95)	63% overall survival with radiotherapy at 10 years compared with 46% with no radiotherapy	⊕○○○ Very Low

¹ Length of follow-up includes participants with stage I or II follicular lymphoma. Range: 3-360 months

² Pugh et al. (2010)

³ No information on what type of treatment the 'no radiotherapy' group received. No radiotherapy group includes patients who were offered radiotherapy and elected to pursue other treatments or no treatment at all.

Evidence Tables

Ardeshtna KM, et al. (2014). Rituximab versus a watch-and-wait approach in patients with advanced-stage, asymptomatic, non-bulky follicular lymphoma: an open-label randomised phase 3 trial. <i>Lancet Oncology</i> , 15; 424-435.							
Pub year: 2014		Patient Characteristics			Intervention	Comparison	Outcome
Country	UK	Inclusion: – At least 18 years old – Low-tumour-burden follicular (grades 1,2 and 3a) – Stage II, III or IV – Asymptomatic (no B symptoms or severe pruritus) – Eastern Cooperative Oncology Group performance status of 0-1 – Entered trial within 3 months of diagnostic biopsy without previous treatment – Near normal full blood count, adequate renal function, normal liver function, disease measurable in two dimensions with no evidence of histological transformation, and no near-critical organ failure or organ compression Randomisation and masking: – Patients were randomly assigned to be carefully observed until treatment was needed (watchful waiting), to receive rituximab induction, or to receive maintenance rituximab. Randomisation done centrally by Cancer Research UK and UCL Cancer Trials Centre by the minimisation approach stratified by institution, grade, stage and age – Study was not masked 463 patients randomised Stage II (N=96): – N=36/187 watch and wait (17 in the three arm trial) – N=19/84 Rituximab induction – N=41/192 Maintenance rituximab On Sept 30 th 2007, recruitment into the rituximab induction group was closed because of a low recruitment rate and because other studies had shown a benefit of maintenance rituximab compared with watchful waiting after induction with or without chemotherapy. The trial design was revised and powered as a two-arm trial. Aim was to detect an improvement in the median time to start of new treatment.			Rituximab induction: – Intravenous rituximab (375 mg/m ²) every week for 4 weeks Watchful waiting	Each other	Median time to start new treatment
Design, period	RCT 2004-2009						
N	36/96/463 Stage IIa						
Follow-up	For all patients Median: 46 months (IQR: 38-50)						
Funding source	UCL Roche Lymphoma association Lymphoma Research Trust						
Results	Table 1.						
		2. Watch and wait		3. Rituximab induction		2 versus 3	
		Events	Total	Events	Total	HR	95% CI
	Three-arm trial*	8	17 (47.1%)	5	19 (26.3%)	0.55	0.18-1.63
Note. *Rituximab maintenance not reported							
Comments	– All descriptive statistics presented for the whole sample not just stage II so not reported – Low sample size and number of events. Author states that in order to detect an improvement in median time to start new treatment in rituximab group of 18 months (30-48 months) with a 5% significance level (allowing for multiple comparisons) and 90% power 192 events and 180 participants in each arm.

	Radiotherapy	505	71	0.01	0.78	0.65-0.94	55	0.01	0.82	0.71-0.95
No radiotherapy	1635	63	46							
Note. P values calculated using log-rank test.										
Comments	<ul style="list-style-type: none"> – All descriptive statistics presented for the whole sample not just stage II so not reported – Multivariate analyses not performed by stage so unclear if survival improvement of RT would remain statistically significant. In the whole sample multivariate analyses RT remained independent, with Stage I disease and upfront treatment with RT the only disease-or treatment-related factors independently associated with improved OS. – No information on what type of treatment the 'no radiotherapy' group received 									

Non Hodgkin's Lymphoma: diagnosis and management

Sack H., et al. (1998). Radiation treatment of follicle centre lymphoma. Results of a German multicentre and prospective study. Strahlenther Onkol, 174(4); 178-185.									
Pub year: 1998		Patient Characteristics			Intervention	Comparison	Outcome		
Country	Germany	Between January 1986 and August 1993 117 adults with follicle centre lymphoma were recruited from 24 institutions to enter the multi-centre prospective, not randomised clinical trial. Patients with histologically proven nodal follicle centre lymphoma of stages I, II and limited III were included. 40/117 Stage II Age range: <40 n=8; 40-60 n=22; >60 n=10 2 patients had B-symptoms (not reported in which stage)			Radiotherapy – Standardised radiotherapy regimen by total nodal irradiation – Dose per fraction was 1.8 to 2.0Gy in the abdominal bath 1.5 Gy up to a total dose of 26 Gy in adjuvant situation and 36 Gy to enlarged lymphoma	N/A	Overall survival Freedom from treatment failure		
Design, period	1986-1993 Prospective non-comparative observational study								
N	40/117								
Follow-up	For whole sample Median: 68 months								
Funding source	NR								
Results	Table 1. Survival rates								
		5 year – 8 year Overall survival	Relapse free survival	5 year Recurrence rate	7 year Recurrence rate	Survival			
	Stage II FL n=40	86 %	69%	31%	44%	at 2 years	at 4 years	at 6 years	at 8 years
Comments	– Article in German. Information extracted predominately from translated abstract. – 2 patients reported B-symptoms but not reported in which stage

Wilder RB, et al. (2001). Long-term results with radiotherapy for stage I-II follicular lymphomas. Int. J. Radiation Oncology Biol. Phys., 51(5); 1219-1227.						
Pub year: 2001		Patient Characteristics		Intervention	Comparison	Outcome
Country	USA	From September 1960 – October 1988: – 248 previously untreated patients with Ann Arbor Stage I or II low grade follicular lymphoma were treated at the Uni of Texas M.D. Anderson Cancer Centre. Pathologists at the centre reviewed the tissue biopsy specimens in every case ○ 148/248 treated on protocols consisting of chemo and RT (previously reported elsewhere) – 100/248 with WHO grade 1 or 2 FL who elected not to be treated on protocol, underwent RT alone (n=80) or chemotherapy alone (n=20) ○ 80 treated with RT alone (45 previously described in Besa et al. 1995) reported in current study – Of 100 age range 24-81 years (median 54 years) and 1 patient had B symptoms – 47/100 Stage II		Radiotherapy For all patients (stage I and II): – Involved-field administered to 7/80 patients – Regional RT administered to 43/80 patients – Extended-field RT used in 30/80 patients (more likely in stage II patients, p<0.001) – None of the patients underwent RT to both sides of the diaphragm – International Commission on Radiation Units and Measurement (ICRU) point doses (10) ranged from 26.2-50.0 Gy (median: 40.0) given in daily 1.0-3.0-Gy fractions (median: 1.7) during 12-51 days (median: 29) – Author notes that all patients with subdiaphragmatic lymphoma had stage II disease and lower total doses of RT were administered to these patients	N/A	Progression free survival Cause specific survival Overall survival
Design, period	Non-comparative retrospective review 1960-1988					
N	47/100/248					
Follow-up	For all (stage I and II) surviving patients (n=20): 3.5 - 28.7 years (median: 19.0)					
Funding source	National Cancer Institute, National Institutes of Health, Department of Health and Human Services					
Results	Table 1. Survival outcomes (%) for stage II patients					
	Ann Arbor stage	n	15-year progression-free survival	15-year cause specific survival	15-year overall survival	
	II	47	26	54	43	
Comments	– No information on why these 100 chose to not be treated according to standard protocol – All descriptive statistics presented for the whole sample not just stage II so not reported – Unclear if stage IIa as 1 patient reported B symptoms and it was not stated whether they had stage I or II disease					

4.1.2: Review question: Is autologous transplantation, allogeneic transplantation or no transplantation the most effective treatment for people with follicular lymphoma at various time points?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) with follicular non-Hodgkin's lymphoma. Exclude: Grade IIIB Transformed FL Composite/discordant FL Subgroups: Line of treatment Length of first remission FLIPI score (early/late/low/high risk) Use of Rituximab Quality of response to pre-transplant therapy	Autologous transplantation Allogeneic/ Allogeneic/ reduced intensity transplantation	No transplantation <i>(record what was used)</i> Rituximab Interferon Each other	Overall survival Disease free survival Progression free survival Treatment related mortality Treatment related morbidity Health-related quality of life
Additional Comments on PICO			
Record what the 'no transplantation' comparison was Report the stage of treatment (e.g. first response, second response, beyond second response) Where available report evidence by age Allogeneic transplantation no comparative data so look for trials TA 137: Rituximab relapsed stage III or IV FL, review analyses and recommendations need to take in to account the following recommendations: Rituximab recommended as an option for the induction of remission and/or maintenance therapy in people with relapsed stage III or IV follicular NHL. Rituximab recommended as an option for the treatment of people with relapsed or refractory stage III or IV follicular NHL when all alternative treatment options have been exhausted (that is, if there is resistance to or intolerance of chemotherapy). Following GDG 3 LB has included the following exclusion criteria: Sample size ≥40 (non-comparative studies) Non-comparative abstracts were excluded due to limited information to appraise

Evidence Statements

Transplantation in previously untreated people with follicular lymphoma

Using autologous transplantation with high-dose chemotherapy may significantly improve PFS when compared to allogeneic transplantation but not when overall survival is considered in patients at first line who have responded to chemotherapy. Similarly, auto-transplantation + high dose chemotherapy showed significantly better PFS compared to rituximab + chemotherapy but this did not remain significant when overall survival is compared, in examination of a meta-analysis reported by Schaaf *et al.* (2012).

This meta-analysis of 4 randomised control trials (RCTs) evaluated high dose chemotherapy + autologous transplantation (HDCT +ASCT) compared to chemotherapy or chemo-immunotherapy. This review provided low quality evidence, from 1093/1105 evaluable people, that significantly increased progression-free survival (PFS) was seen after HDCT+ASCT compared to chemotherapy (HR=0.42, 95% CI 0.33-0.54; $p<0.00001$) but no significant difference seen in overall survival (OS) (HR=0.97, 95%CI 0.76-1.24, $p=0.81$). No significant differences were seen in treatment related mortality (TRM), onset of secondary myeloid leukemia/myelodysplasia syndromes or solid cancers. Adverse events were seldom reported and reporting differed between trials which did not allow for meta-analysis. However, they were generally higher in people in the HDCT +ASCT arm. When HSCT +ASCT was compared to rituximab +chemotherapy; PFS remained advantageous in the HDCT +ASCT group (HR= 0.36, $p=0.001$); with no significant difference in OS (RR=0.88, $p=0.75$).

First transplantation after relapse

Autologous transplantation versus chemotherapy.

In their review, Schaaf *et al* (2012) reported on one trial in which 70 relapsed people were treated with HDCT + ASCT versus chemotherapy with no prior rituximab (Schouten *et al.* 2003). Schouten *et al.* (2012) provided low quality evidence of a survival advantage of HDCT +ASCT compared to chemotherapy in terms of progression-free survival (HR=0.3); 95%CI 0.15-0.61, and overall survival HR=0.4 95%CI 0.18-0.89) but no other outcomes were reported.

Autologous transplantation versus Immuno-chemotherapy.

There is limited evidence on long-term QOL outcome with one study providing evidence. That people with FL reported have lower QOL when compared to the general population. The impact of treatment on QOL outcomes when measured by different instruments (cancer-specific versus general QOL measures) is inconsistent.

Very low quality evidence came from a cross-sectional study (Andresen *et al.* 2012) from Germany which compared the quality of life (QOL) of 124 long-term survivors after HDCT+ASCT compared to R-CHOP using the EORTC QLQ-C30 and EQ-5D. The study reported QOL differences between the two groups (HDCT+ ASCT versus R-CHOP) with significant differences seen in the social functioning scale and pain ($p=0.04$ and 0.01) and index score of the EQ-5D ($p=0.049$) in favour of HDCT +ASCT. However, for both groups, QOL scores were lower than the general population with a significant decrease in QoL for the HDCT group in four of five subcategories of the EORTC QLQ-C30 functional state (physical, role, cognitive and social functioning and six of the nine subcategories of the symptomatic state (fatigue, dyspnea, insomnia, constipation, diarrhea and financial difficulties)($p<0.05$).

Autologous transplantation following rituximab treatment

One observational study compared rituximab status prior to autologous transplantation in 194 relapsed FL patients (Phipps *et al* 2015). Rituximab status was categorised as rituximab- sensitive (RS) (n= 35), rituximab- refractory (RR) (n=65) and no rituximab (noR) (n=94). This study provided very low quality evidence that 3 year PFS was better for RS patients compared to RR and no R patients (85% vs 35% vs 49%, $p=0.004$) and OS (97% vs. 63% 73.4%, $p=0.03$). On multivariate analysis, only RS was associated with improved OS and PS (HR 0.24, $p=0.01$ and HR 0.35, $p=0.006$) respectively.

Autologous transplantation versus allogeneic transplantation (mixed conditioning regimens)

The evidence comparing autologous and allogeneic transplantation, from studies where patients received a variety of different conditioning regimens is inconsistent.

Three studies provided very low quality evidence about the use of ASCT versus alloHSCT with mixed conditioning regimens. Evens *et al.* (2013) reported on a review of the National Comprehensive Cancer Network NHL Outcomes database in the USA. No significant difference in 3 year EFS reported in the ASCT group (n=135) vs. alloHSCT (n=49) of 57% vs 52%, p=0.14. Eighty-nine percent of people received prior rituximab-based therapy. However, statistical significant differences were reported in 3 year OS (87%vs 61%, p= <0.0001) and 100 day and 3 year non-relapse mortality (1% vs 6% and 3% vs 24%, p=<0.001) in favour of auto-transplantation In the ASCT group, 69% of deaths were due to progressive disease compared to 38% in the alloHSCT; with deaths due to second malignancy 15% vs 10% respectively.

Grauer *et al* (2009) reviewed 117 people from a single cancer centre in the USA receiving ASCT (n=81) vs alloHSCT (n=36) with rituximab therapy not reported. 5 year OS was reported as 53% vs 49% for those with relapsed or refractory disease; with higher non-relapsed mortality (NRM) in alloHSCT (25% vs 11%) with OS for all people favouring alloHSCT (67% vs 57%). 5 year PFS was higher in alloHSCT (46% vs 38%).

A retrospective cohort study of 35 people at a single USA centre transplant programme assessed outcomes following ASCT or alloHSCT of which 7% and 33% respectively received prior rituximab)(Reddy *et al* 2012). No significant difference as reported in 5 year PFS (73.3% vs 43%) or rate of relapse (26.6% vs 22.5%), but significant differences in 5 year OS (91.7 vs 53.9%, P=0.01) in favour of auto-transplantation. Non-relapse mortality was 42% in the alloHSCT group and 0% in the ASCT group. No adverse events were reported.

BEAM-Conditioning Transplantation

There is limited evidence on the use of the BEAM- conditioning (BiCNU, etoposide, ara-C and melphalan) regimen in auto and allogeneic transplantation.

One study (Noriega *et al* 2014) was graded as very low quality in which a retrospective analysis of outcomes for 171 people (of which 65% received prior rituximab) receiving BEAM-auto hematopoietic stem cell transplantation or BEAM-alemtuzumab allogeneic hematopoietic stem cell transplantation was undertaken in 2 UK centres. The median follow up was 6.5 (0.4 -18.2 years). A separate analysis of 59 and 38 people with non-transformed FL was reported. A 10 year cumulative relapse rate was reported at 61.6% vs. 30.5% in ASCT vs. alloHSCT, p=0.018, with all other reported outcomes including 71 people with transformed FL.

Myeloablative allogeneic transplantation vs. autologous transplantation

There was inconsistent evidence when myeloablative allogeneic transplantation is compared to autologous transplantation.

Two studies provided very low quality evidence about ASCT versus alloHSCT where myeloablative conditioning regimens were used. Deshpande (2004) reported a US-based retrospective analysis of people receiving ASCT (n=186) or alloHSCT (n=18) with a conditioning regimen of cyclophamide and TBI in 54% and 72% of people respectively with no reporting of rituximab therapy. In a median follow up of 7.8 years (range 1.7-1.92 years); the 5 year EFS was reported as 41% vs. 71%, p=0.034 in favour of myeloablative allo-transplantation; and 5 year OS as 61% vs. 76% p=0.18, again in favour of allo-transplantation

van Besien *et al.* (2003) reported on a retrospective analysis of 904 people registered with the International Bone Marrow Transplant Registry and Autologous Blood and Marrow Transplant Registry, followed up for a median of 36 months for allogeneic transplantation (n=176), 49 months for purged autologous transplantation (n=131) and 41 months for unpurged allogeneic transplantation (n= 597) with no prior rituximab therapy reported. Five year overall survival was 51%, 62% and 55% for purged auto-transplantation, unpurged auto transplantation and allogeneic transplantation respectively. With regard to

causes of non-relapse mortality, death was recorded in 50 (28%) , 18 (13.7%) and 45 (7.5%) of people for purged auto-transplantation, unpurged auto transplantation and allogeneic transplantation respectively; with new malignancies reported as cause of death in 5 and 9 people receiving purged and unpurged autologous transplantation and 10 cases attributed to GVHD.

Allogeneic transplantation vs. autologous transplantation (unknown conditioning regimen)

De Fontbrune (2009) reported a retrospective cohort study of 143 people which provided very low quality evidence on outcomes comparing ASCT or alloHSCT. Median follow up was 4.4 years and 4 years respectively in each group. Five year EFS and OS were reported as 46% vs. 58% and 73% vs 58% (ASCT versus alloHSCT); and after propensity score matching; 52.4% vs. 66% and 77% vs. 67% which were not statistically significant.

Klyuchnikov *et al* 2015 reported 5 year outcomes following reduced intensity conditioning allogeneic transplantation or ASCT, in 518 patients. This study provided very low quality evidence on the probability of NRM, relapse/progression, PFS and OS was 5% vs. 26% ($p<0.001$); 54% vs.20% ($p<0.001$), 41% vs.58% ($p<0.001$) and 74% vs. 66% ($P=0.05$) in favour of alloHSCT. On multivariate analysis, ASCT was associated with reduced NRM (RR 0.21, $p<0.0001$) and time varying effects seen in other outcomes.

Non-myeloablative allogeneic transplantation vs. autologous transplantation

There is inconsistent and very low quality evidence about the use of non-myeloablative allo-transplantation on outcomes when compared to auto-transplantation. The role of adding rituximab to conditioning regimens prior to transplantation was assessed in one retrospective observational study from the USA (Khouri *et al* 2005) which compared autologous versus non-myeloablative allogeneic transplantation after high-dose rituximab containing conditioning regimens for chemo sensitive FL. This study included 68 people who were followed up for a median of 34 months. Three year DFS and OS were reported as 84% vs. 85% (auto versus allo) and 84% and 88% ($p=0.8$); with risk of progression reported as 5% and 3% respectively. In those that had previously failed auto-SCT ($n=8$), a 4 year DFS of 87% was reported.

A retrospective cohort study of 40 people at a single cancer centre in the USA who underwent BEAM conditioning ASCT ($n=20$) and alloHSCT with conditioning regimen of cyclophosphamide, fludarabine and TBI provided very low quality evidence on outcomes reported at median time of 34 months follow up (Lunning 2012). No report of prior rituximab use was given. Three year EFS and OS were reported as 60%vs 79% and 62% and 85% (not statistically significant) respectively, In people whose previous remission duration was <12 months (11/20 and 20/20); 3 year EFS was reported as 36% vs. 79%, $p=<0.03$).

Reduced-intensity Conditioning Allogeneic Transplantation vs. autologous transplantation

A retrospective review of 875 people in the European Bone Marrow Transplant Registry (Robinson *et al* 2013) provided low quality evidence on outcomes of people who underwent ASCT ($n=726$) versus alloHSCT in order to compare outcomes of reduced intensity alloHSCT with median follow up of 59 months (range 3-108 months). 53% and 61% received prior rituximab in each respective group. The NRM was significantly worse for people undergoing reduced-intensity alloHSCT, with 100 days, 1 year and 5 year NRM reported as 2%vs6%, 3%vs 17% and 5%vs 22%, $p<0.001$). For PFS, there was a survival benefit at 1 year PFS favouring ASCT (77%v 68%) but in 3 and 5 years this PFS benefit favoured alloHSCT 57% vs. 62% and 48% vs. 57%, all these differences statistically significant. $p=<0.001$,. Non-significant differences were reported for OS with 1, 3 and 5 year rates reported as 90% vs. 80%, 78% vs68% and 72% vs. 67%, ($p=0.84$), respectively in favour of ASCT . The number of non-relapse deaths were 37 (5%) in the ASCT group and 32 (21%) in the alloHSCT group.

Further very low quality evidence was provided by an observational study of long-term outcomes of RIC alloHSCT compared to ASCT in Grade I/II patients FL patients (Klyuchnikov *et al*, 2015). The 5 year adjusted probabilities of NRM, relapse/progression, PFS and OS of ASCT vs. alloHSCT groups were 5% vs. 26% ($p<0.001$); 54% vs. 20% ($p<0.0001$); 41% vs. 58% ($p <0.001$) and 74% vs. 66% ($p=0.05$)

respectively. On multivariate analysis, ASCT was associated with reduced NRM (RR=0.21, $p < 0.0001$) and time varying effects were seen on other outcomes.

Autologous transplantation (no comparator)

Very low quality evidence from a single centre, non-comparative study of, Jagadesh *et al*, (2014) reported that in 127 patients in whom 93% had prior exposure to rituximab, 10 year PFS and OS were 33.2% and 52.4% respectively, with age at transplant and number of prior therapies (>3 vs. 1-3) significant prognostic factors in both univariate and multivariate analysis (Higher age HR 1.76, 95% CI 1.23-2.52, $p = 0.002$) and >3 prior therapies (HR 2.58, 95% CI 1.21-5.12, $p = 0.006$). Oh *et al* 2014 reported outcomes of 180 patients following relapse of chemotherapy. Very low quality evidence from this study indicated that, in univariate analysis, 5 year OS was significantly higher in patients receiving ASCT at 1st/2nd Line compared to no ASCT and ASCT beyond second relapse (92.4% v 66.5% v 62.5%, $p < 0.001$). Allogeneic transplantation did not affect OS ($p = 0.62$). In a multivariate analysis, ASCT at 1st/2nd relapse was associated with improved OS (HR=4.55, $p = 0.002$) independent of Follicular Lymphoma International Prognostic Index (FLIPI) score 0-2 at diagnosis, no transformation and ever use of rituximab with chemotherapy or as maintenance.

