Non Hodgkin's Lymphoma: diagnosis and management

Williams CD, et al. (2001). High-dose therapy and autologous stem-cell support for chemosensitive transformed low-grade follicular non-Hodgkin's lymphoma: a case-matched study from the European Bone Marrow Transplant Registry. *Journal of Clinical Oncology* 19(3); 727-735.

Comments	Not clear if just first-line treatment
-----------------	--

Non Hodgkin's Lymphoma: diagnosis and management

Calvo-Villas JM., et al. (2011). Impact of rituximab-based therapy after histological transformation on high-dose therapy and autologous stem cell transplantation in follicular transformed lymphomas. Blood, 118 (ID: 4478)							
Pub year: 2011		Patient Characteristics			Intervention	Comparison	Outcome
Country	Spain	Between October 1994 and March 2011 patients with follicular lymphoma who developed confirmed histological transformation to DLBCL treated with HDT-ASCT taken from the Spanish registry (Grupo Español de Linfomas/Transplante Autólogo de Médula Osea [GEL-TAMO]).			Autologous stem-cell transplantation (ASCT) plus prior exposure to Rituximab	Autologous stem-cell transplantation (ASCT)	Overall survival Progression-free survival
Design, period	Observational retrospective review 1994-2011						
N	50	Table 1. Sample characteristics (N=50)					
		Median age at transplantation	55 years	32-70			
Follow-up	Median: 61 months	Median chemotherapy regimens prior to ASCT	2	1-5			
		Median time from diagnosis of FL lymphoma to transformation	49 months	8-135			
		Age-adjusted IPI 2 or 3	11	22%			
		Received rituximab-based regimens at time of transformation	28	56%			
		Treated prior to transformation	20				
		Disease status prior to ASCT					
		First complete remission	4	8%			
Funding source	- No relevant conflicts of interest to declare	Second complete remission	28	56%			
		Active disease	7	14%			
		Sensitive disease	11	22%			
		Refractory disease	3	6%			
		Note. IPI: International Prognostic Index					
Results	Table 2. Survival rates according to treatment type.						
		ASCT + prior Rituximab (n=28)	ASCT (n=22)	P value			
	5-year Overall survival (OS)	66.4	67.2	0.61			
	5-year Progression-free survival (PFS)	48.2	48.4	0.36			
	Relapse or progression	13		-			
	Death due to disease progression		9				
No patients died of transplant-related mortality							
Multivariate analysis: number of regimens prior to ASCT, disease status at transplant and achievement of response after HD-ASCT all significantly influenced OS and PFS. Age-adjusted IPI at transformation had significant influence only on OS.							
Comments	Conference abstract All remissions not just first Authors state that the addition of rituximab to conventional chemotherapy after transformation does not appear to improve the outcomes of subsequent ASCT, although larger prospective studies are required.						

Non Hodgkin's Lymphoma: diagnosis and management

Muccilli A., et al. (2009). The impact of prior exposure to rituximab on autologous stem cell transplantation in patients with follicular and transformed follicular lymphoma. Blood 114 (ID: 1230).					
Pub year: 2009		Patient Characteristics	Intervention	Comparison	Outcome
Country	Canada	Single centre retrospective review of all patients having received autologous stem-cell transplantation (ASCT) at the Ottawa hospital with an initial diagnosis of FL. 259 patients were categorised according to whether they had transformed follicular lymphoma (FL-T) or not. 24 (32%) received rituximab prior to ASCT 51 (68%) no rituximab prior to ASCT	Autologous stem-cell transplantation (ASCT) plus prior exposure to Rituximab	Autologous stem-cell transplantation (ASCT)	Overall survival Progression-free survival
Design, period	Observational retrospective study Period not reported				
N	75/259				
Follow-up	Not reported				
Funding source	– No conflicts of interests to declare				
Results	Table 2. Survival rates according to treatment type.				
		ASCT + prior Rituximab (n=24)	ASCT (n=51)	P value	
	5-year Overall survival (OS)	51%	36%	0.39	
	5-year Progression-free survival (PFS)	55%	22%	0.20	
	Multivariate analysis: – Prior exposure to rituximab appeared to demonstrate a trend toward an improved OS within the FL-T group (Hazard ratio [HR]: 0.5, 95%; Confidence interval [CI]: 0.21-1.18, p=0.11) – PFS demonstrated that prior exposure to rituximab had a positive effect (HR: 0.44, 95% CI: 0.20-0.97, p=0.04)				
Comments	Conference abstract				

4.2: Extranodal marginal zone lymphoma of mucosa-associated lymphoid tissue (MALT) Lymphoma

4.2.1: Review question: What is the most effective first-line treatment for people with MALT lymphoma?

PICO Table

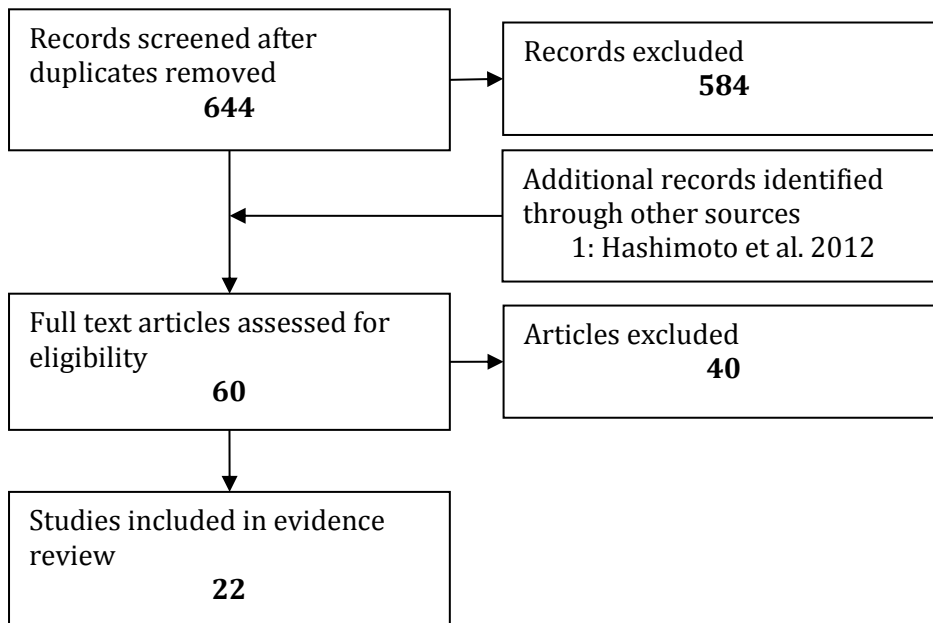

Population	Intervention	Comparison	Outcomes
<p>Adults and young people (16 years and older) with newly diagnosed Mucosal/Mucosa Associated Lymphoid Tissue (MALT) non-Hodgkin's lymphoma.</p> <p>Subgroups: Stages</p> <p>Include: Gastric MALT Non-gastric MALT (Salivary glands, lung, intestinal tract, thyroid gland, breast tissue, genitourinary tract pulmonary/ocular adnexa, orbit)</p> <p>Exclude: Splenic Primary Nodal Skin non-gastric MALT Transformed lymphoma</p>	<p>Antibiotic therapy Antimicrobial E.g. amoxicillin, clarithromycin, omeprazole Helicobacter eradication therapy (gastric MALT only)</p> <p>Radiotherapy</p> <p>Chemotherapy E.g. chlorambucil, CVP Fludarabine</p> <p>Immunotherapy Rituximab</p> <p>Chemo-immunotherapy Rituximab and chlorambucil CVP and rituximab +/- Rituximab for chemotherapy above</p> <p>Radio-immunotherapy Ibritumomab tiuxetan (Zevalin)</p> <p>Surgery</p> <p>Watch and wait/Observation</p>	Each other	<p>Progression free survival Overall survival Disease free survival Treatment related morbidity (radiation, dumping syndrome, B12 deficiency) Health-related quality of life Response to first-line therapy</p>

Additional Comments on PICO

Note for each study how risk is defined (early/low risk, advanced/high risk)
 Bendamustine is excluded from the protocol due to Proposed TA ID434
 12.05.14:
 Search generated large evidence base of 600 articles with over 80 that met the minimum criteria of the PICO table, therefore applied an exclusion criteria to the case series with sample sizes less than 50 due to the small sample sizes per intervention included in these studies.
 06.06.14:
 Regarding the studies concerning non-gastric extranodal MALT: 6 case series assessed interventions for one non-gastric extranodal site only each. Suggested we focus on the papers assessing interventions for more than one site (except for gastric MALT) due to variation in the treatments for individual sites of non-gastric MALT.

Rituximab	27	0					
Radiotherapy+Chemotherapy	25	0					
Surgery + Chemotherapy	3	0					

Note. ^aNo infections required hospitalisation. ^bToxic events were significantly more frequent in the two groups treated with alkylating agents ($p < 0.05$ for the comparison of alkylating agents versus rituximab and $p < 0.01$ for the comparison of combination therapy versus rituximab). ^cChemotherapy + Rituximab group had higher CR rates compared to the Rituximab alone group and the alkylating agents group ($p < 0.05$). ** $p < 0.01$

Evidence Statements

Three randomised trials and six retrospective cohort studies provided evidence about chemotherapy, surgery or radiotherapy as first line treatment for MALT lymphoma. Evidence about antibiotic therapy in positive gastric MALT lymphoma came from 36 case series (26 prospective) in patients with helicobacter positive disease and 11 case series (4 prospective) in those with helicobacter negative disease. One randomised trial and 29 observational studies (21 prospective) provided evidence about treatment after antibiotic therapy for gastric MALT lymphoma.

What is the most effective first-line treatment in patients with MALT lymphoma?

Four observational studies (Kalpadakis *et al.*, 2009; Oh *et al.*, 2010; Papaxoinis *et al.*, 2006; Olszewski *et al.*, 2014) and one randomised control trial (Zucca *et al.*, 2013) assessed the use of chemotherapy, rituximab and radiotherapy as first-line treatment in patients with MALT lymphoma. Overall survival rates ranged from 65-100%.

One observational study (Papaxoinis *et al.*, 2006) compared the use of anthracycline chemotherapy (AC, e.g. CHOP, CEOP, CNOP) to non-anthracycline chemotherapy (C) in 97 patients with MALT lymphoma (in more than 12 body sites) provided very low quality evidence. The study reported complete response rate in the AC group of 73% compared to 68% in the C group. The 5-year progression free survival (AC: 37% versus C: 51%) and overall survival rates (AC: 80% versus C: 65%) were not significantly different between the two groups.

The role of adding rituximab to treatment regimens (chlorambucil, CVP, CHOP, other) was assessed in two retrospective observational studies (Kalpadakis *et al.*, 2009; Oh *et al.*, 2010 [stage IV MALT]) and one randomised control trial (RCT) (Zucca *et al.*, 2013). Zucca *et al.* (2013) reported a randomised control trial in which 227 patients with MALT lymphoma previously untreated (apart from prior local therapy) were randomly assigned to either receive chlorambucil plus rituximab (n=116) or chlorambucil alone (n=115). With a median follow-up of 62 months the RCT provided low quality evidence for a higher overall response rate (94% versus 87%), complete response rate (78% versus 65%), 5-year event free survival rate (68% versus 50%), 5-year progression free survival rate (71% versus 62%) and a lower partial response rate (16% versus 22%) in the chlorambucil plus rituximab group compared to the chlorambucil only group. However, only the 5-year event free survival rate was significantly different in the two groups ($p < 0.01$).

Kalpadakis *et al.* (2009) compared the use of chlorambucil plus rituximab compared to chlorambucil alone in 44 patients with MALT lymphoma (7 body sites, no gastric MALT). The study reported very low quality evidence of an overall response rate of 95% in the chlorambucil plus rituximab group compared to 79% in the chlorambucil only group. The other observational study (Oh *et al.*, 2010) compared the use of chemotherapy plus rituximab to chemotherapy alone in 62 patients with MALT lymphoma. Both observational studies reported very low quality evidence of a higher complete response rates and partial response rates in the chlorambucil plus rituximab group (complete response: 61.3-90%; partial response: 22.6%) versus the chlorambucil only group (complete response: 35.5-75%; partial response: 19.4%) with Oh *et al.* (2010) reporting that the complete response rates were significantly different ($p < 0.05$). The 5-year event-free survival rates were higher in the chlorambucil only group (68%) compared to the chlorambucil plus rituximab group (52%) but this group had lower 10-year progression free survival rates (74% versus 94%) and 5-year overall survival rates (90% versus 100%).

The use of radiotherapy compared to other treatments (predominately surgery) was reported in two observational studies (Olszewski *et al.*, 2014 and Wohrer *et al.*, 2014). Olszewski *et al.* (2014) reported on over 7000 patients with MALT lymphoma (>10 body sites) using the SEER database. The study reported very low quality evidence of an overall lymphoma related death rate ranging from 0-9.3% in the radiotherapy group compared to 4-12.8% in the other treatments group. Olszewski *et al.* (2014) reported no significant differences in the treatment groups and an overall relative survival rate at 10 years of 85.7%. Wohrer *et al.* (2014) reported a retrospective comparison of outcomes according to treatment in a series of 185 patients with extra-gastric MALT. Treatment response ranged from 100% with surgery to 33% with antibiotics, this was very low quality evidence because treatment choice was related to disease stage and

site leading to baseline differences in patient characteristics. Five year progression free survival ranged from 68% with surgery to less than 40% with antibiotics.

Regardless of helicobacter infection, what is the most effective first-line treatment in patients with Gastric MALT lymphoma?

Four studies reported data on the use systemic treatment as first-line treatment in patients with gastric MALT lymphoma. Avilés *et al.* (2005) reported a randomised control trial in which 241 patients with stage I or IIE (according to the Lugano Conference criteria, 1994) low grade Gastric MALT previously untreated were randomly assigned to either receive radiotherapy (n=78), chemotherapy (n=83) or surgery (n=80). With a median follow-up of 7.5 years (range 4.8-11.6 years) the RCT provided high quality evidence for complete response rates of 100% in each treatment arm. The 10-year event-free survival rate was significantly higher in the chemotherapy arm (87%) compared to the radiotherapy (n=52%) and the surgery (n=52%) arms (p=0.01). In addition, 10-year overall survival was highest in the chemotherapy arm (87%) compared to the radiotherapy (75%) and the surgery (80%) arms (p=0.04). There were no treatment related deaths and late toxicity was reported to be mild in all arms.

One observational study (Amiot *et al.* 2014) compared the use of alkylating agents to rituximab and chemotherapy plus rituximab in 107 patients with gastric MALT lymphoma. The study reported very low quality evidence of significantly higher overall response rates in the chemotherapy plus rituximab group (100%) compared to the rituximab alone group (73%, p<0.01)) and the alkylating agents group (68%, p<0.05). The chemotherapy plus rituximab group had higher complete response (92%) compared to the rituximab only group (64%, p<0.05) and the alkylating agents group (66%, p<0.05). In multivariate analysis the 5-year progression free survival rates were higher in the chemotherapy plus rituximab group (89%) compared to the rituximab group (70%) and the alkylating agents group (68%, p<0.04). However, overall survival rates did not differ between the three groups (chemotherapy plus rituximab: 96% versus rituximab: 95% versus alkylating agents: 91%). Toxic events were significantly more frequent in the two groups treated with alkylating agents (p=0.04 for the comparison of alkylating agents versus rituximab and p<0.001 for the comparison of combination therapy versus rituximab).

One observational study (Olszewski *et al.*, 2013) compared the use of radiotherapy and chemotherapy in 347 patients with MALT lymphoma and the use of chemotherapy plus rituximab versus chemotherapy in 102 patients with MALT lymphoma. The study reported very low quality evidence of no difference in lymphoma related death rates between the rituximab (17.7%) and the chemotherapy plus rituximab groups (22.4%) but a significantly lower rate of lymphoma related deaths when comparing radiotherapy (5.3%) to chemotherapy (19.1%, P<0.001). Increased rate of neutropenic infection was reported in the chemotherapy plus rituximab group compared to the rituximab alone group (p<0.01)

One randomised control trial reported the use of systemic treatment as first-line treatment in patients with high grade MALT lymphoma. Aviles *et al.* (2006) reported a randomised control trial in which 108 patients with stage I or IIE (according to the Lugano Conference criteria, 1994) B-cell CD10+ high grade primary gastric lymphoma (diagnosis according to the criteria of Isaacson, 1994) previously untreated were randomly assigned to either receive combined therapy of surgery and chemotherapy (n=52) or chemotherapy alone (n=50). With a mean follow-up of 88.6 months (range: 61-132 months) the RCT provided high quality evidence for complete response rates in the combined therapy group (94%, 95% CI: 88-99%) that were no different to those in the chemotherapy alone group (96%, 95% CI: 89-100%) (p=0.5). In addition, there were no differences in the 5-year event free survival (combined therapy: 70% versus chemotherapy alone: 67%, p=0.5) and 5-year overall survival rates (combined therapy: 78% versus chemotherapy alone: 76%, p=0.8). There were no treatment related deaths and late toxicity related to surgery was reported to be mild.

What is the effectiveness of antibiotic therapy in patients with Gastric MALT lymphoma, positive for helicobacter infection?

One systematic review (Zullo *et al.*, 2009) and two observational studies provided evidence from 36 observational studies reporting very low quality evidence for the use of eradication therapy for *helicobacter pylori* in patients with low graded gastric MALT (and DLBCL-MALT [n=56; 4.7%]) lymphoma positive for the *helicobacter pylori* infection. The 36 studies (26 prospective and 10 retrospective) provided data from 1495

participants (median sample size = 30, range: 4-189) treated most frequently with a standard triple therapy with a proton pump inhibitor plus two antibiotics twice daily (a combination of two of the following: amoxicillin, clarithromycin, metronidazole/tinidazole), administered for 7-28 days. The pooled overall lymphoma regression rate for the 34 observational studies included in the Zullo *et al.* (2009) systematic review was 77.8% and in the Zucca *et al.* (2000) observational study it was 70%. Zucca *et al.* (2000) and Vrieling *et al.* (2008) reported complete remission rates of 66.1% and partial remission rates of 13.4%, with Zucca *et al.* (2000) reporting lymphoma relapse in 7% of their sample (follow-up median: 26 months). Finally, Vrieling *et al.* (2008) reported a 5-year overall survival rate of 89% in their sample.

What is the effectiveness of antibiotic therapy in patients with Gastric MALT lymphoma, negative for helicobacter infection?

Eleven observational studies (data extracted from one systematic review: Zullo *et al.*, 2013) reported very low quality evidence for the use of eradication therapy for *helicobacter pylori* in patients with early stage low grade (I, II) gastric MALT lymphoma negative for the *helicobacter pylori* infection. The 11 studies (4 prospective multicentre studies, 6 retrospective single-centre studies, 1 case report) provided data from 110 participants, treated with predominately standard triple therapy (10/11 studies), administered for 7-28 days. The majority of studies reported were from Asia (n=8; 72.7%), with the remaining from Europe (n=2; 18.2%) and the United States (n=1; 9.1%). Complete remission rate was 15.5% (17/110). Zullo *et al.* (2013) extracted data on lymphoma relapse at long-term follow-up in 3 studies (5.5%) with lymphoma relapse reported in 1 patient at 14 months, with the remaining 7 patients still in remission at 25-48 months follow-up.

What is the effectiveness of antibiotic therapy in patients with Gastric MALT lymphoma, regardless of helicobacter infection status?

Five observational studies reported very low quality evidence for the use of eradication therapy for *helicobacter pylori* in patients with early stage low grade gastric MALT lymphoma (staging systems reported: Blackledge modified Lugano; Ann Arbor). The 5 studies provided data from 455 participants, treated with predominately standard triple therapy (3/5 studies). The majority of patients were positive for the *helicobacter pylori* infection (n=279, 79%; *H. pylori* status was not reported in two studies). Complete remission rates ranging from 64-90% were reported in 4 observational studies (Choi *et al.*, 2013; Park *et al.*, 2010; Stathis *et al.*, 2009; Ueda *et al.*, 2013) and an overall lymphoma regression rate of 73% (Stathis *et al.*, 2009; Yepes *et al.*, 2012) with partial remission rates of 14.2% (Choi *et al.*, 2013; Stathis *et al.* 2009). Lymphoma relapse was reported in 17% of two samples (Choi *et al.*, 2013; Stathis *et al.*, 2009) with a 10-year overall survival (follow-up median 6.3 years) of 83% (Stathis *et al.*, 2009).

What is the most effective management strategy for patients with Gastric MALT lymphoma after treatment for helicobacter pylori infection eradication?

No response to antibiotic therapy

One systematic review (Zullo *et al.*, 2010) provided evidence from 29 studies of low quality evidence assessing treatment of low-grade Gastric MALT lymphoma (stage IE1-IE2 or IIE1 according to Ann Arbor classification as modified by Musshof) unresponsive to *helicobacter pylori* eradication therapy. The 29 studies (21 prospective, 8 retrospective) provided evaluable data from 329 participants, of which 315 underwent oncologic therapy due to lymphoma persistence (successful eradicated patients n=233; infection persistence despite one or more antibiotic therapy n=45; lymphoma relapse at follow-up n=37). A total of 68 (21.6%) received chemotherapy, 112 (35.6%) received radiotherapy; 27 received rituximab (11.6%) and 80 underwent surgery (25.4%). Radiotherapy achieved a significantly higher remission rate (97.3%) compared to chemotherapy (85.3%, p=0.007). Remission rates for surgery (92.5%) were comparable to radiotherapy (p=0.2) and chemotherapy (p=0.2). Following monotherapy, lymphoma remission rate (59.3%) was significantly lower as compared with radiotherapy (p<0.001), surgery (p=0.004) and chemotherapy (p=0.006). When comparing the lymphoma remission rates achieved by a single therapy (overall considered: 287 patients) with that of combined treatments no statistically significant differences emerged (89.6% versus 96.4%, p=0.6). Zullo *et al.* (2010) report that radiotherapy alone was both the most frequently chosen therapy and the most effective in patients with low grade gastric MALT lymphoma unresponsive to anti-*helicobacter* therapy. However, Zullo *et al.* (2010) also reported that of the 329

evaluable patients 14 (4.2%) had a reported remission at follow-up without any further therapy following H. pylori eradication.

Remission after antibiotic therapy

Hancock *et al.* (2008) reported a randomised control trial in which 110 stage I patients (Blackledge modified Lugano staging system) successfully treated for H. pylori infection were randomised to receive either chlorambucil (n=56, given for a median of 29 weeks [3-39 weeks]) or to be observed (n=54). The trial was stopped early due to slow recruitment (power calculations required a total of 173 patients). With a median follow-up of 58 months (4-115 months) the RCT reported moderate quality evidence for 5-year recurrence rates of 21% in the observation arm and 11% in the chlorambucil arm (95% CI: 9-29%; p=0.15). In total 22 patients (11 in each) had disease recurrence/progression or died with no difference between the two arms (Hazard Ratio [HR] =0.96, 95% CI: 0.41-2.2; p=0.91). The overall 5-year recurrence/progression free rate for all randomised patients was 79%. There was no overall survival difference between the two arms (HR=1.93, 95% CI: 0.39-9.58; p=0.42) with a 5-year overall survival rate for all randomised patients of 93%. As treatment was accepted as standard treatment in most European countries at the time of the study, toxicity data were not collected in detail without any cases of severe treatment-related toxicity were reported.

One observational study (Kondo *et al.*, 2012) reported the follow-up of 61 patients who had responded to *helicobacter pylori* eradication therapy. All patients were underwent a watch and wait strategy involving upper gastrointestinal endoscopy, biopsy and abdominal CT every three months in the first year, every 4 months in the second year and at intervals of 6 months in the third year and beyond. With a median follow-up of 78.4 months the study reported very low quality evidence for 5-year overall survival rates of 100% and a lymphoma relapse rate of 14.8%.

GRADE Tables

What is the most effective first-line treatment in patients with MALT lymphoma?

Grade Profile 1: Chemotherapy plus rituximab vs chemotherapy

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Event Chemotherapy +Rituximab	Event Chemotherapy	Effect		
									Relative (95% CI)	Absolute

Evidence Tables

Pub year: 2013		Patient Characteristics				Intervention	Comparison	Outcome																																																															
Country	Switzerland, Italy, France, UK, Spain, Belgium	Between January 2003 to October 2005 patients recruited at 78 centres in six countries and randomly assigned in a 1:1 ratio to chlorambucil alone (arm A, standard treatment) or to the combination of chlorambucil plus rituximab (arm B, study treatment) . Ann Arbor staging with CT and bone marrow biopsy. Diagnostic biopsies reviewed independently by panels of pathologists				Chlorambucil plus rituximab	Chlorambucil	– Event free survival <i>(defined as date of trial registration [including any of disease progression, early discontinuation, initiation of new treatment without documented progression] to failure of death as a result of any cause, or last follow-up)</i>																																																															
Design, period	Randomised control trial 2003-2005	<i>Inclusion criteria:</i> <ul style="list-style-type: none"> – >18 years old – Histologic diagnosis according to WHO classification (2008) CD20+ MALT lymphoma arising at any extranodal site – Patients with disease either newly diagnosed or relapsed after prior local therapy – Patients with primary with primary gastric H. pylori positive MALT in case of clinical (endoscopic) and histologic evidence of disease progression at any time after H. pylori eradication or in a stable disease with persistent lymphoma more than 1 year after H. pylori eradication – Measurable or evaluable disease, according to the National Cancer Institute (NCI) international working group (IWG) criteria was required 				Induction same as comparison plus the following: <ul style="list-style-type: none"> – Rituximab 375 mg/m² administered intravenously on days 1,8,15,22 – After restaging, Rituximab was administered on day 1 of each of the subsequent chlorambucil cycles 	Induction: chlorambucil 6mg/m ² orally for 42 consecutive days (weeks 1-6). After restaging, patients with stable disease or an objective response then received daily chlorambucil 6mg/m ² for 2 weeks every 4 weeks (1 cycle) for up to 4 cycles)	– Overall response rate <i>(defined as sum of complete and partial response rates)</i>																																																															
N	227/252 <i>Based on primary end point calculated on: 20% improvement, 80% power, 50% significance level and assumption that 5-year EFS for patients treated with arm A would be 50%</i>	<i>Exclusion criteria:</i> <ul style="list-style-type: none"> – Evidence of histologic transformation – Central nervous system involvement – Previous or concomitant malignancy – HIV infection – Prior systemic therapy (apart from H. Pylori eradication) 						– Response duration <i>(response measured after first 6 weeks of therapy, at end of therapy and defined according to NCI standardised response criteria)</i>																																																															
Follow-up	<ul style="list-style-type: none"> – Every 4 months for 2 years – Every 6 months for next 3 years – Annually for next five years Included: Physical examination, routine lab tests, chest x-ray, abdominal ultrasound	<i>Randomisation was stratified by tumour site:</i> <ul style="list-style-type: none"> – Gastric versus non-gastric primary site – Nodal involvement (presence versus absence) – Prior local therapy (previous surgical, radiation or antibiotic therapy for gastric lymphoma versus non-pre-treated disease) – International prognostic index (low/low-intermediate risk versus intermediate/high-high risk) 						– Progression free survival

Results	Four eligible patients were excluded from the analysis:							
	– 2 withdrew patient consent before treatment started							
	– 2 major early violations of the study protocol were documented							
	Final eligible sample to treat: N=227							
	171/227 (75%) completed the treatment program without dose reduction							
	4/227 treated according to protocol but not evaluated for response:							
	– 1 patient assigned to arm B withdrew consent during the first part of the treatment program and was lost to follow-up							
	– 1 patients assigned to arm A experienced a fatal ischemic stroke during treatment							
	– 2 patients in arm B died of disease progression after histologic transformation, which occurred during treatment							
	Discontinuation due to toxicity, disease progression or patients' preferences:							
– 33 patients (15%) discontinued treatment with chlorambucil (12 in arm A and 21 in arm B)								
– 16 patients (14% in arm B) discontinued rituximab (14 of whom concomitantly discontinued chlorambucil).								
Table 2. Response to treatment according to treatment groups								
	All N=227		Arm A: Chlorambucil n=113		Arm B: Chlorambucil plus Rituximab n=114

Zucca, E et al. (2013). Addition of Rituximab to Chlorambucil produces superior event-free survival in the treatment of patients with Extranodal marginal-zone B-cell lymphoma: 5-year analysis of the IELSG-19 randomised study. *Journal of clinical oncology*, 5(31); 565-572.

Complete response*	162	71	73	65	89	78
Partial response	43	19	25	22	18	16
Stable disease	8	3	8	7	-	-
Progressive disease	10	5	6	5	4	4
Not assessed	4	2	1	1	3	3

Note. *P=0.069, *P=0.025

The rate of CR was significantly higher (P=0.025) in arm B: 78% (95% CI: 69%-85%) for 89 patients treated with the combination of chlorambucil plus rituximab compared with 65% (95% CI, 55%-73%) for 73 patients treated with chlorambucil. The higher CR rate was observed in both primary gastric and non-gastric MALT lymphomas.

Table 3. Survival rates according to treatment groups

	HR	95% CI	P	Arm A: Chlorambucil n=113	Arm B: Chlorambucil plus Rituximab n=114
				%	%
Event free survival (EFS)	0.52	0.34-0.79	0.002	50 (95% CI: 41-60%)	68 (95% CI: 59-76%)
Progression free survival (PFS)	0.63	0.39-1.02	0.057	62 (95% CI: 51-71%)	71 (95% CI: 61-79%)
Overall survival	1.13	0.52-2.45	0.756	89 (95% CI: 83-92%)	

The 5-year EFS in patients treated with rituximab plus chlorambucil was significantly better (68%, 95% CI: 59-76%) than to those receiving chlorambucil alone (50%; CI: 41-60%). The addition of rituximab resulted in a significant reduction of the risk of EFS events (HR, 0.52; 95% CI: 0.34-0.79).

26 patients (12 in arm A and 14 in arm B) died (8/26 due to lymphoma progression; 7/26 due to second tumour).The 5-year OS rate was 89% (95% CI: 83-92%) and there was no significant difference in OS between treatment arms.

In multivariate analysis only IPI remained significantly associated with longer EFS, PFS, and OS (all p's <0.001). When treatment arm was added to the Cox model, both IPI and treatment in arm B predicted a better EFS (p=0.002) and PFS (p=0.38), although only IPI retained a significant impact on OS

Safety: A low number of reversible grade 1 to 2 events were reported with no clinically significant differences in acute and long-term toxicity observed between the two arms, despite the occurrence of infusion-related symptoms as well as the increased number of patients with grade 3 to 4 neutropenia in the combination arm. The latter, however, did not result in a significant increase of neutropenic fever episodes and infection rates. No toxic death was reported.

Table 4. Safety profile presented by treatment type and grade (G)

Comments	<p>After the enrolment of the planned 252 patients, the study protocol was amended, and in October 2006, the trial was reopened with a three-arm design. The third arm included rituximab alone (arm C, study treatment) and the randomisation was changed to 1:1:6 for the final total sample size of 450 patients. The amended protocol stated that the analysis of chlorambucil versus chlorambucil plus rituximab should be performed and reported first, before any analysis of the third arm.</p> <p>Authors state this is the 1st RCT on the systemic treatment of patients with MALT lymphoma.</p> <p>Includes skin lymphoma</p> <p><i>Publication of the arm C data might be available by update review.</i></p> <p><i>Check things like intent to treat analysis</i></p>

PS (ECOG) Performance status (Eastern Cooperative Oncology Group). ALC: Absolute lymphocyte count.</p> <p>24.5% of patients fulfilled the multiple criteria for stage IV.</p> <p>92/94 were treated (the 2 missing patients were lost to follow-up immediately after diagnosis) 3/92 patients were observed until progression in a watchful wait status 89/92 patients began their initial treatments within 1 month of tissue diagnosis 62/92 patients were treated with chemotherapy-only treatment (<i>remaining patients were treated with a combination of chemotherapy, operation, radiotherapy, observation, all combinations had an n<10</i>)</p> <p>Of the 62 patients, 31 were treated with chemotherapy alone and 31 with chemotherapy plus rituximab. There were no significant differences in the patients' characteristics (as shown in Table 1).</p>										
	Results	Table 2. Response to treatment according to treatment groups									
		Alone n=31		Plus Rituximab n=31		P value					
		<i>n</i>		<i>n</i>							
Complete response		11		19		0.026					
Partial response		6		7							
Progression of disease		5		1							
Stable disease		7		3							
Not evaluable	2		1								
<p>The chemotherapy plus rituximab group exhibited better responses than the chemotherapy alone group (83.9% versus 54.8%, p=0.026). 1 year free progression or relapse rates from the treatment start date were 94% versus 74% (p=0.013) No statistically significant differences in TTP duration were noted (2.4 years versus 2.0 years, p=0.113).</p> <p>For the whole sample, median time to progression was 2.4 years (95% CI: 1.9-2.9 years) with 5-year and 10-year overall survival rates of 84.5% and 79.8% respectively.</p>											
Comments	Age range includes <16 years old										

Oh, SY et al. (2010). Stage IV marginal zone B-cell lymphoma – prognostic factors and the role of rituximab: consortium for improving survival of lymphoma (CISL) study. <i>Cancer Science</i> , 101(11); 2443-2447.	
	Authors state that the addition of rituximab resulted in better responses than conventional chemotherapy alone, as well as lower relapse or progression rates at 1 year, should consider combinations of rituximab with conventional chemotherapy and maintenance therapy clinical trials using non-toxic rituximab monotherapy to extend the achieved benefits of chemotherapy plus rituximab. Rituximab appears to contribute to better responses but not in TTP Authors do not provide a breakdown according to disease site so could include skin

Olszewski, AJ et al. (2014). Radiation therapy administration and survival in stage I/II extranodal marginal zone b-cell lymphoma of mucosa-associated lymphoid tissue. International Journal of Radiation Oncology, 88(3); 642-649.																																																																																																												
Pub year: 2014		Patient Characteristics		Intervention	Comparison	Outcome																																																																																																						
Country	United States	Using the Surveillance, Epidemiology, and End Results (SEER) database authors extracted data on all adult cases of MALT lymphoma diagnosed between 1998 and 2010 (N=10,446) using the international lymphoma epidemiology consortium classification. Classification based on the international classification of diseases for oncology, third edition (ICD-0-3) histology codes. SEER database is curated by the National Cancer Institute integrates records from 18 cancer registries in the United States, currently representing 28% of the population. Provide survival outcomes up to December 31 st 2010. Information on treatment of surgery and radiation therapy administered as part of the first course of therapy, defined as the initial treatment plan delineated in the medical record. A decision to pursue watchful waiting or refusal of treatment is recorded as no initial therapy. Dataset does not contain data on the dose, field, fractionation scheme, and intent (curative or palliative) of radiation or on the use of chemotherapy. Also no information on response to treatment, toxicities, or duration of remission. <i>Inclusion criteria:</i> – Definitive histopathologic confirmation based on the international lymphoma epidemiology consortium classification <i>Exclusion criteria n=2672:</i> – N=38: no definitive histopathologic confirmation – N=4: Autopsy or death certificate confirmed different diagnosis – N=2571: Cases of stage III or IV lymphoma – N=53: Cases with no recorded survival time – N=6: Duplicate codes Table 1. 		<p>Note. IPI: International Prognostic Index; LDH, lactate dehydrogenase; PS, performance status; BM: Bone marrow. MZLPI: Marginal Zone B-cell lymphoma prognostic index. PS (ECOG) Performance status (Eastern Cooperative Oncology Group). ALC: Absolute lymphocyte count. *A total surgical excision rate was not calculated because of lack of a uniform definition of excision surgery (paper records individual excision rates according to disease site range 5.7% [stomach] – 82.4% [thyroid gland]).</p>					
Results	<p>Use of surgical excision was performed most commonly in thyroid, salivary, intestinal and mammary sites and least used in the stomach. Post-excision radiation therapy was prescribed in one-third of cases and was rare in pulmonary intestinal, or gastric MALT but was very common in ocular locations.</p> <p>The relative survival for the entire cohort was 92.0% at 5 years and 85.7% at 10 years. There were 1763 deaths, 30% of which were ascribed to lymphoma on death certificates, but in up to 20% of events the death was ascribed to a 'cancer' of the organ of origin, 'miscellaneous malignancy', or an undefined cause.</p> <p>Authors report factors associated with use of radiation therapy in the database, apart from demographic factors (women, black and Hispanic minorities, socioeconomically disadvantaged patients and underinsured patients may be at risk of not receiving radiation therapy) the following factors were reported:</p> <ul style="list-style-type: none"> – Use of radiation therapy was administered in 46% of patients younger than 50 years but only in 29% of those older than 70 years (OR: 0.70, CI: 0.59-0.83, O=0.0001) – Patients were less likely to receive radiation therapy after surgical excision (OR: 0.65, CI: 0.57-0.75, p<0.0001) <p>Due to the unrecorded presence of H. Pylori infection likely to be a major factor confounding the administration of radiation therapy in gastric MALT lymphoma, authors analysed an analogous model excluding that anatomic location and found no substantial difference in the findings reported above.</p> <p>5-year risk of lymphoma related death: In patients who received radiation therapy, the risk of LRD was very low in all MALT sites except for intestinal and head and neck mucosa. In cutaneous, ocular, salivary and thyroid MALT lymphomas, this risk was essentially zero.</p> <p>Table 2. Cumulative incidence of death related to lymphoma and competing causes in stage IE/IIIE MALT lymphoma patients, stratified by receipt of radiation therapy.</p>

Comments	<p>Includes skin lymphoma No information on systemic treatments with antibiotics or chemotherapy Significant disparities in the use of radiation therapy exist with regard to age, sex, race/ethnicity and socioeconomic and insurance status, after disease-related factors are controlled for. Authors state that considering the significant associated of radiation therapy use with survival in MALT lymphoma, efforts are warranted to minimise the disparities that do not arise from well-defined clinical contraindications. Authors note that patients who do not receive radiation therapy may have other adverse features related to individual characteristics (performance status, contraindications, inter-current events causing treatment delay) or the disease (systemic progression, tumour bulk or location favouring chemotherapy). In addition, some patients with small lesions have elected excision alone, so the 'untreated' group consists of a mix of cases with favourable and unfavourable prognosis.</p>																																																																																		

Pub year: 2008		Patient Characteristics				Intervention	Comparison	Outcome	
Country	Greece	Between December 1989 to December 2006 97 patients diagnosed with MALT lymphoma were treated and followed. Patient data used in the study were derived from the HeCOG registry. <i>Inclusion criteria:</i> – Diagnoses made according to the WHO classification of NHLs (2001)				Anthracycline-based regimens	Non-anthracycline-based regimens	<ul style="list-style-type: none"> – Complete response – Response rate – Progression free survival <i>Determined at the time from the start of treatment to the date of disease progression or death from any cause</i> – Overall survival <i>Considered at the time from the date of first biopsy to the date of death from any cause</i>

5-year Overall survival									80		65	n.s

Note. NP: Authors do not provide n's treated according to disease site.

Among patients treated with chemotherapy only, there was no statistically significant difference in Progression Free Survival (PFS) and Overall Survival (OS) between those who received anthracycline-based or other chemotherapy.

In univariate analysis type of chemotherapy had no significant relationship with PFS (p=0.891) or OS (0.655). Use of rituximab had no significant relationship with PFS (p=0.305) or OS (p=0.855).

In the multivariate analysis Ann Arbor stage III or IV was significantly associated with PFS (RR: 4.8; CI: 2.2-10.3; p<0.001) and OS (RR: 14; CI: 3.2-60.8; p<0.001). Gastric primary site (RR: 8.7; CI:1.8-41; p=0.006), increased serum LDH (RR: 39.8; CI:2.8-566.9; p=0.007), extranodal sites ≥2 (RR: 7.7; CI:1.7-35.1; p=0.008) and presence of B symptoms (RR: 4.2; CI:1.1-15.8; p=0.035) were all associated with overall survival.

Comments
 Includes 1% skin lymphoma
 Due to the way the authors report the results, they state that 91/97 patients received one of the treatments but they do not report the breakdown on n's per group so it is not clear the n's for the gastric and non-gastric lymphomas.
 Authors attempted to compare different treatment regimens apart from chemotherapy but concluded that that the number of patients was not sufficient to draw meaningful conclusions.

Amiot, A et al. (2014).Rituximab, alkylating agents or combination therapy for gastric mucosa-associated lymphoid tissue lymphoma: a monocentric non-randomised observational study. Aliment Pharmacol Ther, 39; 619-628.																																																																																																																																																																																									
Pub year: 2014		Patient Characteristics						Intervention	Comparison	Outcome																																																																																																																																																																															
Country	France	From 1995 to 2012 106 patients with Gastric MALT lymphoma were recruited from the author's personal database and/or a standardised hospital in-patient dataset diagnosis. <i>Inclusion criteria:</i> <ul style="list-style-type: none"> Patients with Gastric MALT lymphoma treated with alkylating agents alone, rituximab alone or the combination of rituximab and chlorambucil Diagnosis based on upper endoscopic examination and then confirmed by a histological analysis of gastric biopsies in all patients by a trained pathologist. Histologic diagnosis was made according to the criteria of Isaacson et al: the presence of diffuse infiltration of the lamina propria (LP) by CD20+ CD5- centrocyte-like cells associated with lymphoepithelial lesions (LELs) and reactive lymphoid follicles Presence of H.pylori was assessed on modified Giemsa-stained sections and using a real-time quantitative polymerase chain reaction assay from 2000 Presence of the t(11;18) translocation was determined by amplification and sequencing of the AP12-MALT1 fusion transcript <i>Exclusion criteria:</i> <ul style="list-style-type: none"> All patients who had been previously treated with chemotherapy before entering the study The allocation of treatment was not randomised and was decided by a multidisciplinary committee including haematologists, gastroenterologists and haematopathologists. Initially, patients were treated with alkylating agents. Subsequently, taking into account the potential risk of adverse events and the initial disappointing results of alkylating agents in t(11;18)-positive patients, t(11;18)-negative patients were treatment with rituximab, and t(11;18)-positive patients were treated with combination therapy.						Rituximab consisted of an induction phase of 4 weekly infusions of rituximab 375mg/m ² intravenously, followed by a maintenance phase of 4 monthly infusions of rituximab (n=28) Combination therapy was administered with oral chlorambucil 6mg/m ² /day for 42 days, followed by 6mg/m ² /day for 14 consecutive days/months for four cycles and rituximab as described above (n=30)	Alkylating agents were administered orally with either chlorambucil 6mg/m ² /day for 14 consecutive days/month for 6-12 months (n=36) or cyclophosphamide 100 mg/day for 12-18 months (n=12).	<ul style="list-style-type: none"> Toxicity NCI common terminology criteria for adverse events (CTCAE v3.0) Complete histological response Defined by the absence of lymphoid infiltrate or scattered plasma cells and small lymphoid cells in the LP without LELs with a normal or empty LP and/or fibrosis Probably minimal residual disease (pMRD) Defined by the presence of aggregates of lymphoid cells or lymphoid nodules in the LP/ muscularis mucosae and/or submucosa without LELs with an empty LP and/or fibrosis Responding residual

Note. *Ann Arbor modified by Musshoff. IPI: International Prognostic Index; LDH, lactate dehydrogenase. EUS: Endoscopic ultrasonography. *Missing numbers. Patients receiving alkylating agents had a longer follow-up period compared to the other groups. Patients receiving combination therapy had a higher frequency of t(11;18) translocation.												
Results	105/106 completed the treatment programme. 1/105 had to discontinue chlorambucil after 8 months because of seizures related to chronic alcohol consumption 12/105 required dose reduction in alkylating agents											
	85 (80%) patients experienced complete response and 98 (92%) experienced overall response. AS shown in Table 2 rates of CR and OR were significantly higher in patients treated with the combination therapy compared with either alkylating agents alone or rituximab compared with either alkylating agents alone or rituximab alone with the exception of the comparison of rituximab versus combination therapy for OR at Week 25.

5-year Overall survival	-	91	-	95	-	-	96	-	-
5-year PFS	-	68	-	70	-	-	89	-	-

Note. PFS: Progression free survival

5-year overall survival did not significantly differ according to treatment group (p=0.86).

5-year progression free survival did not significantly differ according to treatment group (p=0.34). In multivariate analysis, PFS was increased in patients in the combination treatment group (HR=2.66, CI: 1.01-7.00, p=0.04) and decreased by a gastric thickness >10mm (HR=0.25, CI: 0.13-0.51, p<0.001).

Table 3. Safety results according to treatment groups

	A. Alkylating agents n=48 (%)		B. Rituximab n=28 (%)		P value A versus B	C. Combination therapy n=30 (%)		P value A versus C	P value B versus C
Toxicity									
Haematological	14	29	2	7	0.04	16	53	0.05	<0.001
Grade >1	6	12.5	1	4	0.24	6	20	0.52	0.10
Dose reduction	5	10	0	0	0.15	7	23	0.20	0.01
Infectious complication	2	4	2	7	0.62	3	10	0.37	0.99

Note. No missing data. No infections required hospitalisation.

Toxic events were significantly more frequent in the two groups treated with alkylating agents (p=0.04 for the comparison of alkylating agents versus rituximab and p<0.001 for the comparison of combination therapy versus rituximab). The addition of rituximab to alkylating agents was associated with a higher incidence of haematological events compared with alkylating agents alone (p=0.05). This difference was no longer significant after taking into account only haematological events higher than grade 1.

No significant differences in rates of infectious complications in the three groups.

No toxic death was reported.

Comments

Combination of rituximab plus chlorambucil seems more efficient in GML patients compared with rituximab and alkylating agents alone.

Authors note that in the current study combination therapy resulted in high remission and OR rates. These remission rates were higher than those obtained with either alkylating agents or rituximab alone. Remission was frequently achieved as early as week 6 in the combination group. The CR and OR rates were similar in patients treated with either alkylating agents or rituximab alone. In multivariate analysis, remission rates were increased in patients treated with combination therapy at week 25, week 52 and week 104.

Combination therapy was associated with more haematological adverse events compared with alkylating agents alone. This difference was not significant for grades 2-4 adverse events, but was associated with a higher need for the dose reduction in alkylating agents.

OS and PFS seemed excellent regardless of treatment type. Death occurred in 11% of cases and none of these 12 deaths were related to GML or treatment

Patients were initially treated with alkylating agents and then with rituximab to improve tolerance of the treatment; t(11;18)-positive patients were then treated with combination therapy.

Authors report on a difference in response depending on whether a patient is t(11;18)-positive or negative, not included in PICO so not reported in table.

Younger age, advanced stage, better performance status and diagnosis after 2003 were associated with a higher chance of receiving radiotherapy or chemotherapy, but the teaching status of the hospital was not.																																																																																																																																																				

Olszewski, AJ et al. (2013). Comparative outcomes of oncologic therapy in gastric extranodal marginal zone (MALT) lymphoma: analysis of the SEER_medicare database. <i>Annals of Oncology</i> 24; 1352-1359.																																																																																																					
	#U55/CCR921930-02 awarded to the Public Health Institute																																																																																																				
Results	<p>Patients undergoing gastrectomy or with no record of oncologic treatment had a distinctly shorter survival, likely reflecting their unfavourable baseline features. The median overall survival was 6.7 years (95% CI: 6.2-7.5). Cumulative incidence of lymphoma-related death (LRD) at 5 years was 12.1% (95% CI: 10.3%-14.2%), while it was 29.0% (95% CI: 26.2%-31.8%) for competing causes of death.</p> <p>Table 2. Lymphoma related death and death from other causes according to treatment type and stage (N=347)</p> <table border="1"> <thead> <tr> <th></th> <th>Radiotherapy</th> <th>n=185</th> <th>Chemotherapy</th> <th>n=162*</th> <th>P value</th> </tr> <tr> <th>Stage IE lymphoma</th> <th>%</th> <th>95% CI</th> <th>%</th> <th>95% CI</th> <th></th> </tr> </thead> <tbody> <tr> <td>5-year cumulative incidence of lymphoma related death</td> <td>5.3</td> <td>2.6-9.4</td> <td>19.1</td> <td>13.1-26.0</td> <td><0.001</td> </tr> <tr> <td>Risk of death from other causes</td> <td>25.7</td> <td></td> <td>24.8</td> <td></td> <td>0.56</td> </tr> </tbody> </table> <p>Note. CI: Confidence Interval. *n=40 combined therapy (these patients were included in the chemotherapy arm for analyses).</p> <p>Table 3. Propensity score comparing radiotherapy and chemotherapy for stage IE lymphoma patients (N=347)</p> <table border="1"> <thead> <tr> <th>Propensity score adjustment</th> <th>Hazard Ratio</th> <th>95% CI</th> <th></th> </tr> </thead> <tbody> <tr> <td>5-year cumulative incidence of lymphoma related death</td> <td>0.27</td> <td>0.13-0.55</td> <td><0.001</td> </tr> <tr> <td>Overall survival</td> <td>0.73</td> <td>0.51-1.04</td> <td>0.08</td> </tr> <tr> <td></td> <th>Odds Ratio</th> <td></td> <td></td> </tr> <tr> <td>Risk of admission to hospital within 1 year from treatment</td> <td>3.68</td> <td>2.34-5.81</td> <td><0.0001</td> </tr> <tr> <td>Risk of admission to critical care unit within 1 year from treatment</td> <td>3.25</td> <td>1.78-5.92</td> <td><0.0001</td> </tr> </tbody> </table> <p>Note. For the propensity analyses the authors report that the results were consistent regardless of inclusion of prognostic factors in the outcome model, omission of the combined modality therapy cases or restriction of the initial treatment timeframe to 6, 12, 36 or 60 months from diagnosis.</p> <p>As shown in Table 2 and 3, lymphoma related death was significantly lower in patients treated with radiotherapy alone. The overall survival was not significantly different. Patients treated with chemotherapy had a higher risk of admission to a hospital or a critical care unit within 1 year from treatment.</p> <p>Table 4. Lymphoma related death according to use of Rituximab (N=230)</p> <table border="1"> <thead> <tr> <th></th> <th>Rituximab alone</th> <th>n=139</th> <th>Rituximab and chemotherapy</th> <th>n=91</th> <th>P value</th> </tr> <tr> <th></th> <th>%</th> <th>95% CI</th> <th>%</th> <th>95% CI</th> <th></th> </tr> </thead> <tbody> <tr> <td>5-year cumulative incidence of lymphoma related death</td> <td>17.7</td> <td>11.2-25.4</td> <td>22.4</td> <td>13.8-32.4</td> <td>0.46</td> </tr> <tr> <td>Risk of death from other causes</td> <td>33.1</td> <td></td> <td>17.8</td> <td></td> <td>0.004</td> </tr> </tbody> </table> <p>Note. CI: Confidence Interval. Authors state that younger age, stage III/IV disease, presence of B symptoms, lack of co-morbidities and residence in non-metropolitan areas were predictive of the choice of chemo-immunotherapy over rituximab alone.</p> <p>Table 5. <p>Olszewski, AJ et al. (2013). Comparative outcomes of oncologic therapy in gastric extranodal marginal zone (MALT) lymphoma: analysis of the SEER_medicare database. <i>Annals of Oncology</i> 24; 1352-1359.</p>	
	<p>As shown in Tables 4 and 5 cumulative incidence of lymphoma related death at 5 years for patients treated with rituximab alone was no different from the patients treated with chemotherapy plus rituximab. There was a significant difference in the risk of death from non-cancer related causes. The overall survival did not differ nor did the rate of hospitalisation within a year of treatment although the risk of neutropenic infection was higher with combined chemo-immunotherapy.</p>
<p>Comments</p>	<p>Propensity score analysis used to generate comparable study arms. Probability of receiving treatment is first calculated and the calculated score is subsequently incorporated as an adjustment in the survival comparison.</p> <p>Not clear if all the participants included in the analyses were in first-line treatment only (“treatment within 2 years of diagnosis”).</p> <p>Authors state that this observational study demonstrates better survival outcomes in early-stage disease with radiotherapy and no apparent survival benefit of adding rituximab during the initial course of chemotherapy. Gastric MALT has a low potential for systemic involvement and <10% risk of dying as a consequence of the disease.</p>

Avilés, A et al. (2006). Surgery and chemotherapy versus chemotherapy as treatment of high-grade MALT gastric lymphoma. *Medical Oncology*, 23(2); 295-300.

Clinical risk				
Low	2	3.8	3	6
Low-intermediate	19	36.5	13	26
Intermediate-high	31	59.6	34	68
High	4	7.7	7	14

Note. LDH, lactate dehydrogenase.

In an intent-to-treat analysis all patients were considered evaluable for efficacy and toxicity.

Table 2. Response to treatment according to treatment groups

	Arm A: Combined therapy n=52		Arm B: Chemotherapy n=50		P value
	n	%	n	%	
Complete response	49	94 (95% CI: 88-99%)	48	96 (95% CI: 89-100%)	0.5
Relapse	15		16		
5-year Event -free survival		70 (95% CI: 59-73%)		67 (95% CI: 57-69%)	0.5*
5-year Overall survival		78 (95% CI: 70-87%)		76 (95% CI: 70-87%)	0.8

Note. *Author reports 0.05 for the 5-year EFS comparison, assume that this is 0.05 as no mention of a significant result in the discussion.

Safety: No treatment related deaths. Late toxicity related to surgery was mild, no megaloblastic anaemia was observed because patients received supplement vitamin 12 and oral iron begun 6 months after surgery. No acute leukemia, myelodysplastic syndrome, or solid tumour has been observed until now.

Table 3. Acute and late toxicities

Dumping syndrome	1				
Weight loss	6				

Note.

Comments

Number per group does not add up to 108 patients, missing patients not accounted for

No information on whether groups differed according to clinical and laboratory characteristics

Authors states that their results showed that chemotherapy alone achieved the same long-term results when compared to patients who were treated with surgery and adjuvant chemotherapy. Acute and late toxicity were similar in both cases. Conclude that chemotherapy appears to be a sufficient treatment in this selected group of patients.

Pub year: 2005		Patient Characteristics				Intervention	Comparison	Outcome																																																																																																													
Country	Mexico	From January 1989 to December 1997, 447 patients with primary gastric MALT lymphoma. <i>Inclusion criteria:</i> <ul style="list-style-type: none"> Low grade gastric MALT lymphoma <ul style="list-style-type: none"> Small elements provided with centrocytic-like associated with plasmocytoid differentiation and that included the following phenotype: CD20+, CD19+, CD21+, CD5-, CD10-, CD23-, and CD43- Age <70 years old No gender difference ECOG status ≤2 Immunodeficiency virus test negative Tumour mass >5 Stage I or IIE (according to the Lugano Conference criteria, 1994) Previously untreated <i>Exclusion criteria:</i> <ul style="list-style-type: none"> High grade gastric MALT lymphoma <ul style="list-style-type: none"> Large cells or controblastic proliferations that included the following phenotype: CD20+, CD19+, CD21+, CD5-, CD10-, CD23-, and CD43- Diffuse large B-cell lymphoma Stages III and IV low-grade MALT (n=206) After endoscopic biopsy patients were randomised to the three treatment groups.				Radiotherapy	Primary surgical resection	– Complete response <i>Defined as the total disappearance of disease at all sites initially involved, with normal laboratory test that was abnormal before treatment for at least 6 months. Failure was defined as a tumour reduction less than 25%, appearance of new lesions of lymphoma, or extension of known lesions</i>																																																																																																													
Design, period	Randomised open-label control trial 1989-1997					Chemotherapy			Surgery: – Performed with intention to achieve a complete resection, total gastrectomy was performed – An intra-operative rapid-section and lymph node dissection in compartments I and II were mandatory. – Liver biopsies were obligatory, but biopsies of other sites, without grossly appearance of tumour infiltration, were not considered																																																																																																												
N	241/447					Radiotherapy: – Applied after endoscopic diagnosis – 30 Gy was administered to the whole abdomen with the kidneys and liver shielded – The dose to the upper abdomen was then boosted to 40 Gy Chemotherapy: – Three cycles of CHOP every 21 days (standard dose): – Cyclophosphamide – Doxorubicin – Vincristine – Prednisone – Followed by four cycles of CVP every 14 days: – Cyclophosphamide, 1000mg/m ² , iv, d 1 – Vincristine, 2 mg/m ² standard dose – Prednisone, 60 mg/m ² , po, d 1-5																																																																																																															
Follow-up	Median: 7.5 years Range: 4.8-11.6 years – Response was assessed 4 weeks after respective treatment – Every 2 months for first 2 years – Every 6 months during the 3 rd and 4 th years – Annually from 5 year until relapse, death, or last follow-up – Gastric endoscopy was performed every 6 months	Table 1. 	Number of cycles		441	
	Granulocytopenia grade I		68 cycles	
	Granulocytopenia grade II		21 cycles	
	Granulocytopenia grade III		18 cycles	
	Nausea-vomiting grade I	7		
	<p>Note. No deaths secondary to surgery or chemotherapy were observed. No mention of radiotherapy. No late toxicity, including acute leukaemia or second neoplasm, no clinical dates of cardiac toxicity.</p>			
	<p>Multivariate analysis did not show that the mentioned prognostic factors influence EFS and OS, probably because the population was uniform (data not shown).</p>			
Comments	<p>Author states that the actual therapeutic approach in this type of lymphoma did not show any difference with CR rate of 100% in all groups and although, EFS was statistically different, the response to salvage treatment was excellent, confirming the excellent response to radiotherapy or chemotherapy in relapsing patients with gastric MALT lymphoma for this reason overall survival was not different at 10 years (author's report a p value <0.05). No late complications observed Conclude that chemotherapy alone is a sufficient therapy in patients with low-grade gastric MALT lymphoma</p>			

Zullo, A et al. (2009). Eradication therapy for helicobacter pylori in patients with gastric MALT lymphoma: a pooled data analysis. The American Journal of Gastroenterology 104; 1932-1937.																																
Objective of review: Assess the H. pylori eradication rate after different first, second-line and rescue therapies and the re-infection rate in these patients.																																
Pub year: 2009		Review Methods	Results																													
Search Period	English language through June 2008	<p>Inclusion criteria: MALT lymphoma or DLBCL-MALT lymphoma of the stomach. Full paper of all relevant studies were retrieved, and manual searches of reference lists from identified relevant papers were formed to identify any additional studies that may have been missed. When more than one publication of the same investigator group was available, only the most updated version, including the entire sample size, was considered for his pooled data analysis. For those relevant studies not describing either the eradication regimen used or the eradication rate following different regimens, authors contacted the authors. Studies regarding paediatric series, those published only in abstract form, single case reports, or short reports, including less than three patients treated with the same therapy, reviews and those studies published in a language other than English, were not taken into account.</p> <p>Search engines: PUBMED</p> <p>Data extract and study appraisal: Two investigators extracted data from studies meeting the selection criteria. H. pylori re-infection was defined as the reappearance of bacteria ≥ 12 months after a verified eradication, whereas the recrudescence of infection < 12 months was considered as a therapy failure.</p> <p>Quality assessment: The author's state there was strong agreement between the two investigators in data extraction, and a final accord was achieved for the three trials with discordant data interpretation.</p>	34/77 included Reasons for exclusion of 43 studies: Exclusion criteria: (i) manuscripts reporting preliminary data comprehensively provided elsewhere (n=22); (ii) lack of information on the therapy regimen used or the eradication rate was not computable (n=18); (iii) only eradicated patients were included in a long-term follow-up study (n=3) Table 1. Descriptives of the included studies																													
Abstracts reviewed	Not provided 77 studies were retrieved and evaluated		<table border="1"> <thead> <tr> <th></th> <th>Total</th> <th>MALT</th> <th>DLBCL-MALT</th> </tr> </thead> <tbody> <tr> <td>N Studies</td> <td>34</td> <td>29</td> <td>2</td> </tr> <tr> <td>N participants</td> <td>1271</td> <td>1215</td> <td>56</td> </tr> <tr> <td>Median sample size</td> <td>21</td> <td></td> <td></td> </tr> <tr> <td>Range of sample size</td> <td>3-120</td> <td></td> <td></td> </tr> <tr> <td>Prospective trials</td> <td>26</td> <td></td> <td></td> </tr> <tr> <td>Retrospective trials</td> <td>8</td> <td></td> <td></td> </tr> </tbody> </table>		Total	MALT	DLBCL-MALT	N Studies	34	29	2	N participants	1271	1215	56	Median sample size	21			Range of sample size	3-120			Prospective trials	26			Retrospective trials	8

Funding source	No financial support or competing interests	<p>Dual versus either 7 or 14-day triple therapies, p=0.0525; 7 vs. 14-day triple therapies: p=0.9; quadruple therapy vs. either 7 or 14-day triple therapies; p=0.5</p> <p>Infection was cured overall in 1,156 of 1,271 patients (91%; 95% confidence interval: 89.4-92.5), with an eradication rate ranging from 50-100% in different series (median 93.8%)</p> <p>As shown in Table 2 the eradication rate was higher after dual therapy as compared with the 7 or 14-day triple therapies, although the difference was not statistically significant. No significant differences observed in any of the comparisons. Overall eradication rate was significantly higher in Asian than in Western patients (92.4% vs. 88.6%; p=0.02).</p> <p>Similar eradication rates were achieved in MALT and DLBCL-MALT patients (91% versus 89.3%) by sub-grouping patients according to the lymphoma type.</p>																														

<p>Zullo, A et al. (2009). Eradication therapy for helicobacter pylori in patients with gastric MALT lymphoma: a pooled data analysis. <i>The American Journal of Gastroenterology</i> 104; 1932-1937.</p>			
<p>Objective of review: Assess the H. pylori eradication rate after different first, second-line and rescue therapies and the re-infection rate in these patients.</p>			
			<p>After therapy (first and second line therapies) H pylori infection was ultimately cured in 1,250 patients, accounting for eradication rates of 98.3% (95% CI: 97.6-99) and 99.8% (95% CI: 99.6-100) at intention-to-treat and per-protocol analysis levels, respectively. Gastric lymphoma regression was achieved in 973 (77.8%) of 1,250 successfully cured patients with a remission rate ranging from 50 - 100% in different studies.</p> <p>No studies reported data on compliance with the H pylori eradication therapies. Similarly, the incidence of side effects as well as the number of patients who eventually interrupted treatment earlier were not given in any study.</p>
Comments	<p>Includes 2 studies with DLBCL-MLAT and 3 with both MALT and DLBCL-MALT Authors conclude that first-line therapies are highly effective in these patients, achieving an overall cure rate >90%. A 14-day, very high-dose (omeprazole 120mg/day) dual therapy seems to be the best therapeutic approach, achieving the highest eradication rate. Such a regimen was only used in Germany and Austria, in 3 studies with a total of 126 patients, therefore this finding may not be generalisable to other countries and deserves to be confirmed in further trials.</p>		

Pub year: 2012		Patient Characteristics	Intervention	Comparison	Outcome
Country	Colombia	<p>50 cases of gastric MALT lymphomas were retrieved from the archives of the Department of Pathology, undación Santa Fe de Bogotá.</p> <p><i>Inclusion criteria:</i> All cases had to have hematoxylin and eosin-stained sections and Immunohistochemistry (IHC)-marked slides available for re-evaluation. Cases must have had previous Histopathological diagnoses, available archival material and complete information about diagnosis and disease monitoring.</p> <p>Diagnoses – Basis of morphological and immunophenotypic examination according to the criteria described by Isaacson et al. (2001) and subsequently included in the Revised European American Lymphoma/ WHO classification. CD20, CD3, CD43, BCL2, cytokeratin and kappa and lambda light chain immunoglobulin antibodies were performed to confirm the MALT lymphoma diagnosis. Expression of BCL10 was also determined using the immunoperoxidase technique in paraffin-embedded setions with a monoclonal mouse anti-human BCL10 antibody.</p> <p>Detection of H. pylori was performed by histology and/or histochemistry using a Genta stain on all follow-up biopsies.</p> <p>H. pylori eradication was evaluated at first by endoscopic mucosal biopsy conducted 2-3 months after the cessation of antibiotic treatment, followed by endoscopy every 6 months for at least 2 years at the discretion of the treating physician.</p>	<p>Antibiotic therapy</p> <p>All patients were treated with triple antibiotic therapy as the first-choice measure.</p> <p>Consisted of a proton pump inhibitor (such as omeprazole, lansoprazole or pantoprazole) plus two antibiotics (amoxicillin and clarithromycin) administered according to the manufacturer's recommended dose for 14 days</p>	<p>None</p>	<p>Histological responses were graded using the Wotherspoon histological score:</p> <p>0-2 complete lymphoma regression (CR)</p> <p>3: partial remission</p> <p>4-5 no response (no change)</p> <p>Persistence score of 5 mainly characterised by the presence of lymphoepithelial lesions after antibiotic treatment was the criterion for tumour resistance to therapy</p>
Design, period	Retrospective observational study No time period				
N	50				
Follow-up	<p>Median: 29 months Range: 6-39 months</p> <p>Endoscopy every 6 months for at least 2 years at the discretion of the treating physician.</p>				
Funding source	Funding: Grant from Universidad Nacional de Colombia				
Results	<p>33/50 (66%) were classified as responders showing lymphoma regression after receiving antibiotic therapy 17/50 (34%) were classified as non-responders after receiving antibiotic therapy</p> <p>Median time to complete lymphoma regression after the completion of antibiotic therapy was 3.2 months (range 1-18 months). The bacteria were successfully eradicated in all patients treated with the standard triple therapy applied, including all non-responders.</p>				
Comments	No demographic data or statistically analyses presented.				