An observational study of 640 patients undergoing HDT/ASCT between 1989-2007 from the Grupo Español de Linfomas/Trasplante Autólogo de Médula Ósea (GELTAMO) registry provided very low quality evidence on outcomes with a median follow up of 12.2 years from transplantation (Ubito *et al*, 2014). The median PFS and OS were 9.4 and 21.3 years with patients transplanted at first complete response achieving a significantly better PFS (68%) and OS (74%) than those transplanted at 2nd complete response, $p = 0.005$

In another longer term follow up of outcomes with HDCT+ ASCT, Arcani *et al* (2015) report on 117 patients with relapsed/refractory follicular lymphoma. This study provided low quality evidence on the 5 year PFS and OS of patients after a median follow up of 6.7 years, with median time to relapse of 17 months in 46 patients who relapsed after treatment. For the 117 patients, 5 year PFS was 54% (95% CI: 45-63%) and 5 years OS was 83% (95% CI: 74-89%). For patients who were in first relapse, the 5 year OS was 85.3% (95% CI: 74.4-91.9%) and 74% (95% CI: 54.5-86.1%) for patients who underwent ASCT after 3 or more lines ($p = 0.05$).

Allogeneic transplantation (no comparator)

A US based observational study (Khouri *et al* 2008) of 47 patients who received alloHSCT with non-myeloablative conditioning with fludarabine, cyclophosphamide and rituximab provided very low quality evidence on outcomes after a median follow up of 60 months after transplantation. Five year PFS and OS was 85% and 83%. The incidence of grade 2 acute GVHD was 11% and chronic and chronic extensive GVHD was 60% and 36% respectively. Seven patients died (6 due to infection), with no cases due to recurrent lymphoma. Transplantation at second relapse (including relapse following prior autologous transplantation)

Robinson *et al* (2013) provided very low quality evidence of subsequent outcomes for people who relapsed after their ASCT ($n = 292$); with 17 (6%) receiving a second autologous transplantation and 56 (19%) proceeding to an alloHSCT. Only 1 of the 29 patients relapsing in the ASCT received a second transplant (myeloablative alloHSCT). In 56 patients receiving an alloHSCT, the 3 year NRM, disease progression, PFS and OS rates were 30%, 30%, 39% and 50% respectively.

Very low quality evidence came from a retrospective observational study (Okoroji *et al*, 2010) in a single cancer centre in the USA which reported outcomes for 50 people after receiving non-myeloablative allogeneic stem cell transplantation or conventional treatment (single agent rituximab, combination chemo-antibodies or unknown treatment), with reporting that this followed the introduction of rituximab). The median follow up was 49 (range 23-113) months for people receiving alloHSCT and 37 months (range 17-130) months for those not allo-transplanted. Four year actuarial survival was reported as 73% vs. 71%, $p = 0.9$.

Very low quality evidence came from a retrospective analysis of 146 patients in the Germany Registry for Stem Cell Transplantation, Heinzelman *et al* (2015) which reported survival outcomes. This included

Non Hodgkin's Lymphoma: diagnosis and management

90/146 patients who received a prior ASCT (data not reported separately), with a median follow-up of 9.1 years (range 3.6-15.7 years). The estimated 1, 2, 5 and 10 year OS was 67%, 60%, 53% and 48% respectively. The EFS was estimated at 63%, 53%, 47% and 40%. Multivariate analysis suggested treatment-sensitive disease, limited chronic GvHD and TBI-based conditioning in treatment refractory patients as independent prognostic factors for OS (data not reported).

GRADE Tables

Is autologous transplantation, allogeneic transplantation or no transplantation the most effective treatment for people with follicular lymphoma at various time points?

Grade Profile 1: Autologous transplantation vs. chemotherapy as a first-line treatment

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Event Chemotherapy	Event Autologous transplantation	Effect		
									Relative (95% CI)	Absolute	
Overall survival

¹ Evens et al. (2013). Due to the observational nature of the cohort study prior treatment was not uniform but left to the discretion of the patients' treating physicians;

² Evens et al. (2013). Sample includes patients with grade IIIB FL.

³ Evens et al. (2013). Lower range of number of previous therapies is 2 for both treatment arms but 1 for the whole cohort.

⁴ Reddy et al. (2012). Due to the observational nature of the retrospective review prior treatment was not uniform; little information on methods is reported

⁵ Reddy et al. (2012). Sample excluded patients with grade IIIA FL

⁶ Reddy et al. (2012). No 95% confidence intervals reported; small groups and very low number of events

⁷ Grauer et al. (2009). Conference abstract; limited information available to appraise; ⁸ Grauer et al. (2009). No information provided whether sample included grade IIIB or transformed follicular lymphoma

⁸ The direction of effect differs between the two studies

⁹ Grauer et al. (2009). No 95% confidence intervals reported for primary outcomes, number of events unknown, no p-values reported

Grade Profile 8: BEAM-alemtuzumab allogeneic transplantation vs BEAM-autologous transplantation as a treatment for relapsed or refractory follicular lymphoma

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Event Autologous transplantation	Event Allogeneic transplantation	Effect		
									Relative (95% CI)	Absolute	
10-year relapse incidence (follow-up median 6.5 years)											
1	Observational study	Serious ^{1,2}	no serious inconsistency	Serious ³	Serious ⁴	none	61.6%	30.5%	p=0.042	Not reported	⊕○○○ VERY LOW
10-year Overall survival (follow-up median 4 years)											
1	Observational study	Serious ^{1,2}	no serious inconsistency	Serious ³	Serious ⁴	none	39.0%	78.9%	P=0.068	Not reported	⊕○○○ VERY LOW

¹Noriega et al. (2014). Due to the observational nature of the cohort study prior treatment was not uniform but left to the discretion of the patients' treating physicians;

²Noriega et al. (2014). Sample numbers in different paragraphs of publication do not add up to same numbers (e.g. Number of patients in complete remission is referred to as 52 in table 1 and 51 in text)

³Noriega et al. (2014). Study does not distinguish between FL grades. Sample may have included patients with grade IIIB FL; 41% of patients had high grade transformation (sub-group analysis reported for non-transformed patients)

⁴Noriega et al. (2014). Stage at diagnosis percentages add up to 111% in autologous transplantation group; no 95% confidence intervals reported for some outcomes (e.g. TRM, relapse, DFS, OS); low number of events in subgroups

Grade Profile 9: Myeloablative allogeneic vs autologous transplantation as a treatment for relapsed or refractory follicular lymphoma

1	Observational study	Serious ^{6,8}	no serious inconsistency	Serious ⁷	No Serious imprecision	none		33.2%	Not applicable	Not applicable	

¹ Le Gouill et al. (2011). Due to the observational nature of the cohort study prior treatment was not uniform but left to the discretion of the patients' treating physicians. Use of HDC-ASCT may have been due to selection bias of patients who responded to salvage therapy. Decisions for not transplanting could not be assessed. Only second-line treatment data collected and did not examine the use of therapies such as rituximab in subsequent progressions. Included 40% of patients who were not rituximab-naïve.

² Le Gouill et al. (2011). Sample included patients with grade IIB FL and was not systematically documented.

³ Le Gouill et al. (2011). Errors in reporting age range in age of patients not receiving HDC-ASCT, inconsistency in reporting results in text to correct table median age and range of patents reported for transplanted versus non- transplanted is different in the text to tables 1 or 3. Missing data in FLIPI score (n=5 patients). Small numbers reported in sub-group analysis.

⁴ Arcani et al (2015) Observational study, follow up and treatment may have differed across centres

⁵ Arcani et al (2015) May have included transformed/ IIB FL

⁶ Jagadeesh et al (2014), Retrospective analysis, treatment may have changed over time. Limited reporting of patient and disease characteristics

⁷ Jagadesesh et al (2014) Unclear if transformed or grade IIB included

⁸ Jagadeehs et al (2014) Limited data reported no confidence intervals proved around outcomes

Grade Profile 16: Autologous transplantation in first or second relapse vs. no transplantation vs. transplantation beyond second relapse

No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Event Autologous transplantation at first/second relapse	Event No autologous transplantation	Event Autologous transplantation beyond second relapse	Effect		
										P value	Absolute	
5 year OS												
1	Observation	Serious ^{1,2}	No serious inconsistency	Serious Indirectness ²	Serious ³	none	92.4%	66.5%	62.5%	P=<0.001	Not reported	⊕○○ ○ Very LOW

¹ Retrospective analysis, , focused on treatment at 2 different centres with differences in treatment and care reported , patient care may have change over time

² Limited information presented (conference abstract)

¹ Robinson et al. (2013). Due to the observational nature of the retrospective review prior treatment was not uniform;

² Robinson et al. (2013). Sample included patients with grade IIIB FL

³ Robinson et al. (2013). Stage at diagnosis percentages add up to 111% in autologous transplantation group; no 95% confidence intervals reported for main outcomes (e.g. NRM, relapse, PFS, OS)

⁴ Heinzelman et al (2015) Retrospective review with lack of treatment uniformity; limited data reported on patient and clinical characteristics

⁵ Heinzelman et al (2015) Unclear if transformed or IIIB included

⁶ Heinzelman et al (2015) No confidence intervals or p values reported.

Grade Profile 18: Allogeneic transplantation vs. chemotherapy+ rituximab after failed autologous transplantation

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Event R-chemotherapy	Event Allogeneic transplantation	Effect		
									Relative (95% CI)	Absolute	
Actuarial survival at 4 years (follow-up median 49 months)											
1	Observational study	Serious ¹	no serious inconsistency	Serious ²	Serious ³	none	71% (95% CI 46-86)	73% (95% CI 42-89)	P=0.9		⊕○○○ VERY LOW

¹ Okoroji, G.-J. et al. (2010). Conference abstract; Limited information on patient selection and clinical details at baseline. Definition of actuarial survival not clear

² Okoroji, G.-J. et al. (2010). Unknown exposure to rituximab in 24% of patients.

³ Okoroji, G.-J. et al. (2010). Inconsistency in reporting data ; no confidence intervals given.

Systematic review N=1

Schaaf, M. et al. (2012). High-dose therapy with autologous stem cell transplantation versus chemotherapy or immuno-chemotherapy for follicular lymphoma in adults. Cochrane database of systematic reviews (Online) 1: CD007678.

Objective of review: To compare the effectiveness of high-dose therapy with autologous stem cell transplantation to chemotherapy or immuno-chemotherapy in patients with newly diagnosed or relapsed follicular lymphoma.

Pub year: 2012		Review Methods	Results																																				
Search Period	Any language through September 2011	<p>Inclusion criteria: Published or unpublished randomised controlled trials (including internet publication) in any language at any time point which included patients older than 18 years with confirmed diagnosis of follicular lymphoma and compared high-dose therapy followed by autologous stem cell transplantation to any chemotherapy or immune-chemotherapy regimen were included in the review. If articles contained insufficient information to establish eligibility, missing details were sought from the authors.</p> <p>The primary outcome of interest was overall survival. Progression-free survival, response rate, quality of life, treatment-related mortality, adverse events and secondary malignancies were analysed as secondary outcomes. Aggregated data was analysed in a meta-analysis using a random effects model. Subgroup analyses included patients treated as front-line, refractory or relapse with the treatment comparators in question. Sensitivity analyses explored the effects of study quality (full text/abstracts and preliminary results/final results) and applied fixed-effect modelling.</p> <p>Full articles of all relevant studies were retrieved and manual searches of reference lists from identified relevant articles as well as relevant review articles and current guidelines were performed to identify any additional studies that may have been missed using the selection procedure. When more than one publication of the same investigator group were available, all relevant full text and abstract publications were included in the review but data for this pooled-data analysis was extracted</p>	<p>19 (from 5 separate trials)/59 included The quality of the included studies was reported as moderate. Exclusion criteria: n=40: no randomised controlled trial, randomisation of patients with aggressive NHL only, comparators not specified, mixed lymphoma and results for patients with follicular lymphoma not reported separately</p> <p>1093/1105 patients were evaluated; the reasons for exclusion from analysis of the remaining patients were described in the review.</p> <p>The included studies were: CUP trial, GITMO/IIL, GOELAMS 064, GLSG, GELA/GELF-94</p> <p>Table 1. Schaaf, M. et al. (2012). High-dose therapy with autologous stem cell transplantation versus chemotherapy or immuno-chemotherapy for follicular lymphoma in adults. Cochrane database of systematic reviews (Online) 1: CD007678.

Objective of review: To compare the effectiveness of high-dose therapy with autologous stem cell transplantation to chemotherapy or immuno-chemotherapy in patients with newly diagnosed or relapsed follicular lymphoma.

from full text publications. Observational studies, single case reports, reviews and those studies not specifically reporting results for follicular lymphoma only were not taken into account.

Search engines: CENTRAL, MEDLINE, EMBASE
 - Also searched for abstracts in conference proceedings of American Society of Hematology, American Society of Clinical Oncology and European Group for Bone and Marrow Transplantation between 2007 and 2010
 - Databases of ongoing trials

Data extract and study appraisal: Two investigators independently extracted data from studies meeting the selection criteria.

Quality assessment: Two investigators independently evaluated all included trials according to quality criteria recommended in the Cochrane Handbook for Systematic Reviews of Interventions. Disagreements were resolved by consensus.

Table 2. Results of meta-analysis of HDT + ASCT in previously untreated patients

Outcome	n	Comparator	Risk ratio	95% Confidence interval (CI)	P-value
Overall survival	701	Chemotherapy	0.97	0.76-1.24	0.81
	134	Chemotherapy + rituximab†	0.88	0.40-1.92	0.75
Progression-free survival	540	Chemotherapy	0.42*	0.33-0.54	<0.00001
	134	Chemotherapy + rituximab†	0.36*	0.23-0.55	<0.00001
Overall response rate	701	Chemotherapy	1.13	0.96-1.34	0.15
	134	Chemotherapy + rituximab†	1.29*	1.08-1.54	0.006
Complete response	535	Chemotherapy	1.11	0.64-1.92	0.71
	134	Chemotherapy + rituximab†	1.37*	1.11-1.70	0.003
Treatment-related mortality	941	Chemotherapy	1.28	0.25-6.61	0.77
	134	Chemotherapy + rituximab†	1.46	0.25-8.44	0.68
Secondary malignancies (MDS, AML)	1023	Chemotherapy	2.87§	0.70-11.75	0.14
	134	Chemotherapy + rituximab†	4.85	0.58-40.44	0.14
Secondary malignancies (solid cancers)	701	Chemotherapy	1.20	0.25-5.77	0.82
	134	Chemotherapy + rituximab†	0.32	0.03-30.03	0.32

† One study only. Rituximab was part of HDT+ASCT and comparator treatment

*Favouring HDT + ASCT

§ Tendency to favouring control arm (chemotherapy)

Note: ns, not significant

Table 3. Results of meta-analysis of HDT + ASCT in relapsed patients†

Outcome	n	Comparator	Risk ratio	95% Confidence interval (CI)	P-value
Overall survival	70	Chemotherapy	0.40*	0.18-0.89	0.002
Progression-free survival	70	Chemotherapy	0.30*	0.15-0.61	0.0009

† One trial only (CUP trial n=70)

*Favouring HDT + ASCT

Table 4. Adverse events

Schaaf, M. et al. (2012). High-dose therapy with autologous stem cell transplantation versus chemotherapy or immuno-chemotherapy for follicular lymphoma in adults. Cochrane database of systematic reviews (Online) 1: CD007678.

Objective of review: To compare the effectiveness of high-dose therapy with autologous stem cell transplantation to chemotherapy or immuno-chemotherapy in patients with newly diagnosed or relapsed follicular lymphoma.

Outcome	n	Chemotherapy	Chemotherapy + rituximab	HDT + ASCT
Anaemia	227†	0.8%	-	44.8%
Leucocytopenia	227†	51.3%	-	96.2%
Granulocytopenia	227†	37.8%	-	90.5%
Thrombocytopenia	227†	4.2%	-	96.2%
Mucositis	227†	0.0%	-	53.3%
Infections	527	1.7%	6.1%	13.2%-23.1%
Nausea	227†	1.7%	-	32.4%
Diarrhoea	227†	1.7%	-	13.5%
Pulmonary	313	0.9%	-	2.3%-4.8%
Liver	227†	0.9%	-	3.8%
Renal	313	0.0%	-	1.0%-1.2%
Muscle/bone pain	227†	11.0%	-	2.1%
Depression	227†	4.9%	-	1.1%

† One trial only

HDT followed by ASCT did not lead to an overall survival advantage in previously untreated patients in comparison to chemotherapy (RR=0.97; 95% CI: 0.76-1.24; p=0.81) or immune-chemotherapy (RR=0.88; 95% CI: 0.40-1.92; p=0.75). In relapsed patients, HDT + ASCT had significantly better overall survival (RR=0.40; 95% CI: 0.18-0.89; p=0.002) but this was evaluated in one trial only (n=70).

Progression-free survival was significantly improved in both untreated and relapsed patients in the HDT + ASCT group when compared to chemotherapy and immune-chemotherapy.

There were no statistically significant differences in overall or complete response rates, treatment-related-mortality and secondary malignancies between the trial groups in previously untreated patients. These outcomes were not reported for relapsed patients.

Adverse events were more frequently observed in the HDT + ASCT arm in previously untreated patients. These outcomes were not reported for relapsed patients.

Comments
 ↓ Risk of bias: All open-label studies; unclear allocation concealment; protocol of 2 trials was amended while ongoing; heterogeneous comparator (various chemotherapy regimens); small number of evaluated patients may overestimate effect
 ↓ Indirectness: Two of the included trials included patients with grade IIIb

		<p>Medium time from first diagnosis to ASCT group A (years)</p>	<p>2</p>					
		<p>Medium time from first diagnosis to treatment group B</p>		<p>1</p>				
<p>Results</p>	<p>In a one-sample t test, when the HRQOL of the two groups were compared. Significant differences in favour of the HDCT/ASCT were seen in the social functioning scale of the EORTC QLQ-C30 and pain. In the EQ-5D index, scores were reduced in R-CHOP group (mean: 0.85; SD=0.21) compared to HDCT/ASCT group (mean: 0.91; SD=0.13; p=0.049). Linear regression analysis supported the t-test results in terms of significant difference in Social functioning, pain and EQ-5D index score. Age and gender did not show statistically significant difference on HRQOL scores. For both groups, QOL scores were lower than the general population with a significant decrease in QoL for the HDCT group in four of five subcategories of the EORTC QLQ-C30 functional state (physical, role, cognitive and social functioning and six of the nine subcategories of the symptomatic state (fatigue, dyspnea, insomnia, constipation, diarrhea and financial difficulties)(p<0.05). Quality of life scores in the chemotherapy group were significantly decreased compared to the general population in all five subcategories of the functional state (physical, role, emotional, cognitive and social functioning) and in seven of the nine subcategories of the symptomatic state (fatigue, pain, dyspnea, insomnia, constipation, diarrhea and financial difficulties)(p=0.001).</p>

	Attrition bias (systematic differences between the comparison groups with respect to loss of participants)	X		
	Reporting bias?	X		
Other biases?	X			
Comments	<p>The conclusion of the study was that HDCT and R-CHOP regimen had negative impact of patients with follicular lymphoma and should not be underestimated. – this statement seems to be in comparison to the general population so it may be worth putting the comparison in the results to show baseline rates of QOL.</p> <p>↓ Risk of bias: Limited information on patient selection and clinical details at baseline. Patients were not matched against demographic and clinical characteristics. Different follow-up points means definition of long-term survivor is unclear e.g. <5 years for R-CHOP group and >5 years for HDCT group. Mode of administration of questionnaires may have affected confidence in being patient self-reported.</p> <p>↓ Indirectness: Not clear if patients with IIIb excluded.</p> <p>↓ Imprecision: Very large confidence intervals around HRQOL scales reported.</p>			

Reddy, N. et al. (2012). Long-term outcome after autologous or allogeneic stem cell transplantation in patients with recurrent follicular lymphoma. <i>Bone Marrow Transplantation</i> , 47(10); 1318-1320.					
Pub year: 2012		Patient Characteristics	Arm A	Arm B	Outcome
Country	USA	Patients treated between January 2000 to December 2010 at Vanderbilt University Medical Centre adult transplant program were retrospectively reviewed to compare outcomes and risk factors for autologous stem cell transplantation (arm A) or allogeneic stem cell transplantation (arm B) . <i>Inclusion criteria:</i> – Patients over 18 years of age with a confirmed diagnosis of follicular lymphoma (grade 1 or 2) – Receiving high-dose chemotherapy and stem cell transplantation – Patients who received planned rituximab-based induction chemotherapy pre transplant – Chemotherapy-sensitive disease documented pre transplant after salvage chemotherapy – <i>Exclusion criteria:</i>	Autologous stem cell transplantation Stem cells were mobilised using high-dose chemotherapy (CY) and G-CSF in combination.	Allogeneic stem cell transplantation 14 patients received reduced-intensity conditioning (fludarabine plus BU, n=12; others=2)	– Progression free survival (“defined by standard criteria”, no definition reported) – Overall survival
Design, period	Retrospective review 2000-2010				
N	35/35				

Reddy, N. et al. (2012). Long-term outcome after autologous or allogeneic stem cell transplantation in patients with recurrent follicular lymphoma. Bone Marrow Transplantation, 47(10); 1318-1320.								
Follow-up	Median: 6 years from diagnosis. 4 years from transplantation	<ul style="list-style-type: none"> Transformed lymphoma at time of transplantation Grade 3 follicular lymphoma 			CBV (CY 7200 mg/m ² , etoposide 2000 mg/m ² and BCNU 400 mg/m ²) was the conditioning regimen in 87% of patients receiving auto-SCT	9 received myeloablative regimen followed by a PBSC transplant (minimal residual disease=17; matched unrelated donor=6).	("defined by standard criteria", no definition reported)	
	Funding source	Supported by National Centre for Research Resources, National Institute of Health; Grant number 5K-12 CA090625-09, NR)	Table 1. Baseline characteristics:					Others received BEAM (BCNU, etoposide, cytarabine and melphalan) conditioning regimen followed by auto-SCT. No further information reported.
			Arm A: Autologous transplantation n=12	Arm B: Allogeneic transplantation n=23	p-value			
			N (%)	N (%)				
		Male	8 (67%)	16 (70%)	0.86			
		Median age	61	52	0.012			
		Age range	50-62	35-64				
		≥2 salvage therapies prior to transplant	34 (97%)					
		Previous autologous transplantation	-	3 (9%)				
		Stage I and II	4 (33%)	1 (4%)	0.69			
		Stage III and IV	8 (67%)	16 (70%)				
		Median number of extra nodal sites (range)	1 (0-2)	2 (0-3)	0.98			
		Median number of chemotherapy regimens (range)	3 (2-5)	3 (1-6)	0.71			
		Rituximab maintenance prior to transplant	4 (33%)	7 (30%)	0.86			
	Stem cell dose CD34+ cells/kg; mean	2.80 x 10 ⁶	7.35 x 10 ⁶	0.004				
	Stem cell dose CD34+ cells/kg; range	2.3-9.8 x 10 ⁶	3.87-16.48 x 10 ⁶					
	Complete remission pre-transplant	4 (33%)	8 (35%)	0.93				
	Partial response pre-transplant	8 (67%)	15 (65%)					
Results	Final eligible sample included in analysis: N=35 Patients who received autoSCT were significantly older (median 61 compared to 52 years; p=0.012) and received higher stem cell dose (7.35 x 10 ⁶ compared to 2.80 x 10 ⁶ ; p=0.004) compared with alloSCT patients. The overall use of rituximab maintenance prior to SCT was 33% in the autoSCT group and 30% in patients undergoing alloSCT. The median number of previous line of chemotherapy regimens was 3 in both groups (range 2-5 in autoSCT patients, 1-6 in alloSCT patients).							
	Table 2. Survival rates according to treatment groups							
			Arm A: Autologous transplantation n=12	Arm B: Allogeneic transplantation n=23	p-value			
			%	%				
		5-year progression free survival (PFS)	73.3	43.0	0.07			
		5-year Overall survival (OS)	91.7	53.9	0.04			
		Relapse rate	26.6	22.5	0.9			
		Non-relapse mortality (NRM)	0	42.9	0.01			
	There was no significant difference in relapse rate between the two groups ¹ . However, there was a significant advantage for those patients receiving autologous transplantation compared to allogeneic transplantation (mixed reduced-intensity and myeloablative conditioning) regarding progression free survival (hazard ratio=4.3; p=0.052) and overall survival (hazard ratio=6.2; p=0.03). In the multivariate analysis, age, stage of the disease, the number of chemotherapy regimens, pre-SCT rituximab maintenance, type of conditioning regimens, disease status (CR or partial response) pre-SCT, absolute lymphocyte count at day 14 or day 28 and stem cell dose had no impact on long-term outcome.							