Ueda, K et al. (2013). Non-gastric advanced mucosa-associated lymphoid tissue (MALT) lymphoma has worse prognosis than gastric MALT lymphoma even when treated with rituximab-containing chemotherapy. <i>Leukemia and Lymphoma</i> , 54(9); 1928-1933.

Country	Japan	Between March 2001 and October 2008 retrospectively reviewed 98 patients with MALT lymphoma consecutively diagnosed by expert hematopathologists at the Cancer Institute Hospital. Diagnoses were made according to the World Health Organisation classification of NHLs. Treatment strategies were fundamentally determined by disease location and stage. Generally, patients with localised non-gastric lymphoma were treated with radiation therapy, chemotherapy was chosen for patients who were determined to be ineligible for radiation therapy due to the primary site.				Antibiotic therapy		– Complete remission – Progression free survival <i>Determined as the time from the start of treatment to the date of disease progression or death from any cause</i> – Overall survival <i>Determined as the time from the start of treatment to the date of death from any cause</i>

Ueda, K et al. (2013). Non-gastric advanced mucosa-associated lymphoid tissue (MALT) lymphoma has worse prognosis than gastric MALT lymphoma even when treated with rituximab-containing chemotherapy. <i>Leukemia and Lymphoma</i> , 54(9); 1928-1933.			
		Note. IPI: International Prognostic Index; LDH, lactate dehydrogenase; PS, performance status; BM: Bone marrow.	
Results	Table 3. Treatment of 98 patients with MALT lymphoma		
		Total n=98	H. pylori eradication n=50
	Response rate	89.8%	63.3%
	Complete remission	72.4%	90.0%
	3-year overall survival	100%	
	3-year progression free survival	89%	
	<p>Note.</p> <p>The median time of PFS and OS has not yet been reached.</p> <p>Advanced disease and non-gastric lymphoma were significantly associated with shorter progression free survival. None of these factors was significantly associated with overall survival. Multivariate analysis, non-gastric lymphoma retained prognostic significance for PFS (Relative risk: 5.861; 95% CI: 1.369-25.098; p=0.017)</p>		
Comments	Authors state that their investigation indicates that MALT lymphoma is an indolent disease with long survival. H. pylori eradication was an effective first-line treatment for localised gastric MALT lymphoma.		

Park, SH et al. (2010). Prognostic impact of helicobacter pylori infection and eradication therapy in gastric mucosa-associated lymphoid tissue lymphoma. Korean Journal for Laboratory Medicine. 30; 547-53.																																																																								
Pub year: 2010		Patient Characteristics			Intervention	Comparison	Outcome																																																																	
Country	Korea	Since 2000, a total of 292 patients diagnosed with MALT included. Data reported concerns the 198 gastric MALT patients treated with antibiotic therapy. No treatment data provided for non-gastric MALT. Diagnosis: tissue biopsy for MALT. H. pylori infection diagnosed with hematoxylin-eosin and additional Warthin-Starry stains on tissue sections Table 1. Demographics and clinical features of 292 MALT lymphoma patients			Antibiotic therapy	None	Complete remission

	Remission	64.0%	76.1%	0.100	81.0%	30.8%	<0.001																																																																	
Table 3. Multivariate analysis of remission in patients with gastric MALT lymphoma according to various clinical variables																																																																								
		Hazard ratio	95% CI	P value	Adverse effect																																																																			
H. pylori infection at diagnosis (yes versus no)		1.38	0.68-2.80	0.377	NA																																																																			
H. pylori eradication (success versus failure)		0.21	0.06-0.77	0.019	Failure																																																																			
Tumour stage (≤II versus ≥III)		0.39	0.16-0.89	0.025	≥III																																																																			
Tumour location (distal versus both)		1.38	0.72-2.66	0.334	NA																																																																			
Note. CI: confidence interval																																																																								
As shown in Table 3 those with successful H. pylori eradication therapy showed significantly higher remission rates (81.0% versus 30.8%, p<0.001) than those with failure.																																																																								
Comments	Paper published in Korean, data has been extracted from the tables and information on methods and conclusions taken from the abstract																																																																							

<p>Zullo, A et al. (2013). Eradication therapy in helicobacter pylori-negative, gastric low-grade Mucosa-associated lymphoid tissue lymphoma patients: A systematic review. <i>J Clin Gastroenterol.</i> 47(10); 824-827.</p>																																																																			
<p>Objective of review: Evaluate the role of H. pylori eradication therapy in apparently H. pylori-negative MALT lymphoma patients.</p>																																																																			
<p>Pub year: 2013</p>		<p>Review Methods</p>																																																																	
<p>Search Period</p>	<p>English language through March 2012</p>	<p>Inclusion criteria: 3 independent computer-assisted searches using different medical subject heading terms. Only studies concerning primary, low-grade, early-stage (I, II) MALT lymphoma of the stomach were initially considered. Only studies including H. pylori-negative patients exclusively treated with an antibiotic eradication therapy were eventually selected. Full articles of all relevant studies were retrieved, and manual searches of reference lists from identified relevant articles were performed to identify any additional studies that might have been missed. When more than 1 publication from the same investigator or group was available, only the most updated version, including the entire sample size, was considered for this pooled-data analysis. Studies were published only in abstract form, and reviews were not included.</p> <p>Search engines: PUBMED</p> <p>Data extract and study appraisal: Two investigators extracted data from studies meeting the selection criteria.</p> <p>Quality assessment: Both investigators of this study approved the data extraction method, and no discordant data interpretation occurred.</p>																																																																	
<p>Abstracts reviewed</p>	<p>Not provided 247 studies were retrieved and evaluated</p>

<p>Comments</p>	<p>Two possible scenarios for anti-H. pylori therapy achieving remission in 15% of apparently H. pylori-negative patients with early-stage, low-grade MALT lymphoma: 1. H. pylori infection is present, despite the negative results of all diagnostic tests (false negative) 2. Antibiotic therapy acts against other bacteria potentially involved in MLAT lymphoma pathogenesis The execution of multiple (from 3-5) diagnostic tests in all the studies included in this review provides strong, although not irrefutable, evidence against the first hypothesis as there are situations in which the bacteria are confirmed to some "niches" where they are exceedingly difficult to detect. Authors suggest that on the basis of the generally indolent behaviour of primary gastric MALT lymphomas, it would seem reasonable to attempt eradication therapy before resorting to aggressive, costly and potentially more toxic oncologic therapies, even in H pylori-negative cases.</p>																																																																		

<p>Zullo, A et al. (2010). Treatment of low-grade gastric MALT-lymphoma unresponsive to Helicobacter pylori therapy: a pooled-data analysis. <i>Medical Oncology</i> 27; 291-295.</p>																																								
<p>Objective of review: Efficacy of different therapeutic approaches for gastric MALT-lymphoma treatment unresponsive to H. pylori treatment.</p>																																								
<p>Pub year: 2010</p>		<p>Review Methods</p>																																						
<p>Search Period</p>	<p>English language through September 2008</p>	<p>Inclusion criteria: Only studies concerning primary low-grade, MALT-lymphoma of the stomach associated with h. pylori infection were considered, whilst those diffuse large B-cell lymphoma with feature of MALT (DLBCL-MALT) were excluded. Trials enrolling patients with either stage IE1-IE2 or IIE1 lymphoma according to Ann Arbor classification as modified by Musshof were considered, whilst those series also including ≥IIE2 stage cases were excluded, unless it was possible to correctly extrapolate data of a patient subgroup with early stage. Only those studies enrolling patients treated with solely h pylori eradication as initial treatment were considered.</p> <p>Exclusively patients with complete lymphoma regression, defined as post-treatment disappearance of endoscopic lesions and absence of histopathologic evidence of lymphoma in all gastric biopsy samples, were considered as a positive outcome, whilst partial remission was not taken into account.</p> <p>Full article of all relevant studies was retrieved and manual searches of reference lists from identified relevant articles were performed to identify any additional studies that may have been missed using the selection procedure. When more than one publication of the same investigator group were available, only the most updated version including the entire sample size was considered for this pooled-data analysis. Studies regarding paediatric series, transplant patients, those published in abstract form, single case report, reviews and those studies published in a language different from English were not take into account.</p> <p>Search engines: PUBMED</p>																																						
<p>Abstracts reviewed</p>	<p>Not provided 41 studies were retrieved and evaluated</p>

Comments

Authors report second-line oncologic therapy but these are not recording for this PICO.

Authors note that in patients with early-stage MALT lymphoma who received a further therapy due to lymphoma persistence despite H. Pylori therapy lymphoma remission can be achieved in 9 out of 10 patients. Radiotherapy alone was both the most frequently chosen therapy, and the most effective treatment in these patients

No information of stage classification

Kondo, S et al. (2012). Feasibility of watch and wait strategy for histological relapse of gastric MALT lymphoma after helicobacter pylori eradication therapy. AGA abstracts S-761.					
Pub year: 2012		Patient Characteristics	Intervention	Comparison	Outcome
Country	Japan	100 patients with gastric MALT lymphoma who were seen at the authors hospital between November 2003 and September 2008. Biopsy samples were histologically graded according to the scoring system of Wotherspoon 78/100 were positive for H. pylori All 100 patients underwent H. pylori eradication therapy Patients classified as responders and non-responders. A watch-and-wait strategy without any additional treatment was taken for responders who showed histologically relapsed lesions during follow-up	Antibiotic therapy	None	Histological responses were graded using the Wotherspoon histological score: 1-3: Responders: Subjects with both macroscopic disappearance of lymphoma and absence of histopathologic evidence of lymphoma on biopsy 4-5: non-responders 5-year Overall survival
Design, period	Retrospective observational study 2003-2008				
N	100				
Follow-up	Median: 78.4 months Upper gastrointestinal endoscopy, biopsy and abdominal CT every 3 months in the first year, every 4 months in the second year, and at intervals of 6 months in the third year and beyond.				
Funding source	Not provided				
Results	39/100 classified as non-responders - most of the 39 underwent second-line treatments such as radiation therapy, chemotherapy, chemo-radiation therapy or total gastrectomy Median time from complete histologic remission (CR) to recurrence was 7 months. 61/100 classified as responders - 9 showed histologically relapsed lesions during the follow-up -1 showed a macroscopically relapsed lesion, underwent radiation therapy as a second-line treatment and achieved a second CR -8 had only histologically relapsed lesions and a watch-and-wait strategy was employed. All of these subjects achieved a second CR without any further treatment, and none showed disease progression. Median period from recurrence to second CR was 4.4 months 5-year overall survival rate was 100% for responders.				
Comments	Conference abstract No information on diagnosis of MALT or helicobacter pylori. Authors state that a watch-and-wait strategy is a feasible treatment option for histologically relapsed lesions in responders				

Hancock, BW et al. (2008). Chlorambucil versus observation after anti-helicobacter therapy in gastric MALT lymphomas: results of the international randomised LY03 trial. British Journal of Haematology 144; 367-375.						
Pub year: 2008		Patient Characteristics		Intervention	Comparison	Outcome
Country	Italy, France, UK	Between March 1995 and March 2001 a total of 231 patients (132 IELSG, 64 UKLG, 35 GELA) were registered. 110 /231 were randomised (56 to Chlorambucil and 54 to observation). The trial was stopped early due to slow recruitment influenced, it was thought, by increasing awareness of the long-term successes possible with H. Pylori eradication. <i>Inclusion criteria:</i> <ul style="list-style-type: none"> – 18 years of over – Non-resected, partially or completely resected low-grade gastric lymphomas – Stage I according to the Blackledge-modified Lugano staging system (Rohatiner et al, 1994) – With or without histological evidence of H. Pylori infection <ul style="list-style-type: none"> o Patients in whom H. Pylori was successfully eradicated with complete regression of lymphoma were eligible for randomisation o Patients in whom H. Pylori was successfully eradicated with partial regression or stabilisation of lymphoma might be randomised according to the clinician's discretion – All gastric biopsies of patients registered were reviewed independently by a panel of pathologists – Immunohistochemistry performed on paraffin sections using antibodies against CD20, CD3 and cytokeratin where appropriate – Presence of H. Pylori was assessed on modified Giemsa stained sections and in a proportion of cases by culture <i>Exclusion from trial (n=121):</i> <ul style="list-style-type: none"> – 11 patients were not randomised due to disease progression – 44 patients were not randomised due to inadequate response to antibiotics – 66 patients were not randomised despite being eligible – patient refusal, clinician reluctance (as initiation of study preceded recognition of excellent prognosis of antibiotic-treated gastric MALT lymphoma) <i>Trial design:</i> <ul style="list-style-type: none"> – Eligible patients were registered and treated with antibiotics according to local practices for H. Pylori infection – Endoscopies performed 2-3 months after treatment to assess eradication of H. pylori – Confirmation of successful eradication of H. Pylori was according to local practice – Assessment of tumour response performed up to 4-6 months after the organism had been eradicated 		Chlorambucil <ul style="list-style-type: none"> – At time of trial accepted as standard treatment for low-grade non-Hodgkin lymphomas in most European countries – Given 6 mg/m² daily orally for 14 days repeated every 28 days for six cycles 	Observation	Recurrence/ progression free survival <i>Date of randomisation to the date of the first recurrence/ progression or date of death from any cause whichever occurred first; at the time of the analysis survivors without disease recurrence/ progression were censored at the date of the last follow-up</i> Overall survival <i>Date of randomisation to the date of death from any cause; at the time of the analysis survivors were censored at the date of randomisation to the date of death from any cause; at the time of the analysis survivors were censored at the date they were last known to be alive</i>
Design, period	Randomised Control trial 1995-2001					
N	110/231 <i>Anticipated endoscopic relapse rate in patients treated for H. Pylori infection without chlorambucil was 40% at 5 years, meaning a total of 173 patients would be required to demonstrate a reduction to 20% with 5% significance level and 80% power</i>					
Follow-up	Median: 58 months Range: 4-115 months <ul style="list-style-type: none"> – History, physical examination and routine blood tests – Tumour response was assessed at each post treatment endoscopy with at least eight biopsies 	<pre> graph TD A[231 registered] --> B[110 randomized after H. pylori successfully eradicated] B --> C[54 observation] B --> D[56 chlorambucil] C --> E[1 received chlorambucil before disease recurrence] E --> F[54 assessed for outcome measures] D --> G[47 received chlorambucil 1 refusal 8 missing treatment details] G --> H[56 assessed for outcome measures] </pre>

Complete remission
Patient with endoscopic normalisation and a Wotherspoon score (WS) ≤2

Partial remission
Endoscopic normalisation and a WS > 2

Stable disease
Endoscopic stable disease and WS > 2

Progressive disease
Patients with extension of the endoscopic lesions and WS > 2

Disease relapse
Patient had any disease occurred; after a PR or SD

Disease progression
Disease got worse

Note.CR: complete remission, PR: partial remission, SD: Stable disease/no change; PD: progressive disease.							
Results	All analyses were done on an intention-to-treat basis 98% protocol treatment compliance. One patient in the chlorambucil arm did not have the allocated treatment due to the patient's refusal of chemotherapy. In the observation arm, one patient had chlorambucil 10 months after randomisation without disease recurrence. Chlorambucil was given for a median of 29 weeks (range 3-39). As treatment was accepted standard treatment in most European countries at time of the study with a well-known safety profile and high tolerability, toxicity data were not collected in detail. No cases of severe treatment-related toxicity were reported.						
	Table III. Summary events for randomised patients:						
	Total	Observation n=54			Chlorambucil n=56		
		n	%	n	%	n	%
	Alive without recurrence/ progression	43	80	45	80	45	80
	Alive with recurrence/ progression	9	17	7	13	7	13
	Dead without recurrence/ progression	1	2	4	7	4	7
	Recurrence/ progression and dead	1	2	0	0	0	0
	5 year recurrence/ progression		21		11		11
	The 5-year recurrence/progression rates from randomisation were 21% in the observation arm and 11% in the chlorambucil arm, with a difference of 10% and 95% confidence interval of the difference being -9% to 29%, p=0.15. 22 patients (11 in each arm) had disease recurrence/ progression or died. No difference was detected between the two treatment arms (HR=0.96, 95% CI 0.41-2.2, p=0.91). The 5-year recurrence/ progression free rate for all randomised patients was 79%. The two deaths in the observation arm were due to a myocardial infarction in a patient who had disease progression before death in one patient and to a small cell lung cancer in the other. The four deaths in the chlorambucil arm were due to malignant melanoma (n=1), cardiac failure (n=2) and unknown (not lymphoma related: 1). There was no survival difference between the two arms (HR=1.93, 95% CI: 0.39-9.58, p=0.42). The 5-year overall survival rate for all randomised patients was 93%.						
Comments	Hancock et al. state that there was no evidence that chlorambucil was more or less effective than observation in different responses to antibiotics at randomisation for either recurrence/progression or overall survival.						
	Study confirms that H. Pylori eradication results in regression of lymphoma in the majority of cases (65% CR/PR, 29% SD and 5% PD). Addition of 'adjuvant' chlorambucil conferred no benefit.						
	No information on concealment so potential allocation bias						

Pub year: 2009		Patient Characteristics	Intervention	Comparison	Outcome																																																																																																					
Country	Switzerland, Italy	From July 1990 to November 2006, 156 patients with localised (i.e. disease confined to the stomach with or without involvement of the paragastric lymph nodes and with no distant lymph node involvement) marginal zone B-cell lymphoma of the MALT type of the stomach were referred to the authors institutions (Switzerland and Italy).	Antibiotic therapy	None	<p>Lymphoma remission</p> <p><i>Either complete or partial was investigated by regular endoscopic examinations including multiple biopsies, carried out at 6-month intervals. Histological responses were graded using the Wotherspoon histological score considering scores 0-2 a complete lymphoma regression (CR), score 3 a partial remission (PR) and scores 4-5 no response (no change).</i></p> <p>Overall survival</p>																																																																																																					
Design, period	Retrospective observational study 1990-2006	105/156 patients who received exclusively anti-helicobacter eradication therapy as first-line therapy was eligible for the study. The series comprised every new case of localised gastric MALT lymphoma referred to the authors institutions during the study period. Two previous studies (Pinotti et al., 1997; Roggero et al., 1995) have published some of the included patients in early studies of antibiotic therapies.	All patients received as first-line therapy a combination of antibiotics (amoxicillin and claritromycin in 36%, metronidazole and claritromycin in 24%, amoxicillin and metronidazole in 15% and others in 16%) and proton pump inhibitors (mostly omeprazole, less commonly pantoprazole or lansoprazole). A second-line antibiotic treatment was given for patients who failed to eradicate the microorganism. Patients who did not respond to antibiotics were referred to other treatments in accordance with the local guidelines.																																																																																																							
N	105/156	<i>Inclusion criteria:</i> – Previously untreated – Stage I (i.e. stomach only) or II1 (i.e. paragastric lymph nodes involvement) according to the modified Blackledge system that is presently known as the Lugano staging system																																																																																																								
Follow-up	Median: 6.3 years	Diagnoses – histopathology panel composed by expert pathologists from each institution was established to allow a consistent and uniform application of the diagnostic criteria in all the studies cases. Helicobacter pylori detection was on the basis of histology and/or histochemistry.

<p>Stathis, A et al. (2009). Long-term outcome following <i>Helicobacter pylori</i> eradication in a retrospective study of 105 patients with localised gastric marginal zone B-cell lymphoma of MALT type. <i>Annals of Oncology</i> 20 (6); 1086-1093.</p>	
Results	<p><i>Helicobacter pylori</i> was eradicated in all positive patients (85 of 85) but in 19 of them a second-line antibiotic therapy was required. Histological regression of the gastric lymphoma was achieved in 78/102 assessable patients (76%, 95% CI: 67% to 84%) with histological complete remission (CR) in 66 (Wotherspoon score 0-2) and partial remission (PR) in 12 patients (score 3). Median time to CR was 15.5 months and its 25th and 75th percentiles were 5 and 32 months, respectively.</p> <p>Median follow-up time of the 78 patients who attained a lymphoma regression after antibiotics was 6.8 years; for 74 of them the results of follow-up endoscopies were available. The histological remission (Wotherspoon score 0-2) was consistently confirmed at follow-up endoscopies in 33 of these 74 patients (45%, 95% CI: 33%-57%), while 25 (34%, 95% CI: 23%-46%) had histological score fluctuations from 0-4, sometimes with transient histological relapses followed by spontaneous histological remissions.</p> <p>16 patients relapsed (22%, 95% CI: 13% to 33%); 13 had a local low-grade relapse (Wotherspoon score 5), 2 (13% of relapses, 9% CI: 2-38%) had a local relapse with histological transformation to a high-grade lymphoma and one patient only had a distant relapse with axilla lymph nodes involvement.</p> <p>In 14 patients, <i>h. pylori</i> was not detected on gastric biopsy at diagnosis but, according to local policies, they were anyway given an initial antibiotic treatment. 5/14 (33%, 95% CI: 12%-62%) achieved an initial complete lymphoma regression after antibiotics, but 3/5 presented a local relapse and were referred to other treatments while 2 patients presented an histological score fluctuation (0-4) on follow-up endoscopies. 3/5 patients with stage II1, disease presented an endoscopic improvement after antibiotics and in 2 of them a size reduction of perigastric lymph nodes was also observed but no complete response was documented and all 5 stage II1 patients were referred to other treatments for persistence of macroscopic disease.</p> <p>During the study time, 12 deaths were recorded, 10/102 patients assessable for the response.</p> <p>Median age at death was 83.5 years (78-96 years). There was no significant difference in the frequency of deaths between responders (8/78) and nonresponders (2/24). 7 patients died in complete remission. 1 died of disseminated DLBCL (transformation from MALT lymphoma could not be excluded). 5 patients died of cardiovascular reasons and the others for causes reported as not related with the MALT lymphoma.</p> <p>At a median follow-up of 6.3 years for the entire group, the median OS was not reached. The OS rate was 92% (95% CI: 84%-96%) at 5 years and 83% (95% CI: 70%-91%) at 10 years after diagnosis.</p> <p>Univariate analysis of the clinicopathological features at presentation demonstrated a statistically significant associated with a shorter OS for a previous hepatitis C virus infection (P=0.0038), an ECOG PS>0 (P=0.0043) and an age>60 years at presentation (P=0.0006). at multivariate analysis, only age retained statistical significance.</p>
Comments	<p>Author states that after antibiotics, histological remissions were observed in 76% of gastric MALT lymphomas and were associated with improvement or complete regression of endoscopic abnormalities and with resolution of symptoms. In accordance with previous reports, the length of the time necessary to obtain a remission varied from 1 month to >1 year and the patients with lymph node involvement have a reduced chance of responding to antibiotics.</p> <p>Anti-helicobacter treatment in our series was less successful in patients with multifocal disease, and in those with lymphoma presenting in the gastric body, this finding is partially in keeping with a recent study from Korea, which reported tumours in the distal stomach to be associated with more favourable response.</p> <p>Approximately 40% of patients who achieved a histological remission maintained the remission during the follow-up and >30% presented a histological score fluctuation (Wotherspoon score 0-4. These patients were followed with a watch and wait policy (regular clinical and endoscopic evaluations every 6-12 months) and remained long term free of 'macroscopic' disease (i.e. had stable endoscopic features and absence of distant sites of relapse)</p>

Pub year: 2013		Patient Characteristics				Intervention	Comparison	Outcome			
Country	Korea	From May 2003 to April 2012, patients with histologically proven gastric MALT lymphoma were enrolled prospectively in Seoul National University Bundang hospital.				Antibiotic therapy	None	Complete remission <i>Tumour disappeared both grossly and histologically. Patients who did not meet the criteria for CR at the follow-up of 3-4 months after H. pylori eradication were considered non-responders.</i>			
Design, period	Prospective observational study 2003-2012	66 cases with MALT lymphoma were followed up at least 4 months after eradication. Stage was established according to the Lugano staging system. Diagnoses – WHO (2008) classification of lymphoid neoplasms for extranodal marginal zone B-cell lymphoma of MALT type. H. pylori infection status was determined by modified Giemsa staining, culture, and rapid urease testing (CLOtest, Delta West, Bently, Australia). If these tests were all negative, then C-urea breath test and serum IgG, specific for H. pylori, were measured by an enzyme-linked immunosorbent assay (ELISA); Korean strain was used as antigen in this H. pylori antibody test. If one of any of these studies except serology showed positive, the patient was judged to be current H. pylori infected case. Only when all of the test results were negative, was the patient considered to be negative.				All patients received standard-dose proton pump inhibitor (PPI) bid, clarithromycin 0.5 g bid, and amoxicillin 1g bid, all for 7 days.					
N	51/66 received antibiotic therapy							Partial response <i>Reduction in endoscopic or histologic finding. When a PR was recorded, follow-up endoscopy was performed 3 months later.</i>			
Follow-up	Median: 33.5 months Range: 3.3-96.4 months										
Funding source	Funding: Global Core Research Center (GCRC) grant (No. 2012-00011857) from the National Research Foundation (NRF), Ministry of Education, Science and Technology (MEST), Republic of Korea. Authors have no competing interests.	Table 1. Baseline characteristics of sample						A second-line antibiotic treatment was given for patients who failed to eradicate the microorganism.	Stable disease <i>Persistent lesion with no evidence of modified endoscopic or histologic improvement</i>

Comments	Authors argue that H. pylori eradication could be performed as a primary therapy regardless of H. pylori status. Author states that because H. pylori - patients are rare, there are only a small number of studies. In the present study, H. pylori- patients had an advanced clinical stage at a higher frequency than H. pylori + patients. Patients who failed to achieve CR had multiple locations in both parts of the stomach. Authors state that possible that some responders were misclassified into non-responders because treatment response was decided at the time of 3-4months. However, in the clinical setting, it is difficult to persuade patients to hold "wait" long enough till undefined remission. In addition, a number of non-responders were determined more than 6 months after eradication.																																															

Non Hodgkin's Lymphoma: diagnosis and management

Zucca, E et al. (2000). Gastric MALT lymphoma: response to anti-helicobacter therapy in the ongoing LY03 randomised co-operative trial of observation versus chlorambucil after anti-helicobacter therapy. <i>British Journal of Cancer</i> 2000. 83: 15-15.					
Pub year: 2000		Patient Characteristics	Intervention	Comparison	Outcome
Country	Switzerland, Italy, France, UK, Spain, Belgium	From March 1995 to November 1999, 217 patients (39 from the UK) with localised, histologically reviewed low grade MALT lymphoma of the stomach were registered 115 men 102 women Median age: 68 years (range: 20-85) 88% positive for H. pylori at diagnosis	Antibiotic therapy	None	Lymphoma regression Complete remission Partial remission Relapse
Design, period	Observational study 1995-1999				
N	189/217 received antibiotic therapy				
Follow-up	Median: 26 months				
Funding source	Not reported				
Results	189/217 patients have been evaluated for response to anti-helicobacter therapy				
		n	%	95% CI	
	Histological regression of the lymphoma	133	70	63-77%	
	Complete remission	105	55		
	Partial remission	28	15		
	Relapses of lymphoma at median 26 months follow-up	15	7		
	Histological transformation	2			
	Death due to progressive lymphoma after high grade transformation	1			
	Death due to solid cancers (lung and melanoma)	2			
	Coronary thrombosis	1			
Pulmonary embolism	1				
	Note. CI: Confidence Interval				
	Median time to lymphoma regression was 7 months				
	Relapses of lymphoma were most often observed with no evidence of H. pylori re-infection.				
Comments	Conference abstract.				

Vrieling, C et al. (2008). Long-term results of stomach-conserving therapy in gastric MALT lymphoma. Radiotherapy and Oncology 87; 405-411.					
Pub year: 2008		Patient Characteristics	Intervention	Comparison	Outcome
Country	The Netherlands	<p>Between 1975 and 2002 115 patients with gastric MALT lymphoma stage I and II were treated in the Netherlands Cancer Institute.</p> <p>Patients were staged according to Ann Arbor classification system, modified by Musshoff and according to the Paris staging system for primary gastrointestinal lymphomas.</p> <p><i>Diagnosis of MALT:</i></p> <p>Diagnostic gastric biopsies were reviewed by one of the authors and classified as extranodal marginal zone B-cell lymphoma, MALT type.</p> <p><i>Diagnosis of helicobacter pylori:</i></p> <p>Presence of infection scored on the basis of hematoxylin and eosin- and Giemsa-stained sections.</p> <p><i>Exclusion criteria:</i></p> <p>Cases reclassified as other lymphoma entities</p> <p>41/115 (35.7%) positive for H. pylori and received eradication therapy: 35/41 primary HP eradication only 5/41 radiotherapy and HP eradication 1/41 chemotherapy, radiotherapy and HP eradication</p> <p>Of the 35 patients: 33 had stage I 2 had stage II1</p>	Antibiotic therapy	None	<p>Response according to the WHO criteria</p> <p>Complete remission</p> <p><i>Classical clinic-pathological criteria, reviewed and scored according to the histological grading system as proposed by Copie-Bergman et al. (2003)</i></p> <p>Recurrence</p> <p><i>Reappearance of lymphoma at originally involved sites or detection of lymphoma at a novel site in patients in CR following primary therapy</i></p> <p>Overall survival</p> <p><i>Time from date of diagnosis to date of last follow-up or date of death from any cause, whichever came first</i></p> <p>Cancer-specific survival (CSS)</p> <p><i>Time from date of diagnosis to date of last follow-up or date of death from lymphoma whichever came first</i></p>
Design, period	Observational study 1975-2002				
N	35/115				
Follow-up	<p>Median: 5.6 years</p> <p>Patients evaluated every 3 months until histological complete remission or further treatment was given and yearly thereafter</p>				
Funding source	Not reported				
Results	35/115 received H. pylori eradication as first-line therapy. Median time to classical Histopathological CR: 10 months (range: 5-37 months)				
		n	%		
	Classical Histopathological complete remission	15	43 all stage I disease		
	Partial remission	2	5.7		
	No change	16	45.7		
	Progressive disease	2	5.2		
	5-year overall survival*		89		
	5-year cancer specific survival*		100		
<p>Note. *Includes patients who received additional therapy after HP eradication and did not achieve a CR.</p> <p>Of the 20 who did not achieve CR:</p> <p>16: Radiotherapy 1: Radiotherapy + surgery 1: Chemotherapy 2: follow-up</p> <p>Authors state that the CSS of the patients that achieved CR with H. pylori eradication alone was comparable to the group that needed additional therapy following H. pylori eradication to achieve CR, no statistical analyses presented.</p>					
Comments	Authors present data on 56 patients who received radiotherapy only but state that the 53/56 of these patients received this treated prior to the use of h. pylori eradication therapy. Due to Aviles et al. RCT on the use of radiotherapy in low grade gastric MALT this data was not extracted.				

Non Hodgkin's Lymphoma: diagnosis and management

	Authors state that the CR-rate of 43% is low compared to other studies (70-92%) adding that a probably explanation for this low CR-rate is referral bias; a relatively high number of patients already treated with H. pylori eradication or with more extensive tumour load may have been referred to their hospital. When the role of $t(11;18)$ is taken into account the CR rate is 68% for $t(11;18)$ negative patients. Most patients who did not achieve a CR were treated with locoregional radiotherapy and even with short follow-up achieve a comparable OS and CSS to that after RT only.

Comments	Very high risk of bias. Non randomised retrospective study. Limited comparison of baseline characteristics of treatment groups – suggests surgery was not used for stage III-IV disease. Clear differences between types of treatment used for different sites (e.g. surgery for thyroid MALT; chemoimmuno or RT used for ocular and salivary gland disease).							

4.3: Mantle Cell Lymphoma

4.3.1: Review question: What is the most effective first-line treatment for people with mantle-cell lymphoma?

PICO Table

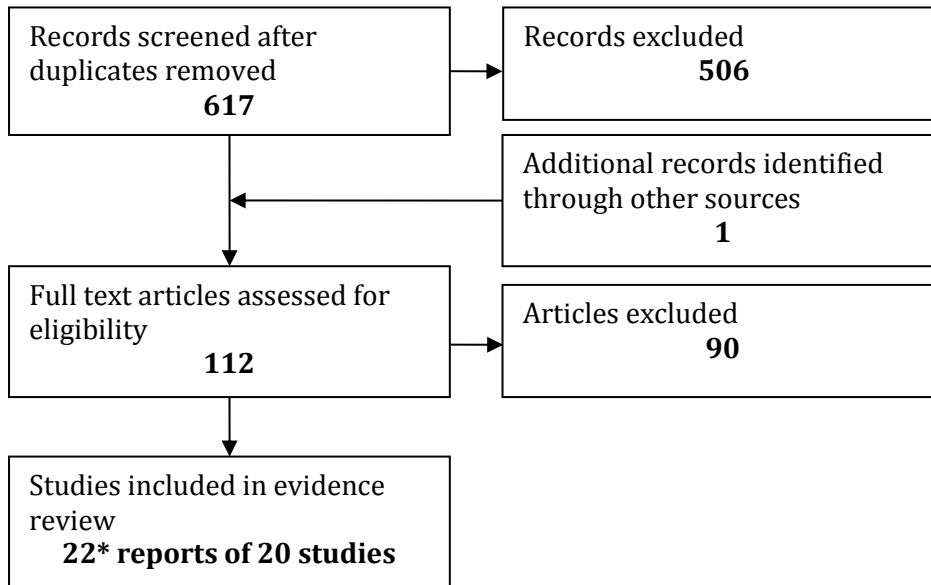

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) newly diagnosed with Mantle-cell lymphoma Subgroups: Stages Variants: Blastoid Non-blastoid: Indolent (e.g. Small cell) Fitness Exclude: Cyclin D1 negative detected by any method Presence of a 11:14 translocation	Radiotherapy Chemotherapy Chemo-immunotherapy R-CHOP/CHOP Cytarabine (Cytosine arabinoside) Rituximab Fludarabine/ FCM/rituximab MCP/rituximab CVP/ COP Watch and wait/observation (for indolent patients)	Each other	Overall survival Disease free survival Progression free survival Treatment related mortality Treatment related morbidity Health related quality of life

Additional Comments on PICO

Where results present by age
 Present results by subtype reported in the literature (make note of when they include blastoid)
 Report when proliferation index reported in literature
 Report when Mantle-cell international prognostic index (MIPI) reported in literature
 Due to the development of a NICE technology appraisal (Bendamustine in combination with rituximab for the first-line treatment of mantle cell lymphoma. NICE technology appraisal ID: 609) the choice of first-line treatment (K1) cannot include Bendamustine. K2 and K3 can include Bendamustine.
 Minimal residual disease status should not be included as an outcome of interest as it is not helpful to answer question
 Note for GDG4: Proposed TA under consultation: Bortezomib for previously untreated mantle cell lymphoma. TA scope states that current studies include bortezomib in combination with rituximab, cyclophosphamide, doxorubicin and prednisone, compared with R-CHOP, in adults with previously untreated stage II, III or IV mantle cell lymphoma for whom bone marrow transplants are unsuitable.
 Note for GDG: LB asked the subgroup about the inclusion of non-comparative studies as the comparative studies appraised accounted for all the interventions included in the PICO.

Summary Tables

Note. NR: Not reported. Zinzani reported no fatalities resulting from drug-toxic effects occurred. Adverse events not presented by NHL subtype. Rule et al. Reported significantly more patients in the FCR arm experienced grade 3 or 4 leucopenia and thrombocytopenia however, the numbers of grade 4 were not significantly different (breakdown of % not reported). *P<0.05; **p<0.01; ***p<0.001; ****p<0.0001

Evidence Statements

Evidence came from seven randomised controlled trials, 12 cohort studies (one prospective) and one retrospective case series.

Chemotherapy regimens

CHOP

One randomised control trial (RCT; evidence appraised at two time points: Lenz *et al.* 2005 and Hoster *et al.* 2008) comparing the use of CHOP+rituximab (RCHOP) to the use of CHOP alone in 123 patients with stage III/IV mantle cell lymphoma provided low quality evidence of higher response rates in the patients treated with RCHOP (complete: 33%, complete plus partial: 92%) compared to the patients treated with CHOP alone (complete: 8%, complete plus partial: 75%, $p<0.05$). The patients treated with RCHOP had a longer median time to treatment failure (28 months) and response duration (29 months) compared to the patients treated with CHOP alone (14 months, $p<0.001$; 29 months, $p<0.01$). However, there was no statistically significant difference in the 5 year overall survival rates (RCHOP: 59%, median not reached; CHOP: 46%, 59 months). Patients treated with RCHOP had higher rates of grade 3 and 4 granulocytopenia (63% versus 53%, $p<0.01$) and grade 1 and 2 allergic reactions (6% versus 0%, $p<0.0001$) compared to the patients treated with CHOP alone.

One observational comparative study (Bernard *et al.* 2001) compared the use of CHOP to C-VAD, CVP and Chlorambucil in 33 patients with blastic mantle cell lymphoma (85% stage IV, median age: 62, range: 29-80), reporting very low quality evidence of complete response rates of 57.9% in the CHOP group compared to 14.3% in the C-VAD group and 0% in the CVP and Chlorambucil groups. Treatment failure rates were 21.1% in the CHOP group, 71.4% in the C-VAD group, 75% in the CVP group and 100% in the Chlorambucil group. The patients in the CHOP group had a 90.9% rate of relapse after complete response. No statistical analyses were presented to compare the response rates in these patients.

One observational comparative study (Ying *et al.* 2012) compared the use of rituximab+CHOP (RCHOP) to conventional chemotherapy regimens in 30 patients with stage I-IV mantle cell lymphoma reporting very low quality evidence of uncertainty concerning any survival benefit of the addition of rituximab to CHOP (2 year progression free survival: 53%; 2 year overall survival: 59%) compared to those patients treated with conventional chemotherapy regimens not containing rituximab (PFS: 25%, $p=0.083$; OS: 72%, $p=0.807$). Response rates for the two groups did not differ significantly.

DHAP

Very low quality evidence from one phase II trial (Le Gouil *et al.* 2010) indicated an overall response rate of 92% and a complete response rate of 51% in 63 patients with mantle cell lymphoma (median age: 57 years, range: 30-65; 77% stage IV). One RCT (Hermine *et al.* 2012; 2013) comparing the use of CHOP+DHAP+rituximab+ARA-C versus the use of CHOP+rituximab in 455 patients with stage III-IV mantle cell lymphoma (median age 55 years, whole sample ≤ 65 years old) provided moderate quality evidence of significantly higher complete response rates of 36% in the CHOP+DHAP+rituximab+ARA-C compared to 25% in the CHOP+rituximab arm ($p=0.012$) but no difference in overall response rates (95% versus 90%), nor relapse rates after response (40% versus 81%). The patients treated with CHOP+DHAP+rituximab+ARA-C had significantly longer time to treatment failure rates (88 months versus 46 months: $p=0.038$) and better overall survival rates (median not reached versus 88 months; $p=0.045$) compared to patients treated with CHOP+rituximab (median follow-up of 51 months). Adverse events were comparable in the two groups with the exception of grade 3/4 haematological toxicity, which were higher in the CHOP+DHAP+rituximab+ARA-C compared to the CHOP+rituximab group (hemoglobin; white blood count; platelets: 30%; 75%; 74% versus 9%; 50%; 10%, no p values presented to assess significance).

FC

One RCT (Rule *et al.* 2011) comparing the use of FC+rituximab (FCR: Fludarabine, Cyclophosphamide) versus the use of FC alone in 370 patients with mantle cell lymphoma (median age: 66 years, range: 36-88) reported moderate quality evidence for better complete and overall response rates in patients treated with the addition of rituximab (complete: 64.7% versus 46.9%, $p<0.01$; overall: 90.6% versus 79.8%, $p<0.01$). There was no difference in progressive disease rates between the two groups (FCR: 5.8% versus FC: 11.9%). The patients treated with the addition of rituximab had significantly longer progression free (30.6 months versus 16.1 months: hazard ratio [HR]: 0.56, 95% confidence interval [CI] 0.43-0.73, $p<0.001$) and overall survival (45.7 months versus 37 months: HR: 0.72, CI: 0.54-0.97, $p<0.05$) rates (median follow-up 38.8 months) compared to those patients treated with FC alone.

One RCT (Kluin-Nelemans *et al.* 2012) comparing the use of FCR to CHOP+rituximab (RCHOP) in 485 patients with stage II-IV mantle cell lymphoma (median age: 66 years, range: 60-87) provided moderate quality evidence for higher overall response rates in the patients treated with RCHOP (86.2%) compared to the patients treated with FCR (78%) and lower rates of progressive disease (5% versus 14%) but higher complete response rates in the FCR group (39.8%) compared to the RCHOP group (33.9%). However, none of these comparisons were significantly different. Patients treated with RCHOP did have significantly higher overall survival rates (62%) compared to the patients treated with FCR (47%; HR: 1.50, CI: 1.13-1.99, $p=0.005$) (median follow-up 37 months). Rates of grade 1 and 2 anemia, leukocytopenia, constipation and neuropathy were higher in the RCHOP group (68%; 29%; 28%; 36%) compared to the FCR group (59%; 18%; 15%; 7%; $p<0.05$). Rates of grade 1 and 2 elevated bilirubin and nausea were higher in the FCR group (15%; 36%) compared to the RCHOP group (8%; 26%, $p<0.05$). Rates of grade 3 and 4 anaemia and leukocytopenia were higher in the FCR group (20%; 73%) compared to the RCHOP group (12%; 59%, $p<0.05$).

MCP

One RCT (Nickenig *et al.* 2006) comparing the use of MCP (Mitoxantrone, Chlorambucil and prednisolone) versus CHOP in 86 patients with stage III/IV mantle cell lymphoma (median age: 61, range: 35-79) provided low quality evidence of no difference between response rates (complete: 20% versus 15.2%; overall: 72.5% versus 87%) and treatment failures (90% versus 80.4%) in the patients treated with MCP versus those treated with CHOP. There was no significant difference in the 5-year time to treatment failure (MCP: 9% [CI: 0-19] versus CHOP: 20% [8-32], $p=0.08$) nor the overall survival rates (MCP: 48 months, 31% [CI: 15-47] versus CHOP: 61 months, 57% [43-72], $p=0.058$).

One RCT (Herold *et al.* 2007) comparing the use of MCP+rituximab (RMCP) versus MCP alone in 90 patients with mantle cell lymphoma (median age not reported) provided very low quality evidence of no difference between the two groups with regards to complete (RMCP: 31.8% versus MCP: 15.2%, $p=0.082$) and overall (RMCP: 70.5% versus MCP: 63%, $p=0.51$) response rates and progression free survival (RMCP: 20.5 months, 31% versus MCP: 19 months 14%, $p=0.25$), event free survival (RMCP: 19 months, 27% versus MCP: 14 months 11.5%, $p=0.14$) and overall survival rates at 42 months (RMCP: 56 months, 60% versus MCP: 50 months 61%, $p=0.49$) (median follow-up: 43 months).

FLU

One RCT (Zinzani *et al.* 2000) comparing the use of FLU-ID (Fludarabine and Idarubicin) to FLU alone in 29 patients with stage II-IV mantle cell lymphoma (median age not reported) provided low quality evidence of uncertainty in the value of adding Idarubicin to the regimen, with no difference in response rates (complete: FLU-ID: 33.3% versus FLU: 27.3%; FLU-ID: 27.8% versus FLU: 45.5%) or relapse rates after complete response (FLU-ID: 16.7% versus FLU: 33.3%) (median follow-up: 19 months). There were no fatalities resulting from drug-toxic effects.

R-HyperCVAD

Three observational comparative studies (LaCasce *et al.* 2012; Udvardy *et al.* 2012; Miura *et al.* 2011) compared the use of R-HyperCVAD (rituximab, cyclophosphamide, vincristine, doxorubicin,

dexamethasone, high dose methotrexate and cytarabine) to R-CHOP in 197 patients with stage I-IV mantle cell lymphoma (age range: 28 to >60). Two studies (Udvardy *et al.* 2012; Miura *et al.* 2011) provided very low quality evidence of higher complete response rates in the patients receiving R-HyperCVAD (80%) compared to the patients receiving RCHOP (42.3-49%, $p < 0.05$ in the Miura *et al.* 2011 study). One study (LaCasce *et al.* 2012) provided very low quality evidence of lower progressive disease in the patients receiving R-HyperCVAD (37%) compared to the patients receiving RCHOP (72% relative risk: 0.52, CI: 0.36-0.74). Progression free survival was reported to be not significantly different in the Miura *et al.* (2011) study but significantly higher in the R-HyperCVAD group (58% [CI: 44-69]) compared to the RCHOP group (18% [CI: 6-36]) in the LaCasce *et al.* (2012) study ($p < 0.01$). Overall survival rates between the two groups did not differ significantly in both the Miura *et al.* (2011, HR: 0.81, CI: 0.23-2.24) and the LaCasce *et al.* (2012, $p = 0.07$) studies. Udvardy *et al.* (2012) reported that adverse events were significantly higher in R-HyperCVAD group (91.6%) compared to the RCHOP group (55.5%, $p < 0.05$). However, LaCasce *et al.* (2012) reported no significant difference between the two groups concerning rates of febrile neutropenia or the rates of complications requiring hospital admission.

Nordic MCL2

One observational comparative study (Abrahamsson *et al.* 2014) compared seven chemotherapy regimens (CHOP, CHOP/cytarabine, FC, Chlorambucil, cytarabine, CVP, other) to the Nordic MCL2 regimen in 1015 patients with stage I-IV mantle cell lymphoma (median age: 70, range: 28-95) reporting low quality evidence of a poorer survival rate for the patients treated with CVP compared to patients treated with the Nordic MCL2 regimen ($p < 0.001$).

Addition of rituximab to chemotherapy regimens

Three observational comparative studies (Leux *et al.* 2014, Kang *et al.* 2014, Griffiths *et al.* 2011) assessed the addition of rituximab to chemotherapy regimens in 897 patients with stage I-IV mantle cell lymphoma (age range: 26-78). Two studies reported an overall survival benefit from the addition of rituximab. Griffiths *et al.* (2011) provided low quality evidence that the addition of rituximab was associated with significantly lower cancer mortality rates at 2 years (HR for cancer mortality: 0.39, 95% CI: 0.23-0.67, $p < 0.001$) but not non-cancer mortality rates ($p = 0.77$). Patients treated with the addition of rituximab were more likely to be alive two years after beginning their first-line therapy (63%) compared to patients treated with chemotherapy alone (52%, $p < 0.001$). Leux *et al.* (2014) provided very low quality evidence that patients treated with chemotherapy + rituximab had higher median overall survival rates (42 months) compared to those treated with chemotherapy alone (24 months, HR: 0.5, 95% CI: 0.1-0.7). However, Kang *et al.* (2014) provided very low quality evidence of uncertainty in the survival benefit for patients treated with rituximab regimens compared to those treated with non-rituximab containing regimens (Event free survival HR: 1.60, 95% CI: 0.93-2.75; Overall survival HR: 0.89, 95% CI: 0.51-1.54).

One observational comparative study (Abrahamsson *et al.* 2014) compared the addition of rituximab to eight chemotherapy regimens (Nordic MCL2, CHOP, CHOP/cytarabine, FC, Chlorambucil, cytarabine, CVP, other) to the Nordic MCL2 regimen in 1015 patients with stage I-IV mantle cell lymphoma (median age: 70, range: 28-95) reporting low quality evidence of a higher survival rate for the patients treated with regimens that included rituximab compared to patients treated with chemotherapy alone ($p < 0.001$).

Radiotherapy

One observational comparative study (Leitch *et al.* 2003) compared the use of radiotherapy to no radiotherapy in 26 patients with stage I-II mantle cell lymphoma (median age not reported, <60: 7; ≥60: 19) reporting very low quality evidence of a 5-year progression free survival benefit in patients receiving radiation therapy (73%) compared to those patients who received no radiation therapy (13%, $p < 0.05$). Overall survival and response rates were not significantly different between the two groups (median follow-up time: 59 months, range: 5-85).

One observational comparative study (Dabaja *et al.* 2014) compared the use of radiotherapy and chemotherapy to either treatment alone in 160 patients with stage I-II mantle cell lymphoma (median age not reported ≤60: 70. >60: 90) reporting very low quality evidence of no survival benefit when combining the

Non Hodgkin's Lymphoma: diagnosis and management

two treatments (10 year disease free survival rate: 44%; 10 year overall survival rate: 61%) compared to chemotherapy alone (DFS: 40%; OS: 70%) and radiotherapy alone (DFS: 54%, $p=0.44$; OS: 56%, $p=0.68$) (median follow-up time: 60 months, range: 4-245).

One observational study (Abrahamsson *et al.* 2014) provided low quality evidence of a 3 year overall survival rate of 93% in 43 patients with stage I-II mantle cell lymphoma receiving radiotherapy.

Watch and wait

One observational comparative study (Martin *et al.* 2009) compared 97 patients with stage I-IV mantle cell lymphoma receiving early treatment to those undergoing watch and wait (median age not reported, range: 40-89). With a median follow-up time of 42.5 months in the early treatment group and 55 months in the watch and wait group, the study provided very low quality evidence of a median overall survival rate of 64 months (CI: 45-85) in the early treatment group with the median overall survival rate not yet reached the watch and wait ($p=0.004$).

One observational study (Abrahamsson *et al.* 2014) provided low quality evidence of a 3 year overall survival rate of 79% in 29 patients with stage IV mantle cell lymphoma undergoing watch and wait.

GRADE Tables

Grade Profile 1: Rituximab plus CHOP versus CHOP

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		
							Rituximab+ CHOP	CHOP	Relative (95% CI)	Absolute	
Complete response (follow-up median 65 months)											
1	randomised trials ¹	serious ^{2,3}	no serious inconsistency	no serious indirectness	serious ⁴	none	21/63 (33.3%)	4/59 (6.8%)	4.9 (1.793-13.48)	26 more per 100 (from 5 more to 85 more)	⊕⊕00 LOW
Partial response (follow-up median 65 months)											
1	randomised trials ¹	serious ^{2,3}	no serious inconsistency	no serious indirectness	serious ⁴	none	37/63 (58.7%)	40/59 (67.8%)	0.87 (0.66-1.14)	9 fewer per 100 (from 23 fewer to 9 more)	⊕⊕00 LOW
Progressive disease (follow-up median 65 months)

¹ Lenz et al. (2005) and Hoster et al. (2008). Same dataset, with Hoster providing an update of survival rates at 5 years (conference abstract)

² No information on allocation and concealment for randomisation

³ Random assignment was stopped early due to significantly higher overall response rate after induction therapy with R-CHOP as compared with CHOP. Low number of events could overestimate the effect.

⁴ Relative effect and its confidence interval not reported

Grade Profile 2: CHOP versus CVAD

Quality assessment							Summary of findings				
							No of patients		Effect		Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	CHOP	CVAD	Relative (95% CI)	Absolute	
Complete response (follow-up median 24 months¹)											
1	observational studies ²	no serious limitations	no serious inconsistency	no serious indirectness	serious ³	none	11/19 (57.9%)	1/7 (14.3%)	2.32 (0.4064 to 13.1959)	19 more per 100 (from 8 fewer to 174 more)	⊕000 VERY LOW
Partial response (follow-up median 24 months¹)

Grade Profile 9: MCP versus CHOP

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		Quality
							MCP	CHOP	Relative (95% CI)	Absolute	
Complete response											
1	randomised trials ¹	serious ²	no serious inconsistency	no serious indirectness	serious ³	none	8/40 (20%) CI:9-36	7/46 (15.2%) CI: 6-29	RR 1.31 (0.52 to 3.30)	5 more per 100 (from 7 fewer to 35 more)	⊕⊕00 LOW
Overall response											
1	randomised trials ¹	serious ²	no serious inconsistency	no serious indirectness	serious ³	none	29/40 (72.5%) CI:56-85	40/46 (87%) CI:74-95	RR 0.88 (0.67 to 1.04)	10 fewer per 100 (from 29 fewer to 3 more)	⊕⊕00 LOW
Treatment failures											
1	randomised trials ¹	serious ²	no serious inconsistency	no serious indirectness	serious ⁴	none	36/40 (90%)	37/46 (80.4%)	Not reported	10 more per 100 (from 5 fewer to 27 more)	⊕⊕00 LOW
5-year Time to treatment failure											
1	randomised trials ¹	serious ²	no serious inconsistency	no serious indirectness	serious ⁴	none	9% 0-19	20% 8-32	P=0.08	11% fewer treatment failures during 5 year follow-up with MCP	⊕⊕00 LOW
5-year overall survival											
1	randomised trials ¹	serious ²	no serious inconsistency	no serious indirectness	serious ⁴	none	48 months 31% CI:15-47	61 months 57% CI:43-72	P=0.058	Median survival time 1.5 months longer with MCP	⊕⊕00 LOW

¹ Nickenig et al. (2006)

² No information on concealment of randomisation

³ C.I. of effect includes no effect and appreciable benefit or harm

⁴ Effect and its C.I. not reported

Grade Profile 10: Rituximab plus MCP versus MCP

Quality assessment							Summary of findings				
							No of patients		Effect		Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Rituximab+ MCP N=44	MCP N=46	Relative (95% CI)	Absolute	
Complete response (follow-up median 43 months)											
1	randomised trials ¹	serious ²	no serious inconsistency	serious ³	serious ⁴	none	31.8%	15.2%	P=0.082	16.6% more complete responders with RMCP	⊕000 VERY LOW
Overall response (follow-up median 43 months)											
1	randomised trials ¹	serious ²	no serious inconsistency	serious ³	serious ⁴	none	70.5%	63%	P=0.51	7.5% more overall responders with RMCP	⊕000 VERY LOW
Progression free survival at 42 months (follow-up median 43 months)											
1	randomised trials ¹	serious ²	no serious inconsistency	serious ³	serious ⁴	none	20.5 months 31%	19 months 14%	P=0.25	Median time to progression 1.5 months longer with RMCP	⊕000 VERY LOW
Event free survival at 42 months (follow-up median 43 months)											
1	randomised trials ¹	serious ²	no serious inconsistency	serious ³	serious ⁴	none	19 months 27%	14 months 11.5%	P=0.14	Median event free survival 5 months longer with RMCP	⊕000 VERY LOW
Overall survival at 42 months (follow-up median 43 months)											
1	randomised trials ¹	serious ²	no serious inconsistency	serious ³	serious ⁴	none	56 months 60%	50 months 61%	P=0.49	Median survival time 6 months longer with RMCP	⊕000 VERY LOW

¹ Herold et al. (2007)

² Conference abstract. No information on inclusion and exclusion criteria or allocation and concealment of randomisation.

³ No information on the population and how mantle cell lymphoma was diagnosed.

⁴ Relative effect and its C.I. not reported

GRade Profile 11: FLU ID versus FLU

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		Quality
							FLU-ID	FLU	Relative (95% CI)	Absolute	
Complete response (follow-up median 19 months¹)											
1	randomised trials ²	serious ³	no serious inconsistency	no serious indirectness	serious ⁴	none	6/18 (33.3%) CI: 0.163-0.563	3/11 (27.3%) CI: 0.97-0.576	RR 1.22 (0.3811 to 3.9198)	6 more per 100 (from 17 fewer to 80 more)	⊕⊕00 LOW
Partial response (follow-up median 19 months¹)											
1	randomised trials ²	serious ³	no serious inconsistency	no serious indirectness	serious ⁴	none	5/18 (27.8%) CI: 0.125-0.509	5/11 (45.5%) CI: 0.213-0.720	0.61 (0.2278 to 1.6395)	18 fewer per 100 (from 35 fewer to 29 more)	⊕⊕00 LOW
Relapse after complete response (follow-up median 19 months¹)											
1	randomised trials ²	serious ³	no serious inconsistency	no serious indirectness	serious ⁴	none	1/6 (16.7%)	1/3 (33.3%)	0.50 (0.0453 to 5.5141)	17 fewer per 100 (from 32 fewer to 150 more)	⊕⊕00 LOW

¹ Follow-up only reported for total sample of patients with NHL (N=208)

² Zinzani et al. (2000)

³ No information on allocation and concealment of randomisation.

⁴ C.I. of effect includes appreciable benefit and harm

Grade Profile 12: Rituximab-plus HyperCVAD versus Rituximab plus CHOP

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		Quality
							Rituximab+ HyperCVAD	Rituximab+ CHOP	Relative (95% CI)	Absolute	
Overall survival (follow-up median 24-36 months¹)											
2	observational studies ²	serious ³	no serious inconsistency	no serious indirectness	serious ⁴	none	3 yr: 85% (74-92)	3 yr: 69% (46-83)	3 yr: P=0.07 5 yr: HR: 0.81 (0.23-2.24)	-	⊕000 VERY LOW

Design, period	RCT open-label multicentre 2000-2002				
N	121/128				
Follow-up	Median: 18 months				
Funding source	<ul style="list-style-type: none"> – Supported in part by a grant from Deutsche Krebshilfe – One author received honoraria, research funding from Roche 				

Non Hodgkin's Lymphoma: diagnosis and management

Lenz G., et al. (2005). Immunochemotherapy with rituximab and cyclophosphamide, doxorubicin, vincristine, and prednisone significantly improves response and time to treatment failure, but not long-term outcome in patients with previously untreated Mantle Cell Lymphoma: Results of a prospective randomized trial of the German low grade lymphoma study group (GLSG). *Journal of Clinical Oncology*, 23(9); 1984-1992.

In patients up to 65 years of age achieving a complete or partial response after induction therapy, participation in a second randomised trial comparing the progression free survival after myeloablative radiochemotherapy followed by ASCT or IFN α maintenance, was offered.

In April 2002, the sequential test showed a significantly higher overall response rate after induction therapy with R-CHOP as compared with CHOP. However, subgroup analysis revealed that this advantage was mainly due to the benefit detected in MCL patients. The GLSG decided to stop random assignment for MCL patients.

Adverse events
 - Recorded according to the WHO classification

Non Hodgkin's Lymphoma: diagnosis and management

Lenz G., et al. (2005). Immunochemotherapy with rituximab and cyclophosphamide, doxorubicin, vincristine, and prednisone significantly improves response and time to treatment failure, but not long-term outcome in patients with previously untreated Mantle Cell Lymphoma: Results of a prospective randomized trial of the German low grade lymphoma study group (GLSG). *Journal of Clinical Oncology*, 23(9); 1984-1992.

III/IV	61	67
Neurotoxicity		
I/II	42	34
III/IV	2	1
Allergies****		
I/II	0	6
III/IV	0	1

Note. **P<0.01; ****p<0.0001

- Allergic reactions occurred predominately after the first infusion; however, they were of moderate degree and did not require an early cessation of R-CHOP therapy.
- Author states that the difference between levels of granulocytopenia of minor clinical relevance, as infectious complications were not observed more frequently in the R-CHOP group (39%) compared to the CHOP group (35%)

Comments

- Authors note adjustment for multiple testing to maintain the global significance level $\alpha=0.05$
- Assuming overall response rate of 85% following CHOP, an improvement to 95% after R-CHOP was expected. For the rate of CRs, an improvement of 20-40% was considered a clinically relevant goal. Both tests were adjusted to a power of 95% for the expected improvement
- Intention to treat analyses performed
- No information on blinding/concealment
- Low number of events and low sample size.
- Random assignment was stopped early due to significantly higher overall response rate after induction therapy with R-CHOP as compared with CHOP. Low number of events could overestimate the effect.

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2008		Patient Characteristics	Intervention	Comparison	Outcome
Country	Germany	<p><i>Inclusion criteria:</i></p> <ul style="list-style-type: none"> – Untreated patients, >18 years, Ann Arbor stage III or IV follicular lymphoma, mantle cell lymphoma or lymphoplasmacytic lymphoma according to 2001 WHO criteria. Non Hodgkin's Lymphoma: diagnosis and management

Hoster E., et al. (2008). The addition of rituximab to first-line chemotherapy (R-CHOP) results in superior response rates, time to treatment failure and response duration in patients with advanced stage Mantle Cell Lymphoma. Blood, 112: 3049. **CONFERENCE ABSTRACT, ALL INFORMATION FOR PATIENT CHARACTERISTICS AND OUTCOME TAKEN FROM FULL TEXT LENZ (2005) ARTICLE**

comparing the progression free survival after myeloablative radiochemotherapy followed by ASCT or IFN α maintenance, was offered.

In April 2002, the sequential test showed a significantly higher overall response rate after induction therapy with R-CHOP as compared with CHOP. However, subgroup analysis revealed that this advantage was mainly due to the benefit detected in MCL patients. The GLSG decided to stop random assignment for MCL patients.

Results

Table 1. Response and remission rates after CHOP and R-CHOP

	CHOP N=59	R-CHOP N=63 (Lenz reported n=62)
	%	%
CR or PR*	75	92
Complete remission***	8	33

Note. *Only 59 patients assessable, as in one patient, no staging was performed after therapy. *P<0.05; ***p<0.001

Table 2. Survival rates according to type of treatment

	CHOP N=60		R-CHOP N=62	
	n	%	n	%
Median months TTF***	14	-	28	-

5-year Overall survival	-	46	-	59
Overall survival	59 months	-	Median not reached	-

Note. *p<0.05; **p<0.01; ***p<0.001

- Author notes that toxicity was not significantly higher for R-CHOP treated patients

Comments

- Conference abstract
- Numbers differ to those reported in the full text article for factors that you would not assume would change (e.g. recruitment terminated in 2002 with 62 patients in the R-CHOP according to Lenz but it is reported as 63 in this article which changes the response rates.
- Low number of events and low sample size.
- Random assignment was stopped early due to significantly higher overall response rate after induction therapy with R-CHOP as compared with CHOP. Low number of events could overestimate the effect.

	PD	11.9%	5.8%	-	-	-
	Median OS	37 months	45.7 months	0.72	0.54-0.97	0.03
	Median PFS	16.1 months	30.6 months	0.56	0.43-0.73	<0.001
	Note. CI: Confidence interval. HR: Hazard ratio Lymphoma commonest cause of death, but 29% of patients in the FCR arm and 24% in the FC arm died of other causes, of which almost half were infection related. An additional 11 patients died of a second malignancy, 4 of whom had AML. 14% of patients in the FCR arm and 10% in the FC arm died without evidence of disease progression. Significantly more patients in the FCR arm experienced grade 3 or 4 leucopenia and thrombocytopenia however, the numbers of grade 4 were not significantly different (breakdown of % not reported)					

Non Hodgkin's Lymphoma: diagnosis and management

Rule S., et al. (2011). The addition of rituximab to fludarabine and cyclophosphamide (FC) improves overall survival in newly diagnosed mantle cell lymphoma (MCL): results of the randomized UK national cancer research institute (NCRI) trial. Blood 118(440).