Non Hodgkin's Lymphoma: diagnosis and management

Reddy, N. et al. (2012). Long-term outcome after autologous or allogeneic stem cell transplantation in patients with recurrent follicular lymphoma. Bone Marrow Transplantation, 47(10); 1318-1320.				
	At the time of analysis, 24 patients were alive with an actuarial OS rate of 66.5%, the estimated 5-year disease free survival was 53% and non-relapse mortality was 28.6% for all patients. Grade II-IV acute GVHD occurred in 6 (26%) patients and chronic GVHD in 5 (22%) patients. Three patients had extensive chronic GVHD. These outcomes were not reported separately for the treatment groups.

	Deaths due to progressive disease (PD)	18/26 (69%)	8/21 (38%)	Not reported	
	Deaths due to second malignancy	4/26 (15%)	2/21 (10%)	Not reported	
<p>There was no significant difference in FFS between the two groups at 3 years. However, the 3-year OS in patients treated with autologous stem cell transplantation was significantly better (87%; 95% CI: 81%-94%) compared to those undergoing allogeneic transplantation (61%; 95% CI: 47%-76%).</p> <p>47 patients (26 in arm A and 21 in arm B) died (26/47 due to lymphoma progression; 6/47 due to second tumour, 2/47 due to acute and 4/47 due to chronic graft versus host disease (GVHD) after allogeneic transplantation).</p> <p>In multivariate analysis, overall survival and FFS were affected by patient age >60 years and number of prior therapies > 3 in the autoSCT group and by age >50 years and resistant disease in the alloSCT group. In the direct comparison of auto SCT and allo SCT, alloSCT was associated with significantly increased risk of death (HR=2.7; 95% CI: 1.4-5.23; p=0.003). This was also true when grade III patients were removed from the Cox regression multivariate analysis (HR=2.66; 95% CI: 1.37-5.17; p=0.004). After exact patient matching (43 matched pairs) with propensity scoring on age, number of prior therapies and disease resistance at time of SCT, the risk of death remained more than twice as high in the alloSCT group compared to autoSCT.</p>

Time from diagnosis to relapse	2.95 years (91.9-5.65)	2.45 years (1.6-3.6)	0.02
---------------------------------------	---------------------------	-------------------------	------

Results

At first relapse 42 (24%) proceeded to HDC-ASCT; 11 had progressed during the induction stage with 7 patients in CHVP-I arm and 4 patients in RCHVP-I arm.

In patients with relapsed or progressive disease; Remission rates were:

- Complete remission. / complete unconfirmed remission n=80 (46%)
- Partial remission n=37 (21%)
- Less than partial remission n= 37 (21%)
- Missing data n=14

Progression and mortality

At time of analysis, 45 patients had experienced a second progression after salvage therapy and 55 patients had died; 34 were lymphoma related; infection related in 6 patients, myelodysplastic syndrome in 2 non-transplanted patients solid tumour 1 3, encephalopathy in 2 or others (n=8)

Table 3: Outcomes (all patients n=175)

Outcome	
3 year EFS	50% (95% CI, 42-58%)
5 year EFS	26% (95% CI, 14-39%)
3 year OS	72% (95% CI, 64-78%)
5 year OS	52% (96% CI 36-66%)

Univariate analysis was reported to show no statistical difference (SD) in EFS or OS according to type of initial therapy received in the FL2000 study or chemotherapy received at fist progression. Parameters influencing EFS and OS (SD shown) in univariate analysis were: age, FLIPI score, period of disease progression, transplantation at progression and use of rituximab. In the multivariate analysis [where variables with a P value of 0.2 or below were entered into the analysis], for EFS; SD were seen in progression period (induction versus follow up Hazzard Ratio (HR)=2.5 (95% CI, 1.4-4.38), consolidation versus follow up HR=2.76 95% CI, 1.5504.8), p=0.004; and, transplantation at progression(yes versus no, HR=0.38 95%CI, 0.2-0.72, p=0.003). For OS, SD were seen in in progression period (induction versus follow up HR=4.08 95% CI, 1.97-8.4, consolidation versus follow up, HR=3.83 95% CI 1.83-8) P=0.0001.

Table 4: Outcomes (impact of rituximab and HDC-ASCT as part of therapy at disease progression)

	Impact of rituximab at first progression according to first line therapy (=165)			Impact of eligibility for HDC-ASCT (n=153)		
	With rituximab n=112	Without rituximab n=53	P Value	Patients receiving HDC-ASCT n=42	Patients not receiving HDC-ASCT n=111	P Value
3 year EFS	52% (95% CI, 41-62%)	40% (95% CI, 24-55%)	0.075	73% (95% CI, 56-84%)	39% (95% CI, 29-50%)	0.005

Comments	<p>The study concludes by stating that the results support the role of HDC-ASCT as consolidation therapy at first relapse/progression for FL patients presenting with high tumour burden at diagnosis, independent of any rituximab used up-front and the timing of progression.</p>							
	<p>↓ Risk of bias: Due to the observational nature of the cohort study subsequent treatment post-trial follow up was not uniform but left to the discretion of the patients' treating physicians. Use of HDC-ASCT may have been due to selection bias of patients who responded to salvage therapy. Decisions for not transplanting could not be assessed. Only second-line treatment data collected and did not examine the use of therapies such as rituximab in subsequent progressions. Included 40% of patients who were not rituximab naïve.</p> <p>↓ Indirectness: Sample included patients with grade IIIB FL and was not systematically documented.</p>							

Non Hodgkin's Lymphoma: diagnosis and management

Le Guill, S. et al. (2011). Impact of the use of autologous stem cell transplantation at first relapse both in naïve and previously rituximab exposed follicular lymphoma patients treated in the GELA/GOELAMS FL2000 study. *Haematologica*, 96(11); 1128-1135.

↓ Imprecision: Errors in reporting age range in age of patients not receiving HDC-ASCT, inconsistency in reporting results in text to correct table median age and range of patents reported for transplanted versus non- transplanted is different in the text to tables 1 or 3. Missing data in FLPI score (n=5 patients). Small numbers reported in sub-group analysis.

Noriega, V. et al. (2014). Long term follow-up of BEAM-autologous and BEAM-alemtuzumab allogeneic stem cell transplantation in relapsed advanced stage follicular lymphoma. <i>Leukemia Research</i> , 38(7); 737-743.																																																																																				
Pub year: 2014		Patient Characteristics			Arm A	Arm B	Outcome																																																																													
Country	UK	Consecutive patients undergoing either BEAM-autologous hematopoietic stem cell transplantation (arm A) or BEAM-alemtuzumab allogeneic hematopoietic stem cell transplantation (arm B) between 1992 and 2010 at 2 UK centres (King's College Hospital, London and Nottingham University Hospital, Nottingham) were retrospectively reviewed in order to compare outcomes and risk factors. <i>Inclusion criteria:</i> – Follicular lymphoma diagnosed – Chemosensitive disease following salvage treatment (for AlloSCT) – Donor availability for at least 9 out of 10 HLA match (sibling or unrelated volunteer; for alloSCT) – Failed CD34 stem cell mobilisation (for alloSCT) – <i>Exclusion criteria:</i> – None reported Table 1. Baseline characteristics:			Autologous stem cell transplantation Conditioning regimen: BCNU carmustine 300 mg/m ² day-6, cytarabine 200 mg/m ² twice daily day-5 to day-2, etoposide 200 mg/m ² day-5 to day-2 and melphalan 140 mg/m ² day-1. CD34+ stem cell mobilisation regimen: Cyclophosphamide 1.5 g or 3 g/m ² plus G-CSF 5 µg/kg for 5 days Stem cell source: 110 (95%) patients: Peripheral blood stem cell (PBSC) 6 (5%) patients: Bone marrow (BM)	Allogeneic stem cell transplantation Conditioning regimen: BCNU carmustine 300 mg/m ² day-6, cytarabine 200 mg/m ² twice daily day-5 to day-2, etoposide 200 mg/m ² day-5 to day-2 and melphalan 140 mg/m ² day-1. G-CSF 10 µg/kg for 4 days if peripheral blood transplant Alemtuzumab (Campath 1-H) 10 mg/d or 20 mg/d (Nottingham and King's College Hospital respectively) day-5 to day-1. Ciclosporin (1.5 mg/kg i.v.) was used for GVHD prophylaxis from day-1, and tapered from day +56 in the absence of GVHD. Antimicrobial and antifungal prophylaxis and acyclovir. Granulocyte colony-stimulating factor was administered from day +7 post-transplant. Stem cell source: 48 (89%) patients: Peripheral blood stem cell (PBSC) 6 (11%) patients:	– Disease free survival (<i>defined as the time from the day of transplant until disease relapse or death</i>) – Cumulative incidence of relapse – Overall survival (defined as time in years from day of transplant to death or last follow-up) – Non-relapse mortality (<i>defined as death without disease</i>)

Noriega, V. et al. (2014). Long term follow-up of BEAM-autologous and BEAM-alemtuzumab allogeneic stem cell transplantation in relapsed advanced stage follicular lymphoma. <i>Leukemia Research</i> , 38(7); 737-743.				
				Bone marrow (BM) Sibling donors 67% Unrelated volunteer donor 33% (of which 87% were 10/10 matched).
Results	Final eligible sample included in analysis: N=171			
	There was no significant difference in most baseline characteristics between the 2 groups including duration of last remission, number of prior chemotherapy lines, and disease status at the time of transplantation. Patients in the autoSCT group were older (p<0.0001) with a median age of 57 (range 27-69) compared to the alloSCT group (48 years; range 30-63) and had higher incidence of high grade transformation (48.3% vs. 28.3%; p=0.015). The overall use of rituximab prior to SCT was 61% in the autoSCT group and 74% in patients undergoing alloSCT (p=0.109). None of the patients in the autoSCT group had a previous transplant while 3 patients in the alloSCT group had had one previous autograft.

	2-year cumulative relapse incidence	32.9	8.3	
	5-year cumulative relapse incidence	61.0	8.3	
	10-year cumulative relapse incidence	66.5	8.3	
Non-transformed population	n=59	n=38	-	
10-year cumulative relapse incidence	61.6	30.5	0.018	
Patients who received rituximab prior to transplant†	n=69	n=40	-	
10-year cumulative relapse incidence	46.3	19.7	0.078	
*Includes 71 patients (41%) with high grade transformation				
† Might include patients with high grade transformation				
There were 51 cases (43.6%) of disease relapse in the autoSCT group of which 17 (33.3%) relapsed more than 2 years after transplantation. In the alloSCT group, 12 patients (22.2%) relapsed and 3 of these patients (25.0%) relapsed more than 2 years after transplantation (at 2.5, 4, 6.3 years and 2 remained alive and in complete remission after donor lymphocyte infusion and chemotherapy at the end of follow-up). Cumulative relapse incidence was lower in the alloSCT group compared to autoSCT (31.4% vs. 55.1% at 10 years; p=0.042). Patients without histological transformation had better relapse rate after allogeneic transplantation (30.5%) compared to autologous transplantation (61.6%; p=0.018) whereas there was no statistically significant difference between transplantation groups for patients with high grade transformation (p=0.848). Patients who underwent transplantation in complete remission had a better relapse incidence in the alloSCT group compared to auto SCT (p=0.007) while outcomes of patients not in CR prior to transplant showed no differences in relapse rate between the two transplantation types (no p-value reported). Patients who received rituximab prior to transplantation had a better relapse incidence in the alloSCT group compared to auto SCT (p=0.078) while outcomes of patients without rituximab prior to transplant showed no differences in relapse rate between the two transplantation types (no p-value reported).				

Noriega, V. et al. (2014). Long term follow-up of BEAM-autologous and BEAM-alemtuzumab allogeneic stem cell transplantation in relapsed advanced stage follicular lymphoma. *Leukemia Research*, 38(7); 737-743.

There were no significant differences in 10-year relapse incidence between the two transplantation groups according to having received more than 3 lines of chemotherapy or duration of last remission.

Table 3. Survival rates according to treatment groups

	Arm A: Autologous transplantation	Arm B: Allogeneic transplantation	p-value
	%	%	
Total population*	n=117	n=54	-
1-year disease free survival (DFS)	80.1	63.0	0.785
2-year disease free survival (DFS)	64.1	57.4	
5-year disease free survival (DFS)	49.9	53.4	
10-year disease free survival (DFS)	34.7	48.1	
1-year Overall survival (OS)	90.1	72.2	0.506
2-year Overall survival (OS)	78.7	68.5	
5-year Overall survival (OS)	62.9	66.6	
10-year Overall survival (OS)	48.3	64.4	
1-year transplant-related mortality (TRM)	2	24	0.000
Patients in complete remission†	n=37	n=14	-
10-year disease free survival (DFS)	27.7	71.4	0.056
10-year Overall survival (OS)	46.5	78.6	0.148
Non-transformed population	n=59	n=38	-
10-year Overall survival (OS)	39.0	78.9	0.068

*Includes 71 patients (41%) with high grade transformation

† Might include patients with high grade transformation

There was no significant difference in DFS and OS between the two at 1, 2, 5 or 10 years ($p=0.785$ and 0.506 , respectively). Patients without histological transformation had better 10-year overall survival after allogeneic transplantation (78.9%) compared to autologous transplantation (39%; $p=0.068$) whereas there was no statistically significant difference between transplantation groups for patients with high grade transformation for OS and DFS ($p=0.192$).

Patients who underwent transplantation in complete remission had better disease free survival in the alloSCT group compared to auto SCT ($p=0.056$) but not overall survival ($p=0.148$) while outcomes of patients not in CR prior to transplant showed no differences in DFS or OS between the two transplantation types (no p-value reported).

There were no significant differences in DFS and OS between the two transplantation groups according to prior exposure to rituximab, having received more than 3 lines of chemotherapy or duration of last remission.

Nine patients (16.6%) developed grade I-IV acute graft versus host disease (GVHD) in the alloSCT group. Only 1 case (1.8%) was classified as grade IV, and the patient died subsequently. Of the 44 patients alive after day 100, chronic GVHD was observed in 10 (22%), with 3 classified as chronic extensive GVHD (7%). Three patients developed limited chronic GVHD following donor lymphocyte infusion.

18 patients (5 in arm A and 13 in arm B) died from non-relapse causes. The patients in the autoSCT group died from bacterial sepsis ($n = 3$), metastatic lung adenocarcinoma ($n = 1$) and acute myeloid leukaemia ($n = 1$). The 13 deaths in the alloSCT group were identified as bacterial sepsis ($n = 3$), adenovirus infection ($n = 2$), cytomegalovirus (CMV) pneumonitis, aspergillosis ($n = 1$), pseudomonas infection ($n = 1$), multi-organ failure ($n = 3$), thrombotic thrombocytopenic purpura ($n = 1$), splenic rupture ($n = 1$) and graft versus host disease ($n = 1$). Only 2 of these 13 patients died more than 2 years after transplantation (15.4%), one at 2.5 years due to progressive disease and the other at 6 years due to second malignancy.

In multivariate analysis, OS, DFS and relapse rate were not affected by the disease status pre-transplant (CR vs No-CR), Rituximab used prior to transplant, transformation, number of chemotherapy lines, duration of last remission, age at transplant or CD34+ dose infused. There was a trend to an improved DFS when patients had a high grade transformation prior to transplant ($p = 0.081$) and when they received <3 chemotherapy lines ($p = 0.07$). However, none of these variables showed statistical significance in the multivariate analysis.

In the alloSCT group, only the age affected statistically the OS ($p = 0.005$) and DFS ($p = 0.019$) with worse outcome for patients older than 45 years old. Disease status pre-transplant, Rituximab prior to transplant, transformation, number of chemotherapy lines, duration of last remission, CD34+ dose infused, donor (unrelated/related) or grade of mismatch (HLA 10/10 or 9/10 match) did not affect OS,

Non Hodgkin's Lymphoma: diagnosis and management

Noriega, V. et al. (2014). Long term follow-up of BEAM-autologous and BEAM-alemtuzumab allogeneic stem cell transplantation in relapsed advanced stage follicular lymphoma. <i>Leukemia Research</i> , 38(7); 737-743.				
	DFS or relapse incidence with statistical significance. Patients who received Rituximab prior to transplant showed a trend to a lower relapse rate ($p = 0.069$), and patients with <3 chemotherapy lines demonstrated a trend to improved OS ($p = 0.084$).

<p>Robinson, S. P. et al. (2013). The outcome of reduced intensity allogeneic stem cell transplantation and autologous stem cell transplantation when performed as a first transplant strategy in relapsed follicular lymphoma: An analysis from the Lymphoma Working Party of the EBMT. Bone Marrow Transplantation, 48(11); 1409-1414.</p>					
					<i>pse occurring at any time after transplant)</i>
Results	<p>Final eligible sample included in analysis: N=875 Patients who received autoSCT were significantly older at time of FL diagnosis and SCT compared with the alloSCT cohort, whereas alloSCT patients had received a higher number of therapies prior to SCT compared with autoSCT patients. The overall use of rituximab prior to SCT was 53% in the autoSCT group and 61% in patients undergoing alloSCT. The median time from original FL diagnosis to SCT was 39 months (range: 5-143 months) for patients who underwent autoSCT compared with 43 months (range: 7-344 months) for those who underwent alloSCT (P=0.1).</p>				
	<p>Table 2. Response to treatment according to treatment groups</p>				
		Arm A: Autologous transplantation n=726	Arm B: Allogeneic transplantation n=149		P-value
		%	%		
	1-year cumulative relapse incidence	20	17		<0.001
	3-year cumulative relapse incidence	38	17		
	5-year cumulative relapse incidence	47	20		
	<p>There were 292 cases (40%) of disease relapse in the autoSCT group and 29 (19%) in the alloSCT group occurring at a median of 13 months (range 0.6–107) and 5.4 months (range 0.1–76) post-transplant, respectively. Of the 292 patients relapsing after an autoSCT, 17 (6%) proceeded to a second autologous transplant and 56 (19%) to an alloSCT. Only 1 of the 29 (3%) patients relapsing in the alloSCT group received a second transplant (myeloablative alloSCT). The remaining patients received either conventional chemotherapy or palliative care. For the 56 patients who underwent a alloSCT after a failed autoSCT, the 3-year NRM, disease progression/relapse, PFS and OS rates were 30, 30, 39 and 50%, respectively.</p>				
	<p>Table 3. Survival rates according to treatment groups</p>				
		Arm A: Autologous transplantation n=726	Arm B: Allogeneic transplantation n=149		p-value
	%	%			
1-year progression free survival (PFS)	77	68		<0.001	
3-year progression free survival (PFS)	57	62			
5-year progression free survival (PFS)	48	57			
1-year Overall survival (OS)	90	80		0.84	
3-year Overall survival (OS)	78	68			
5-year Overall survival (OS)	72	67			
100-day non-relapse mortality (NRM)	2	6		<0.001	
1-year non-relapse mortality (NRM)	3	17			
3-year non-relapse mortality (NRM)	5	22			
Number of non-relapse deaths	37 (5%)	32 (21%)		Not reported	
<p>There was no significant difference in PFS between the two groups in the first 24 months post-transplant. However, after 24 months there was a significant PFS advantage for those patients receiving a reduced intensity allogeneic transplantation compared to autologous transplantation (relative risk=4.6; 95% CI: 2.4-8.7; p<0.001). Other factors predictive of improved PFS were age <50 years, disease stages I and II at diagnosis, chemosensitive disease at transplantation and good performance status.</p>					

Robinson, S. P. et al. (2013). The outcome of reduced intensity allogeneic stem cell transplantation and autologous stem cell transplantation when performed as a first transplant strategy in relapsed follicular lymphoma: An analysis from the Lymphoma Working Party of the EBMT. *Bone Marrow Transplantation*, 48(11); 1409-1414.