Note. Missing data for WHO PS, MIPI and Rituximab.

Table 5. Multivariate analysis on overall survival in patients receiving systemic therapy for MCL, adjusted for gender and MIPI

	Hazard Ratio	95% confidence interval	p value
Nordic MCL2	Ref	Ref	-
CHOP	1.080	0.73-1.59	0.698
CHOP/cytarabine	0.900	0.53-1.52	0.692
FC	1.018	0.61-1.70	0.945
Chlorambucil	1.167	0.73-1.85	0.514
Cytarabine	1.202	0.62-2.33	0.585
CVP	2.827	1.68-4.76	<0.001
Other regimens	1.613	0.97-2.68	0.65
Rituximab	0.660	0.51-0.85	0.001

Note. Hazard ratio ≥1= inferior in terms of overall survival.

- All chemotherapy regimens that did not involve high-dose chemotherapy compared with CHOP adjusted for MIPI, gender and rituximab. Only CVP was found to be significantly inferior in terms of survival (HR=2.23; 95% CIL 1.40-3.56)
- CVP was also compared with chlorambucil, as these regimens frequently used in patients unable to tolerate CHOP or more intensive regimens. Of all patients, 132 received chlorambucil as first-line therapy and 32 patients were treated with CVP. Rituximab was added to 19 of the patients in each group. When adjusting for MIPI, gender and rituximab in multivariate analysis, OS was significantly inferior in the group treated with CVP (HR=2.34; 95%: 1.32-4.14; p=0.003).

Non Hodgkin's Lymphoma: diagnosis and management

Abrahamsson A., et al. (2014). Real world data on primary treatment for mantle cell lymphoma: a Nordic lymphoma group observational study. 124(8); 1288-1295	
	273 patients underwent ASCT (data available for 1143 patients)
Comments	– Study includes 51 patients treated with bendamustine. These patients were excluded from the results section

Non Hodgkin's Lymphoma: diagnosis and management

Dabaja B., et al. (2014). Favourable outcome in stage I-II Mantle Cell Lymphoma: a report of 160 patients from the International Lymphoma Radiation Oncology Group (ILROG). International Journal of Radiation Oncology Biology Physics 90(1 suppl. 1); S151-S152.							
Pub year: 2014		Patient Characteristics			Intervention	Comparison	Outcome
Country	13 ILROG institutions	Retrospectively reviewed 160 patients with stage I or II MCL seen in 13 ILROG institutions between 1990 and 2012.			Combined modality with chemotherapy and consolidative radiation therapy	Each other	Disease free survival (DFS) Overall survival (OS)
Design, period	Observational retrospective comparative study 1990-2012

Non Hodgkin's Lymphoma: diagnosis and management

Bernard M., et al. (2001). Blastic variant of mantle cell lymphoma: a rare but highly aggressive subtype. <i>Leukemia</i> , 15; 1785-1791.						
		Bcl gene rearrangement was assessed using the following three techniques in 28 cases: (1) conventional cytogenetic analyses or FISH detected t(11;14)(q13;q32) in 11 cases. Bcl gene rearrangement using PCR was found in two cases. Using RT-PCR or the slot-blot technique, cyclin D1 overexpression was detected in 15 cases. In the five cases in which molecular analysis could not be performed, histological examination was consistent with blastic form and the cells showed CD5+/CD23- phenotype.

Evidence Statements

Evidence came from one randomised controlled trial and eleven retrospective cohort studies.

Progression free survival

Upfront consolidation with autologous stem-cell transplantation (ASCT) compared to no consolidation or maintenance therapy significantly improved progression free survival rates in patients with mantle cell lymphoma

One RCT (Dreyling *et al.* 2005) reported moderate quality evidence of a longer median progression free survival in 62 patients with mantle cell lymphoma receiving myeloablative radio-chemotherapy (12Gy) and ASCT (39 months, 54%) compared to 60 patients receiving interferon- α maintenance therapy (17 months, 25%) ($p=0.01$). Assessing sub-group analyses by induction therapies the author notes that the difference in progression free survival no longer remained significant when only assessing patients treated with R-CHOP as their induction therapy ($p=0.73$). Lenz *et al.* (2005) reported very low quality evidence of a significant progression free survival benefit of any consolidation therapy (ASCT or interferon- α) in 85 patients with mantle cell lymphoma compared to no post remission treatment in 8 patients with mantle cell lymphoma ($p=0.0002$).

Five retrospective comparative reviews provided very low quality evidence of a progression free survival benefit in 168 patients with mantle cell lymphoma receiving induction therapy and ASCT compared to 129 patients receiving induction therapy alone (Nastoupil *et al.* 2015; Frosch *et al.* 2015; Ahmadi *et al.* 2012; Schaffel *et al.* 2009; Hicks *et al.*, 2006).

Overall survival

The value of consolidation with ASCT on overall survival rates in patients with mantle cell lymphoma varied between studies.

Dreyling *et al.* 2005 reported moderate quality evidence of no difference in the 3-year estimated overall survival rates in 122 patients with stage II-IV mantle cell lymphoma randomised to receive ASCT or interferon- α ($p=0.18$). When comparing consolidation to no further therapy two retrospective comparative studies provided very low quality evidence of no overall survival benefit of ASCT (Nastoupil *et al.*, 2015; Schaffel *et al.*, 2009) whereas four retrospective comparative studies provided very low quality evidence of an overall survival benefit of ASCT (Abrahamsson *et al.*, 2014; Vose *et al.*, 2012; Fieldman *et al.*, 2010; Hicks *et al.*, 2006). However, Fieldman *et al.* (2010) reported that ASCT provided an overall survival benefit only when comparing to patients treated with chemotherapy and rituximab and not when compared to patients treated with R-HyperCVAD. Finally, Cortelazzo *et al.* (2007) reported an increased overall survival rate in patients treated with doxorubicin or cisplatin, rituximab and ASCT compared to patients treated with Anthracycline or fludarabine alone but they did not report significance levels for these comparisons (conference abstract).

Adverse events

The majority of studies did not report any information concerning adverse events following ASCT. Dreyling *et al.* (2005) reported moderate quality evidence of a higher incidence of grade III and IV adverse events (e.g. Mucositis, anaemia, leukocytopenia, granulocytopenia, thrombocytopenia) in 60 patients treated with interferon- α compared to 62 patients treated with ASCT. However, patients treated with ASCT had a higher rate of infection related mortality (5%) compared to the patients treated with interferon- α (0%) (P value not reported). Nastoupil *et al.* (2015) and Mangel *et al.* (2004) provided very low quality evidence of no treatment related deaths in patients in their studies and Cortelazzo *et al.* (2007) reported 1.3% in their patients treated with ASCT compared to 0.8% in the patients receiving anthracycline or cyclophosphamide-fludarabine alone. Mangel *et al.* (2004) provided very low quality evidence of high rates of neutropenia (90%) and mucositis (60%) and moderate rates of pneumonitis (30% after ASCT) in patients treated with ASCT and rituximab maintenance but provided no comparison to the case controls who received induction therapy only. Finally, Frosch *et al.* (2015) provided very low quality evidence of significantly higher adverse events in patients treated with both R-HyperCVAD induction and ASCT (median 4) compared to R-CHOP

Non Hodgkin's Lymphoma: diagnosis and management

and ASCT (median: 2, $p=0.007$), R-HyperCVAD alone (median: 1, $p=0.008$) and R-CHOP alone (median: 1.5, $p=0.016$).

There was no evidence to assess the effectiveness of upfront consolidation with allogeneic transplantation in patients with mantle cell lymphoma

GRADE Tables

Grade Profile 1: ASCT versus Interferon alpha

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Treatment		P value	Effect	Quality
							ASCT	Interferon- α			
Median Progression free survival (median follow-up range: 25-34 months)

Relapse	n=42	-	n=27	-	-
Death in remission	n=0	-	n=3	-	-
Median Progression free survival	17 months	-	39 months	-	0.0108
3 year PFS	25%	12-37%	54%	39-69%	
Intention to treatment, median TTF	15 months	n=116	29 months	n=114	0.0023
Deaths at median 34 month follow-up	19	-	13	-	
Overall survival at 2 years	82%	71-92%	86%	76-95%	
3-year estimated Overall survival	77%	65-88%	83%	73-93%	0.18
Intention to treat, Overall survival	68%	58-78%	76%	66-85%	0.16

PFS and Induction therapy:

- Patients who received CHOP (n=74) and subsequently underwent ASCT (n=39) had a median PFS of 46 months and a 3-year PFS of 62% (95% CI: 44-79%) compared with a median PFS of only 23 months and a 3-year PFS of 27% (95% CI: 11-43%) in patients receiving IFN α (n=35, p=0.019)
- Patients who received CHOP and rituximab (n=32) and subsequently underwent ASCT had a median PFS median not yet met and a 2-year PFS of 51% (95% CI: 21-82%) compared with a median PFS of 17 months and a 2-year PFS of 44% (95% CI: 8-79%) in patients receiving IFN α (p=0.73; follow-up time 12 months)

PFS and response to induction therapy:

- Patients who received transplants in CR (n=22) had a median PFS of 46 months and a 3-year PFS of 71% (95% CI: 28-93%) in comparison to 24 months and 19% (0-38%) in the IFN study group (n=17) (p=0.0019)
- Patients who received transplants in PR (n=40) had a median PFS of 33 months and a 3-year PFS of 45% (95% CI: 26-64%) in comparison to 15 months and 29% (13-45%) in the IFN study group (n=43) (p=0.122)

Overall survival and response:

- No significant differences of the OS so far observed between patients who received transplants in CR and PR

In Cox regression analysis ASCT (Hazard Ratio [HR]: 0.42; p=0.0015) and a low IPI (HR: 0.54; p<0.0001) were independently associated with an improved PFS

Non Hodgkin's Lymphoma: diagnosis and management

Frosch Z., et al. (2015). R-CHOP or R-HyperCVAD with or without autologous stem cell transplantation for older patients with mantle cell lymphoma. *Clinical Lymphoma, Myeloma and Leukemia*, 15(2), 92-97.

Reason for not undergoing ASCT:

- Physician preference: 6
- Patient preference: 5
- Not possible to collect adequate stem cells: 1

Adverse events:

- No ASCT-related mortality
- Infection (15 patients, 71%) and Mucositis requiring patient-controlled analgesia or nutritional support (8 patients, 38%)
- 5 patients (24%) required a stay in the intensive care unit, and 4 patients (19%) required readmission after discharge within 100 days for ASCT-related complications
- Patients treated with R-CHOP+ASCT experienced a median of 2.0 total adverse events from induction and consolidation combined, whereas patients treated with R-HyperCVAD alone had a median of 1.0 adverse event (p=0.297)
- Patients treated with both R-HyperCVAD induction + ASCT (median of 4.0) significantly more than with R-CHOP+ASCT (median of 2.0, p=0.007), R-HyperCVAD alone (median 1.0; p=0.008) and R-CHOP alone (median: 1.5; p=0.016)

Table 2. Survival rates according to treatment group

	a. R-CHOP+ASCT n=14	b. R-HyperCVAD+ASCT n=7	c. R-HyperCVAD alone n=5	d. R-CHOP alone n=12
Progression free survival	3.2	0.9	4	1.6

a versus c p=0.013
a versus d p=0.009
All other comparisons not statistically significantly different

No significant differences in overall survival

6 recipients of R-HyperCVAD alone (50%) received rituximab maintenance.
1 patient of R-CHOP+ASCT received rituximab maintenance
No difference in PFS between those who received rituximab maintenance after R-HyperCVAD and those who received R-HyperCVAD alone (p=0.410)

- Response to induction for the ASCT-Rituximab group: 100% (8 patients, 40% attaining complete remission [CR] or unconfirmed CR [Cru], and 12 [60%] achieving a partial remission [PR])
 - One patient in the control group received ASCT
- Toxicity:
- 1 reactivation of hepatitis B during induction
 - 18/20 patients experienced febrile neutropenia during transplant
 - 13/20 mucositis (5/13 grade 3 severity)
 - 2 patients required brief transfers to the coronary care unit: 1 for atrial fibrillation with a rapid ventricular response; 1 for chest pain and hypotension
 - No transplant related mortality
 - Post-transplant: 6 cases of interstitial pneumonitis (resulting in a dose reduction in BCNU)
 - No significant infusion-related toxicities during rituximab administration but two patients experienced transient neutropenia during treatment
 - No data available on toxicity in the control patients

Evidence Statements

Evidence came from two randomised controlled trials and four retrospective cohort studies.

Efficacy of maintenance therapy post-induction

Three studies reported the effectiveness of rituximab maintenance after first-line induction therapies in 349 patients with mantle-cell lymphoma, suggesting that the use of rituximab maintenance significantly increases duration of remission (Kluin-Nelemans *et al.*, 2012) and progression free survival (Ahmadi *et al.*, 2012; Vokurka *et al.*, 2014) compared to other types of maintenance therapy (interferon- α) or no maintenance therapy at all ($p < 0.05$).

One randomised control trial (RCT; Kluin-Nelemans *et al.*, 2012) comparing the use of rituximab maintenance therapy to the use of Interferon- α maintenance therapy in 316 patients with stage II-IV mantle cell lymphoma provided low quality evidence of longer durations of remission in the patients receiving rituximab compared to those receiving interferon- α ($P < 0.01$). Overall survival rates did not differ significantly between the rituximab and interferon- α groups (79% versus 67%, respectively), however, the author reports that type of induction therapy influenced the survival benefit of rituximab maintenance. In the 111 patients treated with the induction regimen R-FC there was no difference in the rates of remission nor the overall 4-year survival rate in patients treated with rituximab maintenance compared to those treated with interferon- α . Patients ($N = 163$) treated with the induction regimen R-CHOP did show survival benefits from the use of rituximab maintenance, with such patients having longer duration of remission (not yet reached versus 36 months, $p < 0.01$) and better 4-year overall survival rates (not yet reached versus 64 months, $p < 0.01$) compared to patients treated with interferon- α . Patients tolerated rituximab maintenance better than interferon- α , with a third of patients in the rituximab maintenance group stopping therapy at 4 years (28%) compared to nearly 50% of patients in the interferon- α group at 1 year. In addition, patients receiving interferon- α experienced significantly higher rates of grade 3 and 4 leukocytopenia (33% versus 19%), thrombocytopenia (15% versus 6%), fatigue (5% versus 1%) and Infection (11% versus 9%) ($p < 0.05$) compared to patients receiving rituximab maintenance.

Two retrospective comparative studies compared rituximab maintenance therapy to no additional therapy (Ahmadi *et al.*, 2012; Vokurka *et al.*, 2014) and to autologous stem cell transplantation (ASCT) (Ahmadi *et al.*, 2012) in 101 patients with mantle cell lymphoma reporting very low quality evidence of longer progression free survival in those receiving maintenance compared to no further therapy ($P < 0.05$). Overall survival was not reported by either study with Vokurka *et al.* (2014) noting that the follow up was not yet long enough to assess overall survival. Ahmadi *et al.* (2012) reported no statistically significant difference between maintenance and consolidation therapy (3.9 years versus 4.5 years).

Efficacy of maintenance therapy post-consolidation

Three studies compared the effectiveness of rituximab maintenance after first-line consolidation therapy with autologous stem-cell transplantation, reporting a significant benefit, with patients receiving the additional maintenance therapy having an increased event free (Le Gouill *et al.*, 2014) and progression free survival rate (Vokurka *et al.*, 2014; Mangel *et al.*, 2004 [update data from: Hicks *et al.*, 2006]) compared to those who did not. There was variation in the overall survival benefit of rituximab maintenance in these studies.

One randomised control trial (RCT; Le Gouill *et al.*, 2014; conference abstract) comparing the use of rituximab maintenance therapy to watch and wait in 238 patients with mantle cell lymphoma all treated with ASCT provided low quality evidence of significantly longer event free and progression free survival ($p < 0.05$) in the patients receiving the maintenance therapy. There was however, no significant difference in the 2-year overall survival rates between the patients receiving maintenance (93.4%) compared to those patients undergoing watch and wait (93.9%).

One retrospective cohort study (Vokurka *et al.*, 2014) provided very low quality evidence of a significant progression free survival benefit in 14 patients receiving rituximab maintenance (median not yet reached) compared to 12 patients receiving no maintenance therapy (46 months, $p < 0.05$).

Non Hodgkin's Lymphoma: diagnosis and management

One retrospective cohort study (Mangel *et al.*, 2004, updated data in conference abstract by Hicks *et al.*, 2006) provided very low quality evidence of a significant progression free and overall survival benefit in 20 patients with mantle cell lymphoma receiving consolidation (ASCT) plus rituximab maintenance (5 year: 72%, 80%) compared to 40 patients with mantle cell lymphoma receiving conventional induction chemotherapy alone (19% P<0.001; 38%, P<0.01).

GRADE Tables

Grade Profile 1: Rituximab versus interferon alpha

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Treatment		Effect		
							Rituximab	Interferon- α	P value	Absolute	
Duration of remission											
1	Randomised control trial ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious imprecision ³	none	75 months	27 months	P=0.001	48 more months of remission after Rituximab maintenance therapy	⊕⊕00 LOW
4-year remission rate											
1	Randomised control trial ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious imprecision ³	none	58%	29%	P=Not reported	29% higher remission rates after Rituximab maintenance therapy	⊕⊕00 LOW
4-year overall survival											
1	Randomised control trial ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious imprecision ³	none	79%	67%	P=n.s.	12% better survival rates after Rituximab maintenance therapy	⊕⊕00 LOW
Leukocytopenia grade 3 and 4											
1	Randomised control trial ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious imprecision ³	none	19%	33%	P=0.01	14% fewer incidences of leukocytopenia after Rituximab maintenance therapy	⊕⊕00 LOW
Thrombocytopenia grade 3 and 4											
1	Randomised control trial ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious imprecision ³	none	6%	15%	P=0.01	10% fewer incidences of thrombocytopenia after Rituximab maintenance therapy	⊕⊕00 LOW
Fatigue grade 3 and 4											
1	Randomised control trial ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious imprecision ³	none	1%	5%	P=0.001	4% fewer incidences of fatigue after Rituximab maintenance therapy	⊕⊕00 LOW
Infection grade 3 and 4											
1	Randomised control trial ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious imprecision ³	none	9%	11%	P=0.05	2% fewer incidences of infection after Rituximab maintenance therapy	⊕⊕00 LOW

Note. ¹Kluin-Nelemans et al. (2012). ²No information on allocation and concealment of treatment arms. ³Relative effect and confidence interval not reported. Small sample size and low event rates, especially for the subgroup analyses means that C.I.s are likely to be large. N.s.: not significantly different.

Grade Profile 2: Rituximab versus no Rituximab

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Treatment		Effect		Quality
							Rituximab	No Rituximab	P value	Absolute	
Median Progression free survival											
2	observational studies ^{1,2}	Serious ³	No serious inconsistency	Serious ⁴	Serious ⁵	none	Not yet reached-3.9 years	20 months - 2.3 years	P<0.05	-	⊕000 VERY LOW
2-year Progression free survival											
2	observational studies ^{1,2}	Serious ³	No serious inconsistency	Serious ⁴	Serious ⁵	none	86%	26%	P=Not reported	60% more progression free survival after Rituximab maintenance therapy	⊕000 VERY LOW

Note. ¹Ahmadi et al. (2012). ²Vokurka et al. 2014. ³Unclear reason for allocation to the different post-induction treatment options. ⁴Ahmadi et al.: 6/44 patients had received prior treatment (13.6%), breakdown was not provided by treatment groups. ⁵ Relative effect and confidence interval not reported. N.s.: not significantly different.

Grade Profile 3: Rituximab versus ASCT

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Treatment		Effect		Quality
							Rituximab	ASCT	P value	Absolute	
Median Progression free survival											
1	observational studies ¹	Serious ²	No serious inconsistency	Serious ³	Serious ⁴	none	3.9 years	4.5 years	P=n.s	-	⊕000 VERY LOW

Note. ¹Ahmadi et al. (2012). ²Unclear reason for allocation to the different pos-induction treatment options. ³6/44 patients had received prior treatment (13.6%), breakdown was not provided by treatment groups. ⁴ Relative effect and confidence interval not reported.. N.s.: not significantly different.

Grade Profile 4: ASCT plus rituximab versus ASCT plus watch and wait

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Treatment		P value	Effect	Quality
							ASCT + Rituximab	ASCT + Watch and wait		Absolute	
2-year event free survival											
1	Randomised control trial ¹	Very Serious ^{2,3}	No serious inconsistency	No serious indirectness	No serious imprecision	none	93.2% 95% CI: 86.9-96.6	81.5% 95% CI: 72.7-87.7	P=0.015	11.7% fewer events after Rituximab maintenance therapy	⊕⊕00 LOW
Overall survival											
1	Randomised control trial ¹	Very Serious ^{2,3}	No serious inconsistency	No serious indirectness	No serious imprecision	none	93.4% 95% CI: 86.6-96.9	93.9% 95% CI: 86.7-97.3	P=n.s.		⊕⊕00 LOW

Note. ¹Le Gouill et al. (2014). ²No information on allocation concealment of treatment arms. Conference abstract with very limited information to appraise randomization, and patient selection biases. N.s.: not significantly different. CI: Confidence interval

Grade profile 5: ASCT plus rituximab versus no rituximab

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Treatment		P value	Effect	Quality
							ASCT + Rituximab	No Rituximab		Absolute	
3 year Progression free survival											
1	observational studies ^{1,2}	Very Serious ^{2,3}	No serious inconsistency	No serious indirectness	Serious ⁴	none	89%	29%	P=0.0001	60% more progression free survival after Rituximab maintenance therapy	⊕000 VERY LOW
5 year Progression free survival											
1	observational studies ^{1,2}	Very Serious ^{2,3}	No serious inconsistency	No serious indirectness	Serious ⁴	none	72%	19%	P=0.001	53% more progression free survival after Rituximab maintenance therapy	⊕000 VERY LOW
3 year Overall survival											
1	observational studies ^{1,2}	Very Serious ^{2,3}	No serious inconsistency	No serious indirectness	Serious ⁴	none	88%	65%	P=n.s.	-	⊕000 VERY LOW
5 year Overall survival											
1	observational studies ^{1,2}	Very Serious ^{2,3}	No serious inconsistency	No serious indirectness	Serious ⁴	none	80%	38%	P=0.01	42% better survival rates after Rituximab maintenance therapy	⊕000 VERY LOW

Note. ¹Mangel et al. (2004). ²Hicks et al. (2006). Hicks provides an update on survival rates using the same dataset as Mangel et al. (2004). ³Unclear reason for allocation to the different post-induction treatment options. Unclear if participant characteristics differed significantly at baseline as authors provided no statistical analyses. ⁴Variation in induction therapies within the control comparison group with some patients receiving radiotherapy and/or intrathecal chemotherapy. ⁵Relative effect and confidence interval not reported. N.s.: not significantly different.

Grade Profile 6: ASCT plus rituximab versus ASCT

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Treatment		Effect		Quality
							ASCT+ Rituximab	ASCT	P value	Absolute	
Median Progression free survival											
1	observational studies ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious ³	none	Not yet reached	46 months	P=0.05	-	⊕000 VERY LOW
2 year Progression free survival											
1	observational studies ¹	Serious ²	No serious inconsistency	No serious indirectness	Serious ³	none	95%	75%	P=not reported	20% more progression free survival after Rituximab maintenance therapy	⊕000 VERY LOW

Note. ¹Vokurka et al. (2012). ²Unclear reason for allocation to the different post-induction treatment options. ³Relative effect and confidence interval not reported.. N.s.: not significantly different.

- Response to induction for the ASCT-Rituximab group: 100% (8 patients, 40% attaining complete remission [CR] or unconfirmed CR [Cru], and 12 [60%] achieving a partial remission [PR])
 - One patient in the control group received ASCT
- Toxicity:
- 1 reactivation of hepatitis B during induction
 - 18/20 patients experienced febrile neutropenia during transplant
 - 13/20 Mucositis (5/13 grade 3 severity)
 - 2 patients required brief transfers to the coronary care unit: 1 for atrial fibrillation with a rapid ventricular response; 1 for chest pain and hypotension
 - No transplant related mortality
 - Post-transplant: 6 cases of interstitial pneumonitis (resulting in a dose reduction in BCNU)
 - No significant infusion-related toxicities during Rituximab administration but two patients experienced transient neutropenia during treatment
 - No data available on toxicity in the control patients

Table 2. Survival rates according to treatment group

Exocrine pancreatic deficiency	1	0	0	0
Pulmonary fibrosis	1	0	0	0
Musculoskeletal disorders	2	0	0	0
Pulmonary embolism	1	0	0	0

Note #Patients whose bulk was surgically removed and who did not receive RT as planned in protocol are not included in the analyses (11). Follow-up available in 65/67 patients.## Follow-up available in 29/35 patients.

Evidence Statements

Evidence came from four cohort studies (one prospective).

Compared to immunochemotherapy alone, immunochemotherapy + consolidation radiotherapy is associated with similar or longer overall survival (4 observational studies [Dorth *et al.*, 2012; Held *et al.*, 2014; Marcheselli *et al.*, 2011; Phan *et al.*, 2010]; total N = 1200; very low quality evidence), longer event-free survival (3 observational studies [Dorth *et al.*, 2012; Held *et al.*, 2014; Marcheselli *et al.*, 2011]; total N = 731; very low quality evidence), similar or longer progression-free survival (2 observational studies [Held *et al.*, 2014; Phan *et al.*, 2010]; total N = 939; very low quality evidence), similar or higher rates of complete response (1 observational study [Held *et al.*, 2014]; total N = 470; very low quality evidence), similar or higher rates of treatment-related mortality (1 observational study [Held *et al.*, 2014]; total N = 470; very low quality evidence), and similar or higher rates of treatment-related morbidity (1 observational study [Held *et al.*, 2014]; total N = 470; very low quality evidence).

GRADE Tables

Grade Profile1: Immunochemotherapy plus radiotherapy (RT) versus immunochemotherapy (noRT)

Non Hodgkin's Lymphoma: diagnosis and management

<p>Dorth et al. (2012). Impact of consolidation radiation therapy in stage III-IV diffuse large B-cell lymphoma with negative post-chemotherapy radiologic imaging. International Journal of Radiation Oncology, Biology, Physics, 84: 762-767.</p>					
		<p>International Harmonization Project in Lymphoma". "Post-chemotherapy CT scans were interpreted as negative if there were no sites of residual lymphadenopathy greater than 1 cm. Patients achieving a negative interim PET/gallium scan did not routinely have functional imaging performed at the completion of chemotherapy. All patients who had a positive interim PET/gallium scan had an additional study performed at least 2 weeks after the last cycle of chemotherapy."</p> <p>"Post-chemotherapy imaging consisted of PET/CT in 73% of patients, gallium and CT in 14% of patients, and CT only in 13% of patients."</p>	<p>targeting uninvolved regions". "Megavoltage radiation was delivered in 1.8- to 2-Gy fractions to a median dose of 25 Gy (range, 18-40 Gy)."</p>	<p>occurred first").</p> <p>Overall survival ("the time from completion of chemotherapy until death as a result of any cause").</p>	
<p>Results</p>	<p><u>RT treatments received:</u> RT group: "Most patients were treated with consolidation RT to all sites of initial disease (n = 24 [63%]), although 14 patients (37%) were treated at select sites, given individual clinical scenarios."</p>				
	<p>All patients:</p>				
		<p>noRT</p>	<p>RT</p>	<p>Unadjusted/univariate analysis</p>	<p>Adjusted/multivariate analysis*</p>
	<p>N</p>	<p>41</p>	<p>38</p>		
	<p>5-year in-field control (95% CI)</p>	<p>69 (55-88)%</p>	<p>92 (83-100%); p = 0.028</p>	<p>HR = 3.85, p = 0.04, favouring RT</p>	<p>HR = 8.01 (1.5-41.79), p = 0.014, favouring RT</p>
<p>5-year overall survival (95% CI)</p>	<p>78 (64-96)%</p>	<p>85 (73-98%); p = 0.015</p>	<p>HR = 2.11, p = 0.16.</p>	<p>HR = 2.08 (0.57-7.59), p = 0.28</p>	
<p>5-year event-free survival</p>	<p>65 (50-84)%</p>	<p>85 (73-92%); p = 0.014</p>	<p>HR = 3.18, p = 0.02, favouring RT</p>	<p>HR = 4.3 (1.3-13.8), p = 0.014, favouring RT</p>	
<p>Note. It is unclear of the event-free survival results are reported at 5 years. *These analyses were adjusted for IPI score, tumour diameter and rituximab.</p>					
<p><u>Secondary malignancies:</u> "One patient, a former smoker, received consolidation RT to the neck, bilateral axilla, and lumbar spine. He was diagnosed with lung cancer arising in the right hilum (outside the radiation field) 4 years later. One patient who did not receive RT was diagnosed with a colon cancer 6 years after treatment and was managed successfully with surgery and adjuvant chemotherapy. There were no other secondary malignancies among the 79 patients included in this study during the follow-up period."</p>					
<p>Study quality and Comments</p>	<p>Applicability: Please note that 10/41 patients in the noRT group and 12/38 patients in the RT group did not receive rituximab, and are therefore not applicable to the question.</p> <p>Selection bias: High risk (patients were not randomised to treatment, and the treatment groups differed at baseline [noRT patients had smaller tumours than RT patients])</p> <p>Performance bias: High risk (it is unclear whether the patients received the same care apart from comparison treatment, no mention of any blinding, but unlikely to have taken place)</p> <p>Attrition bias: Unclear risk (length of follow up is not reported split by treatment group, so it is unclear if it differed between the groups, no data reported for toxicities for any of the groups)</p> <p>Detection bias: High risk (unclear what follow up the treatment groups received, outcome definitions and measurement specified, no blinding of outcome assessor)</p>

	3-year OS, % (95% CI)	90 (84-97)	65 (49-81)	p = 0.001	3-year OS, HR (95% CI), p-value	4.3 (1.7-11.1), p = 0.002
	Patient death:	10/78	13/35			
	Treatment-related death, n	2	4			
	Lymphoma-related death	6	8			
	Other death reason	2	1			
Note The multivariable analysis adjusted for IPI factors (i.e., age > 60 years, lactate dehydrogenase > normal, ECOG PS > 1, stages III and IV, and extra lymphatic involvement > 1). In addition age > 70 was also adjusted for as this was a stratification variable during randomisation in the RICOVER-60 trial						
Persistent toxicities during follow up in RT patients who underwent RT and in noRT patients who did not:						
		RT (n = 67)*		noRT (n = 35)**		
		All grades	Grade III-IV	All grades	Grade III-IV	
	Immune system disorders	0	0	1	0	
	Periphreal neuropathy	19	0	8	0	
	Dysgeusia	0	0	1	0	
	Cardiac disorders	0	0	1	1	
	Exocrine pancreatic deficiency	1	0	0	0	
	Pulmonary fibrosis	1	0	0	0	
	Musculoskeletal disorders	2	0	0	0	
	Pulmonary embolism	1	0	0	0	
Note * Patients whose bulk was surgically removed and who did not receive RT as planned in protocol are not included in the analyses (11). Follow-up available in 65/67 patients.** Follow-up available in 29/35 patients.						
Study quality and Comments	Selection bias: High risk (patients were not randomised to treatment, and the treatment groups differed at baseline [noRT patients were older, more often had stage III or IV disease and extralymphatic involvement, but they less often had bulky disease]) Performance bias: High risk (it is unclear whether the patients received the same care apart from experimental treatment, no mention of any blinding, but unlikely to have taken place) Attrition bias: High risk (length of follow up differed between the groups, data missing for toxicities for chemotherapy for a large proportion of patients in both groups) Detection bias: High risk (unclear what follow up the treatment groups received, outcome definitions and measurement underspecified, no mention of blinding of outcome assessor)					

Non Hodgkin's Lymphoma: diagnosis and management

Marcheselli et al. (2011). Radiation therapy improves treatment outcome in patients with diffuse large B-cell lymphoma. <i>Leukemia & Lymphoma</i> , 52, 1867-72.																																																																																
Pub year: 2011		Patient Characteristics			Intervention	Comparison	Outcome																																																																									
Country	Italy	Patients were retrieved from the Gruppo Italiano Studio Linformi (GISL) archive. <i>Inclusion criteria:</i> - Patients aged > 18 years with histologically confirmed diagnosis of CD20+ DLBCL, previously untreated, no primary central nervous system, no HIV, no hepatitis B or C virus, no severe coincident illnesses, and available data on their clinical and laboratory characteristics. Treatments, outcome and follow-up. Patients included in this study were enrolled in two GISL clinical trials (Anzinter 3, ClinicalTrials.gov Identifier NCT148446; and LA05, ClinicalTrials.gov Identifier NCT00866203) <i>Exclusion criteria:</i> - Not further reported, but 34/216 patients enrolled in the two GISL protocols between 2003 and 2007 received < 6 cycles of R-CHOP or achieved < a PR and were excluded from the study. The remaining 182 patients (153 CR, 29 PR) were the target cohort for the study. Baseline characteristics:			<u>Group RT:</u> 6 cycles of R-CHOP + involved-field RT "At the completion of chemotherapy, consolidative or adjuvant IFRT was allowed, at the treating physician's discretion, in patients who had obtained complete (CR) or partial (PR) remission, because the trial protocols did not specify how RT was to be used. It is assumed that IFRT was more likely to be given to patients with previously bulky disease, disease with extranodal involvement, and disease that failed to achieve CR upon chemotherapy."	<u>Group noRT:</u> 6 cycles of R-CHOP	Event-free survival (EFS: time from the end of chemotherapy to the last follow up or one of the following events: progression, relapse, or death from any cause). Overall survival (OS: time from the end of chemotherapy to the last observation or death from any cause).

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2010		Patient Characteristics				Intervention	Comparison	Outcome
Country	USA	Patients were retrieved from the Gruppo Italiano Studio Linformi (GISL) archive. <i>Inclusion criteria:</i> - The records of 491 patients who were referred to M. D. Anderson with DLBCL between January 2001 and December 2007 were reviewed. "A total of 469 patients with a histologically confirmed diagnosis of DLBCL were included in the analysis." <i>Exclusion criteria:</i> - Not further reported, but "Twenty-two patients were excluded either for lack of pathology confirmation or because they were not treated at M. D. Anderson." Baseline characteristics:				RT v noRT: "A total of 394 patients (84%) were given R-CHOP: 327 patients received six to eight cycles of R-CHOP (121 patients had stage I or II disease), and 67 patients received fewer than six cycles of R-CHOP. Other chemotherapy regimens administered include rituximab plus hyperfractionated cyclophosphamide, vincristine, doxorubicin, and dexamethasone in 53 patients (11.3%) and other regimens in 20 patients (4%). One hundred forty-two (30.2%) of 469 patients were given RT. Of the 190 patients with stage I or II disease, RT was given to 103 patients (49 of 103 had bulky disease). RT was given to 39 of 279 patients with stage III or IV (23 of 39 patients had bulky disease)." <i>No further information reported.</i>	Progression-free survival (PFS) Overall survival (OS)

Study quality and Comments	<p>Applicability: The population is mixed across of stages and treatments, and the results are only applicable to the extent that the relevant results for the current question can be extracted therefrom.</p> <p>Selection bias: High risk (patients were not randomised to treatment, and the treatment groups differed at baseline [noRT patients more often had stage III or IV disease and a high IPI score, but they less often had bulky disease])</p> <p>Performance bias: High risk (it is unclear whether the patients received the same care apart from comparison treatment, no mention of any blinding, but unlikely to have taken place)</p> <p>Attrition bias: Unclear risk (length and type of follow up is not reported split by treatment group, so it is unclear if it differed between the groups, no data reported for toxicities for any of the groups)</p> <p>Detection bias: High risk (unclear what follow up the treatment groups received, outcome definitions and measurement underspecified, no mention of blinding of outcome assessor)</p>																																																																																			

4.4.2: Review question: What are the risk factors associated with central nervous system (CNS) relapse in patients with diffuse large B-cell lymphoma?

PICO Table

Population	Factors	Outcomes
Adults and young people (16 years and older) newly diagnosed with diffuse large B-cell lymphoma.	Patient characteristics Disease characteristics International prognostic index (IPI) score Lactate dehydrogenase (LDH) Extranodal disease Cerebrospinal fluid (CSF) detection of occult disease Disease site: Testicular, bone marrow, pharynx, facial sinus, breast, primary bone, para-spinal, epidural, kidney	CNS relapse Time to relapse Sites of relapse Isolated to CNS compared to systemic relapse General relapse Parenchymal Meningeal
Additional Comments on PICO		
First-line treatment only Date limit: publications ≥2003 Sifting update: Fletcher et al. (2014) systematic review concerning prognostic factors for CNS relapse had the following inclusion criteria: ≥18 years with histologically proven aggressive B-cell lymphoma Trials conducted from 1994-2013 Exclusion criteria: Immuno-compromised patients, studies with T-cell lymphoma as primary histology, patients with primary CNS lymphoma, Studies performed on patients with intravascular lymphoma or the very 'aggressive' lymphomas (BL or Burkitt-like histology), trials adding chemotherapy without known/appreciable CNS penetration, trials not reporting CNS related data, lack of peer review or clear peer review process, publications including <25 patients. Fletcher et al. (2014): systematic review and ordered all papers included in the review then re-sifted and ordered all articles published from 2013 onwards.		

Study Quality

Figure 1. Study flow diagram

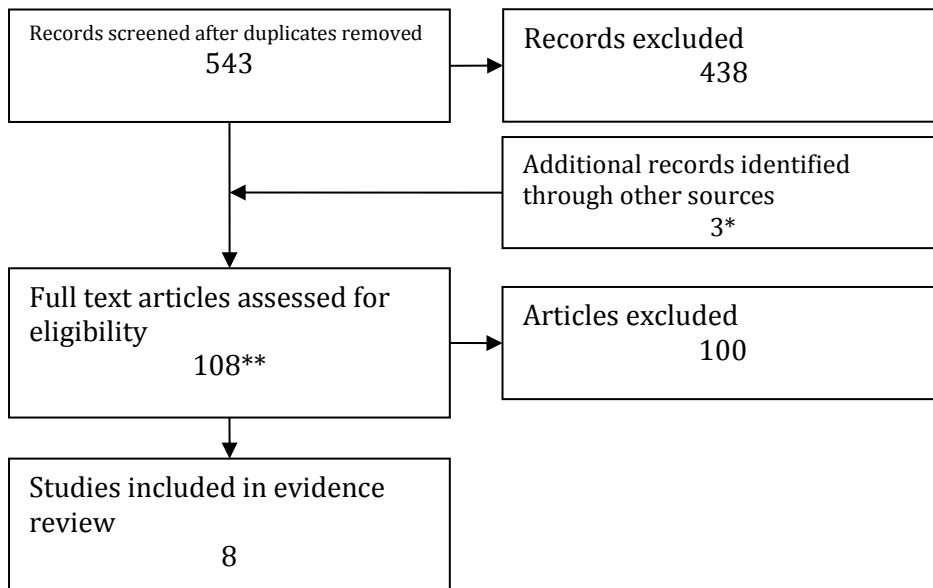

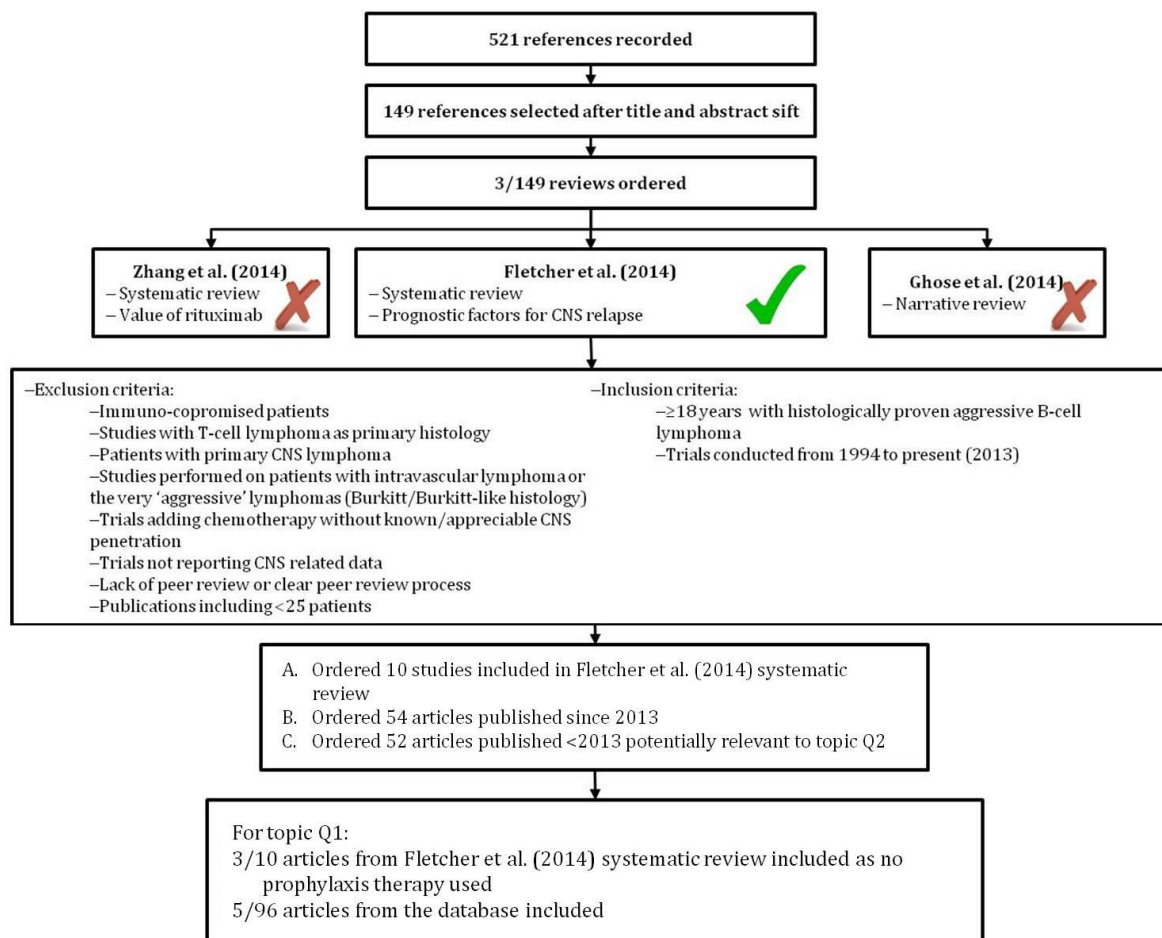

Figure 2. Rationale for inclusion of 8 articles in review

Quality of the evidence

The main challenges to the validity of the evidence as a whole concerned (1) variation in how the outcome (CNS relapse) was measured with two studies using clinical and neurological symptoms alone compared to radiographic and cerebrospinal fluid assessment as standard in the remaining studies; (2) a lack of information from conference abstracts about the prognostic factors included and statistical analyses, and (3) the included samples of participants representing a 'reduced risk' population, with those at highest risk of CNS relapse being treated up-front with prophylaxis under individual hospital protocols. Whilst, only a hypothesis, this could explain the lack of consistency in the results of relevant prognostic factors (because allocation to prophylaxis varied across hospital institutions) and the lack of evidence supporting known CNS relapse risk factors (e.g., involvement of the testis).

Table 1. Summary of the risk of bias associated with each of the included studies

Summary Tables

Table 2. Study characteristics and prognostic factors considered related to Central Nervous System (CNS) relapse

Study	N	Disease	Stage	Population	Treatment	N CNS relapse	Factors considered	Independent prognostic factors
Feugier, 2004 France RCT	399	DLBCL 49 mis-diagnosed at pathology review (4 of the 20 CNS relapse patients)	II-IV	Inclusion criteria: Untreated elderly (60-80 years old), diagnosed according to the Revised European-American Lymphoma classification or the WHO classification. Performance status 0-2 (ECOG) Exclusion criteria: CNS involvement at diagnosis	RCHOP=202 CHOP=197	20 5% (11 RCHOP; 9 CHOP)	Age ($\leq 65/65-70/ >70$), Gender, LDH (elevated/normal), Stage (1-2/3-4), B symptoms, performance status (0-1/ >1), extranodal sites (0-1/ <1), age adjusted IPI,	Multivariate without age adjusted IPI: Poor performance status, elevated LDH Multivariate with age adjusted IPI: Age adjusted IPI 0 and 1 versus 2 and 3: odds ratio=3.05, 95% CI: 1.58-5.88
Morabito, 2005 Italy Retrospective Review	623	DLBCL	NR	NR	PROMACE-CytaBOM	11 1.8%	NR	Multivariate: Elevated LDH (RR=5.49, p=0.042) >1 extranodal site (RR=5.86, p=0.019) White blood cell count above 10_109/l (RR=1.22, p=0.001)
Yamamoto, 2010 Japan Retrospective Review	375	DLBCL	I-IV	Inclusion criteria: Newly diagnosed and received CHOP or RCHOP (every 3 weeks) chemotherapy as the primary treatment Exclusion criteria: CNS involvement at diagnosis Received any CNS prophylaxis during clinical course	RCHOP=195 CHOP=167	13 3.5% (8 RCHOP; 5 CHOP)	Age ($\leq 60/ >60$), Gender, LDH ($\leq N/ >N$; $\leq 2N/ >2N$), Stage (1-2/3-4), B symptoms, performance status (0-1/2-4), extranodal sites ($<2/ \geq 2$), Bulky mass, bone marrow involvement, IPI, treatment (low-low intermediate/ high intermediate-high), treatment, systemic relapse	Multivariate showed no independent predictor of CNS involvement When only conducted on RCHOP group, no independent predictor of CNS involvement
Tomita, 2012 Japan	1221	DLBCL	I-IV	Inclusion criteria: De novo CD20+ disease and undergone primary therapy	RCHOP	82 6.7%	Age ($\leq 60/ >60$), Gender, Stage (1-2/3-4), LDH (Elevated/normal; $\leq 2N/2N$), Performance	Multivariate: Age (RR: 2.0, 95% CI: 1.2-3.4; p=0.011)

Non Hodgkin's Lymphoma: diagnosis and management

Study	N	Disease	Stage	Population	Treatment	N CNS relapse	Factors considered	Independent prognostic factors
Retrospective Review				between September 2003 and December 2006, ≥15 years old age Exclusion criteria: Primary CNS and intraocular lymphoma; distinct forms of DLBCL, such as intravascular lymphoma, primary effusion lymphoma and primary mediastinal large B-cell lymphoma; patients who received any CNS prophylaxis during the clinical course; initial CNS involvement at presentation; patients with active cancer; patients with HIV infection			status (0-1/2-4), B symptoms, IPI (low-low intermediate/ high intermediate-high), extranodal sites (0-1/≥2), individual sites	Breast (RR: 10.6, 95% CI: 4.2-26.4; p<0.001) Adrenal gland (RR: 4.6, 95% CI: 1.6-13.1, p<0.005) Bone (RR: 2.0, 95% CI: 1.1-4.0; p=0.034)
Schmitz, 2013 Germany Retrospective Review Conference abstract	2164	Aggressive B-cell lymphoma	NR	Inclusion criteria: 18-80 years of age who had been treated with modern therapies including rituximab and CHOEP. All patients treated on prospective studies of the German High Grade NHL Study Group (DSHNHL) and represent all age groups and IPI scores Exclusion criteria: Not reported	Rituximab and CHO[E]P	~65 3%	Not reported	Age >60 years LDH>normal Stage 3 or 4 ECOG >1 Involvement of the kidneys 1104 (51%) with 0 or 1 factors had a 2-year CNS relapse rate of 0.6% (95% CI: 0.2-1.0%) 945 (44%) with 2 or 3 factors had a 2-year CNS relapse rate of 4.1% (95% CI: 2.7-5.5%) 113 (5.2%) with 4 or 5 factors had a 2-year CNS relapse rate of 17.0% (95% CI: 9.4-24.6)
Deng, 2013 China Retrospective Review	599	DLBCL	I-IV	Inclusion criteria: Consecutive patients treated at Peking University Cancer hospital from February 2001 to July 2010, pathological diagnosis confirmed by pathologists at author's institution.	RCHOP=305 CHOP=294	32 5.3%	Age (≤60/>60), Gender, stage (I-II/III-IV), B symptoms, performance status (0-1/2-4), IPI (0-2/3-5), LDH (+/-), Bulky disease (≥10cm, +/-),	Multivariate: LDH (HR: 4.36, 1.53-12.40, p=0.007) Breast (HR: 10.67, 95% CI: 2.67-42.20, p=0.001) Testis (HR: 5.24, 95% CI: 1.06-25.77, p=0.005)

Non Hodgkin's Lymphoma: diagnosis and management

Study	N	Disease	Stage	Population	Treatment	N CNS relapse	Factors considered	Independent prognostic factors
				Exclusion criteria: Patients with CNS involvement at the time of initial diagnosis			extranodal sites (0-1/≥2), use of rituximab, sites of involvement	
Savage, 2014a Canada Retrospective Review Conference abstract	1597	DLBCL	I-IV	Inclusion criteria: At least one cycle of curative intent RCHOP chemotherapy. Consecutive patients from the British Columbia Cancer Agency (BCCA)	RCHOP	Not reported	Not reported	Age >60 years LDH>normal Stage 3 or 4 Extranodal sites >1 Involvement of the kidneys/adrenal gland Low risk: with 0 or 1 factors had a 2-year CNS relapse rate of 0.8% (95% CI: 0.0-1.6%) Intermediate risk: with 2 or 3 factors had a 2-year CNS relapse rate of 3.9% (95% CI: 2.3-5.5%) High risk: with 4 or 5 factors had a 2-year CNS relapse rate of 12% (95% CI: 7.9-16.1%) Median time to CNS relapse was 6.7 months from the time of diagnosis Kidney/adrenal involvement was highly associated with CNS relapse (2 year CNS risk 33%)
Savage, 2014b Country not reported Retrospective Review Conference abstract	447	DLBCL	I-IV	Inclusion criteria: Cases of pre-treatment formalin fixed paraffin embedded DLBCL in two tissue microarrays, independently scored by two expert hematopathologists for expression of MYC, BCL2, BCL6, MUM1 Exclusion criteria:	RCHOP At least one cycle with curative intent	Not reported	Not reported	Multivariate: IPI (HR: 2.18, p=0.02) MYC+ BCL2+ [IHC] (HR: 3.76, p=0.007) Within IPI risk groups: MYC+BCL2+ status further stratified patients in the intermediate risk group (IPI2 or 3,

				Not reported				<p>n=206) into higher CNS risk group (2 year CNS relapse rate: 12.6%) and a low CNS risk group (2 year CNS relapse rate: 2.9%) (p=0.01)</p> <p>In the higher IPI risk group trend observed (p=0.18)</p> <p>No value in the low IPI risk group (p=0.40)</p>

Note.CNS, central nervous system; (R)CHO(E)P, (rituximab), cyclophosphamide, doxorubicin, vincristine, (etoposide), prednisolone ; LDH: Lactate dehydrogenase; IPI: International Prognostic Index. ECOG: Eastern Cooperative Oncology Group. CI: Confidence interval. DLBCL: Diffuse Large B-cell lymphoma. RR: Relative risk. HR: Hazard ratio.

Table 3. Prognostic factors for central nervous system relapse

	Feugier	Morabito	Yamamoto	Tomita	Deng	Savage (b)
Age	-		-	✓	-	
Performance status	✓		-	-	-	
LDH	✓	✓	-	-	-	
IPI			-	-	-	✓
Age adjusted IPI	✓*					
Breast				✓	✓	
Adrenal gland				✓		
Bone				✓	-	
Testis					✓	
MYC+ BLC2+						✓
>1 extranodal site		✓				
White blood count >10_109/l		✓				

Note. Key: ✓ significant independent prognostic factor, - not significant independent prognostic factors, grey areas indicate the study did not consider the prognostic factor (please note that Savage et al. and Morabito et al may have considered some of the factors in grey but did not report full list of included factors in the conference abstract). *When age adjusted IPI was included in the multivariate model performance status and LDH did not remain significant independent prognostic predictors of CNS relapse. LDH: Lactate dehydrogenase; IPI: International Prognostic Index.

Non Hodgkin's Lymphoma: diagnosis and management

Table 4. Prognostic value of risk factor models for two-year central nervous system relapse rates.

Schmitz: 5 factor model	0 – 1 factors	2 – 3 factors	4 – 5 factors
1. Age > 60 years 2. LDH > normal 3. Stage III or IV 4. ECOG > 1 5. Involvement of the kidneys	0.6% (95% CI: 0.2-1.0%)	4.1% (95% CI: 2.7-5.5%)	17.0% (95% CI: 9.4-24.6%)
Savage (a): 6 factor model	0 – 1 factors	2 – 3 factors	4 – 6 factors
1. Age > 60 years 2. LDH > normal 3. Stage III or IV 4. ECOG > 1 5. Extranodal > 1 6. Involvement of the kidneys or adrenal gland	0.8% (95% CI: 0.0-1.6%)	3.9% (95% CI: 2.3-5.5%)	12% (95% CI: 7.9-16.1%)

Note. LDH: Lactate dehydrogenase. ECOG: Eastern Cooperative Oncology Group.

Evidence Statements

Evidence came from one randomised controlled trial and seven retrospective case series.

The main challenges to the validity of the evidence as a whole concerned (1) variation in how the outcome (CNS relapse) was measured with two studies using clinical and neurological symptoms alone compared to radiographic and cerebrospinal fluid assessment as standard in the remaining studies; (2) a lack of information from conference abstracts about the prognostic factors included and statistical analyses, and (3) the included samples of participants representing a 'reduced risk' population, with those at highest risk of CNS relapse being treated up-front with prophylaxis under individual hospital protocols. Whilst, only a hypothesis, this could explain the lack of consistency in the results of relevant prognostic factors (because allocation to prophylaxis varied across hospital institutions) and the lack of evidence supporting known CNS relapse risk factors (e.g. involvement of the testis).

Six studies reported the prognostic value of clinical characteristics (age; performance status; lactate dehydrogenase; international prognostic index; involvement of extranodal sites/specific organ sites, *MYC+BCL2+* and white blood cell count) on the development of secondary central nervous system relapse, in patients with diffuse large B-cell lymphoma. However, only two factors (involvement of the breasts, elevated LDH) were shown to be significantly independent in four of the studies (involvement of the breasts: Tomita *et al.* 2012, Deng *et al.* 2013; elevated LDH: Feugier *et al.* 2004, Morabito *et al.* 2005) with Yamamoto *et al.* (2010) reporting no independent prognostic indicator in 375 patients with DLBCL and Tomita *et al.* (2012) reporting that four out of seven factors assessed were independently associated with CNS relapse (age, involvement of the breasts, bone or adrenal glands) in 1221 patients with DLBCL.

Two studies (Schmitz *et al.* 2013; Savage *et al.* 2014a) reported the prognostic value of models (containing 5 or 6 factors), which group patients by the number of risk factors (low: 0-1 factors, moderate: 2-3 factors, higher: 4-5(6) factors) with a corresponding percent risk for developing a secondary CNS relapse within two years of diagnosis. Schmitz *et al.* (2013) reported a five factor model including age (>60 years), lactate dehydrogenase (>normal), stage (III or IV), Eastern Cooperative Oncology Group score (>1) and involvement of the kidneys. Savage *et al.* (2014a) reported the same five factor model included in the Schmitz *et al.* (2013) article (with the same cut-off points) but also included the factor extranodal sites (>1) and the involvement of kidneys or the adrenal glands. Both studies reported that an increase in the number of risk factors was associated with an increase risk of CNS relapse within two years of diagnosis with those reporting 0-1 factors having between a 0.6% (95% CI: 0.2-1.0%) and 0.8% (95% CI: 0.0-1.6%) risk for developing a CNS relapse within two-years, those with 2-3 risk factors having between a 3.9% (95% CI: 2.3-5.5%) and 4.1% (95% CI: 2.7-5.5%) risk for developing a CNS relapse within two-years and those with ≥4 factors having between 12% (4-6 risk factors; 95% confidence interval: 7.9-16.1%) and 17% (4-5 risk factors; 95% CI: 9.4-24.6%) risk for developing a CNS relapse within two-years. It is worthy to note that Savage *et al.* (2014a) reported that kidney/adrenal involvement was highly associated with CNS relapse (2 year CNS risk 33%), but no information of individual risk for CNS relapse for the other risk factors included in their factor model was provided because the article was a conference abstract. This could suggest that the risk factors included in the model do not carry equal weighting for CNS relapse risk and this may be problematic when considering a risk factor model that sums the risk factors because a patient with only kidney/adrenal gland involvement may have a higher risk for CNS relapse compared to a patient with 4 or more of the other risk factors.

Non Hodgkin's Lymphoma: diagnosis and management

Feugier P, et al. (2004). Incidence and risk factors for central nervous system occurrence in elderly patients with diffuse large-B-cell lymphoma: influence of rituximab. *Annals of Oncology*, 15(1); 129-133

	Extranodal sites					0.246
	0-1	3	3	183	7	
	>1	8	6	196	13	
	Age adjusted IPI					<0.001
	0	0	0	41	0	
	1	0	0	117	0	
	2	8	7	166	15	
	3	3	2	55	5	
	Revised histological diagnosis					-
	Aggressive lymphoma	8	8	-	-	
	Mantle-cell lymphoma	1	0	-	-	
	Follicular lymphoma	0	3	-	-	
	CNS occurrence diagnosis					-
	Cytology/histology	5	5	-	-	
	Clinical/radiological findings	4	6	-	-	
	Treatment					0.688
	CHOP	-	-	188	9	
	CHOP+Rituximab	-	-	191	11	
Complete response	2	2	-	-	-	
Partial response	3	1	-	-		
Developing CNS on therapy	6	6	-	-		

Exclusion of non-diffuse lymphoma or non-cytologically or histologically documented patients did not change results.

Multivariate analysis of all parameters found to be significant (p<0.10) without age adjusted IPI: poor performance status and elevated LDH independent predictive factors of CNS occurrence

Multivariate analysis of all parameters found to be significant (p<0.10) including age adjusted IPI: age adjusted IPI only independent factor associated with a higher risk of CNS occurrence (aa IPI 0 and 1 versus 2 and 3: odds ratio=3.05, 95% confidence intervals: 1.58-5.88).

Risk of Bias	Risk of bias question	YES	NO	UNCLEAR
	The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results?		X Pathology review revealed 49 misdiagnosis with 4 of the 20 CNS patients	
	Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias?	X		
	The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias?	X		
	The outcome of interest is adequately measured in study participants, sufficient to limit potential bias?			X varying techniques for CNS diagnosis including symptoms alone

Non Hodgkin's Lymphoma: diagnosis and management

Feugier P., et al. (2004). Incidence and risk factors for central nervous system occurrence in elderly patients with diffuse large-B-cell lymphoma: influence of rituximab. <i>Annals of Oncology</i> , 15(1); 129-133				
	Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest?	X		
	The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results?	X		
Comments				

Non Hodgkin's Lymphoma: diagnosis and management

Morabito F., et al. (2005). Incidence and risk factors for central nervous system (CNS) occurrence in patients with diffuse large-B-cell lymphoma (DLBCL) homogenously treated with PROMACECYTABOM derived protocols: a GISL retrospective study					
Pub year: 2005		Patient Characteristics	Intervention		Outcome
Country	Italy	<ul style="list-style-type: none"> - Patients with DLBCL treated with PROMACE-CytaBOM derived protocols - No prophylactic intrathecal treatment was administered - 623 patients achieved complete response to date 	PROMACE-CytaBOM		CNS recurrence
Design, period	Retrospective cohort study				
N	623				
Follow-up	Median: 51 months				
Funding source	Not reported				
Results	<p>172/623 relapsed (28%) 11 CNS relapse (1.8%)</p> <p>Median time to CNS recurrence was 2 months (range: 1-15 months)</p> <p>Regression analysis identified following independent risk factors for CNS relapse:</p> <ul style="list-style-type: none"> - Elevated LDH (risk ratio=5.49, p=0.042) - >1 extranodal site (risk ratio=5.86, p=0.019) - White blood cell count above 10_109/l (risk ratio=1.22, p=0.001)

Systemic relapse	140	8	0.03

Note. NS: Not significantly different

- The multivariate analysis showed no independent predictor of CNS involvement.
- When multivariate analyses conducted on R-CHOP group only, no independent predictors of CNS involvement.

Risk of bias question		YES	NO	UNCLEAR
Risk of Bias	The study sample represents the population of interest with regard to key characteristics, sufficient to limit potential bias to the results?	X		
	Loss to follow-up is unrelated to key characteristics (that is, the study data adequately represent the sample), sufficient to limit potential bias?	X		
	The prognostic factor of interest is adequately measured in study participants, sufficient to limit potential bias?	X		
	The outcome of interest is adequately measured in study participants, sufficient to limit potential bias?	X		
	Important potential confounders are appropriately accounted for, limiting potential bias with respect to the prognostic factor of interest?	X		
	The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results?	X

4.4.3: Review question: What is the efficacy of central nervous system prophylaxis for people with diffuse large B-cell lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) newly diagnosed with diffuse large B-cell lymphoma. Subgroups: Risk factors of Central Nervous System (CNS) relapse	CNS prophylaxis: Intrathecal chemotherapy Number of administrations Omayra reservoir/ no reservoir Drug type and dosage Schedule (early or after chemotherapy) Intravenous chemotherapy Number of cycles Drug type and dosage Schedule (early or after chemotherapy)	No CNS prophylaxis Each other	CNS relapse Time to relapse Sites of relapse (Isolated General relapse Parenchymal Meningeal) Overall survival Treatment related mortality Treatment related morbidity Health related quality of life
Additional Comments on PICO			
papers may be pre or post Rituximab Post GDG 1: Removed people who have received CNS prophylaxis from the population as the comparison is 'no CNS prophylaxis' so we have to have a population that reflects this.			