In the multivariate analysis, there was no significant difference in the OS between those patients in the autoSCT group and those in the alloSCT group. The only factors negatively impacting on OS were age >50 years, refractory disease at transplant and poor performance status at transplant.

69 patients (37 in arm A and 32 in arm B) died from non-relapse causes (29/69 due to infection; 3/69 due to second tumour, 3/69 due to graft versus host disease (GVHD) after allogeneic transplantation and 15/69 due to GVHD and infection).

Table 4. Factors associated with impaired outcomes after SCT

	Relative risk	95% confidence interval	p-value
<i>Non-relapse mortality</i>			
Allogeneic transplantation	4.0	2.3-6.8	<0.001
Refractory disease	2.6	1.5-4.4	0.001
Age >50 years	1.8	1.1-3.0	0.025
<i>Relapse/progression</i>			
Autologous transplantation	3.2	2.0-4.9	<0.001
Poor performance status	3.0	1.6-5.6	<0.001
Refractory disease	2.0	1.4-2.7	<0.001
Stage III and IV at diagnosis	1.4	1.1-1.8	0.003
<i>Progression-free survival</i>			
Autologous transplantation (>24 months post SCT)	4.6	2.4-8.7	<0.001
Poor performance status	3.1	1.8-5.2	<0.001
Refractory disease	2.2	1.7-2.9	<0.001
Age >50 years	1.4	1.1-1.7	<0.001
<i>Overall survival</i>			
Poor performance status	3.6	2.0-6.4	<0.001
Refractory disease	2.8	2.1-3.9	<0.001
Age >50 years	1.5	1.1-2.0	0.004

In multivariate analysis, alloSCT was associated with significantly increased risk of non-relapse death (RR=4.0; 95% CI: 2.3-6.8; p<0.001) whereas autoSCT was associated with significantly increased relapse incidence (RR=3.2; 95% CI: 2.0-4.9; p<0.001) and impaired progression-free survival >24 months post-transplant (RR=4.6; 95% CI 2.4-8.7; p>0.001). There was no significant difference in the OS between those patients in the autoSCT group and those in the alloSCT group.

Note: LDH, lactate dehydrogenase; CHOP, cyclophosphamide, hydroxydaunomycin, oncovin, prednisone

Final eligible sample included in analysis: N=904

There was no significant difference in most baseline characteristics between the groups including patient age, disease stage at diagnosis, presence of B symptoms at diagnosis and interval from diagnosis to transplant. Patients in the autologous transplantation group were more likely to have poor performance status, advanced disease, increased LDH, chemo resistant disease and bone marrow involvement at transplantation while autologous transplantation patients were more likely to have follicular large cell lymphoma (p-values <0.01). Bone marrow grafts and total body irradiation conditioning were most commonly used for allogeneic transplantation whereas chemotherapy conditioning was used more frequently in autologous transplantation with peripheral blood as preferred stem cell source in unpurged autologous transplantation.

Table 2. Relapse rate according to treatment groups

	Arm A1: Purged autologous transplantation n=131	Arm A2: Unpurged autologous transplantation n=597	Arm B: Allogeneic transplantation n=176
	%	%	%
1-year cumulative relapse incidence	25 (95% CI: 18-34)	36 (95% CI: 32-40)	19 (95% CI: 14-26)
3-year cumulative relapse incidence	40 (95% CI: 32-50)	52 (95% CI: 48-57)	21 (95% CI: 15-28)
5-year cumulative relapse incidence	43 (95% CI: 35-54)	58 (95% CI: 53-63)	21 (95% CI: 15-28)

The recurrence rate after allogeneic transplantation was 19% at 1 year and only few relapses occurred thereafter (median follow-up was 4.08 years). In the autologous transplantation group, 25% had relapsed after one year in the purged subgroup and 36% in the unpurged subgroup increasing to 43% and 58%, respectively at year 5. The risk of disease recurrence was 54% lower in the allogeneic transplantation group (relative risk RR=0.46; 95% CI: 0.33-0.66) compared to unpurged auto transplants (p<0.001) and 28% lower than in the purged autologous transplantation group. Other risk factors for relapse were advanced disease (RR=1.29; 95% CI: 1.06-1.58; p=0.01), high serum LDH at transplantation (RR=1.51; 95% CI: 1.21-1.87; p<0.001), chemotherapy-resistant disease (RR=1.69; 95% CI: 1.27-2.23; p<0.001), poor Karnofsky performance score (RR=1.31; 95% CI: 1.07-1.61; p=0.01), bone marrow involvement (RR=1.31; 95% CI: 1.04-1.65; p=0.02) and an interval greater than 1 year between diagnosis and transplantation (RR=1.37-1.40; 95% CI: 1.01-1.87; p=0.01-0.05) while the use of total body irradiation reduced the risk of relapse (RR=0.77; 95% CI: 0.62-0.95; p=0.02).

Table 3. Survival rates according to treatment groups

Results

van Besien, K. et al. (2003). Comparison of autologous and allogeneic hematopoietic stem cell transplantation for follicular lymphoma. *Blood*, 102(10); 3521-3529.

1-year disease free survival (DFS)	66 (95% CI: 58-74)	59 (95% CI: 55-63)	55 (95% CI: 48-62)
3-year disease free survival (DFS)	48 (95% CI: 39-57)	41 (95% CI: 37-45)	48 (95% CI: 40-55)
5-year disease free survival (DFS)	39 (95% CI: 30-48)	31 (95% CI: 27-38)	45 (95% CI: 36-53)
1-year Overall survival (OS)	82 (95% CI: 76-89)	81 (95% CI: 78-84)	61 (95% CI: 54-68)
3-year Overall survival (OS)	71 (95% CI: 63-79)	65 (95% CI: 61-69)	54 (95% CI: 47-62)
5-year Overall survival (OS)	62 (95% CI: 53-72)	55 (95% CI: 50-60)	51 (95% CI: 43-60)
1-year transplant-related mortality (TRM)	8 (95% CI: 5-15)	4 (95% CI: 3-6)	24 (95% CI: 18-32)
3-year transplant-related mortality (TRM)	10 (95% CI: 6-17)	6 (95% CI: 4-8)	28 (95% CI: 21-36)
5-year transplant-related mortality (TRM)	14 (95% CI: 8-22)	8 (95% CI: 6-11)	30 (95% CI: 23-40)

There was no significant difference in DFS and OS between the three groups at 1, 3 or 5 years (no p-values reported). Patients undergoing allogeneic transplantation had higher treatment-related mortality compared to autologous transplantation. In the first 6 months after transplant, the risk of treatment failure (relapse or death) was higher in patients who underwent allogeneic transplantation compared to autologous transplantation (p<0.001). Among patients who survived the first 6 months in remission, the subsequent risk of failure was significantly lower in patients receiving allogeneic transplants compared to autologous transplants (p<0.001).

Table 4. Factors associated with impaired outcomes after transplantation (unpurged autologous transplantation RR=1.00)

	Relative risk	95% confidence interval	p-value
<i>Non-relapse mortality</i>			
Allogeneic transplantation (n=175)	4.44	2.81-7.02	<0.001
Chemo resistant disease (n=111)	2.71	1.69-4.36	<0.001
Abnormal serum LDH (n=243)	2.03	1.32-3.14	0.001
Age >40 years (n=703)	1.98	1.21-3.26	0.007
Total body irradiation (n=348)	1.80	1.16-2.77	0.008
<i>Disease-free survival</i>			
Allogeneic transplantation (first 6 months post-transplant)*	1.77	1.34-2.34	<0.001
Purged autologous transplantation (>6 months post-transplant)	2.15	1.50-3.08	<0.001
Advanced disease (n=400)	1.27	1.07-1.52	0.007
Chemo resistant disease (n=111)	1.92	1.52-2.44	<0.001
Abnormal serum LDH (n=243)	1.58	1.30-1.93	<0.001
Poor performance status (n=260)	1.31	1.09-1.57	0.004
1-2 years from diagnosis to transplant (n=244)	1.37	1.04-1.80	0.03

Non Hodgkin's Lymphoma: diagnosis and management

van Besien, K. et al. (2003). Comparison of autologous and allogeneic hematopoietic stem cell transplantation for follicular lymphoma. Blood, 102(10); 3521-3529.							
Pub year: 2005		Patient Characteristics			Arm A	Arm B	Outcome
Country	USA	194 consecutive patients at one cancer research centre in the USA analysed			Rituximab sensitive ASCT	Rituximab refractory ASCT	Relapse rate
Design, period	Retrospective review April 1993-October 2011	Exclusion criteria: Aggressive transformation Grade 3b lymphoma Centroblastic lymphoma, follicular and diffuse (Kiel classification)					
N	194/194	All patients had relapsed FL prior to ASCT					
Follow-up	Median: 34 months	Response to chemotherapy defined as chemosensitive if patient achieved completion remission (CR) or partial remission (PR) from last chemotherapy prior to ASCT and chemorefractory if they had not achieved at least a PR or had disease progression within 6 months of therapy.					
Funding source	Funding from NIH PO1CA44991, the Mary Wright Memorial Research Fund and a donation from Frank and Betty Vandemeer. Full disclosure forms available at full-text article.	R-refractoriness was defined as failure to achieve at least a PR or documented disease progression within 6 months of 1) receiving the first dose of full course of single agent R, 2) completion of R maintenance or progression before next scheduled R dose or 3) completion of two course of R combined with chemotherapy.					
			Rituximab sensitive	Rituximab-refractory

Comments	↓ Risk of bias: Different regimens and selection criteria for transplantation, follow up and patient care ↓ Indirectness: No information provided whether sample included grade IIIb or transformed follicular lymphoma ↓ Imprecision: No 95% confidence intervals reported for primary outcomes, number of events unknown, no p-values reported for most outcomes; low patient numbers			

Aracini et al (2014) Autologous stem cell transplantation with in vivo purged progenitor cells shows long-term efficacy in relapsed/refractory follicular lymphoma. Am J Haematol; 2014; 90: 230-234								
Pub year: 2014		Patient Characteristics		Arm A	Arm B	Outcome		
Country	Italy	Patients with histological diagnosis of FL (relapsed or refractory) after at least one line of therapy, expression of CD20 by lymphoma cells, normal cardiac, renal and hepatic function and no viral infection.		Patients receiving HDCT/autoHCT after at least one course of immunochemotherapy	No comparator	<ul style="list-style-type: none"> - Progression free survival - Disease free survival - Event free survival - Overall survival - Cumulative incidence of secondary malignancies 		
Design, period	Observational study following patients enrolled in a phase 2 trial Time period not reported	Patient characteristics at baseline						
N	117/ 124 patients							
Follow-up	Median follow up 6/7 years							
Funding source	None reported. No personal interests declared.	No prior treatments	1 line >1 line (range)				90/124 34/124	73 27
		Bone marrow Bcl-2 baseline pos/neg					52/60	46/54
		Peripheral Bcl-2 baseline pos/neg					32/35	48/52
		Treatment was an anthracycline-based debulking chemotherapy, followed by R-CHOP, mobilisation of in vivo purged peripheral stem cells with high dose cytarabine and rituximab and ASCT.						
		Mobilisation was based on rituximab and cytarabine administered on days 1 and 9 and days 2 and 4, GCSF administered from day 6 until collection.						
Transplantation included conditioning with BEAM followed by infusion of in vivo purged PBSC. In 85 patients with complete haemopoietic recovery, two infusions of rituximab on day +14 and day +21 were administered.								
All patients who received at least one course of immunochemotherapy were considered accessible for response.

De Fontbrune, F. (2009). Allogeneic Versus Autologous Stem Cell Transplantation in Patients with Relapsing Follicular Lymphoma: Use of the Propensity Score to Reduce Recruitment Bias in A Retrospective Comparative Study. Haematologica-the Hematology Journal, 94; 290-290.					
	5-year overall survival (OS)	73	58		
	5-year EFS after propensity score matching ¹	52.4	66	0.18	
	5-year OS after propensity score matching ¹	77	67	0.71	
¹ Propensity score matching allowed for comparison of 19 patient pairs					
There was no significant difference in event-free survival and overall survival between the two patient groups despite a trend towards better event-free survival in the alloSCT group.					
In the allo SCT group, 13 patients (12/13 were treatment-related_ and 1/27 patient relapsed. Six patients (22%) had grade 3-4 acute graft versus host disease (GVHD) and 9 experienced chronic extensive GVHD. Lower treatment-related mortality and no relapse were reported after non-myeloablative conditioning all SCT (no further detail provided). Adverse event information was not reported for the autologous transplantation group.

	On multivariate analysis autoHCT was associated with reduced NRM (RR=0.21, p<0.0001)						
AutoHCT associated with higher risk of relapse/progression beyond 5 months post HCT (RR=4.4. p<0.0001) and worse PFS (RR 2.9, P<0.0001) beyond 11 months							
In first 24 months post HCT, auto HCT was associated with improved OS (RR=0.41, p<0.0001) but beyond 24 months, inferior OS (RR 2.2., p=0.006)							

Non Hodgkin's Lymphoma: diagnosis and management

Klyuchnikov et al (2015) Reduced intensity conditioning (RIC) allo transplantation is associated with superior long-term disease control in relapsed/refractory Grade I/II Follicular Lymphoma				
	Analysis of patients alive and progression free at 2 years post HCT confirmed observations showing no difference in NR but significantl higher relapse/progression (RR 7.3 P<0.0001) and inferio PFS (RR3.2. P<0.0001) and OS (RR 2.1. P=0.04) following auto HCT

Comments	↓ Risk of bias: Conference abstract; limited information available to appraise, significant differences at baseline on characteristics ↓ Indirectness: No information provided whether sample included grade IIIb or transformed follicular lymphoma ↓ Imprecision: No 95% confidence intervals reported for primary outcomes, number of events unknown, data poorly reported			

Non Hodgkin's Lymphoma: diagnosis and management

Lunning, M. A. (2012). Remission duration < 12 months for early relapsed and refractory follicular lymphoma is predictive of early failures post-high dose therapy and autologous stem cell rescue. <i>Blood</i> , 120(21); abstract 3136.						
Pub year: 2005		Patient Characteristics		Arm A	Arm B	Outcome
Country	USA	Between 2006 and 2010, patients undergoing high-dose therapy and autologous stem cell rescue (arm A) or non-myeloablative allogeneic stem cell transplantation (arm B) as first transplantation at the Memorial Sloan-Kettering Cancer Center in new York were included in the review.		Autologous stem cell transplantation	Allogeneic stem cell transplantation	- Event free survival <i>(defined as progression of follicular lymphoma post-transplant or death from any cause)</i>
Design, period	Retrospective review 2006-2010	20 patients underwent autologous stem cell transplantation and 47 received allogeneic transplantation. Patients were considered for autoSCT if they did not have a matched sibling donor and patients with a match sibling donor, especially if they had experienced more than one relapse or failed a prior autoSCT were eligible for allogeneic transplantation.		Conditioning regimen: BEAM (carmustine, etoposide, cytarabine, melphalan)	Conditioning regimen: Cyclophosphamide, fludarabine, total body irradiation 200 cGy	
N	40/40	<i>Inclusion criteria:</i> - Early relapse and/or refractory (multiply relapsed) follicular lymphoma - Grade 1 to 3a		No further information reported.	No further information reported.	- Overall survival
Follow-up	Median: 34 months	<i>Exclusion criteria:</i> - Pathologic evidence of transformation at the time of re-induction prior to transplant consolidation				
Funding source	None reported.	Table 1. Baseline characteristics:				
	No personal interests declared.		Arm A: Autologous transplantation n=20	Arm B: Allogeneic transplantation n=20		
		Median age in years (range)	51 (33-70)	55 (34-69)		
		Median number of previous lines of therapy (range)	2 (2-4)	3 (2-7)		
		Chemosensitive disease	19/20 (95%)	20/20 (100%)		
		- Complete remission	8	7		
		- Partial remission	11	13		
		Median remission duration prior to re-induction therapy; months (range)	11.5 (0-31)	5 (0-12)		
	Remission duration ≤ 12 months from re-induction therapy	11/20 (55%)	20/20 (100%)			
Results	Table 2. Rates according to treatment groups					
		Arm A: Autologous transplantation n=21	Arm B: Allogeneic transplantation n=47	p-value		
		%	%			
	3-year event-free survival (EFS)	60	79	<i>Not significant</i>		
	3-year overall survival (OS)	62	85	<i>Not significant</i>		
3-year event-free survival for patients with previous remission duration ≤ 12 months	36	79	<0.03			
There was no significant difference between the two groups for 3-year event-free survival and overall survival. Patients with a remission duration ≤ 12 months prior to re-induction therapy proceeding to consolidative high dose therapy and autologous stem cell rescue had significantly shorter EFS compared to patients with previous remission duration >12 months receiving the same treatment (p<0.05).						

Non Hodgkin's Lymphoma: diagnosis and management

Lunning, M. A. (2012). Remission duration < 12 months for early relapsed and refractory follicular lymphoma is predictive of early failures post-high dose therapy and autologous stem cell rescue. <i>Blood</i> , 120(21); abstract 3136.				
	<p>Patients with remission duration \leq 12 months prior to transplant had significantly better event-free survival after allogeneic transplantation compared to autologous transplantation ($p < 0.03$) suggesting better disease control with allogeneic transplantation in this patient group.</p> <p>In the allo SCT group, 2 patients died from graft versus host disease (GVHD), 1 patient died from cytomegalovirus infection and one patient developed diffuse large B-cell lymphoma. In the autoSCT group, 8 events were related to disease progression of follicular lymphoma. Three of these eight patients subsequently underwent allogeneic transplantation.</p>

Oh et al 2014. Autologous Stem Cell Transplantation Improves Survival for Patients with Follicular Lymphoma in First or Second Relapse: Results of a Comparative Effectiveness Instrumental Variable Analysis. Blood, 2014; 124 (21)					
Pub year: 2014		Patient Characteristics	Arm A	Arm B	Outcome
Country	Canada	568 patients were reviewed from the Alberta Cancer Registry to identify patients with FL. Patients aged 18-60 years at initial diagnosis and experienced a relapse post initial chemotherapy regardless of first line management were included. Exclusion criteria: Grade 3b or areas of concurrent diffuse large B cell lymphoma at initial diagnosis Patients were treated at centre A (n=96) or centre B (n=84) No significant difference in patient and disease characteristics noted but no information given.	AutoSCT following first or second relapse	No comparator	Overall survival
Design, period	Retrospective analysis from 2001-2010				
N	180/568				
Follow-up	Median follow up of 104.4 months (28.1-156.1) following diagnosis and 65.3 months (0.3-151.8) months from first relapse Group B = 37 months (range 17-130 months)	Differences in treatments between centres were reported: Proportion of patients receiving ASCT higher in centre A than B Centre A had more allogeneic transplantation (16.7 vs. 3.6%, P=0.04) Other regimens were similar			
Funding source	Not reported				
Results	<p>Projected 5 years OS from first relapse was significantly higher in centre A vs B (88.9% vs 59.5%, HR 3.24, P<0.001) For these 180 patients, 10 year OS from initial diagnosis was 85.4% in centre A vs 60.5% in centre B (HR 3.02, p=0.003)</p> <p>Factors associated with improved OS at relapse in univariate analysis were female gender (p=0.01), no comorbidities (p=0.01), FLIPI score 0-2 at diagnosis (p<0.002) and TTP> 1 year (p=0.02)</p> <p>5 year OS for patients receiving ASCT at 1st/2nd relapse of 92.4% vs. 66.5% for no ASCT vs. 62.5% for ASCT beyond second relapse (p<0.001) Allogeneic transplantation did not affect OS (p=0.62)</p>				

Non Hodgkin's Lymphoma: diagnosis and management

Oh et al 2014. Autologous Stem Cell Transplantation Improves Survival for Patients with Follicular Lymphoma in First or Second Relapse: Results of a Comparative Effectiveness Instrumental Variable Analysis. Blood, 2014; 124 (21)				
	<p>In multivariate analysis, treatment centre A (HR 3.16, p=0.001), FLIPI score 0-2 at diagnosis, no transformation ever use of rituximab with chemotherapy and every use of R maintenance (data not reported)</p> <p>ASCT at 1st/2nd relapse was associated with improved OS (HR 4.55, p=0.003). independent of FLIP score, no transformation, ever use of rituximab with chemotherapy and ever use of r maintenance. Treatment centre and use of ASCT at 1st/2nd relapse highly correlated prohibiting combination in same model.</p>

--	--------------------	--	--	--	--

Results	Table 2: Survival and toxicity			
	Outcome		Rate	
	1 year overall survival (OS)		67%	
	2 year overall survival (OS)		60%	
	5 year overall survival (OS)		53%	
	10 year overall survival (OS)		48%	
	1 year event-free survival (EFS)		63%	
	2 year event-free survival (EFS)		53%	
	5 year event-free survival (EFS)		47%	
	10 year event-free survival (EFS)		40%	
	Incidence grade II-IV acute GVHD		35%	
	Incidence chronic GVHD (limited form)		34%	
Incidence chronic GVHD (extensive form)		27%		
Extensive chronic GVHD associated with advanced donor age (P=0.016)				
Of the 116 patients with documented CR after allogeneic transplantation 17 (15%) relapsed. Only two late relapses (beyond year 3) were diagnosed among the 77 patients with a follow-up >5 years..				
Univariate statistical analysis suggested limited chronic GvHD, donor age <42 years, and TBI-based conditioning in treatment-refractory patients to be correlated with favorable OS (data not reported). Multivariate analysis revealed treatment-sensitive disease, limited chronic GvHD, and TBI-based conditioning in treatment-refractory patients as independent beneficial prognosticfactors for OS.