Summary Tables

Figure 1. Study flow diagram

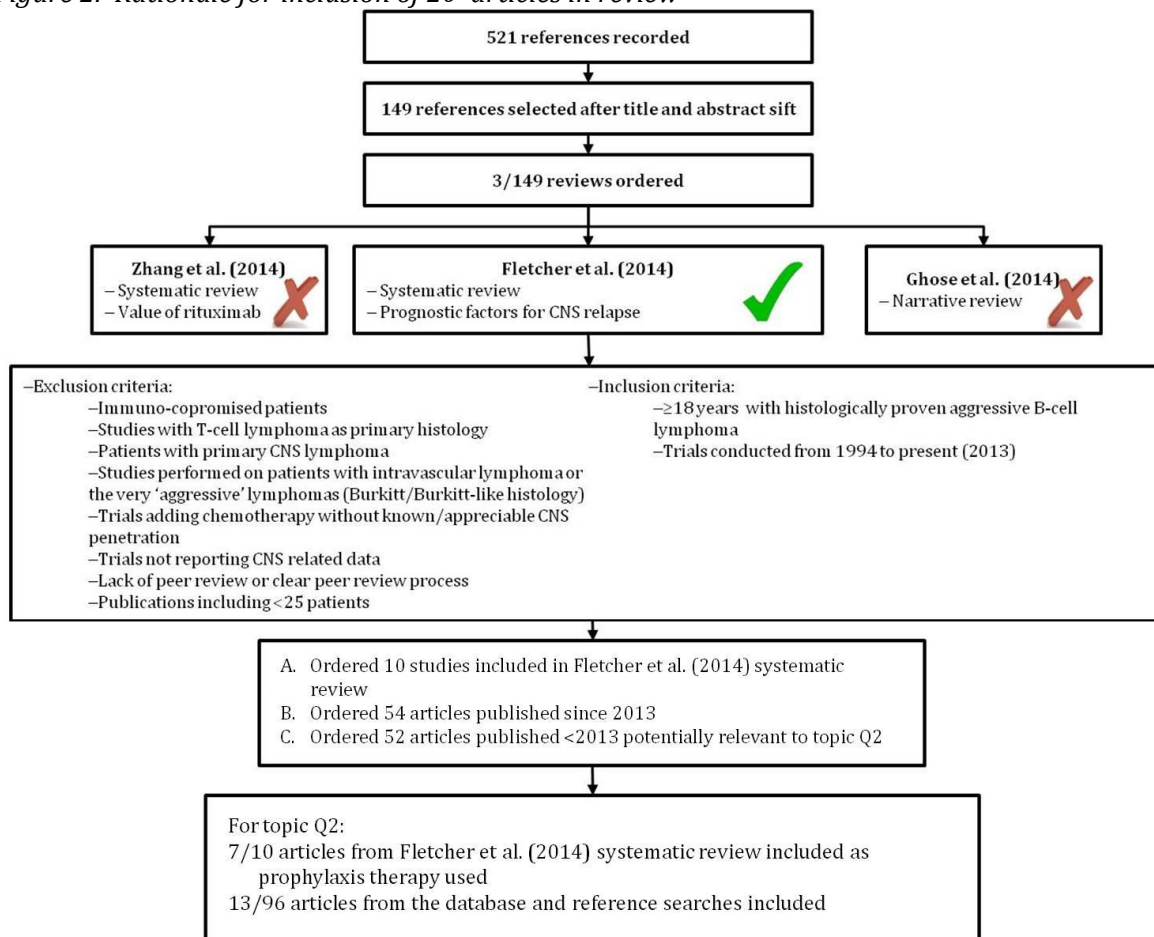

Note. *Three studies were picked up from reference list searches (Tilly et al., 2003; Récher et al., 2011; Haioun et al., 2000). One paper (Ferreri et al. 2015) picked up by GC member.

**One systematic review (Fletcher and Khal, 2014) of prognostic factors for CNS relapse conducted a search up to 2013, therefore all studies included in this review (n=10) and 54 articles published from 2013 onwards and 52 articles published pre 2013 (concerning topic Q2) considered relevant from the title and abstract sift were ordered and assessed in full text.

Evidence Statements

Evidence came from two randomised trials and 18 retrospective cohort studies.

Methotrexate

Intrathecal methotrexate versus no CNS prophylaxis

Eleven studies provided evidence concerning the use of intrathecal methotrexate (ITMTX) for central nervous system (CNS) prophylaxis (n=1084) compared to no CNS prophylaxis (n=4851) in patients with diffuse large B-cell lymphoma (6/11 studies samples were 100% DLBCL). The evidence base was inconsistent with six comparative observational studies reporting very low quality evidence of higher CNS relapse rates and relapse free survival rates in patients receiving ITMTX and four comparative observational studies reporting very low quality evidence of lower CNS relapse rates in these patients compared to patients receiving no CNS prophylactic therapy, but, none of these comparisons were significantly different (4/10 studies did not report significance values for CNS relapse rates). Only one randomized control trial reported the difference between the two groups to be statistically significant, with Tilly *et al.* (2003, 78.9% DLBCL) reporting very low quality evidence of a higher CNS relapse rate in 312 patients receiving no prophylaxis compared to 323 patients receiving ITMTX prophylaxis (8.3% versus 2.8%, p=0.002). However, patients receiving ITMTX had higher rates of treatment related adverse events (leucopenia, thrombocytopenia, infection and Mucositis, p<0.01) and a higher number of treatment related deaths (43%) compared to the patients receiving CHOP alone (23%, p=0.014).

Intravenous methotrexate (+/- intrathecal cytarabine) versus inadequate prophylaxis (IT chemotherapy only) or no CNS prophylaxis

One retrospective cohort study (Ferreri *et al.* 2015) provided very low quality evidence of significantly lower CNS relapse rates in 33 patients with high-risk DLBCL receiving IV MTX (0%) compared to 74 patients with high-risk DLBCL receiving either inadequate prophylaxis (IT chemotherapy only, n=7) or no prophylaxis at all (n=67) (12%; p=0.03). In addition, patients receiving IV MTX had significantly higher 5-year overall survival rates (87±6%) compared to the patients receiving inadequate or no prophylaxis (54±6%, p=0.001).

Intrathecal or intravenous methotrexate versus no CNS prophylaxis

Two cohort studies (Guirguis *et al.* 2012; Kumar *et al.*, 2012) provided very low quality evidence of no significant reduction in CNS relapse rates or increased overall survival in 144 patients with diffuse large B-cell lymphoma receiving methotrexate either via intravenous or intrathecal prophylaxis compared to 1059 patients with DLBCL treated with no CNS prophylactic therapy.

Intrathecal methotrexate versus intravenous methotrexate versus HyperCVAD/CODOXM-IVAC

One comparative observational study (Cheah *et al.* 2014) provided very low quality evidence of lower CNS relapse rates in 43 patients receiving HyperCVAD or CODOXM-IVAC therapies (2.3%, 0.3-15.4%) compared to 125 patients receiving IV methotrexate (6.9%, 3.5-13.4%) and 49 patients receiving IT methotrexate (18.4%, 9.5-33.1%) (p=0.009). There was no reported significant difference in the 3-year relapse free survival rates between the three groups (p=0.051: IT: 65.5% [49.8-77.3%]; IV: 82.9% [74.7-88.6%]; HyperCVAD/CODOXM-IVAC: 70.6% [53.9-82.2%]), but the patients receiving HyperCVAD or CODOXM-IVAC had the highest rates of 3-year overall survival (89.2%) compared to the IT (68%) and IV (85.9%) methotrexate groups (p=0.029). The authors noted that in the patients receiving IV methotrexate there were high rates of renal impairment, occurring in 70% of cycles overall, although all patients recovered without the need for haemodialysis. No information regarding adverse events were reported for the other two treatment groups.

Consolidation with intrathecal methotrexate versus no CNS prophylactic consolidation

One randomised controlled trial (Récher *et al.* 2011) comparing the value of consolidative ITMTX in patients with aggressive B-cell lymphoma (97.5% DLBCL) who had been treated with ITMTX during their

Non Hodgkin's Lymphoma: diagnosis and management

induction therapy (R-CHOP) provided very low quality evidence of no statistically significant difference in CNS relapse rates in the 196 patients treated with consolidative ITMTX (0%) compared to the 183 patients who received no ITMTX consolidation (1.09%). However, patients who received consolidation ITMTX had a significantly higher 3-year overall survival rate (92%) compared to those who received no consolidation therapy (84%, $p=0.0071$). Higher rates of adverse events were reported in the ITMTX consolidation group compared to the group not receiving ITMTX consolidation therapy, but significance values were not provided for these comparisons.

Any CNS prophylaxis

Five comparative observational studies (Aviles *et al.* 2013; Bernstein *et al.* 2009; Wilson *et al.* 2014; Ventre *et al.* 2013) compared the use of any CNS prophylaxis therapy in 1249 patients with DLBCL compared to 2552 patients with DLBCL receiving no CNS prophylaxis therapy. Aviles *et al.* (2013) and Bernstein *et al.* (2009) provided very low quality evidence of no significant benefit of CNS prophylaxis therapy on the CNS relapse rates in their patients. Aviles *et al.* (2013) further reported no relapse free or overall survival benefit from CNS prophylaxis. However, both Ventre *et al.* (2013) and Wilson *et al.* (2014) reported survival benefits in patients receiving CNS prophylaxis with Ventre *et al.* (2013) reporting very low quality evidence of an increased overall survival rate in 40 patients with DLBCL treated with CNS prophylaxis ($94\pm 7\%$) compared to 64 patients with DLBCL who received no CNS prophylaxis ($46\pm 6\%$, $p=0.001$) and Wilson *et al.* (2014) reporting very low quality evidence of a relapse free survival benefit in 132 patients with DLBCL who received more than 2 doses of intrathecal methotrexate, cytarabine or triple prophylactic therapy compared to 69 patients who received none, or less than 2 doses, of prophylactic therapy ($p=0.025$).

Allocation of patients to prophylaxis

Unfortunately allocation to CNS prophylaxis in the majority of the studies was based on level of risk (which varied across studies) or physician discretion (which varied within studies), which may bring into question the value of the comparison of at risk (for CNS relapse) patients treated with prophylaxis to low risk patients not treated with prophylaxis. A non-significant difference when comparing high risk to low risk patients could lend support for the hypothesis that CNS prophylaxis is providing a benefit because the CNS relapse rates after prophylaxis become comparable to those CNS relapse rates in low risk patients where prophylaxis would rarely be considered. Only one study (Tilly *et al.* 2003) reported the value of prophylaxis in a randomised controlled trial, reporting a benefit of prophylaxis. However, these patients did not receive rituximab and whilst the aim of the present study was not to address the use of rituximab in relation to CNS relapse rates, there were no RCTs and only one of the observational studies post rituximab reported a benefit for the addition of prophylaxis when compared to no prophylaxis in patients who were matched on their risk for CNS relapse.

GRADE Tables

Grade Profile 1: Intrathecal methotrexate versus no CNS prophylaxis

Quality assessment							Summary of findings

3-year Overall survival											
1	RCT ¹	Serious ^{2,3}	no serious inconsistency	Serious ⁴	No serious imprecision	none	92%	84%	Log rank P=0.0071	8% better survival rates after consolidative prophylaxis	⊕000 VERY LOW

Note. Sig NR: Significance level was not reported

¹Récher et al.

²Unclear how CNS relapse was detected and diagnosed

³Allocation bias (trial was not masked) and detection bias (unclear if blinding of outcomes)

⁴Sample included patients with other NHL subtypes

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 5: Intrathecal methotrexate versus intravenous methotrexate

Quality assessment							Summary of findings				
							No of patients		Effect		Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	IT MTX	IV MTX	Relative (95% CI)	Absolute	
CNS relapse rate											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	18.4%	6.9%	Not reported	15.4% more CNS relapses after IT MTX	⊕000 VERY LOW
3-year Relapse free survival											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	65.5%	82.9%	Not reported	5.1% more relapses after IT MTX	⊕000 VERY LOW
3-year Overall survival											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	68%	85.9%	Not reported	17.9% lower survival rates	⊕000 VERY LOW

Note. ¹ Cheah et al.

² Allocation to CNS prophylaxis based on risk level

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 6: Intrathecal methotrexate versus HyperCVAD/CODOXM-IVAC

Quality assessment							Summary of findings				
							No of patients		Effect		Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	IT MTX	HyperCVAD or CODOXM IVAC	Relative (95% CI)	Absolute	
CNS relapse rate											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	18.4%	3%	Not reported	15.4% more CNS relapses after IT MTX	⊕000 VERY LOW
3-year Relapse free survival											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	65.5%	70.6%	Not reported	5.1% more relapses after IT MTX	⊕000 VERY LOW
3-year Overall survival											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	68%	89.2%	Not reported	21.2% lower survival rates after IT MTX	⊕000 VERY LOW

Note. ¹ Cheah et al.

² Allocation to CNS prophylaxis based on risk level

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 7: intravenous methotrexate versus HyperCVAD/CODOXM-IVAC

Quality assessment							Summary of findings				
							No of patients		Effect		Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	IV MTX	HyperCVAD or CODOXM IVAC	Relative (95% CI)	Absolute	
CNS relapse rate											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	6.9%	3%	Not reported	3.9% more CNS relapses after IV MTX	⊕000 VERY LOW
3-year Relapse free survival											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	82.9%	70.6%	Not reported	12.3% fewer relapses after IV MTX	⊕000 VERY LOW
3-year Overall survival											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	85.9%	89.2%	Not reported	3.3% lower survival rates after IV MTX	⊕000 VERY LOW

Note. ¹ Cheah et al.

² Allocation to CNS prophylaxis based on risk level

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 8: Intravenous methotrexate (+/- intrathecal cytarabine) versus inadequate prophylaxis (IT chemotherapy only) or no CNS prophylaxis

Quality assessment							Summary of findings				
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect		Quality
							IV MTX	Inadequate prophylaxis (IT chemotherapy alone) or no prophylaxis	Relative (95% CI)	Absolute	
CNS relapse rate											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	0%	12%	Not reported	12% more CNS relapses after inadequate prophylaxis	⊕000 VERY LOW
5-year Overall survival											
1	observational studies ¹	Serious ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	87% ±6%	54% ±6%	Not reported	33% lower survival rates after inadequate prophylaxis	⊕000 VERY LOW

Note. ¹ Ferreri et al.

² Baseline characteristics of groups differed significantly on a number of the risk factors. Unclear what decision making physicians used when deciding whether or not to administer IT liposomal cytarabine.

Non Hodgkin's Lymphoma: diagnosis and management

Ferreri AJM, et al. (2015). Risk-tailored CNS prophylaxis in a mono-institutional series of 200 patients with diffuse large B-cell lymphoma treated in the rituximab era. *British Journal of Haematology*, 168; 654-662.

Kidney	7	17	8	12	0.57
Paranasal sinus	4	10	0	0	0.01
Breast	1	2	0	0	0.37
CNS risk factors					
Cns-IPI	6	15	50	75	0.00001
High-risk extranodal	23	58	7	10	0.00001
Both	11	28	10	15	0.11
Methotrexate with IT liposomal	10	25	-	-	-
Methotrexate without IT liposomal	23	57.5	-	-	-
IT chemotherapy alone	7	17.5	-	-	-

Table 2. Contraindications for methotrexate (n=17)

Contraindications for methotrexate	17	100
Due to age ≥80 years	6	35.3
MTHFR 677TT polymorphism	5	29.4
HBVB/HCV-related hepatocellular disease	3	17.6
Chronic renal insufficiency	2	11.8
Patient refusal	1	5.9

Note. All of these 17 patients were from the post 2008 cohort and not eligible to receive methotrexate, 7 of these patients received IT chemotherapy alone and the remaining 10 were analysed in the pre-2007 cohort of 'no cns prophylaxis group'

First-line therapy: 4-8 courses of R-CHOP

- 167 patients achieved a complete remission (CR: 84%; 95% CI: 79-89%)
- 27 patients (14%) experienced progressive disease (PD)
- 6 patients (3%) died of toxicity
- 80 responders received consolidation involved-field irradiation (30-45 Gy)

Table 3. High risk patients who experienced CNS relapse (n=9)

	n	%
IV prophylaxis	0	0
IT chemotherapy alone	1	11.1
No prophylaxis	8	88.9
Cns-IPI	8	88.9
Extranodal organ	6	66.7
Orbit	1	11.1
Kidney	3	33.3
Testis	2	22.2
CNS prophylaxis	1 (IT)	11.1
Relapse site		
Brain	4	44.4
Meningeal	4	44.4
CN; CSF	2	22.2
Median Time to CNS relapse range (months)	12	6-36
Death due to CNS disease	8	88.9

- CNS relapse occurred in 3 (5%) of 56 patients with cns-IPI, in 1 (3%) of the 30 patients with high-risk extranodal disease (testis) and in 5 (24%) of 21 patients with both risk factors (3 kidney, 1 testis, 1 orbit), suggesting an additive risk effect of both variables.
- Degree of LDH elevation was not associated with risk of CNS recurrence; this event was detected in 6/60 patients with 2x normal LDH value and in 3/44 patients with simply elevated LDH level (p=0.73)
- CNS relapses occurred in 8(12%) of the 67 patients who did not receive prophylaxis and in 1 (2.5%) of the 40 patients who received IT (p=0.08); the latter occurred in a patient managed with IT only due to concomitant renal insufficiency
- CNS relapse rate was 12% (9/74) for patients treated with "inadequate" prophylaxis (none or IT only)(and 0% (0/33) for patients managed with intravenous high-dose methotrexate-based prophylaxis (p=0.03)
- Rates remained unchanged when patients in PD and toxic deaths excluded and analysis was limited to patients in CR after chemoimmunotherapy (13% versus 0%; p=0.04), which excludes a selection bias related to different disease aggressiveness
- Considering all together the high-risk extranodal sites, 5/17 (29%)patients treated without intravenous prophylaxis experienced CNS relapse compared to 0/27 in the patients with high-risk extranodal sites managed with prophylaxis (p=0.007)

Non Hodgkin's Lymphoma: diagnosis and management

Ferreri AJM, et al. (2015). Risk-tailored CNS prophylaxis in a mono-institutional series of 200 patients with diffuse large B-cell lymphoma treated in the rituximab era. *British Journal of Haematology*, 168; 654-662.

– 8/33 high-risk patients managed with intravenous CNS prophylaxis experienced lymphoma relapse without CNS involvement with a 5-year PFS: 75 ±7%

Table 4. Overall survival rates according to CNS prophylaxis treatment group

	High-risk CNS prophylaxis	N=33	High risk no prophylaxis	N=74	P value
5 year overall survival	87	±6%	54	±6%	0.001

Adverse events in 33 patients receiving methotrexate:

- No cases of dose reduction, interruption or grade 3-4 toxicity
- 2 cases of grade 2 neutropenia

Quality assessment	Biases	Yes	No	Unsure
	Conference abstract		X	
	Retrospective observational study	X		
	Patient selection bias (systematic differences between the comparison groups?)	X		
	Performance bias (systematic differences between groups in the care provided, apart from the intervention under investigation)		X	
	Detection bias (Bias in how outcomes are ascertained, diagnosed or verified)		X	
	Attrition bias (systematic differences between the comparison groups with respect to loss of participants)		X	
	Reporting bias?		X	
	Other biases?	X Comparison is high risk no contraindications CNS prophylaxis versus high risk + contraindications no CNS prophylaxis so mixture of samples in the no prophylaxis group. Not clear if the comparison of eligible CNS patients (no contraindications) would make a difference to the CNS relapse rates, are contraindications associated with CNS relapse?		

Comments ↓ Risk of bias: Unclear what physician preference was for decision to administered IT liposomal cytarabine. Baseline characteristics defined risk differed according to treatment group
 Note: Not clear how many of the patients not receiving prophylaxis (the pre 2008 cohort) would have had contraindications for methotrexate

Results	Response rates to treatment:					
	– 157 patients achieved either complete remission (CR) or CR unconfirmed (Cru) with R-CHOP (73.4%)					
	CNS relapse					
	– 8 patients developed CNS relapse (3.7%)					
	– Median time from diagnosis to CNS relapse was 17 months (6-35 months)					
	– CNS relapse diagnosis by CT/MRI: 87.5% (n=7 patients)					
	– CNS relapse diagnosis by CSF cytology: 22.5% (n=1 patient)					
	– 62.5% (n=5) brain parenchymal CNS relapse					
	– 25% (n=2) leptomeningeal disease CNS relapse					
	– 12.5% (n=1) both parenchymal and leptomeningeal disease					
– 62.5% (n=5) CNS relapse occurred after a systemic CR or Cru						
– 50% (n=4) occurred in patients with testicular lymphoma (2 had parenchymal and 2 had Leptomeningeal disease						
– 3/4 testicular patients with CNS relapse had received CNS prophylaxis with both HDMTX and ITMTX						
– If testicular patients removed CNS relapse rates of 0% in the 21 patients who received CNS prophylaxis and 2% in the 185 patients who did not						
Table 2.						
		CNS prophylaxis		No CNS prophylaxis		
		n=27		n=187		
	CNS relapse	3	11.1%	5	2.7%	
	Median time to CNS relapse	11.4 months	7-35 months	22 months	6-35 months	
Univariate analysis						
– Receipt of CNS prophylaxis was associated with an increased risk of CNS relapse (HR: 4.93, 95% CI: 1.17-20.72, p=0.030)						
– HDMTX +/- IT chemotherapy associated with an increased risk of CNS relapse (HR: 8.34, 95% CI: 1.98-35.11, p=0.0038)						
Multivariate analysis						
– CNS prophylaxis no impact on CNS Relapse free survival						
Table 3. Relationship between CNS relapse and prophylaxis in higher risk patients						
	CNS risk score	CNS prophylaxis	%	No CNS prophylaxis	%	P value
	High risk Haioun score					0.415
	No CNS relapse	9	90	32	96.9

Non Hodgkin's Lymphoma: diagnosis and management

Schmitz N, et al. (2012). CNS disease in younger patients with aggressive B-cell lymphoma: an analysis of patients treated on the Mabthera International Trial and trials of the German High-Grade NHL study group. *Annals of Oncology*, 23: 1267-1273

		<p>treated on the High-CHOEP and MegaCHOEP phase III studies were to have a lumbar puncture with subsequent injection of MTX (15 mg each on days 1 and 15 of the first two courses) and cytocentrifuge preparations of cerebrospinal fluid (CSF) were evaluated for the presence of lymphoma cells</p> <ul style="list-style-type: none"> Of the 65 patients with an extranodal involvement in the neck, head, BM, or testes from High-CHOEP and MegaCHOEP phase III trials, 32 (57.1%) had a lumbar puncture documented, while 24 patients (42.9%) had no lumbar puncture. Data are missing for nine patients. For patients treated on any of the other study protocols, neither a lumbar puncture nor CNS prophylaxis was mandatory. Brain imaging was done only when clinical symptoms suggested involvement; no routine imaging was carried out. 																												
<p>Results</p>	<p>Only patients with complete data (2190) were included in multivariate analyses</p>																													
	<ul style="list-style-type: none"> 56 patients developed CNS disease DLBCL estimated 2-year incidence of CNS disease was 2.2% (did not significantly differ to the remaining aggressive B-cell lymphomas, p=0.261) Median time from diagnosis to CNS disease was 7.0 months (lower quartile: 4.9 months; upper quartile: 16.4 months; range: 0.2-85.2 months) Median survival after occurrence of CNS relapse or progression was 5.0 months <p>Treatment and CNS disease</p> <p>Etoposide:</p> <p>NHL-B1: CHOP versus CHOEP</p> <ul style="list-style-type: none"> Addition of etoposide to CHOP significantly reduced the incidence of CNS events <p>MInT: CHOP versus CHOEP</p> <ul style="list-style-type: none"> No significant differences in time to CNS disease were seen between CHOP without and with etoposide regardless if rituximab had been administered or not <p>Rituximab:</p> <p>MInT (n=610)</p> <ul style="list-style-type: none"> 14 patients (2.3%) developed relapse or progression in the CNS Kaplan-Meier estimates for time to CNS disease with a significant difference in favour of rituximab (p=0.035) <p>CHO(E)P-14 or -21 (n=1570)</p> <ul style="list-style-type: none"> Adjusting for IPI factors (except age), rituximab significantly decreased the RR for CNS disease to 0.3 (CI: 0.1-0.9, p=0.029) <p>MegaCHOEP studies (n=210)</p> <ul style="list-style-type: none"> 11 patients (5.2%) developed CNS disease The addition of rituximab did not significantly reduce the risk for CNS events (p=0.733) <p>Table 2.</p> <table border="1" data-bbox="268 1581 1484 1809"> <thead> <tr> <th rowspan="2">Study</th> <th colspan="2">NHL-B1</th> <th rowspan="2">P value</th> <th colspan="2">MInT</th> <th rowspan="2">P value</th> <th colspan="2">MInT</th> <th rowspan="2">P value</th> </tr> <tr> <th>CHOP</th> <th>CHOEP</th> <th>CHOP</th> <th>CHOEP</th> <th>+ Rituximab</th> <th>No rituximab</th> </tr> </thead> <tbody> <tr> <td>2 year CNS rate</td> <td>2.4% (95% CI: 0.6%-4.2%)</td> <td>1.0% (95% CI: 0.0%-2.2%)</td> <td>0.05</td> <td>0.8% (95% CI: 0.0%-1.8%)</td> <td>1.8% (95% CI: 0.4%-3.2%)</td> <td>0.368</td> <td>0.0%</td> <td>0.6%</td> <td>0.877</td> </tr> </tbody> </table> <p>Prophylaxis and CNS disease</p> <ul style="list-style-type: none"> ITMTX was mandatory in the High-CHOEP and MegaCHOEP phase III studies for patients with risk factors Patients on other studies not intended to receive CNS prophylaxis. Because case report forms failed to exactly show which lymph nodes in the upper or lower neck were involved authors cannot precisely tell how many patients received CNS prophylaxis as per protocol and how many protocol violations occurred Authors compared patients who actually did not receive MTX prophylactically No significant differences in cumulative risks of CNS disease were seen between those receiving MTX prophylactically (n=145) and those not (n=1593) (p=0.386) 					Study	NHL-B1		P value	MInT		P value	MInT		P value	CHOP	CHOEP	CHOP	CHOEP	+ Rituximab	No rituximab	2 year CNS rate	2.4% (95% CI: 0.6%-4.2%)	1.0% (95% CI: 0.0%-2.2%)	0.05	0.8% (95% CI: 0.0%-1.8%)	1.8% (95% CI: 0.4%-3.2%)	0.368	0.0%	0.6%

Results

Median time interval between diagnosis and CNS disease was 8 months (range: 1-39), median survival after CNS disease was only 2.5 months
 273 (22.4%) patients received i.th.MTX at least during one cycle of chemotherapy, and 202 patients (16.6%) received 4 i.th. injections
 11/58 (19.0%) patients with a CNS event had received i.th.MTX

Protocol violations:

- Patients with involvement of the upper neck could not exactly be evaluated for protocol violation because the case report forms failed to precisely define “upper neck.”
- 120/210 patients (57.1%) with involvement of testes, BM, or head received i.th. MTX as per protocol, whereas 90 patients (42.9%) were not treated.
- Author notes the high number of protocol violations was unexpected and suggested that the “treating physicians obviously were not convinced that BM involvement (57.5% protocol violations) or involvement of sites adjacent to the skull (40.0% protocol violations) put patients at sufficiently high risk for CNS disease to require i.th. MTX”
- Protocol violations for testicular involvement were 16.7%
- With high number of protocol violations authors analysed the efficacy of i.th. MTX in high-risk populations treated with R-CHOP-14 or CHOP-14:
 - The percentage of CNS events in prophylaxis patients was slightly lower (2.5%) than in patients without CNS prophylaxis (4.4%), but this difference was not significant.
 - In univariate analysis of patients with involvement of testes, BM, or any site adjacent to the skull, the risk of CNS disease was higher for patients without i.th. prophylaxis—if they had not received rituximab.
 - When therapy included rituximab, the risk for CNS relapse was significantly lower regardless whether i.th. MTX had been administered or not. The proportional hazard model with an interaction term between rituximab and prophylaxis adjusted for the IPI-factors confirmed a relevant interaction (RR = 6.1). Thus, no effect of i.th. MTX on any type of CNS event was detectable when modern immunochemotherapy including rituximab was administered.
- Author concludes that i.th.MTX failed to reduce the risk of CNS relapse with the possible exception of patients with testicular involvement

Non Hodgkin's Lymphoma: diagnosis and management

Bernstein SH, et al. (2009). Natural history of CNS relapse in patients with aggressive Non-Hodgkin's lymphoma: a 20 year follow-up analysis of SWOG 8516 – the Southwest Oncology Group. *Journal of Clinical Oncology*, 27(1): 114-119

		>1 extranodal site	36	38	32	35				
		IPI risk								
		Low	18	24	21	22				
		Low-intermediate	39	31	37	37				
		High-intermediate	32	32	29	27				
		High	10	13	12	14				
		Bone marrow involvement	24	24	26	25				
		No significant differences between the treatment groups								

- No significant differences in either PFS or OS among the four treatment groups, even when adjusting for IPI
- 25/899 patients had a CNS relapse (cumulative incidence of 2.8%)
- 100% of CNS relapse occurred by year 2
- Median time from diagnosis to CNS relapse was 5.4 months (range: 0.6-18.3 months)
- 13/25 patients developed CNS disease during chemotherapy
- 9/13 were responding systemically, 2/13 were progressing and 2/13 were not assessed for systemic progression
- 3/25 patients developed CNS disease within 1 month of chemotherapy completion (all responding systemically)
- No patients who had a CNS relapse more than 13 months after completion of chemotherapy
- 11/25 had isolated CNS relapse
- 10/25 had systemic progression
- 21/25 had leptomeningeal disease, 14/21 had no evidence of brain parenchymal disease, 2/21 had concomitant brain parenchymal disease
- Brain not assessed in 5 patients
- 3 patients had brain parenchymal disease without assessment of the CSF
- 1 patients had intradural disease
- Median survival after relapse: 2.2 months
- 2-year survival estimates: 0%

Table 2. CNS relapse rates

CNS prophylaxis strategy n=238				0.44
Yes	3	121	2.5	
No	5	117	4.3	

- Author notes possible post randomisation selection biases for prophylaxis because not all patients eligible for the therapy received it (59-50% received the therapy)
- Because post randomisation selection biases relate to both the probability of getting prophylaxis (i.e. remission response) and to the outcome (CNS relapse), an alternative analysis would be to compare the strategy of

Non Hodgkin's Lymphoma: diagnosis and management

Bernstein SH, et al. (2009). Natural history of CNS relapse in patients with aggressive Non-Hodgkin's lymphoma: a 20 year follow-up analysis of SWOG 8516 – the Southwest Oncology Group. <i>Journal of Clinical Oncology</i> , 27(1): 114-119				
	prophylaxis within the baseline BM positive group. This approach would represent an intention-to-treat analysis. However, this still yielded no significant difference between the two groups (p=0.44)			
Quality assessment	Biases	Yes	No	Unsure

4.4.4: Review question: What is the most appropriate salvage strategy for people with relapsed/refractory diffuse large B-cell lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) who have relapsed/refractory diffuse large B-cell lymphoma. Exclude: Transformed follicular Low grade (indolent) lymphoma Composite low/high grade lymphoma Central Nervous System lymphoma	Chemo-immunotherapy Chemo-immunotherapy with autologous transplantation Chemo-immunotherapy with allogeneic/ allogenic/ reduced intensity transplantation Chemo-immunotherapy with autologous transplantation followed by allogeneic/allogenic/ reduced intensity transplantation at relapse	Each other	Overall survival Disease free survival Progression free survival Treatment related mortality Treatment related morbidity Health-related quality of life Response to chemo-immunotherapy
Additional Comments on PICO			
<p><i>Record duration of response</i></p> <p><i>Record time to relapse</i></p> <p><i>Where available report by age</i></p> <p><i>Record response to chemo-immunotherapy</i></p> <p><i>For the third intervention: These are patients presenting for an allogeneic transplantation but with a history of past autologous transplantation. Therefore I will need to record any past transplantations patients may have had.</i></p> <p><i>immunotherapy agents to be considered are restricted to rituximab, which came into use circa 2002.</i></p> <p><i>include non comparative studies of chemo-immunotherapy with allogeneic transplantation if N≥40</i></p>			

Summary Tables

Figure 1. Study flow diagram

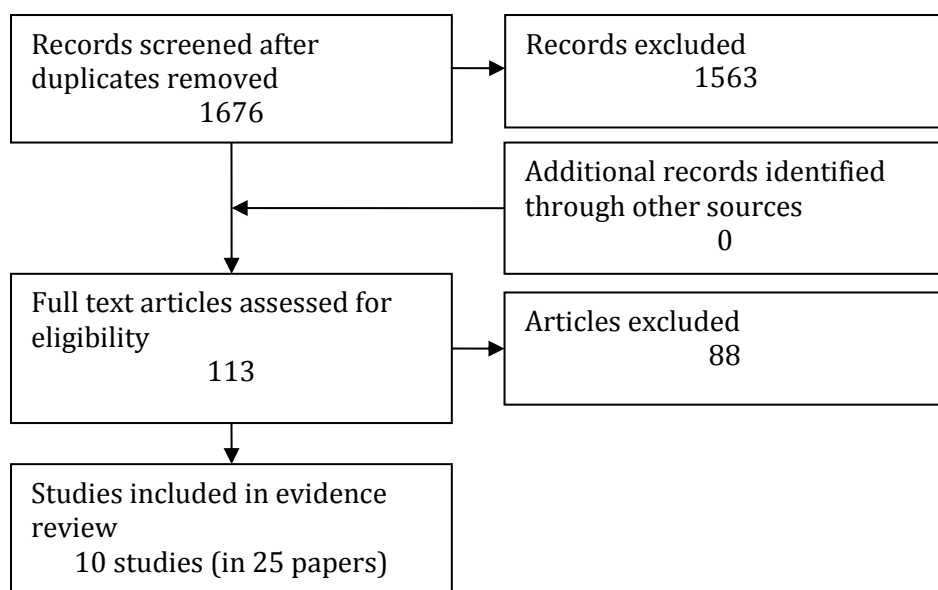

Table 1. Summary of findings (inferential statistical analyses)

Treatment options and comparisons			Studies	N	Outcome
Rituximab-BEAM followed by ASCT(a)	Vs.	Tositumomab and ¹³¹ I-tositumomab-BEAM followed by ASCT (b)	1	224	No difference between (a) and (b) in progression-free survival, overall survival, causes of death, treatment-related mortality, absolute neutrophil count, platelet recovery and grade 3-5 non-haematologic toxicities apart from overall and mucositis (both significantly lower in (a) than (b))
Phase 1: Rituximab-ICE followed by ASCT (c)	Vs.	Rituximab-DHAP followed by ASCT(d)	1	477	Phase 1: No difference between (c) and (d) in event-free survival, progression-free survival, overall survival or mobilization-adjusted response.
Phase 2: Patients who received ASCT in either (c) or (d) were randomly assigned to receive observation (obs) or rituximab (R) maintenance therapy after ASCT.					Phase 2: No difference between (obs) and (R) in event-free survival, progression-free survival or overall survival.
Rituximab (if CD20+)-ICE followed by ASCT (if < 66 years and response) (e)	Vs.	Rituximab (if CD20+)-DHAP followed by ASCT (if < 66 years and response) (f) or Rituximab (if CD20+)-GDP followed by ASCT (if < 66 years and response) (g)	1	113	- No difference between (e), (f) and (g) in overall response, CR, ASCT rate, median time from first progression to second progression or last follow up, or grade 3-4 haematological side effects; - No difference in 2-year overall survival between (e) and (f-g combined); - Significantly longer median 2 nd PFS in (e) than (f-g combined), and in (e) than (f), but no difference between (e) and (g); - Significantly more grade 3-4 renal dysfunction in (f) than (e) and (g).
(Rituximab)-GDP followed by ASCT according to local policies (h)	Vs.	(Rituximab)-DHAP followed by ASCT according to local policies (i)	1	619	- No difference between (h) and (i) in overall response rate, rate of ASCT transplantation, event-free survival, overall survival, event-free survival after transplantation, overall survival after transplantation, grade 3-4 adverse events apart from nausea, febrile neutropenia and overall, which were all significantly less in (h) than (i); - Significantly fewer platelet transfusions, also during the first 2 cycles of treatment, and hospitalisations, also for management of adverse events or other illness in (h) than (i); - Quality of life was either better or similar in (h) compared to (i)
Rituximab-DICEP followed by ASCT (j)	Vs.	Rituximab-MICE followed by ASCT (k)	1	38	Median time to progression was significantly longer in (k) than in (j)
Rituximab-GemOx (l)	Vs.	Rituximab-ICE (m)	1	65	Significantly more neutrocytopenia and gastrointestinal tract reaction in (m) and (l)

Abbreviations: ASCT autologous stem cell transplant; BEAM (carmustine, etoposide, cytarabine and melphalan) ; DHAP (dexamethasone, high-dose cytarabine and cisplatin); GDP (gemcitabine, dexamethasone and cisplatin) ; ICE (ifosfamide, carboplatin and etoposide).