	Other biases?	X	
Comments	<p>↓ Risk of bias: Limited information on patient selection and clinical details at baseline. Unclear how complete response determined or what was used to define prognostic No comparator group.</p> <p>↓ Imprecision: Errors in reporting numbers- sub groups do not add up to total reported for conditioning treatments and number of evaluable patients. Statistical methods not reported</p>		

Ubeito et al 2014. High does therapy with autologous stem cell transplantation (HDT/ASCT) support in follicular lymphoma (FL) a very long follow up analysis of 640 patients of Gelatamo Spanish Group that suggests that FL might be cured, even in high risk patients. Blood 2014; 12(21)												
Pub year: 2014		Patient Characteristics		Arm A	Arm B	Outcome						
Country	Spain	- Patients with FL were reported to the GELTAMO registry.		HDCT/ASCT	No comparator	- Progression free survival (no definition provided) - Overall survival (no definition provided) - Mortality						
In	Retrospective observational study 1989-2007	Exclusion criteria: Patients with histological transformation at time of HDCT/ASCT Follow up of less than 7 years Undergoing a second transplant										
N	666/666	Table 1. Patient characteristics: <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left;">Characteristic</th> <th style="text-align: left;">Result</th> </tr> </thead> <tbody> <tr> <td>Age</td> <td>Mean 47 years</td> </tr> <tr> <td>Sex</td> <td>49% Male, 51% Female</td> </tr> </tbody> </table>					Characteristic	Result	Age	Mean 47 years	Sex	49% Male, 51% Female
Characteristic	Result											
Age	Mean 47 years											
Sex	49% Male, 51% Female											
Follow-up	Median 12.2 years from HDCT/ASCT 14.2 years from diagnosis	Follow up from HDCT/ASCT was over 16 years for 153 patients (3 rd quartile) Median time from diagnosis to HSCT/ASCT was 1.8 years										
Funding source	No information on funding source provided No competing financial interests declared by authors.	247 (38%) never achieved a complete remission (CR) 200 (31%) received HSCT/ASCT after achievement of first CR 43% required more than one chemotherapy line to achieve CR1, 26% in CR2 and 5% in CR3, 21% in 1 st partial response, 12% in chemosensitive recurrence and 5% in active disease FLIPI score 321 patients assessable, 33% had low risk; 36 % had intermediate risk and 45% had high risk FLIPI II score 305 patients assessable: 22% had low risk, 38% had an intermediate risk and 40% had high risk Of 127 patients in CR1 assessable, 28% had low risk, 40% had intermediate risk and 32% high risk Of 115 patients in CR1 risk, 14% had low risk, 46% had intermediate risk and 40% high risk One third had received rituximab prior to transplant										
Results	Median PFS: 9.4 years Median OS: 21,3 years Patients transplanted in CR1 achieved significantly better final PFS (68%) and OS (73%) than those in in 2 nd CR (median 110 months and final OS 58%, P<0.0005)											

Ubeito et al 2014. High does therapy with autologous stem cell transplantation (HDT/ASCT) support in follicular lymphoma (FL) a very long follow up analysis of 640 patients of Gelatamo Spanish Group that suggests that FL might be cured, even in high risk patients. Blood 2014; 12(21)

Neither FLIPI 1 or FLIPI2 reached statistical significance in patients transplanted in CR1 (p=0.5 and p=0.2) for PFS and OS

Overall rituximab prior to HDCT/ASCT had better prognosis than those who did not (median OS- 246 months vs. 92 months, p=0.005), rituximab had no prognostic index in cases transplanted in CR1

6 patients died beyond 10 years of follow up (1 disease progression, 3 second malignancies, 2 unrelated causes)

Accumulated incidence of second malignancies o=12%

Plateau observed in PFS and OS curves for patients transplanted in CR1 beyond 15.9 years.

Comments

- ↓ Risk of bias: Methods of analysis only briefly reported; no comparison group
- ↓ Indirectness: Not clear if grade 3 patients included 3b.
- ↓ Imprecision: Lack of confidence intervals,, outcomes poorly described

4.1.3 Review question: Is immediate treatment or deferred chemotherapy (watch and wait) the more effective treatment for people with advanced asymptomatic follicular lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
<p>Adults and young people (16 years and older) newly diagnosed with advanced asymptomatic follicular non-Hodgkin's lymphoma (≥ Stage II).</p> <p>Include: Stage II and above</p> <p>Exclude: Grade IIIb Transformed FL, composite/discordant FL/DLBCL</p>	<p>Chemotherapy</p> <p>Immunotherapy (+/- Rituximab)</p> <p>Radio-immunotherapy</p>	<p>Watch and wait (<i>deferred chemotherapy</i>)</p> <p>Active surveillance/ active monitoring</p> <p>No treatment</p> <p>Each other</p>	<p>Overall survival</p> <p>Progression free survival</p> <p>Treatment related mortality</p> <p>Treatment related morbidity</p> <p>Health-related quality of life</p> <p>Patient satisfaction</p> <p>Patient preference</p> <p>Time to first treatment</p> <p>Time to second treatment</p> <p>Transformation to aggressive lymphoma</p> <p>Treatment free survival</p> <p>Response to next line of treatment</p>
<p>Additional Comments on PICO</p>			
<p>Look at Stage II separately Record Flipi scores separately Radiotherapy could be counted as no treatment or as an intervention 06.06.14: Noted that we should included 'each other' in the comparison column as there are studies that look at rituximab versus chemotherapy 06.06.14: TA137: Rituximab induction of remission (maintenance therapy) in people with relapsed stage II or IV FL: Asked GDG if there was overlap and the GDG added 'newly diagnosed' to the population, with this inclusion there is no overlap with the TA. 6.10.15: The comparison implied by "each other" in the "Comparison" column and the first note from 06.06.14 suggests that studies comparing active treatments without the inclusion of a 'watch and wait' group should be included in this evidence review. Such studies have not been included as these would not answer the clinical question which is about whether one should treat at all.</p>			

Summary Tables

Figure 1. Study flow diagram

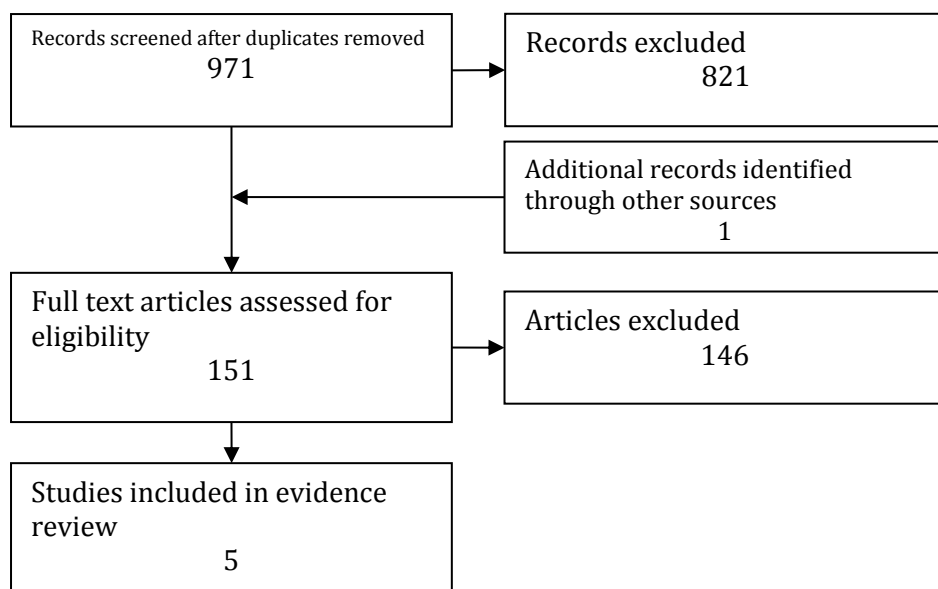

Table 1. Summary of findings (inferential statistical analyses)

Treatment options and comparisons		Studies	N	Outcome	GRADE quality
Watch and wait (a)	Vs. Chlorambucil (b)	1	309	No difference between (a) and (b) in overall and cause-specific-survival; significantly longer time to secondline treatment in (a) than (b)	Very low
	Vs. Rituximab induction (c)	1	252	At 3 years more (a) than (c) patients needed new treatment; time to new treatment was longer in (c) than in (a), overall and in some, but not all subgroup analyses; 3-year progression-free survival was higher in (c) than in (a); 3-year overall survival did not differ between (a) and (c); Time to transformation did not differ between (a) and (c); Adverse events for (c): Infections (1), allergies (3; 1 was grade 3), neutropenia (0), no deaths; Quality of life did not differ between (a) and (c)	Very low
	Vs. Rituximab maintenance (d)	1	463	At 3 years more (a) than (d) patients needed new treatment; time to new treatment was longer in (d) than in (a), overall and in subgroup analyses; 3-year progression-free survival was higher in (d) than in (a) ; 3-year overall survival did not differ between (a) and (d); Time to transformation did not differ between (a) and (d); Adverse events for (d): Infections (8; 5 were grade 3), allergies (2; both were grade 3), neutropenia (4; all grade 3 or 4), no deaths; Quality of life was either better or similar in (d) compared to (a); (a) and (d) did not differ in anxiety or depression scores	Low
	Vs. Prednimustine (e)	1	193	No difference between (a), (e) and (f) in overall survival or in 'Freedom from treatment'* (a) and 'Freedom from treatment failure'* (e, f) Toxicity: Prednimustine: "mild, especially hematologic toxicity with no grade 3/4 toxicity." Toxicity: Interferon alfa: Side effects (e.g., fever, chills, and asthenia) commonly observed; treatment withdrawn in 10 patients, with the withdrawal in 5/10 being transient and definitive in 5/10 due to adverse events; no deaths occurred during treatment with interferon alfa.	Very low
	Vs. Interferon alfa (f)	1	193		Very low
	Vs. Chemotherapy (NOS) ± rituximab (g)	1	79	'Time to next treatment' and progression-free survival were longer in (g) than in (a); overall survival did not differ between (a) and (g)	Very low
	Vs. Immunochemotherapy (NOS) (h)	1	116	Overall survival did not differ between (a) and (h)	Very low

*'Freedom from treatment' = delay between diagnosis and initiation of treatment; 'Freedom from treatment failure' = delay between diagnosis and date of the second treatment for lymphoma whether patients had responded to the first treatment or not.

Evidence Statements

Three randomised controlled trials and two retrospective cohort studies were included as evidence.

Chlorambucil versus 'watch and wait'

Very low quality evidence from one randomised trial in 309 patients (Ardeshna *et al* 2003) reported that time to second line chemotherapy (HR = 1.422, 95% CI 1.086-1.861), but not overall survival (HR = 1.026, 95% CI 0.798-1.319) was longer after treatment with chlormabucil compared to 'watch and wait'.

Rituximab induction versus 'watch and wait'

Very low quality evidence from one randomised trial in 167 patients (Ardeshna *et al* 2014) reported that the need for new treatment (HR = 0.35, 95% CI 0.22-0.56) and progression-free survival (HR = 0.55, 95% CI 0.37-0.83), but not overall survival (HR not reported), time to transformation (HR not reported) and quality of life (HR not reported) were superior after treatment with rituximab induction compared to 'watch and wait'.

Rituximab imaintenance versus 'watch and wait'

Low quality evidence from one randomised trial in 379 patients (Ardeshna *et al* 2014) reported that the need for new treatment (HR = 0.21, 95% CI 0.14-0.31) and progression-free survival (HR = 0.23, 95% CI 0.16-0.32), but not overall survival (HR = 0.73, 95% CI 0.34-1.54) or time to transformation (HR = 0.62, 95% CI 0.3-1.26) were superior after treatment with rituximab maintenance compared to 'watch and wait'. Quality of life was either superior or similar after treatment with rituximab maintenance compared to 'watch and wait' (HRs not reported).

Prednimustine versus 'watch and wait'

Very low quality evidence on 'Freedom from treatment'/'freedom from treatment failure' (HR not reported) and overall survival (HR not reported) was reported in one randomised trial with 130 patients (Brice *et al* 1997) with no difference reported after treatment with prednimustine compared to 'watch and wait'.

Interferon alfa versus 'watch and wait'

Very low quality evidence from one randomised trial with 129 patients (Brice *et al*, 1997) reported that 'freedom from treatment'/'freedom from treatment failure' (HR not reported) and overall survival (HR not reported) did not differ after treatment with interferon alfa compared to 'watch and wait'.

Chemotherapy ± rituximab (NOS) versus 'watch and wait'

Very low quality evidence from one retrospective cohort study with 79 patients (Pereira *et al* 2014) reported that time to next treatment (HR not reported) and progression-free survival (HR not reported), but not overall survival (HR not reported) were superior after treatment with chemotherapy ± rituximab (NOS) compared to 'watch and wait'.

Immunochemotherapy (NOS) versus 'watch and wait'

Very low quality evidence from one retrospective cohort study with 116 patients (Stemmelin *et al*, 2014) reported that overall survival (HR not reported) did not differ after treatment with immunochemotherapy (NOS) compared to 'watch and wait'.

GRADE Tables

Grade Profile 1: Should chlorambucil therapy vs 'watch and wait' be used for advanced stage asymptomatic follicular lymphoma?

Settings: UK

Quality assessment							Summary of findings			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect	Quality
							Chlorambucil therapy	Watch and wait	Relative (95% CI)	
Overall survival (follow-up median 16 years)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	serious indirectness ³	serious imprecision ⁴	none	158	151	HR = 1.026 (0.798-1.319)	⊕○○○ Very low
Time to second line chemotherapy (follow-up median 16 years)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	serious indirectness ³	No serious imprecision	none	158	151	HR = 1.422 (1.086-1.861) favouring chlormabucil	⊕⊕○○ Low

¹ Ardeshtna et al. (2003)

² The trial was open, including of outcome assessment.

³ 34% of the included patients did not have follicular lymphoma

⁴ Confidence interval for the effect estimate includes both no effect and significant harm.

Grade Profile 2: Should rituximab induction therapy vs 'watch and wait' be used for advanced stage asymptomatic follicular lymphoma?

Settings: UK

Quality assessment							Summary of findings			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect	Quality
							Rituximab induction therapy	Watch and wait	Relative (95% CI)	
Need for new treatment (at 3 years)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	no serious imprecision	none	84	83	HR = 0.35 (0.22-0.56) favouring rituximab induction	⊕⊕⊕○ Moderate
Progression-free survival (at 3 years)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	no serious imprecision	none	84	83	HR = 0.55 (0.37-0.83) favouring rituximab induction	⊕⊕⊕○ Moderate
Overall survival (at 3 years)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	very serious imprecision ³	none	84	83	The groups did not differ significantly	⊕○○○ Very low
Time to transformation (follow-up median 50 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	very serious imprecision ³	none	84	83	The groups did not differ significantly	⊕○○○ Very low
Quality of life (at baseline and 7 months) measured using EORTC QLQ-C30										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	very serious imprecision ³	none	84	83	The groups did not differ significantly	⊕○○○ Very low

¹ Ardeshtna et al. (2014)

² The trial was open, including outcome assessment.

³ Confidence intervals of effect estimates not reported

Grade Profile 3: Should rituximab maintenance therapy vs 'watch and wait' be used for advanced stage asymptomatic follicular lymphoma?

Settings: UK

Quality assessment							Summary of findings			
							No of patients		Effect	
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Rituximab maintenance therapy	Watch and wait	Relative (95% CI)	
Need for new treatment (at 3 years)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	192	187	HR = 0.21 (0.14-0.31) favouring rituximab maintenance	⊕⊕⊕○ Moderate
Progression-free survival (at 3 years)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	192	187	HR = 0.23 (0.16-0.32) favouring rituximab maintenance	⊕⊕⊕○ Moderate
Overall survival (at 3 years)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	serious imprecision ³	none	192	187	HR = 0.73 (0.34-1.54)	⊕⊕○○ Low
Time to transformation (follow-up median 46 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	serious imprecision ³	none	192	187	HR = 0.62 (0.3-1.26)	⊕⊕○○ Low
Quality of life (at baseline and 7 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	192	187	Better or similar QoL in the rituximab maintenance group than in the 'watch and wait' group	⊕⊕⊕○ Moderate

¹ Ardeshtna et al. (2014)

² The trial was open, including of outcome assessment.

³ Confidence interval for the effect estimate includes both appreciable benefit and appreciable harm.

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 4: Should prednimustine therapy vs 'watch and wait' be used for advanced stage asymptomatic follicular lymphoma?

Settings: France

Quality assessment							Summary of findings			
							No of patients		Effect	
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Prednimustine therapy	Watch and wait	Relative (95% CI)	
'Freedom from treatment' and 'freedom from treatment failure' (follow-up median 45 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	very serious imprecision ³	none	64	66	The groups did not differ significantly	⊕○○○ Very low
Overall survival (follow-up median 45 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	very serious imprecision ³	none	64	66	The groups did not differ significantly	⊕○○○ Very low

¹ Brice et al. (1997)

² The trial was open, including of outcome assessment, patient selection methods unclear.

³ Confidence intervals of effect not reported

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 5: Should interferon alfa therapy vs 'watch and wait' be used for advanced stage asymptomatic follicular lymphoma?

Settings: France

Quality assessment							Summary of findings			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect	Quality
							Interferon alfa therapy	Watch and wait	Relative (95% CI)	
'Freedom from treatment' and 'freedom from treatment failure' (follow-up median 45 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	very serious imprecision ³	none	63	66	The groups did not differ significantly	⊕ ○ ○ ○ Very low
Overall survival (follow-up median 45 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	very serious imprecision ³	none	63	66	The groups did not differ significantly	⊕ ○ ○ ○ Very low

¹ Brice et al. (1997)

² The trial was open, including of outcome assessment, patient selection methods unclear.

³ Confidence intervals for effect not reported

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 6: Should chemotherapy ± rituximab (NOS) vs 'watch and wait' be used for advanced stage asymptomatic follicular lymphoma?

Settings: Unclear

Quality assessment							Summary of findings			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect	Quality
							Chemo-therapy	Watch and wait	Relative (95% CI)	
Time to next treatment (follow-up median 48 months)										
1	observational study ¹	no serious limitations	no serious inconsistency	no serious indirectness	very serious imprecision ²	none	58	21	Significantly longer in chemotherapy group	⊕ ○ ○ ○ Very low
Progression-free survival (follow-up median 48 months)										
1	observational study ¹	no serious limitations	no serious inconsistency	no serious indirectness	very serious imprecision ²	none	58	21	Significantly longer in chemotherapy group	⊕ ○ ○ ○ Very low
Overall survival (follow-up median 48 months)										
1	observational study ¹	no serious limitations	no serious inconsistency	no serious indirectness	very serious imprecision ²	none	58	21	The groups did not differ significantly	⊕ ○ ○ ○ Very low

¹ Pereira et al. (2014)

² Confidence intervals for effect not reported

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 7: Should immunochemotherapy (NOS) vs 'watch and wait' be used for advanced stage asymptomatic follicular lymphoma?

Settings: Argentina

Quality assessment							Summary of findings			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect	Quality
							Immuno-chemo-therapy	Watch and wait	Relative (95% CI)	
Overall survival (follow-up not reported)										
1	observational study ¹	no serious limitations	no serious inconsistency	no serious indirectness	very serious imprecision ²	none	86	30	The groups did not differ significantly	⊕ ○ ○ ○ Very low

¹ Stemmelin et al. (2014)

² Confidence intervals for effect not reported.

Need for new treatment (2-arm study):

- 105/187 'watch and wait' patients and 33/192 rituximab maintenance patients needed new treatment (all but N = 6 for disease progression)
- Median time to start of new treatment was 31.1 (95% CI 25.5-46) months in the 'watch and wait' group and 'not reached' in the rituximab maintenance group.
- At 3 years, 46% (95% CI 39-53) 'watch and wait' patients and 88% (95% CI 83-92) rituximab maintenance patients did not need new treatment; HR = 0.21 (95% CI 0.14-0.31), p < 0.0001
- Subgroup analyses by age (≤ 60, 60-70, > 70), gender, ECOG PS (0,1), FL grade (1, 2, 3a), stage (II, III, IV), bone marrow trephine (abnormal, normal), FLIPI (0-1, 2, 3-4) and β2 microglobulin (> 2.4, ≤ 2.4) showed that the time to new treatment was significantly longer in all these subgroups of patients who had received rituximab maintenance compared to 'watch and wait'.

Need for new treatment (3-arm study):

- 52/83 'watch and wait' patients, 25/84 rituximab induction patients, and 20/85 rituximab maintenance patients needed to start new treatment.
- Median time to start of new treatment was 'not reached' in the rituximab induction group.
- At 3 years, 78% (95% CI 69-87) rituximab induction patients did not need new treatment; HR for rituximab induction versus 'watch and wait' = 0.35 (95% CI 0.22-0.56), p < 0.0001, and HR for rituximab induction versus rituximab maintenance = 0.75 (95% CI 0.41-1.34), p = 0.33
- Subgroup analyses by age (≤ 60, 60-70, > 70), gender, ECOG PS (0,1), FL grade (1, 2, 3a), stage (II, III, IV), bone marrow trephine (abnormal, normal), FLIPI (0-1, 2, 3-4) and β2 microglobulin (> 2.4, ≤ 2.4) showed that the time to new treatment was significantly longer in all these subgroups of patients who had received rituximab induction compared to 'watch and wait', with the exception of the following subgroups where there was no difference between the 2 arms: Patients aged > 70 years, patients with ECOG PS of 1, FL grade 3a, stage II or FLIPI 3-4. Moreover, none of these subgroups differed in time to new treatment between the rituximab induction and maintenance groups with the exception that females who had received rituximab maintenance experienced a longer time to initiation of new treatment than those who had received rituximab induction.

Progression-free survival (2-arm study):

- 121/187 'watch and wait' patients and 43/192 rituximab maintenance patients developed progressive disease or died.
- Median progression-free survival was 24.1 (95% CI 17.1-25.3) months in the 'watch and wait' group and 'not reached' in the rituximab maintenance group.
- 3-year progression-free survival = 36% (95% CI 29-43) in the 'watch and wait' patients and 82% (95% 77-88) in the rituximab maintenance group, HR = 0.23 (95% CI 0.16-0.32), p < 0.0001.

Progression-free survival (3-arm study):

- 41/84 rituximab induction patients developed progressive disease or died.
- 3-year progression-free survival = 60% (95% CI 49-71) in the rituximab induction group, HR for rituximab induction versus 'watch and wait' = 0.55 (95% CI 0.37-0.83), p = 0.0034, favouring induction; and HR for rituximab induction versus rituximab maintenance = 0.53 (95% CI 0.32-1.87), p = 0.011, favouring maintenance.

Overall survival (2-arm study):

- 16/187 'watch and wait' patients and 12/192 rituximab maintenance patients died.
- 3-year overall survival = 94% (95% CI 90-98) in the 'watch and wait' patients and 97% (95% 94-99) in the rituximab maintenance group, HR = 0.73 (95% CI 0.34-1.54), p = 0.4.

Overall survival (3-arm study):

- 8/84 rituximab induction patients died.
- 3-year overall survival = 96% (95% CI 92-100) in the rituximab induction group; the 3 groups did not differ significantly from each other.

Transformation (biopsy-proven)

<p>Ardeshna, K.M., et al. (2014). Rituximab versus a watch-and-wait approach in patients with advanced-stage, asymptomatic, non-bulky follicular lymphoma: an open-label randomised phase 3 trial. <i>Lancet Oncology</i>, 15; 424-435.</p>	
	<ul style="list-style-type: none"> - 2-arm study: 20/187 'watch and wait' patients and 13/192 rituximab maintenance patients had biopsy-proven transformation. Time to transformation did not differ between the 2 groups, HR = 0.62 (95% CI 0.3-1.26), p = 0.19 - 3-arm study: 8/84 rituximab induction patients had biopsy-proven transformation. Time to transformation did not differ significantly between the 3 groups. <p>Adverse events:</p> <ul style="list-style-type: none"> - Rituximab induction: Infections (1), allergies (3; 1 was grade 3), neutropenia (0) - Rituximab maintenance: Infections (8; 5 were grade 3), allergies (2; both were grade 3), neutropenia (4; all grade 3 or 4) - There were no deaths due to study treatments. <p>Quality of life (2-arm study):</p> <ul style="list-style-type: none"> - Significantly better quality of life was observed in the rituximab maintenance group compared to the 'watch and wait' group in terms of 'mental adjustment to cancer' at month 7, illness coping style at month 7, being worried about the need for treatment or for more treatment at month 7. No other clinically significant (change of 5 points) differences were observed between the groups. The patient groups did not differ in depression or anxiety scores either. <p>Quality of life (3-arm study):</p> <ul style="list-style-type: none"> - No differences between baseline and 7 months between the 'watch and wait' group and the rituximab induction group. - Superior quality of life was observed in the rituximab maintenance group compared to the induction group in terms of 'mental adjustment to cancer' at month 7, otherwise no differences were found.
Comments	<ul style="list-style-type: none"> - ITT analysis for time-to-event outcomes - Patient selection bias (randomisation sequence, allocation concealment)? Low risk - Central randomisation - Performance bias (blinding of patients, personnel)? High risk - Open trial - Detection bias (blinding of outcome assessor)? High risk - Open trial - Attrition bias (missing data)? Low risk - Apart from for response, data from all patients appear to have been included for the remaining outcomes. - Reporting bias? Low risk - Other bias? Low risk

Economic evidence

Review question

Is immediate treatment or deferred chemotherapy (watch and wait) the most effective treatment for people with advanced asymptomatic follicular lymphoma?

Table 1: PICO table for the most effective treatment for people with advanced asymptomatic follicular lymphoma

Population	Intervention	Comparison	Outcomes
<p>Adults and young people (16 years and older) newly diagnosed with advanced asymptomatic follicular non-Hodgkin's lymphoma (≥ Stage II).</p> <p>Include:</p> <ul style="list-style-type: none"> • Stage II and above <p>Exclude:</p> <ul style="list-style-type: none"> • Grade IIIb Transformed FL, composite/disco rdant FL/DLBCL 	<ul style="list-style-type: none"> • Chemotherapy • Immunotherapy (+/- Rituximab) • Radio-immunotherapy 	<ul style="list-style-type: none"> • Watch and wait (<i>deferred chemotherapy</i>) • Active surveillance/ active monitoring • No treatment • Each other 	<ol style="list-style-type: none"> 1. Overall survival 2. Progression free survival 3. Treatment related mortality 4. Treatment related morbidity 5. Health-related quality of life 6. Patient satisfaction 7. Patient preference 8. Time to first treatment 9. Time to second treatment 10. Transformation to aggressive lymphoma 11. Treatment free survival 12. Response to next line of treatment

Information sources and eligibility criteria

The following databases were searched for economic evidence relevant to the PICO: MEDLINE, EMBASE, COCHRANE, NHS EED and HEED. Studies conducted in OECD countries other than the UK were considered.

Studies were selected for inclusion in the evidence review if the following criteria were met:

- Both cost and health consequences of interventions reported (i.e. true cost-effectiveness analyses)
- Conducted in an OECD country
- Incremental results are reported or enough information is presented to allow incremental results to be derived

- Studies that matched the population, interventions, comparators and outcomes specified in PICO
- Studies that meet the applicability and quality criteria set out by NICE, including relevance to the NICE reference case and UK NHS

Note that studies that measured effectiveness using quality of life based outcomes (e.g. QALYs) were desirable but, where this evidence was unavailable, studies using alternative effectiveness measures (e.g. life years) were considered.

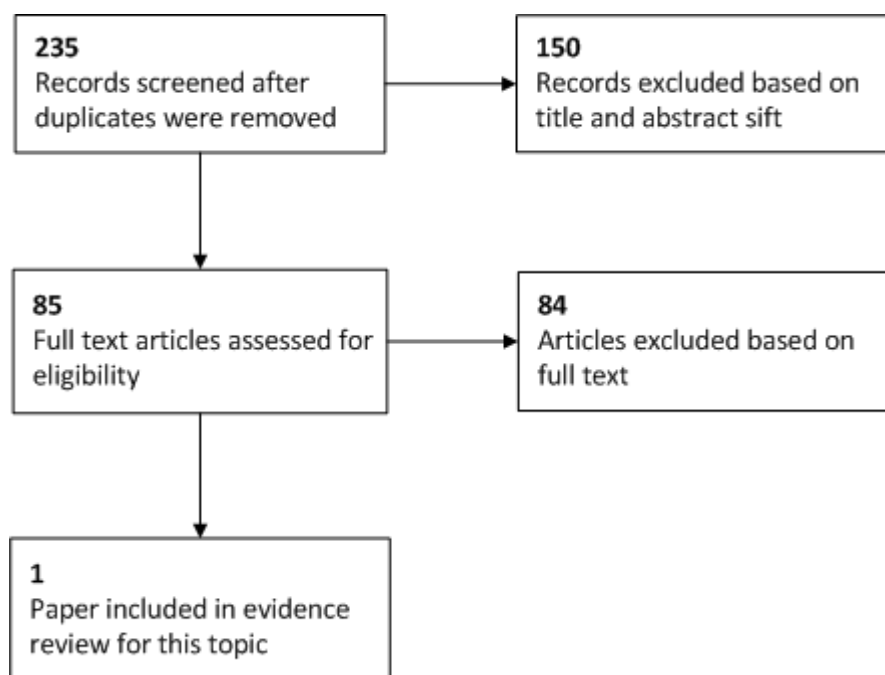

Selection of studies

The literature search results were screened by checking the article's title and abstract for relevance to the review question. The full articles of non-excluded studies were then attained for appraisal and compared against the inclusion criteria specified above.

Results

The diagram below shows the search results and sifting process.

Figure 1: Summary of evidence search and sifting process for this topic

It can be seen that, in total, 235 possibly relevant papers were identified. Of these, 150 papers were excluded at the initial sifting stage based on the title and abstract while 85 full papers were obtained for appraisal. A further 84 papers were excluded based on the full text as they were not applicable to the PICO or did not include an incremental analysis of both costs and health effects. Therefore, only one paper was included in the systematic review of the economic evidence; Prica

et al. 2015. The study included a cost-effectiveness analysis where effectiveness was measured using quality adjusted life years (QALYs) i.e. a cost-utility analysis.

Quality and applicability of the included study

Prica et al. 2015 was deemed to be only partially applicable to the decision problem that we are evaluating because a healthcare system other than the UK was considered (Canada). In addition, future costs and benefits were not discounted at the NICE recommended rate of 3.5% (costs were discounted at 5% while discount rate for benefits was not reported).

The study was thought to be of high quality with only a few minor limitations identified. In particular, some of the assumptions made were thought to be favourable to the rituximab interventions when perhaps a more conservative approach could have been adopted. For example, even though utility scores could not be derived from the QoL data in Ardeshtna et al. 2014, the findings of the study were used to inform percentage reductions in utility scores such that QoL in the first six months of watchful waiting was lower than QoL with rituximab strategies.

Table 2: Methodological quality and applicability of the included study

<i>Methodological quality</i>	<i>Applicability</i>	
	Directly applicable	Partially applicable
Minor limitations		Prica et al. 2015
Potentially serious limitations		
Very serious limitations		

Modified GRADE table

The primary results of the analysis by Prica et al. 2015 are summarised in the table below.

Table 3: Summary table showing the included evidence on the most effective treatment for *people with advanced asymptomatic follicular lymphoma*

Study	Population	Comparators:	Costs	Effects	Incr costs	Incr effects	ICER	Uncertainty	Applicability and limitations
Prisca et al. 2015	Patients with asymptomatic advanced (stage II-IV) follicular lymphoma	Rituximab induction	\$59,953	6.16 QALYs	-	-	-	<p>One-way sensitivity analysis The rituximab strategies were found to dominate the watchful waiting strategy in all one-way sensitivity analyses.</p> <p>The model was found to be sensitive to the probability of progressing after treatment, the average age of patients and the modelled time horizon.</p> <p>Probabilistic sensitivity analysis (PSA) At a threshold of \$50,000 per QALY, rituximab induction, rituximab induction + maintenance and watchful waiting were found to be cost-effective in 55%, 44% and 1% of simulations, respectively.</p>	<p>Partially applicable. The evaluation does not consider the UK health care system (Canada). Future costs and benefits were not discounted at a rate of 3.5%.</p> <p>Minor limitations. A conservative approach was not always followed. Some of the assumptions made were thought to be favourable to the rituximab strategies, such as a lower QoL in the first six months of watchful waiting (compared to rituximab strategies).</p>
		Rituximab induction + maintenance	\$67,489	6.28 QALYs	\$7,536	0.12 QALYs	\$62,360 per QALY		
		Watchful waiting	\$75,895	5.71 QALYs	\$15,942	-0.45 QALYs	Dominated		
<p>Comments: Full incremental results are reported to determine the optimal strategy overall (using a threshold of \$50,000 per QALY).</p>									

Evidence statements

The base case results of the cost-effectiveness analysis suggested that rituximab induction was cost-effective in patients with advanced asymptomatic follicular lymphoma.

In one-way sensitivity analysis, the rituximab strategies were found to dominate the watchful waiting strategies in all modelled scenarios. In probabilistic sensitivity analysis (PSA), at a threshold of \$50,000 per QALY, rituximab induction, rituximab induction + maintenance and watchful waiting were found to be cost-effective in 55%, 44% and 1% of simulations,, respectively.

The study was thought to be of high quality with only a few minor limitations identified. However, the analysis was deemed to be only partially applicable to the decision problem in the UK setting as it was based on the Canadian public health payer perspective.

These factors coupled with the high economic importance of the topic, led to the conclusion that the study was not sufficient to address the decision problem in the UK context.

Primary details	Design	Patient characteristics	Data sources	Outcome measures	Results
<p>Author: Prica et al.</p> <p>Year: 2015</p> <p>Country: Netherlands</p> <p>Funding: No specific funding was disclosed.</p> <p>Comments</p>	<p>Type of analysis: Cost-utility analysis</p> <p>Interventions</p> <ol style="list-style-type: none"> Rituximab induction - 375mg/m² weekly for 4 weeks Rituximab induction plus maintenance - 375mg/m² weekly for 4 weeks followed by 12 further doses every 2 months for 2 years Watchful waiting (WW) <p>Model structure: Markov decision analysis model.</p> <p>Cycle length: 6 months</p> <p>Time horizon: 30 years</p> <p>Perspective: Canadian public health payer</p> <p>Currency unit: Canadian dollars (\$)</p> <p>Cost year:</p>	<p>Included population: Patients with newly diagnosed, untreated asymptomatic advanced (stage II-IV) follicular lymphoma</p> <p>Sample size: Not specified. Per patient outcomes are presented.</p> <p>Age: 60 years old</p> <p>Gender: Not specified.</p> <p>Subgroup analysis: Not conducted.</p>	<p>Source of effectiveness data: A systematic review of the literature was conducted to identify the available evidence. One randomized controlled trial was identified that compared the strategies of interest – Ardeschna et al. 2014.</p> <p>The probability of progression after initial management strategy was derived using data from Ardeschna et al. 2014 and the British National Lymphoma Investigation.</p> <p>The probability of death during the progression-free health state was estimated using age-related mortality from published Canadian life tables (Statistics Canada).</p> <p>The probability of response after bendamustine and rituximab (used as a subsequent treatment following progression) was derived using data from the trial by Rummel et al 2013. This probability was assumed to be lower in patients treated with rituximab in previous line to account for the potential for ‘rituximab resistance’ whereby previous rituximab exposure leads to a lower response to subsequent immunochemotherapy.</p> <p>Treatment response probabilities in subsequent treatment lines were</p>	<p>Base case</p> <p>Effectiveness (QALYs): Rituximab induction Rituximab induction + maintenance Watchful waiting</p> <p>Costs Rituximab induction Rituximab induction + maintenance Watchful waiting</p> <p>ICER (cost per QALY) – full incremental analysis: Rituximab induction Rituximab induction + maintenance Watchful waiting</p> <p>Sensitivity analysis:</p> <p>One-way sensitivity analysis The authors performed a range of one-way sensitivity analyses using upper and lower estimates for each of the input parameters.</p> <p>The authors report that rituximab induction was the least costly strategy across a broad spectrum of variable ranges. They also report that the rituximab strategies dominate the watchful waiting strategy in all analyses.</p> <p>The model was found to be sensitive to the probability of progressing after treatment with rituximab induction. Rituximab induction was found to be dominant if this</p>	<p>6.16</p> <p>6.28</p> <p>5.71</p> <p>\$59,953</p> <p>\$67,489</p> <p>\$75,895</p> <p>-</p> <p>\$62,360</p> <p>Dominated</p>

Non Hodgkin's Lymphoma: diagnosis and management

Primary details	Design	Patient characteristics	Data sources	Outcome measures	Results
	<p>2012</p> <p>Discounting: Costs were discounted at 5%. Discount rate for benefits was not reported</p>		<p>modelled on the basis of long-term data from the EORTC study by van Oers et al 2010. In addition, it was assumed that there would be a penalty of 20% applied to the response rate of each subsequent therapy line.</p> <p>Source of utility data: Utility data for patients in a progression free health state were derived from an unpublished British study that used the EQ-5D instrument to assess the quality of life in patients with follicular lymphoma.</p> <p>Detriments were applied to these values in the first 6 months after treatment. This was performed as a way of capturing the variations in QoL observed in the first 7 months after treatment in the Ardeshtna et al. 2014 study (note that utilities could not be derived directly from these QoL values). Detriments of 6% and 16% were applied to the rituximab induction utility and watchful waiting arms, respectively.</p> <p>The QoL value for patients with progressive disease after first line treatment was based on the unpublished British study mentioned above. The QoL value for patients with progressive disease in subsequent treatment lines and the QoL value for patients in palliative care were based on a previous cost-effectiveness analysis by Fagoni et al. 2009.</p>	<p>probability < 0.024 while rituximab induction + maintenance was found to be cost-effective (at a threshold of \$50,000 per QALY) if this probability > 0.036.</p> <p>The model was found to be similarly sensitive to the probability of progressing after treatment with bendamustine and rituximab in second line. Rituximab induction was found to be dominant if this probability < 0.024 while rituximab induction + maintenance was found to be cost-effective (at a threshold of \$50,000 per QALY) if this probability > 0.045.</p> <p>The model was sensitive to the average age of patients. Rituximab induction + maintenance was found to be more cost-effective for patients <50 years old. Rituximab induction was found to be dominant for patients > 80 years old.</p> <p>The model was also found to be sensitive to changes in the time horizon. Rituximab induction was always found to be less expensive but it became less effective than rituximab induction + maintenance with a time horizon < 25 years.</p> <p>Probabilistic sensitivity analysis (PSA) The results of 1000 PSA simulations were reported.</p> <p>At the commonly used threshold of \$50,000 per QALY, rituximab induction, rituximab induction + maintenance and watchful waiting were found to be cost-</p>	

Non Hodgkin's Lymphoma: diagnosis and management

Primary details	Design	Patient characteristics	Data sources	Outcome measures	Results
			<p>Source of cost data: Drug acquisition costs of rituximab and bendamustine (used in subsequent treatment lines) were derived from published Canadian cost analyses (Mittman et al. 2012 and a Pan-Canadian Oncology Drug Review report on Bendamustine).</p> <p>The cost of salvage chemotherapy was based on a cost analysis by Herold et al 2002 who presented pre-rituximab era data on salvage therapy and associated costs in follicular lymphoma in Canada. The cost of 6 cycles of rituximab was added only to the first course of salvage because patients would likely not get rituximab with any subsequent salvage lines.</p> <p>Resource utilization and overhead costs were based on published guidelines and statistics. Unit costs for medical visits and laboratory and radiologic tests were based on the Ontario schedules of benefits for physician and laboratory services. Pharmacy and nursing costs were obtained from hospital human resources departments. Supportive drug costs were derived from hospital pharmacies.</p> <p>The costs of adverse events were derived from the literature. The cost of palliation for the last 6 months of life</p>	<p>effective in 55%, 44% and 1% of simulations, respectively.</p> <p>At a higher threshold of \$80,000 per QALY, rituximab induction and rituximab induction + maintenance had equivalent probabilities of being cost-effective. While at a threshold of \$100,000 per QALY, rituximab induction + maintenance became cost-effective in more simulations than rituximab induction alone.</p>	

Non Hodgkin's Lymphoma: diagnosis and management

Primary details	Design	Patient characteristics	Data sources	Outcome measures	Results
			was based on a Canadian costing study.		

4.1.4: Review question: What is the effectiveness of first-line consolidation with high-dose therapy with autologous or allogeneic transplantation in people with histological transformation of follicular lymphoma to diffuse large B-cell lymphoma or concurrent presentation with follicular lymphoma & diffuse large B-cell lymphomas, compared with other strategies?

PICO Table

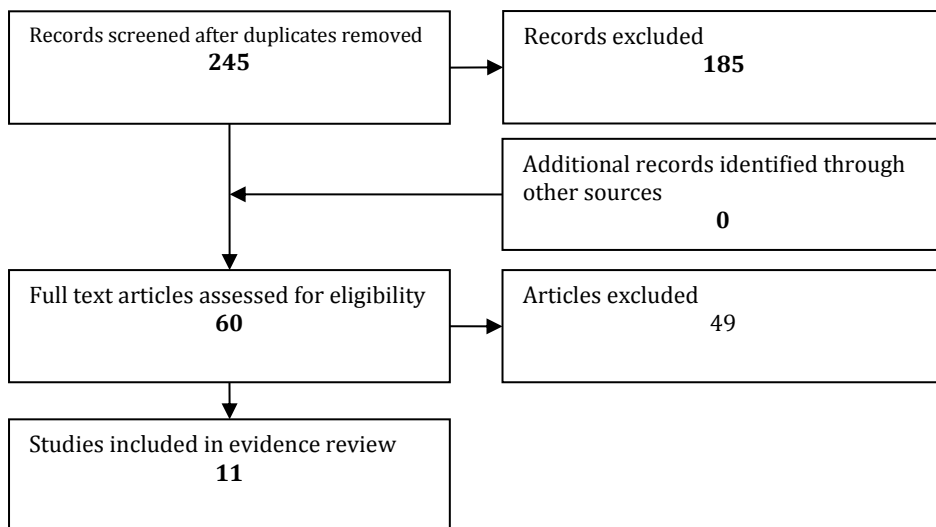

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) who have undergone first-line treatment for histological transformation of follicular lymphoma to diffuse large B-cell lymphoma or concurrent presentation with follicular lymphoma & diffuse large B-cell lymphomas.	Autologous transplantation Allogeneic (Allogenic/ reduced intensity transplantation)	No transplant Radiotherapy Maintenance therapy (Rituximab) Each other	Overall survival Disease free survival Progression free survival Treatment related mortality Treatment related morbidity Health-related quality of life Patient satisfaction Patient preference Diagnosis at relapse

Additional Comments on PICO

Present results by isolated disease limited stage versus advanced stage
 Record previous treatment for follicular lymphoma (prior to transformation)
 Record transformation Flipi
 Record time to transformation
 Where available present results by composite versus discordant
 Could be chemotherapy or immuno-chemotherapy. Present where possible by treatment type
 Present evidence where possible by the two possible situations mentioned in the background
 06.06.14:
 Regarding FL grade 3. Exclude 3b as this is not considered transformation.
 07.06.14:
 Following on from discussions at GDG3 inclusion criteria of sample size n>40 for single arm trials has been applied. This was taken from the inclusion criteria of K2 which is also a consolidation with transplant question in a different population
 20.06.14:
 Exclusion of 'double-hit' lymphomas: Email to Graham regarding inclusion of articles with populations with 'double hit' NHL. Graham replied that 'double hit' refers to 2 genetic changes, 1 involving BCL2 gene (which is the classic follicular lymphoma gene) and one involving c-myc (of Burkitt fame). It's rare, and a very nasty disease with poor outcomes. Usually the double hits arise de novo, with no prior history of follicular. Occasionally you can get a true c-myc driven transformation which therefore becomes a double hit. So on balance I would say it's not part of the population as usually it arises de novo.

Evidence Statements

Six retrospective observational studies provided evidence comparing the effectiveness of the two types of transplantation (allogeneic versus autologous), five retrospective observational studies provided evidence comparing the effectiveness of transplantation to other strategies and four single arm retrospective observational studies provided additional evidence of the use of autologous transplantation in patients with transformed lymphoma.

Autologous versus allogeneic

Overall survival

Five retrospective observational studies (Ban Hoefen *et al.* 2013; Micallef *et al.* 2006; Reddy *et al.* 2012; Villa *et al.* 2013a; Wirk *et al.* 2014) provided very low quality evidence about overall survival rates after autologous versus allogeneic transplantation in 393 patients with histological transformation of indolent lymphoma (76-100% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL). Reporting overall survival rates (range 2-5 years; follow-up range 0.25 – 7.5 years) of 50-83% in the autologous group compared to 22-68.5% in the allogeneic group. Micallef *et al.* (2006) reported median overall survival time of 3 years in the autologous group compared to 9 months in the allogeneic group. Villa *et al.* (2013a) and Reddy *et al.* (2012) reported no significant difference in overall survival rates in the two groups (Ban Hoefen *et al.* 2013, Micallef *et al.* 2006 and Wirk *et al.* 2014 provided no statistical analysis comparing the two groups).

Progression free survival

Three retrospective observational studies (Reddy *et al.* 2012; Villa *et al.* 2013a; Wirk *et al.* 2014) provided very low quality evidence about 5-year progression free survival rates after autologous versus allogeneic transplantation in 297 patients with histological transformation of indolent lymphoma (100% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL). Reporting 5-year progression-free survival rates (follow-up range 0.25 – 7.5 years) of 35-55% in the autologous group compared to 18-46% in the allogeneic group. Villa *et al.* (2013) and Reddy *et al.* (2012) reported no significant difference in 5-year progression free survival rates in the two groups (Wirk *et al.* 2014 provided no statistical analysis comparing the two groups).

Response rates

Two retrospective observational studies (Reddy *et al.* 2012; Villa *et al.* 2013a) provided very low quality evidence about response rates after autologous versus allogeneic transplantation in 156 patients with histological transformation of indolent lymphoma (100% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL). The autologous group had complete (56.7%) and partial response rates (23.4%) comparable to those in the allogeneic group (complete: 55.2%, partial: 17.2%).

Adverse events

Five retrospective observational studies (Ban Hoefen *et al.* 2013; Micallef *et al.* 2006; Reddy *et al.* 2012; Villa *et al.* 2013; Wirk *et al.* 2014) provided very low quality evidence about adverse events after the treatment of autologous or allogeneic transplantation in 393 patients with histological transformation of indolent lymphoma (76-100% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL).

Two studies (Ban Hoefen *et al.* 2013; Villa *et al.* 2013a) reported higher rates of death due to treatment related toxicity (follow-up median: 3.4-7.5 years) in the allogeneic group (27.5%) compared to the autologous group (4.1%). Villa *et al.* (2013a) reported that this difference was significant at 1 year post transplantation ($p=0.01$) and at 4-years post transplantation ($p=0.001$). Death due to disease progression was comparable between the autologous group (18%) and the allogeneic group (22%) (Ban Hoefen *et al.* 2013). However, non-relapse mortality rates were higher in the allogeneic group (31.4-41%) compared to the autologous group (4.6-8%) (Reddy *et al.* 2012: 0.06; no statistical analysis reported by Wirk *et al.* 2014).

Autologous versus no transplantation

Overall survival

Two retrospective observational studies (Ban Hoefen *et al.* 2013; Villa *et al.* 2013b) provided very low quality evidence about overall survival rates after autologous versus no transplantation in 250 patients with histological transformation of indolent lymphoma (86-94% follicular lymphoma) to aggressive B-cell lymphoma (94-100% DLBCL). Reporting overall survival rates (range 2-3 years; follow-up range 3.3-3.4 years) of 54-83% in the autologous group compared to 7-65% in the no treatment group (Villa *et al.* 2013b reported that patients not treated with autologous transplantation due to progressive disease had an overall survival rate of 7% whilst patients with other reasons [e.g. age \geq 65 years; declined the transplant] for not receiving a transplantation had an overall survival rate of 65%). Neither study reported on whether the overall survival rates were significantly different.

Response rates

One retrospective observational study (Villa *et al.* 2013b) provided very low quality evidence about response rates following autologous versus no transplantation in 150 patients with histological transformation of indolent lymphoma (94% follicular lymphoma) to aggressive B-cell lymphoma (94-100% DLBCL). The autologous group had a better complete (14%) and partial response rate (82%) compared to those in the no treatment group (complete: 6%, partial: 15%, $p < 0.001$).

Adverse events

Two retrospective observational studies (Ban Hoefen *et al.* 2013; Villa *et al.* 2013b) provided very low quality evidence about adverse events after the treatment of either autologous or other treatment in 250 patients with histological transformation of indolent lymphoma (76-94% follicular lymphoma) to aggressive B-cell lymphoma (94-100% DLBCL). The rate of death due to treatment related toxicity (follow-up median: 3.3-3.4 years) was comparable in the two groups (autologous: 3.8% versus no transplantation: 5%). However, Villa *et al.* 2013b reported that there were significantly more late deaths [>100 days] in the autologous group [6%] compared to the no treatment group [0%; $p < 0.01$]. Death due to disease progression in the autologous group (8%) was not reported to be significantly different to the rate reported in the no transplantation group (10%, Ban Hoefen *et al.* 2013).

Allogeneic versus no transplantation

Overall survival

One retrospective observational study (Ban Hoefen *et al.* 2013) provided very low quality evidence about 2-year overall survival rates after allogeneic versus no transplantation in 68 patients with histological transformation of indolent lymphoma (86% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL). Reporting a 2-year overall survival rate (follow-up 3.4 years) of 65% (95% confidence interval: 39-83%) in the allogeneic group compared to 53% (95% confidence interval: 39-68%) in the no treatment group. It was not reported if these survival rates were significantly different in the two groups.

Adverse events

One retrospective observational study (Ban Hoefen *et al.* 2013) provided very low quality evidence about adverse events after allogeneic transplantation or other treatment in 68 patients with histological transformation of indolent lymphoma (86% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL). The rate of death due to treatment related toxicity (follow-up 3.4 years) was 22% in the allogeneic group compared to 10% in the no transplantation group. Death due to disease progression (follow-up 3.4 years) was 22% in the allogeneic group compared to 34% in the no transplantation group. It was not reported if these adverse events were significantly different in the two groups.

Overall survival

Two retrospective observational studies (Madsen *et al.* 2013; Villa *et al.* 2013a) provided very low quality evidence about 5-year overall survival rates after autologous transplantation versus chemotherapy plus rituximab in 245 patients with histological transformation of indolent lymphoma (100% follicular lymphoma in Villa *et al.* 2013a; Madsen *et al.* 2013 did not provide breakdown of indolent lymphomas) to diffuse large B-cell lymphoma (DLBCL; Madsen *et al.* 2013 did not provide detail on transformation diagnosis). Reporting 5-year overall survival rates (follow-up 7.5 years reported by Villa *et al.* 2013a only) of 57-65% in the autologous group compared to 36-61% in the chemotherapy plus rituximab group. Both reported that patients receiving autologous transplantation had a significantly improved overall survival compared with those who received chemotherapy plus rituximab ($p=0.09$; $p<0.001$).

One retrospective observational study (Madsen *et al.* 2013) provided very low quality evidence about 5-year overall survival rates after autologous transplantation versus chemotherapy plus rituximab in 95 patients with a primary diagnosis of transformed indolent lymphoma (composite lymphoma). Reporting that the 5-year overall survival rates in the autologous group (80%) did not significantly differ compared to the chemotherapy plus rituximab group (67%).

Progression free survival

Two retrospective observational studies (Madsen *et al.* 2013; Villa *et al.* 2013a) provided very low quality evidence about 5-year progression free survival rates after autologous transplantation versus chemotherapy plus rituximab in 245 patients with histological transformation of indolent lymphoma (100% follicular lymphoma in Villa *et al.* 2013a; Madsen *et al.* 2013 did not provide breakdown of indolent lymphomas) to diffuse large B-cell lymphoma (DLBCL; Madsen *et al.* 2013 did not provide detail on transformation diagnosis). Reporting 5-year progression free survival rates (follow-up 7.5 years reported by Villa *et al.* 2013a only) of 47-55% in the autologous group compared to 6-40% in the chemotherapy plus rituximab group. Madsen *et al.* (2013) reported that patients receiving autologous transplantation had a significantly improved progression free survival compared with those who received chemotherapy plus rituximab ($p=0.003$).

One retrospective observational study (Madsen *et al.* 2013) provided very low quality evidence about 5-year progression free survival rates after autologous versus allogeneic transplantation in patients with a primary diagnosis of transformed indolent lymphoma (composite lymphoma). Reporting that the 5-year progression free survival rates in the autologous group (75%) did not significantly differ compared to the chemotherapy plus rituximab group (61%).

Allogeneic versus chemotherapy plus rituximab

Overall survival

One retrospective observational study (Villa *et al.* 2013a) provided very low quality evidence about 5-year overall survival rates after allogeneic transplantation versus chemotherapy plus rituximab in 119 patients with histological transformation of indolent lymphoma (100% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL). Villa *et al.* (2013a) reported no significant difference 5-year overall survival rates (follow-up 7.5 years) in the allogeneic group (46%: standard error: 11) compared to the chemotherapy plus rituximab group (61%: standard error: 7).

Progression free survival

One retrospective observational study (Villa *et al.* 2013a) provided very low quality evidence about 5-year progression free survival rates after allogeneic transplantation versus chemotherapy plus rituximab in 119 patients with histological transformation of indolent lymphoma (100% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL). Villa *et al.* (2013a) reported no significant difference 5-year progression free survival rates (follow-up 7.5 years) in the allogeneic group (46%: standard error: 11) compared to the chemotherapy plus rituximab group (40%: standard error: 7).

Autologous transplantation

Overall survival

Two non comparative retrospective observational studies (Eide *et al.* 2011; Williams *et al.* 2001) provided very low quality evidence about 5-year overall survival rates after autologous transplantation in 80 patients with histological transformation of indolent lymphoma (91-100% follicular lymphoma) to any high grade lymphoma (76-100% DLBCL). Reporting 5-year overall survival rates (follow-up 4.92 years, reported in Williams *et al.* 2001 only) of 47-51%.

Progression free survival

Two non comparative retrospective observational studies (Eide *et al.* 2011; Williams *et al.* 2001) provided very low quality evidence about 5-year progression free survival rates after autologous transplantation in 80 patients with histological transformation of indolent lymphoma (91-100% follicular lymphoma) to any high grade lymphoma (76-100% DLBCL). Reporting 5-year progression free survival rates (follow-up 4.92 years, reported in Williams *et al.* 2001 only) of 30-32%.

Response rates

Two non comparative retrospective observational studies (Eide *et al.* 2011; Williams *et al.* 2001) provided very low quality evidence about response rates after autologous transplantation in 80 patients with histological transformation of indolent lymphoma (91-100% follicular lymphoma) to any high grade lymphoma (76-100% DLBCL). Complete response rates were 76.3% and partial response rates were 31.3%, with Eide *et al.* (2011) reporting a relapse rate of 43.3%.

Adverse events

Two non comparative retrospective observational studies (Eide *et al.* 2011; Williams *et al.* 2001) provided very low quality evidence about adverse events after autologous transplantation in 80 patients with histological transformation of indolent lymphoma (91-100% follicular lymphoma) to any high grade lymphoma (76-100% DLBCL). Death due to disease progression (follow-up 4.92 years, reported in Williams *et al.* 2001 only) was reported in both observational studies at a rate of 21.3% with procedure related death reported in one study (Williams *et al.* 2001) at 18%.

Exposure to rituximab prior to transplantation

Five retrospective observational studies assessed prior exposure to rituximab and use of transplantation (Ban Hoefen *et al.* 2013; Calvo-Villas *et al.* 2011; Muccilli *et al.* 2009; Villa *et al.* 2013b; Wirk *et al.* 2014).

Overall survival

Two non comparative retrospective observational studies (Calvo-Villas *et al.* 2011; Muccilli *et al.* 2009) provided very low quality evidence about 5-year overall survival rates after autologous transplantation in 125 patients with histological transformation of indolent lymphoma (100% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL, transformation diagnosis not reported in Muccilli *et al.* 2009). Reporting 5-year overall survival rates (follow-up 61 months, reported in Calvo-Villas *et al.* 2011) of 36-66.4%. These two studies also reported the overall survival rates according to prior exposure to rituximab, finding that overall survival rates in the autologous with no prior exposure group were between 36-48.2% compared to 51-66.4% in the autologous patients who had prior exposure to rituximab. Calvo-Villas *et al.* (2011) reported that there was no significant difference between the two groups, however, Muccilli *et al.* (2009) reported a trend for prior exposure to improved overall survival compared to no prior exposure ($p=0.11$). Wirk *et al.* (2014) reported that 37% of their sample ($n=141$) had prior exposure to rituximab finding that exposure prior to transplantation had no impact on overall survival rates in the patients receiving autologous or allogeneic transplantations. Ban Hoefen *et al.* (2013) reported that 70% of their sample ($n=118$) had prior exposure to rituximab finding that there was no survival difference based on rituximab exposure prior to transplantation. Villa *et al.* (2013b) reported that 77% of their sample ($n=105$) had prior

exposure to rituximab finding that there was no survival difference based on rituximab exposure prior to transplantation.

Progression free survival

Two non comparative retrospective observational studies (Calvo-Villas *et al.* 2011; Muccilli *et al.* 2009) provided very low quality evidence about 5-year progression free survival rates after autologous transplantation in 125 patients with histological transformation of indolent lymphoma (100% follicular lymphoma) to diffuse large B-cell lymphoma (DLBCL, transformation diagnosis not reported in Muccilli *et al.* 2009). Reporting 5-year progression free survival rates (follow-up 61 months, reported in Calvo-Villas *et al.* 2011) of 22-67.2%. These two studies also reported the progression free survival rates according to prior exposure to rituximab, finding that the rates in the autologous with no prior exposure group were between 22-48.4% compared to 55-67.2% in the autologous patients who had prior exposure to rituximab. Calvo-Villas *et al.* (2011) reported that there was no significant difference between the two groups, however, Muccilli *et al.* (2009) reported a significant difference for prior exposure to improved progression free survival compared to no prior exposure ($p=0.04$). Wirk *et al.* (2014) reported that 37% of their sample ($n=141$) had prior exposure to rituximab finding that exposure prior to transplantation had no impact on overall progression free survival rates in the patients receiving autologous or allogeneic transplantations.

GRADE Tables

Grade Profile 1: Autologous versus allogeneic in Transformed Lymphoma (TL), Follicular Transformed Lymphoma (FTL)

•

Quality assessment							Summary of findings				Quality

Grade Profile 4: Autologous versus Chemotherapy plus rituximab in TL, FTL

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Autologous	Chemo +Rituximab	Effect		
									Relative (95% CI)	Absolute	
5-year Overall survival (follow-up 7.5 years)^a											
2	observational studies	serious ¹	no serious inconsistency	Serious ²	None	none	57-65%	36-61%	HR = 0.13 [0.05 to 0.34]	Not applicable	⊕○○○ VERY LOW
5-year Progression-free survival (follow-up 7.5 years)^a											
2	observational studies	serious ¹	no serious inconsistency	Serious ²	Serious ³	none	47-55%	6-40%	Not reported	Not applicable	⊕○○○ VERY LOW

^a Madsen et al. 2013 did not report follow-up.

¹ Madsen et al. 2013 conference abstract with limited information out participants and outcomes.

² Villa et al. 2013 unclear if the sample receiving first-line therapy for the transformed lymphoma.

³ Confidence interval not reported for the effect estimate

Grade Profile 5: Allogeneic versus Chemotherapy plus rituximab in TL, FTL

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Allogeneic	Chemo +Rituximab	Effect		
									Relative (95% CI)	Absolute	
5-year Overall survival (follow-up 7.5 years)											
1	observational studies	no serious limitations	no serious inconsistency	serious ¹	Serious ²	none	46% SE: 11	61% SE: 7	HR = 0.44 [0.16 to 1.24]	Not applicable	⊕○○○ VERY LOW
5-year Progression-free survival (follow-up 7.5 years)											
1	observational studies	no serious limitations	no serious inconsistency	serious ¹	Serious ³	none	46% SE: 11	40% SE: 7	Not reported	Not applicable	⊕○○○ VERY LOW

¹ Villa et al. 2013 unclear if the sample receiving first-line therapy for the transformed lymphoma.

² Confidence interval of effect estimate includes appreciable benefit and harm

³ Confidence interval not reported for the effect estimate

Grade Profile 6: Autologous versus Chemotherapy plus rituximab in Composite lymphoma

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Autologous	Chemo +Rituximab	Effect		
									Relative (95% CI)	Absolute	
5-year Overall survival (follow-up not reported)											
1	observational studies	serious ¹	no serious inconsistency	no serious indirectness	Serious ²	none	80%	67%	Not reported	Not applicable	⊕○○○ VERY LOW
5-year Progression-free survival (follow-up not reported)											
1	observational studies	serious ¹	no serious inconsistency	no serious indirectness	Serious ²	none	75%	61%	Not reported	Not applicable	⊕○○○ VERY LOW

¹Madsen et al. 2013 conference abstract with limited information concerning participants and outcomes.

² Confidence interval not reported for the effect estimate

Grade Profile 7: Autologous in TL, FTL

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Autologous	Effect			
								Relative (95% CI)	Absolute		
Complete response (follow-up 4.92 years)^a											
2	observational studies	serious limitations ⁴	no serious inconsistency	serious ^{1,2}	Serious ³	none	61/80 (76.3%)	Not applicable-	Not applicable	⊕○○○ VERY LOW	
Partial response (follow-up 4.92 years)^a											
2	observational studies	serious limitations ⁴	no serious inconsistency	serious ^{1,2}	Serious ³	none	25/80 (31.3%)	Not applicable-	Not applicable	⊕○○○ VERY LOW	
5-year Overall survival (follow-up 4.92 years)^a											
2	observational studies	serious limitations ⁴	no serious inconsistency	serious ^{1,2}	Serious ³	none	47-51%	Not applicable-	Not applicable	⊕○○○ VERY LOW	
5-year Progression-free survival (follow-up 4.92 years)^a											
2	observational studies	serious limitations ⁴	no serious inconsistency	serious ^{1,2}	Serious ³	none	30-32%	Not applicable-	Not applicable	⊕○○○ VERY LOW	
Relapse rate (follow-up not reported)											
1	observational studies	serious limitations ⁴	no serious inconsistency	serious ¹	Serious ³	none	13/30 (43.3%)	Not applicable-	Not applicable	⊕○○○ VERY LOW	
Death due to disease progression (follow-up 4.92 years)^a											

Non Hodgkin's Lymphoma: diagnosis and management

Quality assessment							Summary of findings			Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Autologous	Effect		
								Relative (95% CI)	Absolute	
2	observational studies	serious limitations ⁴	no serious inconsistency	serious ^{1,2}	Serious ³	none	17/80 (21.3%)	Not applicable-	Not applicable	⊕○○○ VERY LOW
Procedure related death (follow-up 4.92 years)										
1	observational studies	serious limitations ⁴	no serious inconsistency	serious ²	Serious ³	none	9/50 (18%)	Not applicable-	Not applicable	⊕○○○ VERY LOW

^a Eide et al. 2011 did not report follow-up.

¹Eide et al. 2011 sample includes all indolent lymphomas.

²Williams et al. 2001 unclear if sample are receiving first-line therapy for the transformed lymphoma.

³ Confidence interval not reported for the effect estimate

⁴Non comparative study design

Grade Profile 8: Autologous versus autologous with past use of rituximab TL, FTL

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Autologous	Autologous +Rituximab	Effect		
									Relative (95% CI)	Absolute	
5-year Overall survival (follow-up 61 months)^a											
2	observational studies	serious ¹	no serious inconsistency	no serious indirectness	Serious ²	none	36-48.2%	51-66.4%	HR =0.5 [0.21 to 1.18] (reported in 1 study)	Not applicable	⊕○○○ VERY LOW
5-year Progression-free survival (follow-up 61 months)^a											
2	observational studies	serious ¹	no serious inconsistency	no serious indirectness	None	none	22-48.4%	55-67.2%	HR 0.44 [0.20 to 0.97] (reported in 1 study)	Not applicable	⊕○○○ VERY LOW

^a Muccilli et al. 2009 did not report follow-up.

¹ Muccilli et al. 2009 conference abstract with limited information out participants and outcomes.

² C.I. of effect includes appreciable benefit and no effect.

Nodal	2	2										
Splenic	2	2										
Small lymphocytic lymphoma	4	3										

Note. Patients in the allo-SCT group never received an auto-SCT

Results	At time of transplant, 78% of the auto-SCT and 67% of allo-SCT patients demonstrated a response to salvage treatment prior to their transplant.									
	Patients in the auto-SCT group were older compared to the allo-SCT group (60 versus 52 years, p<0.0001)									
	Patients not transplanted were older than those transplanted (64 versus 56 years, p=0.002). Higher percentage of patients receiving any transplant for HT were exposed to an anthracycline-based regimen prior to HT compared to their non-transplanted counterparts (60% versus 38%, p=0.03) and a lower percentage of patients transplanted for HT were chemotherapy-naïve compared to patients not transplanted for HT (10% versus 32%, p=0.005).									
	Table 2. Percentage survival rates for the total sample and according to treatment after HT									
		N=118	95% CI	Auto SCT n=50	95% CI	Allo SCT n=18	95% CI	No-SCT n=50	95% CI	
	2-year Overall survival (OS)	68	59-76	83	70-91	65	39-83	53	39-68	
	5-year Overall survival	49	37-59							
	Median OS, years	4.9	-							
	Note. CI: Confidence interval									
	In the auto-SCT group, there was no survival difference based on Rituximab exposure prior to HT. Of the no-SCT patients, those who were untreated prior to HT (no chemotherapy or monoclonal antibody therapy; n=16) experienced a superior survival compared to the no-SCT patients who were treatment-exposed prior to HT (81% versus 39%, p=0.003). Although there was no survival difference detected between anthracycline exposure prior to HT when examining the entire cohort of 118, this was not the case in the subgroup of non-transplanted patients. The non-transplanted patients who were naïve to anthracyclines prior to HT experienced a superior survival compared to those who were anthracycline-exposed (2-year OS of 61% versus 38%, p=0.05)

	Unknown	8	15	4	27	0		4	14
	Note. MDS: Myelodysplastic syndrome.								
Comments	<p>Not really consolidation as only patients who received no transplant had some systemic therapy after HT.</p> <p>Includes other NHL's not just FL</p> <p>Authors state that outcomes for HT are improving with higher OS compared to historical data from the pre-rituximab era, autologous stem cell transplants continue to yield favourable survival outcomes despite previous rituximab exposure and there is a potential subgroup of patients specifically those that are naïve to any chemotherapy or rituximab prior to HT, who experience a prolonged survival without undergoing transplantation (could be due to better prognostic outcome to start with?)</p>

Non Hodgkin's Lymphoma: diagnosis and management

Villa D., et al. (2013). Autologous and allogeneic stem-cell transplantation for transformed follicular lymphoma: a report of the Canadian blood and marrow transplant group. *Journal of Clinical Oncology* 31(9); 1164-1171.

Note. *These patients died before response could be assessed or did not have a response assessment, or response information was unknown.

Table 3. Five-year overall (OS) and progression-free (PFS) survival estimates (%)

Survival	Allo SCT n=22	Auto SCT n=97	R Chemo n=53	P value
From date of transformation n=172	%	%	%	
5-year OS	46	65	61	0.24
SE	11	5	7	
5-year PFS	46	55	40	0.12
SE	11	6	7	
From date of SCT n=119	%	%	%	
5-year post-SCT OS	45	57	NA	0.12
SE	12	8	NA	
5-year post SCT PFS	45	55	NA	0.52
SE	11	6	NA	

Note. NA: not applicable . R: Rituximab

5-year Overall survival for the entire sample was 61%

5-year progression free survival for the entire sample was 48%

Among patients treated with alloSCT, acute and chronic graft-versus-host disease (all grades) occurred in 50% and 42%, respectively.

Multivariate analysis:

Patients who underwent autoSCT had a significantly improved overall survival compared with those who received rituximab-containing chemotherapy (Hazard ratio [HR]: 0.13; 95% CI: 0.05-0.34, p<0.001).

There was no statistically significant difference in overall survival between those who were treated with alloSCT compared with rituximab-containing chemotherapy (HR: 0.44; 95% CI: 0.16-1.24, p=0.12)

There was no statistically significant difference in overall survival between patients treated with alloSCT and autSCT (HR: 1.50; 95% CI: 0.65-3.47, p=0.35)

Similar treatment effects were observed for PFS.

Comments

Includes patients who received SCT for second CR or PR

Not clear if all patients received rituximab

Authors state that autoSCT seems to improve OS and PFS, whereas alloSCT seems to improve PFS only, compared with conventional-dose chemotherapy with rituximab for patients with this condition. The benefit of alloSCT seems to be offset by higher transplant related mortality. However, not a randomised trial and risk factors for outcome were not balanced among groups, particularly older age at transformation in patients treated with rituximab-containing chemotherapy. Patients treated with SCT had improved PFS compared with those treated with rituximab-containing chemotherapy, suggesting that patients who relapse after an intensive strategy may be less effectively managed.

Could be an era effect, including improved supportive care around salvage chemotherapy and SCT, with potentially better patient selection for such treatments in more recent years.

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2013		Patient Characteristics					Intervention	Comparison	Outcome																																																																																																															
Country	Canada	Retrospective, single-centre review of a prospectively collected computerised database and medial records of all (n=110) transplant-eligible patients with transformed aggressive histology lymphoma (TRIL) consecutively referred to the autologous blood and marrow transplant program at Princess Margaret Hospital between 1996 and 2009.					Autologous stem-cell transplantation (ASCT)	Each other	Overall survival <i>From date of ASCT to death from any cause of the last follow-up. For patients not undergoing ASCT it was calculated from the date the decision was made not to proceed with ASCT</i>																																																																																																															
Design, period	Observational retrospective study 1996--2009	<i>Inclusion criteria:</i> – Patients with biopsy-proven indolent B-cell non-hodgkin lymphoma who developed transformation to aggressive histology B-cell non-hodgkin lymphoma <i>Exclusion criteria:</i> – N=5: Patients in whom the diagnosis of indolent lymphoma occurred simultaneously (i.e. discordant or composite histology) with that of transformation were excluded. – Patients with an initial diagnosis of aggressive lymphoma who were diagnosed with indolent lymphoma at subsequent relapse					Chemotherapy																																																																																																																	
N	105/110	Patients received combination chemotherapy to assess chemosensitivity before proceeding with stem-cell collection. – Patients not previously exposed to anthracyclines were treated with the following: ○ CHOP – Patients previously treated with CHOP, or those who developed TRIL shortly after cyclophosphamide, vincristine and prednisone for indolent disease were treated with the following: ○ Platinum-based chemotherapy – Patients previously treated with anthracyclines and platinum were treated with the following: ○ Alternate regimens most commonly carmustine, etoposide, cytarabine and melphalan (mini-BEAM)																																																																																																																						
Follow-up	Median: 3.3 years Range: 0.25-8.3 years	Patients achieving at least a PR proceeded to stem-cell mobilization and ASCT. Patients did not proceed with ASCT for the following reasons: – n=39: Progressive disease (PD) – n=4: Inability to collect/mobilise stem cells – n=3: PD and inability to collect/mobilise stem cells – n=1: Death due to toxicity of chemotherapy – n=8: Other reasons included Comorbidity																																																																																																																						
Funding source	– No conflicts of interest declared.	Patients not proceeding with ASCT for the following reasons: – n=39: Progressive disease (PD) – n=4: Inability to collect/mobilise stem cells – n=3: PD and inability to collect/mobilise stem cells – n=1: Death due to toxicity of chemotherapy – n=8: Other reasons included Comorbidity								Remission according to the 1999 International Working Group criteria Complete remission (CR) Unconfirmed CR Partial remission (PR)

Non Hodgkin's Lymphoma: diagnosis and management

Villa D., et al. (2013). Outcome of patients with transformed indolent non-Hodgkin lymphoma referred for autologous stem-cell transplantation. <i>Annals of Oncology</i> 24(6); 1603-1608.			
Note. *Data only presented for the 13 patients who did not receive ASCT due to reasons other than PD. Allo-SCT: Allogeneic transplant.			
Table 3. Five-year overall (OS) and progression-free (PFS) survival estimates (%)			
Survival	No ASCT (n=55)		ASCT (n=50)
	Patients with PD (n=42)	Other reasons (n=13)	
	%	%	%
3-year OS	7	65	54
SE	4	14	7
3-year PFS			42
SE			7
Number of lines of therapy pre-ASCT did not impact on OS (p=0.54) or PFS (p=0.14) in those patients receiving ASCT.			
27% of the sample (n=28) had received rituximab for treatment of indolent lymphoma before TRIL. Exposure to rituximab for indolent lymphoma had no effect on time to TRIL or stage at TRIL. Exposure to rituximab for indolent lymphoma did not affect OS after transformation (p=0.29) or patients' ability to proceed with ASCT (p=0.39).			
In the 50 patients who underwent ASCT, post-transplant OS was not affected by exposure to rituximab for indolent lymphoma (p=0.25). Patients who received rituximab with the last line of chemotherapy before ASCT experienced improved 3-year post-transplant OS compared with those who did not (71% versus 47%, p=0.046) (- trend) The addition of rituximab did not affect response or relapse rates after ASCT.			
Comments	Unclear if patients included are also reported in the Villa et al. (2013) included article. Not just follicular lymphoma but any indolent NHL (including FL grade 3b) Could be more than first-line treatment post transplant; authors often refer to salvage chemotherapy. Authors note that the number of patients in their series is small and the power to detect a difference in effect of rituximab on survival and transplant rate is low. Authors note the highly selective samples that undergo ASCT (age, fitness, response to systemic therapy)

	Incidence of grade II-IV aGVHD at 100 days	-	-	42	26-59				
Incidence of grade III-IV aGVHD at 100 days	-	-	27	14-42					
1-year incidence of cGVHD	-	-	26	13-43					
Note. CI: confidence interval									
Authors did not statistically compare the two groups for the outcomes. They ran individual analysis for each group. Exposure to rituximab before HCT in the auto-HCT group had no impact on PFS (p=0.98) or overall mortality (p=.17) nor in the allo-HCT group (PFS: p=0.59, OS: p=.46)									
Comments	Not just first-line treatment								
	More rituximab in the allo-ACT group (no statistics to say if significantly different) Authors note small sample size for the use of prior rituximab and state that conclusions regarding the impact of previous rituximab therapy await larger studies Sub-analyses by type of allo-HCT but not recorded as not included in PICO.								

Non Hodgkin's Lymphoma: diagnosis and management

Madsen C., et al. (2013). Upfront autologous stem-cell transplantation in transformed indolent non-Hodgkins lymphoma: an outcome analysis. Hematol Oncol 31(suppl. 1): 151-200.						
Madsen, C., et al. (2015). Outcome determinants for transformed indolent lymphomas treated with or without autologous stem-cell transplantation. Annals of Oncology, 26(2)						
Pub year: 2013		Patient Characteristics		Intervention	Comparison	Outcome
Country	Denmark	95 patients (<65 years) with indolent NHL and histologically proven transformation diagnosed from 2002-2012 were identified from three Danish centres using the Danish Pathology Registry.		Autologous stem-cell transplantation (ASCT)	Rituximab-containing chemotherapy	Overall survival Progression-free survival
Design, period	Observational retrospective study 2002-2012	Analyses were conducted on the cohort as a whole and on subdivisions of patients primarily diagnosis with TRIL (composite lymphoma) and patients where the transformation process occurred over time (sequential lymphoma) 65 (67%) treated with ASCT 31 (33%) treated with rituximab-containing chemotherapy alone				
N	95	No significant differences in clinicopathological parameters were found between the two groups.				
Follow-up	Not reported					
Funding source	Not reported					
Results	Table 2. Survival rates according to treatment type (%).					
		ASCT	Rituximab-containing chemotherapy	P value		
	Whole sample (n=95)					
	5-year Overall survival (OS)	65	48	0.11		
	5-year Progression-free survival (PFS)	57	30	0.02		
	Composite lymphoma (n=NR)					
	5-year Overall survival (OS)	80	67	0.51		
	5-year Progression-free survival (PFS)	75	61	0.35		
	Sequential lymphoma (n=NR)					
	5-year Overall survival (OS)	57	36	0.09		
5-year Progression-free survival (PFS)	47	6	0.003			
Note. NR: not reported						
Comments	Conference abstract Authors state that PFS but not OS was significantly improved in patients treated with upfront ASCT as compared with rituximab-containing conventional chemotherapy alone. Impact of ASCT differs depending on type of transformed lymphoma.					

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2012		Patient Characteristics	Intervention	Comparison	Outcome																																																																																																
Country	USA	Between January 2000 and December 2010 51 consecutive patients were included <i>Inclusion criteria:</i> – Patients age >18 years with a confirmed diagnosis of TL receiving high dose chemotherapy – Patients who received planned rituximab-based chemotherapy pre-SCT – Patients with chemotherapy-sensitive disease documented pre-SCT after salvage chemotherapy <i>Exclusion criteria:</i> – Patients with progression from follicular lymphoma (FL) grade 1 or 2 to FL grade 3 <i>Diagnosis:</i> – A diagnosis of follicular low grade (1-2) lymphoma followed by a transformation to an intermediate (DLBCL) or an aggressive (Burkitt) lymphoma was referred to as TL. Progression from FL grade 3 to a grank DLBCL was considered TL. – Early transformation: patient in whom there was histologic evidence of transformation at the time of diagnosis or transformation within 1 year – Late transformation: patients who have had a transformation more than a year after initial presentation	Autologous stem cell transplant (Auto SCT) Allogeneic stem cell transplant (Allo SCT)	Each other	Response criteria was based on guidelines from the International Workshop on NHL Complete remission (CR) <i>Complete radiological regression of all previous measurable disease or bone marrow involvement</i> Partial response (PR) <i>Reduction of 50% or greater reduction in the sum of the products of the longest and perpendicular diameter of measurable lesions within 30-day period before transplant and at days +30 and +100.</i> Overall survival (OS) Event-free survival (EFS) Non-relapse mortality (NRM)

Non Hodgkin's Lymphoma: diagnosis and management

Reddy N., et al. (2012). Superior long-term outcome of patients with early transformation of non-Hodgkin lymphoma undergoing stem cell transplantation. <i>Clinical Lymphoma, Myeloma and Leukemia</i> 12(6); 406-411.																				
Results	3/16 patients who received transplant in PR had progressive disease, and the rest attained a complete remission after SCT.																			
	36 patients carried a diagnosis of early transformation (auto-SCT=32; allo-SCT: 4) and 15 patients had have late transformation (auto-SCT=12; allo-SCT=3). Patients with early transformation had superior OS (5-year, 80.4% versus 31.5%, p=0.018), EFS (5-year, 59.3% versus 16.2%, p=0.027) with a trend toward decreased risk of relapse (2-year, 28.1% versus 65.1%, p=0.06) and NRM (2-year, 6.4% versus 13.3%, p=0.11). When analysing auto-SCT data separately, timing of transformation and numbers of pre-SCT chemotherapy regimens remained a predictive factor for outcome. Multivariate analysis showed that early transformation was idependently associated with improved overall survival (Hazard Ratio [HR]: 3.29; 95% confidence interval [CI]: 1.14-9.51; p=0.028) and event-free survival (HR: 2.49; 95% CI: 1.1-5.6, p=0.029).																			
	Table 2. Outcomes according to transplant group (%)																			
	<table border="1"> <thead> <tr> <th></th> <th>Auto-SCT (n=44)</th> <th>Allo-SCT (n=7)</th> <th>P value</th> </tr> </thead> <tbody> <tr> <td>NRM</td> <td>4.6</td> <td>31.4</td> <td>0.06</td> </tr> <tr> <td>2-year rate of relapse</td> <td>38.9</td> <td>33.3</td> <td>N.S</td> </tr> <tr> <td>5-year EFS</td> <td>44.6</td> <td>45.7</td> <td>N.S</td> </tr> <tr> <td>5-year OS</td> <td>61.8</td> <td>68.5</td> <td>N.S</td> </tr> </tbody> </table>		Auto-SCT (n=44)	Allo-SCT (n=7)	P value	NRM	4.6	31.4	0.06	2-year rate of relapse	38.9	33.3	N.S	5-year EFS	44.6	45.7	N.S	5-year OS	61.8	68.5
	Auto-SCT (n=44)	Allo-SCT (n=7)	P value																	
NRM	4.6	31.4	0.06																	
2-year rate of relapse	38.9	33.3	N.S																	
5-year EFS	44.6	45.7	N.S																	
5-year OS	61.8	68.5	N.S																	
Comments	<p>Note. NS: not significantly different Age, sex, pre-SCT rituximab maintenance, stage, disease stauts pre-SCT (CR or PR) and conditioning regimen did not affect long-term outcome.</p> <p>Not clear if just first-line treatment Authors state that results indicate that an initial aggressive approach for eacly-TL might improve survival. Patients who present with transformation at a later stage have an inferior survival even with dose-intense approaches.</p>																			

Non Hodgkin's Lymphoma: diagnosis and management

Micallef INM., et al. (2006). The international prognostic index predicts outcome after histological transformation of low-grade non-Hodgkin lymphoma. <i>Leukemia and Lymphoma</i> 47(9); 1794-1799.																																																																																																																																		
Pub year: 2006		Patient Characteristics			Intervention	Comparison	Outcome																																																																																																																											
Country	USA	Between November 1979 and September 2000, 93 patients who met these criteria were identified and their medical records reviewed. All biopsies were reviewed by a hematopathologist and classified according to WHO criteria. Patients were treated for both low-grade lymphoma and histological transformation with various management strategies, including initial observation, chemotherapy, radiation, biological therapy and autologous or allogeneic stem cell transplantation (SCT) as determined by the treating physician. <i>Exclusion criteria:</i> - Patients with Mantle cell lymphoma were not included as low-grade histology - Patients with follicular large cell (grade 3 by WHO criteria) lymphoma were not included as either low-grade or transformed histology. - Patients with discordant histology on presentation or whose transformation occurred within 6 months of diagnosis <i>Diagnosis:</i> - Conversion of low-grade lymphoma to a diffuse large cell lymphoma. Histologies included as "low grade" lymphoma were follicular grade 1 or 2, lymphoplasmacytic, small lymphocytic and marginal zone lymphoma.			Autologous stem cell transplant (Auto SCT)	No consolidation therapy	Overall survival (OS) <i>Date of biopsy establishing histological transformation to date of death or last follow-up</i>

Articles with patients receiving autologous SCT only:

Eide MB. et al. (2011). High dose chemotherapy with autologous stem cell support for patients with histologically transformed B-cell non-Hodgkin lymphomas. A Norwegian multi-centre phase II study. British Journal of Haematology 152; 600-610.																																															
Pub year: 2011		Patient Characteristics		Intervention	Comparison	Outcome																																									
Country	Norway	Consecutive patients referred from 5 Norwegian study centres between January 1999 and June 2004 with transformed B-cell lymphoma were considered for inclusion. <i>Inclusion criteria:</i>		High-dose chemotherapy with autologous stem-cell support (HDT)	N/A	Overall survival <i>From date of inclusion to date of death or last follow-up. Patients alive at last follow-up were censored</i>																																									
Design, period	Observational retrospective study 1999-2004	<ul style="list-style-type: none"> Patients with transformed marginal zone lymphoma to diffuse large B-cell lymphoma; follicular lymphoma (FL to DLBCL (including lymphoma with features intermediate between DLBCL and Burkitt lymphoma); unclassifiable indolent lymphomas to DLBCL Age 18-65 years Ann-Arbor stage II-IV 1-3 previous chemotherapy regimens Normal heart, lung, liver and renal functions Negative human immunodeficiency virus/acquired immunodeficiency syndrome serology Satisfactory bone marrow function, defined as platelets $\geq 100 \times 10^9/l$ and neutrophil count $\geq 1.5 \times 10^9/l$ (except if bone marrow dysfunction was due to lymphoma infiltration) No involvement of the central nervous system (CNS) 																																													
N	30/47	<ul style="list-style-type: none"> <i>Inclusion criteria for High Dose chemotherapy with stem cell support (HDT):</i> chemotherapy-sensitive disease, defined as at least partial response (PR) after three cycles of salvage chemotherapy (CHOP was preferred when an anthracycline-based chemotherapy regimen had not been used previously) and <20% bone marrow involvement, no bulk tumour >5cm in diameter, performance status 0-1, blood harvest of $>2 \times 10^6$ CD34+ autologous cells/kg or a sufficient number of mononuclear cells harvested from autologous bone marrow. 																																													
Follow-up	Not reported	<ul style="list-style-type: none"> Biopsies obtained at primary diagnosis of indolent B-cell lymphoma and biopsies representing histological transformation from all patients assessed for eligibility were reviewed according to the WHO classification (2008) by two haematopathologists, except for four from whom either the primary biopsy or the biopsy obtained at transformation was not available for review. The review of the pathology altered the diagnosis in a few cases; one FL grade 3 was revised to FL grade 1 with small centroblasts, two FL grade 1-2 were revised to FL grade 3a, one FL grade 3 was altered to DLBCL with a large stromal component and one unspecified malignant lymphoma was changed to FL grade 3a 60% and DLBCL 40%. Analyses of primary endpoints were performed based on results from 47 patients with DLBCL, of whom 30 completed HDT.

Non Hodgkin's Lymphoma: diagnosis and management

Eide MB. et al. (2011). High dose chemotherapy with autologous stem cell support for patients with histologically transformed B-cell non-Hodgkin lymphomas. A Norwegian multi-centre phase II study. British Journal of Haematology 152; 600-610.			
	Complete response	18	60
	Partial response	7	23
	Progressive disease	3	10
	Death	2 (2 progressive disease)	7
	Early deaths (100 days after HDT)	0	0
	Complete response after follow-up	23	77
Median time of hospitalisation was 26 days (range: 13-61).			
Table 3. Survival rates			
	Response		95% Confidence Interval
	Median Progression-free survival (PFS)	26 months	15-∞ months
	Median Overall survival (OS)	47 months	43-∞ months
	2-years PFS	50%	0.32-0.68
	5-year PFS	32%	0.18-0.46
	2-year OS	73%	0.57-0.89
	5-year OS	47%	0.29-0.65
	Relapse	13	
	FL	4/7	
	DLBCL	3/7	
	Death	7*	
Note. *Remaining six patients survived 3 years or more following relapse; three had limited disease and received radiation therapy, other three had advanced relapses of indolent disease.			
In univariate analysis the number of previous treatments and patient sex significantly influenced survival. Shorter PFS and OS were observed in patients who had received ≥2 courses of chemotherapy prior to HDT as compared to those with one prior chemotherapy course (Log Rank p=0.015, p=0.022, respectively). Men had a significantly shorter PFS compared to women, while OS for men and women did not differ (Log Rank p=0.023, p=0.282, respectively)			
Comments	Not just follicular lymphoma but other indolent NHLs Could be more than first-line treatment post transplant; authors often refer to salvage chemotherapy. Study was closed before the desired N was reached due to the introduction of rituximab in the salvage treatment of patients with transformed B-cell NHL.