Evidence Statements

Evidence came from three randomised controlled trials, three retrospective cohort studies and four retrospective case series.

R-BEAM followed by ASCT versus B-BEAM followed by ASCT

Low quality evidence from one study of 224 patients reported that overall rate of grade 3-5 non-haematologic toxicities and grade 3-5 mucositis, but not other individual grade 3-5 non-haematologic toxicities, overall survival, progression-free survival, and treatment-related mortality were significantly lower in R-BEAM than B-BEAM (HRs not reported [BMT CTN 0401]).

R-ICE followed by ASCT versus R-DHAP followed by ASCT

One study (CORAL) with 477 patients provided moderate quality evidence that overall survival, progression-free survival, and event-free survival did not differ significantly between R-ICE and R-DHAP (HRs not reported).

(R-)GDP followed by ASCT versus (R-)DHAP followed by ASCT

One study with 619 patients (NCIC-CTG LY.12) provided low quality evidence that quality of life was significantly better or similar in (R-)GDP compared to (R-)DHAP and grade 3-4 nausea, febrile neutropenia and overall occurred significantly less in (R-)GDP than in (R-) DHAP, but the treatment groups did not differ in other individual grade 3-4 adverse events, overall survival, overall survival after transplantation, event-free survival, event-free survival after transplantation, overall response rate and rate of ASCT transplantation (HRs not reported).

R-ICE versus R-GDP as salvage chemotherapy

Low quality evidence from an indirect comparison of two randomised trials (CORAL and NCIC-CTG LY.12) suggested uncertainty about whether outcomes are better with R-GDP than with RICE.

R(if CD+)-ICE followed by ASCT (if < 66 years and response) versus R(if CD+)-DHAP followed by ASCT (if < 66 years and response) versus R(if CD+)-GDP followed by ASCT (if < 66 years and response)

Very low quality evidence from one study with 113 patients (Kusano *et al*, 2014) reported median second progression-free survival was longer in (R-)ICE than in two other two treatment groups combined and in (R-)ICE compared to (R-)DHAP alone, but not to (R-)GDP alone. There was significantly more grade 3-4 renal dysfunction with (R-)DHAP than in other two treatment groups, but the three treatment groups did not differ in overall or complete response, overall survival ((R-)ICE versus the other two treatment groups combined), median time from first progression to second progression or last follow up, and grade 3-4 haematological side effects (HRs not reported).

R-MICE versus R-DICEP

Oh *et al* (2015) provided very low quality evidence that median time to progression was significantly longer in R-MICE than R-DICEP (HR not reported; n=38).

R-GemOx versus RICE

Very low quality evidence from one study with 65 patients (Zhang *et al*, 2011) suggest that neutrocytopenia and gastrointestinal tract reactions occurred significantly more in RICE than R-GemOx (HR not reported).

Allogeneic transplantation

Very low quality evidence about outcomes following allogeneic transplantation came from 4 retrospective case series (Avivi *et al*, 2014; Rigacci *et al*, 2012; Sirvent *et al*, 2010 and van Kampen *et al* 2011) including 807 patients. Overall survival at five years after allogeneic stem cell transplant (allo-SCT) ranged from 34% to 43% and five year progression free survival ranged from 30% to 37%. The rates of non-relapse mortality

Non Hodgkin's Lymphoma: diagnosis and management
ranged from 28% to 38%, rates of acute graft-versus-host disease ranged from 32% to 51% and rates of
chronic graft-versus-host disease ranged from 35% to 42%.

GRADE Tables

Grade Profile 1: Should R-BEAM followed by ASCT therapy vs B-BEAM followed by ASCT therapy be used for relapsed/refractory diffuse large B cell lymphoma?

Settings: USA

Quality assessment							Summary of findings			
							Event rates		Effect (95% CI)	Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	R-BEAM	B-BEAM		
Overall survival (follow-up median 25.5 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	serious imprecision ³	none	65.6% (N=113)	61.9% (N=111)	HR = 1.14 (0.73 to 1.78)	⊕⊕○○ Low
Progression-free survival (follow-up median 25.5 months)										
1	randomised trials ¹	serious limitations ²	no serious inconsistency	no serious indirectness	serious imprecision ³	none	48.6% (N=113)	47.9% (N=111)	HR = 1.08 (0.76 to 1.54)	⊕⊕○○ Low
Treatment-related mortality (follow-up median 25.5 months)

Radiotherapy after transplantation was not allowed and was considered to be an event. Supportive treatments were given according to standard use in each center."</p>	<p>Patients who received ASCT were randomly assigned to receive observation or rituximab maintenance therapy (375mg/m² every 8 weeks for 1 year) on day 28 after ASCT. Radiotherapy after transplantation was not allowed and was considered to be an event. Supportive treatments were given according to standard use in each center."</p>	
Results	<p>SALVAGE THERAPY (Gisselbrecht 2010 [N = 396] and 2012 [N = 477]): Response to treatment: - After salvage, but before transplantation: overall response rate (CR, Cru, PR) was 63% (95% CI 57.2-69.7) in R-ICE and 64% (95% CI 57.8-70.5) in R-DHAP. (Gisselbrecht 2012) - Univariate analysis examining the factors affecting the overall response rate found that a significantly negative impact was associated with refractory disease/relapse less than 12 months after diagnosis, saalPI 2-3, and prior rituximab treatment, but not the treatment arm. (Gisselbrecht 2010) - "For patients with prior exposure to rituximab and progression within 12 months of diagnosis, the overall response rate was 46%" (Gisselbrecht 2012) BEAM and ASCT: - 101 R-ICE patients and 105 R-DHAP patients received BEAM and ASCT per protocol, and five more patients had stable disease. The main reason for premature withdrawal from the study was disease progression. Three months after transplantation and random assignment, 132/181 evaluable patients had CRor CRu, 24 PR, 1 SD, and 17 PD. - ASCT: --Median CD34+ cells collected, million/kg: R-ICE: 4.5; R-DHAP: 4.9; --Collection failure < 2,000,000 CD34+ cells: R-ICE N = 20, R-DHAP N = 15 (Gisselbrecht 2010); --mobilisation-adjusted response: R-ICE = 51.5% and R-DHAP = 56.5% (p = 0.27; Gisselbrecht 2012) Survival (all Gisselbrecht 2010, unless indicated): - 3-year EFS (median follow-up time = 27 months) was 26% in R-ICE and 35% in R-DHAP (p = 0.6); - EFS (median follow up of 44 months) was 26% (95%CI, 20-32; median = 6.5 months, 95% CI 5-9.6) in R-ICE and 34% (95% CI, 36-50; median = 7.5 months, 95% CI 5.7-12.6) in R-DHAP (p = 0.2; Gisselbrecht 2012); - 3-year PFS (median follow-up time = 27 months) was 31% in R-ICE and 42% in R-DHAP (p = 0.4); - 3-year overall survival (median follow-up time = 27 months) was 47% in R-ICE and 51% in R-DHAP (p = 0.4); - 4-year overall survival (median follow up of 44 months) was 43% (95% CI, 36-50; median = 34.5 months, 95% CI 22.9-51.4) in R-ICE and 51% (95% CI, 44-58; median = 59 months, 95% CI 22.4-NA) in R-DHAP (p = 0.3; Gisselbrecht 2012); - Patients who underwent ASCT, 3-year PFS was 53%, which did not differ for patients who achieved CR or PR just before ASCT. - Univariate (and possibly multivariate) analysis examining the factors affecting EFS, PFS and overall survival found that a significantly negative impact was associated with refractory disease/relapse less than 12 months after diagnosis, saalPI 2-3, and prior rituximab treatment, but not the treatment arm. - Analysis according to early relapse and prior rituximab treatment showed no difference in PFS, EFS, or overall survival for patients with relapse more than 12 months after diagnosis (N = 160) whereas patients with relapse < 12 months after diagnosis and prior rituximab treatment (N = 187) had shorter EFS than patients with relapse < 12 months after diagnosis and no prior rituximab treatment (N = 41; p = 0.001), and the 3-year PFS for patients with relapse < 12 months after diagnosis and prior rituximab treatment (N = 187) was only 23%. However, for such patients who responded and underwent ASCT (N = 68), 3-year PFS was 39%, compared with 14% for patients who did not receive ACST (N = 119; p < 0.001).</p>				

CORAL (only most complete results reported, that is, form the newest or fullest publications)

- Deaths: N = 92 deaths in R-ICE arm, and N = 82 in R-DHAP arm (mainly due to lymphoma).

Relapse and Progression (all Gisselbrecht 2010):

- Progression or relapse: 104 R-ICE patients and 97 R-DHAP patients (mostly at the initial site and by half of patients during the treatment period).
- Treatments administered included radiotherapy and chemotherapy, +/- transplantation (32 autotransplantations and 14 allografts). "A second CR was experienced by 32 of 176 patients. In all, 48 patients, 24 in each treatment arm, reported an event as a result of a new treatment after progression."

Adverse Events (all Gisselbrecht 2010):

- "Grade 3 to 4 hematologic toxicities were more severe in the R-DHAP arm than the R-ICE arm, and more patients required at least one platelet transfusion during the induction phase (57% in R-DHAP arm v 35% in R-ICE arm)."
- Serious adverse events: N = 90 events occurred in 58 R-ICE patients, and N = 120 events occurred in 68 R-DHAP patients. "In both arms, the most common serious adverse events were infections, with a similar rate of infection as a result of neutropenia (16%) in both arms. Grade 3 to 4 nonhematologic toxicities were more severe in the R-DHAP arm and included grade 4 renal toxicity in 11 patients."
- "Patients who underwent BEAM followed by ASCT experienced the usual patterns of hematologic and nonhematologic toxicity, and three toxic deaths occurred."

MAINTENANCE THERAPY (Gisselbrecht 2012)

Response:

- In the maintenance group, 78 patients received all six cycles (new progression was the primary reason for patients not completing the full treatment).
- End of the maintenance treatment CR rates = 57% in the rituximab group and 50% in the observation group (including all deaths).

Survival

- 4-year EFS in patients who received ASCT and were randomly assigned after ASCT was 52% (95% CI, 42-61) in the rituximab group and 53% (95% CI, 44-62) in the observation group (p = 0.7).
- 4-year PFS in patients who received ASCT and were randomly assigned after ASCT was 52% in the rituximab group and 56% in the observation group (p = 0.8).
- 4-year overall survival in patients who received ASCT and were randomly assigned after ASCT was 61% in the rituximab group and 65% in the observation group (p = 0.7).
- It seems that univariate analyses revealed that prior rituximab, being male, treatment failure within 12 months (only 4-year EFS, not PFS or overall survival) and saalPI 2-3 all were associated with significantly worse 4-year EFS, PFS and overall survival, but that only saalPI 2-3 remained significant in multivariate analyses (although it is unclear which covariates were entered into the multivariate analyses). Prior salvage regimen (R-ICE or R-DHAP) or response (to salvage regimen?; CR/Cru or PR) did not influence 4-year EFS, PFS and overall survival.
- The detrimental effect of being male on 4-year EFS, PFS and overall survival was only evident in the rituximab group, not in the observation group.
- Further description of the multivariate analyses for PFS showed that maintenance arm (rituximab, observation), salvage arm (R-ICE, R-DHAP), prior treatment with rituximab, response after salvage treatment (CR/Cru, PR) and time to treatment failure from diagnosis (more or less than 12 months) did not significantly affect PFS, but that both saalPI 2-3 (HR = 2.099; 95% CI 1.396-3.156) and male gender (HR = 1.799; 95% CI 1.141-2.836) both were associated with shorter PFS.
- Further subgroup analyses of PFS showed that the relative risk (RR) of being male was 2.43 (p = 0.006) relative to being female in the rituximab group and 1.19 (p = 0.56) in the observation group. In the rituximab group the RR remained significantly raised for being male whether it was in patients aged < 50 years (RR = 2.35, p = 0.019) or ≥ 50 years (RR = 2.43, p = 0.015). In those those rituximab patients aged ≥ 50 years with a BMI ≥ 25 the RR was 1.55 (p = 0.3) whereas it was 4.13 (p = 0.03) in those with a BMI < 25. *It should be noted that the numbers of patients in all these subgroups within the rituximab group ranged from 14-48, so these analyses should be treated with caution.*
- "in a subset analysis based on sex that compared the rituximab and observation groups, the 3-year EFS was 43% (95% CI, 31-54) in men and 69% (95% CI, 53-81) in women (p = 0.1).
- Rixuimab maintenance did not differ significantly from observation in either females (p = 0.24) or males (p = 0.2).

Relapse and Progression

- First progression or relapse was observed in 47 rituximab patients and 46 observation patients (primarily during the follow-up period). "Although this occurrence was at the initial site, half included a new site of involvement."
- "These patients underwent various additional treatments, including radiotherapy (25%) and chemotherapy (76%) with transplantation (14 allografts)."
- 21 patients had a second CR, 13 patients had a PR.
- Deaths: N = 43 (the majority due to lymphoma) in the rituximab patients and 17 of these occurred within 1 year after the transplantation; N = 38 in the observation group, and 19 of these occurred within 1 year after ASCT.

Adverse Events

- "The treatment was well tolerated"
- A total of 87 events were reported in 54 rituximab patients within 100 day, and 75 events were reported in 50 observation patients.
- A total of 75 events were reported in 35 rituximab patients > 100 days after ASCT, and 24 events were observed in 20 observation patients.

CORAL (only most complete results reported, that is, form the newest or fullest publications)

- "The majority of the AEs were infections; 45 episodes of infection were reported in the rituximab group, and 13 episodes were reported in the observation group."
- "Grade 3 or greater delayed neutropenia after day 100, excluding values after additional treatment, was reported in 11 patients (9%) in the rituximab group and in seven patients (6%) in the observation group."
- "Forty-three serious AEs (SAEs) were reported in the rituximab group, and 22 SAEs were reported in the observation group."
- " After day 100, 23 SAEs were reported in the rituximab arm, and only five were reported in the observation group."
- "Fatal outcomes were observed in six patients in the rituximab group and three patients in the observation group; four deaths resulted from secondary cancers (two in the rituximab group and two in the observation group), one death resulted from varicella and one death resulted from myocarditis several months after the end of the treatment, and three deaths resulted from infections and pneumonia.

SUBSET ANALYSES (Trneny et al., 2009)

129/394 patients had end-of-induction treatment PET scans (FDG avid/non-avid): 61 negative, 62 positive; 60 patients completed 63 cycles of R-ICE and 58 patients of R-DHAP; 50 PET-negative and 26 PET-positive patients received BEAM.

- PET-negative patients had 42 CR, 11 CRu, and 7 PR, PET-positive patients had 1 CR, 4 CRu, and 26 PR. There was a significant difference in response rate per CT between PET-negative and PET-positive patients ($p < 0.0001$)
- EFS = 40% for PET-negative patients and 16% for PET-positive patients ($p < 0.0001$).
- PFS = 43% for PET-negative patients and 28 for PET-positive patients (p reported as significant).
- Overall survival = 66% for PET-negative patients and 49% for PET-positive patients ($p = 0.007$).
- "For the 26 patients submitted to transplantation with PET positivity there was a significant difference for EFS ($p=0.03$) when compared to PET negative patients, but no statistical difference in PFS and OS."
- "Factors affecting response rate in multivariate analysis were early relapse/refractory < 12 months and PET+ve following induction. The same factors were found in cox's model for EFS and PFS."

SUBSET ANALYSES (Thieblemont et al., 2011)

249/396 patients with histologic material were analysed. 8/249 patients had PMBL and 12 had follicular lymphoma.

- Immunohistochemistry: CD10, BCL6, MUM1/IRF4 and BCL2 positivity/negativity did not affect overall survival, PFS or CR, but FOXP1 (Barrans) did influence overall survival ($p = 0.036$) and PFS ($p = 0.024$), but not CR.
- Chromosomal break point (FISH): BCL2/18q21 and BCL6/3q27 did not affect overall survival, PFS or CR, but c-MYC/8q24 did influence overall survival ($p = 0.02$), PFS ($p = 0.04$), and CR ($p = 0.005$).
- ImmunoFISH index published by Copie-Bergman (number of occurrences) did not influence overall survival, PFS or CR.
- GCB/ABC algorithm publication: Hans, Muris or Nyman did not influence overall survival, PFS or CR. *BUT for the significant results, these should be interpreted with caution as a large number of analyses were conducted and there was no correction of the alpha-value.*
- Analyses of the clinical outcome according to the treatment arms in each biomarker subgroup showed:
 - (1) "PFS was significantly different when we studied BCL6 protein expression, BCL2/18q21 gene rearrangement, GCB/non-GCB classification on the basis of the Hans algorithm, and ABC phenotype on the basis of the algorithm by Nyman, in the R-ICE arm and R-DHAP arms. Interaction between GCB/non-GCB Hans classification and the R-ICE treatment versus R-DHAP treatment was significant ($p < .035$). Patients with GCB DLBCL according to the algorithm by Hans, who were treated with R-DHAP, had a better PFS than patients with non-GCB DLBCL (3-year PFS rate [standard deviation, SD], 52% [7%] v 32% [7%], respectively; $p = .01$).
 - The PFS for patients treated with R-ICE did not differ between the GCB (3-year rate [SD] = 31% [7%]) and non-GCB Hans (27% [7%]) phenotypes ($p = 0.81$).
 - Overall survival for patients treated with R-DHAP did not differ between the GCB (3-year rate = 61%) and non-GCB Hans (45%) phenotypes ($p = 0.081$).
 - Overall survival for patients treated with R-ICE did not differ between the GCB (3-year rate = 50%) and non-GCB Hans (49%) phenotypes ($p = 0.96$).
 - "Analysis realized after removing PMBL and transformed FL occurrences resulted in unchanged results neither in PFS (non-GC v GC, 34% v 72%; 2-year PFS for R-DHAP, $P = .04$; 41% v 51% for R-ICE; $P=.60$), nor in OS (non-GC v GC, 51% v 83%; 2-year OS for R-DHAP, $P=.11$; 57% v 62% for R-ICE; $P=.65$).
 - "Multivariate analysis showed an independent prognostic impact of the following parameters on PFS: GCB/non-GCB Hans phenotype interaction with treatment ($P = .04$), prior rituximab exposure ($P = .0052$), secondary aalIPI ($P = .039$), and FoxP1 expression ($P = .047$)." *Please note that the direction of these effects as well as all the covariates entered into the analyses are not reported.*
 - GEP (Alizadeh; N = 46): 51% predicted as GCB occurrences, and 49% were predicted as ABC occurrences. Two samples could not be predicted. GCB-like DLBCLs have a better PFS and OS than ABC-like DLBCLs (3-year OS = 74% for GCB and 40% for ABC; 3-year PFS = 70% for GCB and 28% for ABC). Analyses grouping patients according to their GEP groups and treatment (R-DHAP or R-ICE; n = 10, 16, 12, and 8, respectively), analyses showed that R-DHAP patients with GCB-like DLBCL had a better PFS but not OS than R-ICE patients with GCB-like DLBCL (3-year PFS = 100% for R-DHAP patients with GCB-like DLBCL and 27% for R-ICE patients with GCB DLBCL, $p = 0.01$). 3-year PFS in patients with ABC-like DLBCL = 60% for R-ICE and 30% for R-DHAP.

SUBSET ANALYSES (Cuccuini et al., 2012)

Non Hodgkin's Lymphoma: diagnosis and management

CORAL (only most complete results reported, that is, form the newest or fullest publications)	
	<p>161/477 patients with a successful FISH analysis were analysed. All patients had DLBCL. 133 patients were MYC-negative, whereas 28 patients had a MYC rearrangement (N =21 were double- or triple-hits). 13 and 15 of the 28 MYC+ patients were treated with R-DHAP and R-ICE, respectively.</p> <ul style="list-style-type: none"> - Overall response rate after induction treatment did not differ between MYC+ (50%) and MYC- (69%, p = 0.052) - CR rate after induction treatment was lower in MYC+ (25%) than MYC- (45%, p < 0.05). - After the induction treatment 43% MYC+ and 60% MYC- patients underwent HDT/ASCT(p = 0.1). - 4-year PFS after was lower in MYC+ (18%) than MYC- (42%, p = 0.032). - 4-year overall survival was lower in MYC+ (29%) than MYC- (62%, p = 0.011). - MYC+ patients who underwent HDT/ASCT had 4-year PFS and overall survival of 14% and 23%, respectively. - In MYC+ patients there were no differences in overall response between patients who had received R-ICE (40%) or R-DHAP (62%, p = 0.16) - In MYC+ patients there were no differences in CR between patients who had received R-ICE (23%) or R-DHAP (26%, p = 0.83) - In MYC- patients the CR rate was significantly lower in patients who had received R-ICE (35%) than R-DHAP (54%, p = 0.025) - MYC+ patients: 3-year PFS = 19% in R-ICE and 17% in R-DHAP - MYC+ patients: 3-year overall survival = 26% in R-ICE and 31% in R-DHAP - MYC- patients: 3-year PFS = 31% in R-ICE and 53% in R-DHAP - MYC- patients: 3-year overall survival = 51% in R-ICE and 71% in R-DHAP - When all 161 patients were classified into GCB and non-GCB phenotype according to the Hans algorithm, the complete remission rate in the GCB patients treated with R-DHAP (49%) was higher than the non-GCB DLBCL patients (31%, p = 0.035). - "Multivariate analysis using a Cox proportional hazard model including the presence or absence of MYC aberrations, the type of induction treatment, R-ICE versus R-DHAP, and the GC versus non-GC phenotype based on the Hans algorithm confirmed that the only significant factor for both PFS and OS was the presence of a MYC aberration, with a relative risk (RR) of 1.8 for PFS (p = .0248), and an RR of 2 for OS (p = .0162)." <p>SUBSET ANALYSES (Van den Neste et al., 2013)</p> <p>220 patients refractory to R-DHAP/ICE before scheduled ASCT (REF, N = 145) or who relapsed after BEAM/ASCT (REL, N = 75) were included.</p> <ul style="list-style-type: none"> - MYC was rearranged in 18/75 patients, 51/122 patients were non-GC. Third-line therapy consisted of ICE-type (24%), DHAP-type (20.5%), gemcitabine-containing (20%), CHOP-like (9.5%), dexaBEAM (5.5%), and miscellaneous (26%) regimens. - "Overall response rate was 43% (CR 24%, CRu 6%, PR 14%) and was similar between REF and REL pts." - In the REF group, median time between CORAL inclusion and failure = 2.3 months, median overall survival from progression (follow up of 32.8 months) was 6 months and not influenced by the type of third-line regimen; "Overall response rate to third-line chemotherapy was 43%, with 21% complete response (CR), 8% CR unconfirmed (CRu), and 14% PR. CR/CRu and PR rates among pts treated with ICE-type, DHAP-type, gemcitabine-containing, or CHOP-like regimens were 23 and 23%, 35 and 8%, 9 and 4%, 25 and 25%, respectively." "OS was statistically different (p<.0001) according to IPI at CORAL failure: IPI 0-2: 11.1 months (1-y OS 42.9%), IPI > 2: 3.7 months (1-y OS 7.7%, HR 3.021). OS in pts achieving CR/CRu, PR, or no response after third-line regimen was 63.6 m (1-y OS 72.1%, p<.0001), 12.8 m (1-y OS 53.5%, p=.04), and 4.4 months (1-y OS 9.2%), respectively." 64 patients were transplanted: median overall survival after ASCT (N = 56) = 11.5 months, and 7.9 months after alloSCT (n = 8). "Median OS of pts transplanted in CR after third-line regimen was not reached as compared to those in PR (11.8 months) or those with no response (4.4 months, p<.0001). There was no statistically-significant difference in median OS between ASCT and alloSCT, taking into account the low numbers. In multivariate Cox analysis, IPI at relapse (HR 2.409) and transplantation (HR 0.381) independently predicted for OS." - "In the REL group, median time between CORAL inclusion and failure = 10.3 months, median overall survival from progression was 10 months, 16 REL patients received a second transplantation (13 alloSCT; 3 ASCT), the median overall survival after alloSCT = 17.4 months. - "Overall, OS for the 80 transplanted pts was significantly longer (11.8 m, 95% CI: 8.5-19.5) as compared with pts treated with chemo alone (5.8m, 95% CI: 5-7.2, p = 0.0004). Median OS was 11.5 m, after ASCT (n = 59), and 15.4m after alloSCT (n = 21). Age >50 years independently predicted for OS (HR 1.4, p = 0.04)."

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2012		Patient Characteristics	Intervention	Comparison	Outcome
Country	Italy	<p>Inclusion: "DLBCL patients treated with autologous transplant from 1995 to 2008 in 93 Italian transplant units, who relapsed after autologous haematopoietic stem cell transplantation (auto-HSCT) and were treated with allogeneic haematopoietic stem cell transplantation (allo-SCT)"</p> <p>Rituximab was used in association with first-line chemotherapy in all patients diagnosed after 2002 and in association with salvage therapy in patients relapsed after 2002. Choice of conditioning regimen was made according to local protocols. Based on the date of treatment it is therefore assumed (but not explicitly stated by the authors) that 147 patients (89%) received rituximab.</p> <p>Median age at allo-SCT: 43 years (range 16–65). Interval from auto-HSCT to allo-SCT: 13 months (range 3–128) Conditioning regimen: Myeloablative: 49 (30%) Reduced intensity: 116 (70%) Disease status before allo-HSCT: Complete remission: 55 (33%) Relapsed or persistent disease, chemosensitive: 29 (18%) Relapsed or persistent disease, untreated after auto-HSCT: 26 (16%) Relapsed or persistent disease, chemoresistant: 55 (33%)</p>	allogeneic haematopoietic stem cell transplantation (allo-SCT)	Not applicable	Overall survival Progression free survival Treatment response Treatment-related mortality
Design, period	Multicentre retrospective cohort study, 1995 to 2008				
N	165				
Follow-up	Median 39 months (range 1–144 months)				
Funding source	Not reported				
Results	<p>Kaplan-Meier estimates of overall survival after transplant: 1 year: 55% 3 years: 42% 5 years: 39%</p> <p>Kaplan-Meier estimates of progression-free survival after transplant: 1 year: 48% 3 years: 34% 5 years: 31%</p> <p>Response to allo-SCT (evaluable for 110 patients; not evaluable for 55 patients): Complete response: 72 patients (65%) Partial response: 9 patients (8%) Non-responders/rapid disease progression: 29 (26%) Overall response rate (all patients): 49%</p> <p>Number of deaths at last follow-up: 91: 45 from progressive disease, 33 due to toxicity other than GvHD, and 13 from acute GvHD. Nonrelapse mortality rate: 28% Mortality associated with progressive disease: 25%</p>				
Comments	<ul style="list-style-type: none"> - Patient selection bias? Unclear risk - Performance bias? Not applicable (single arm study) - Detection bias? Low risk - Attrition bias (missing data)? Unclear risk 				

Non Hodgkin's Lymphoma: diagnosis and management

Avivi I, Canals C, Vernant JP et al. Matched unrelated donor allogeneic transplantation provides comparable long-term outcome to HLA-identical sibling transplantation in relapsed diffuse large B-cell lymphoma. Bone Marrow Transplantation 2014; 49: 671-678.																																							
Pub year: 2014		Patient Characteristics	Intervention	Comparison	Outcome																																		
Country	International (mainly European)	Patients older than 18 years with DLBCL who received an HLA-sib or URD- HCT from January 2000 to December 2007 and were reported to the European Group for Blood and Marrow Transplantation (EBMT) were included in the analysis. Patients undergoing allo-SCT for transformed lymphoma, those receiving umbilical cord blood transplant and individuals, who had a prior allo-HCT, were excluded from the study. Matched sibling donor allogeneic hematopoietic cell transplantation (SIB-allo-HCT) Unrelated donor allogeneic hematopoietic cell transplantation (URD-allo-HCT)	SIB-allo-HCT	URD-allo-HCT	Non-relapse mortality, progression free survival, overall survival,

4.5 Burkitt Lymphoma

4.5.1: Review question: What is the most effective first-line treatment for people with Burkitt lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) newly diagnosed with Burkitt lymphoma. Exclude: Endemic Burkitt DLBC-Burkitt Tumours which lack myc rearrangements but have gene expression patterns resembling BL Post-transplant lymphoproliferative disease L3 ALL	Chemotherapy Codox-m/IVAC +/- Hyper-Cvad GALGB 9251 LMB/A (+ year) SFOP (French) BFM (German) Chemo-immunotherapy Dose-Adjusted EPOCH-Rituximab (Da-epoch-R) Chemotherapy regimens+/- Rituximab	Each other	Overall survival Treatment related mortality Treatment related morbidity Health-related quality of life Central Nervous System (CNS) progression

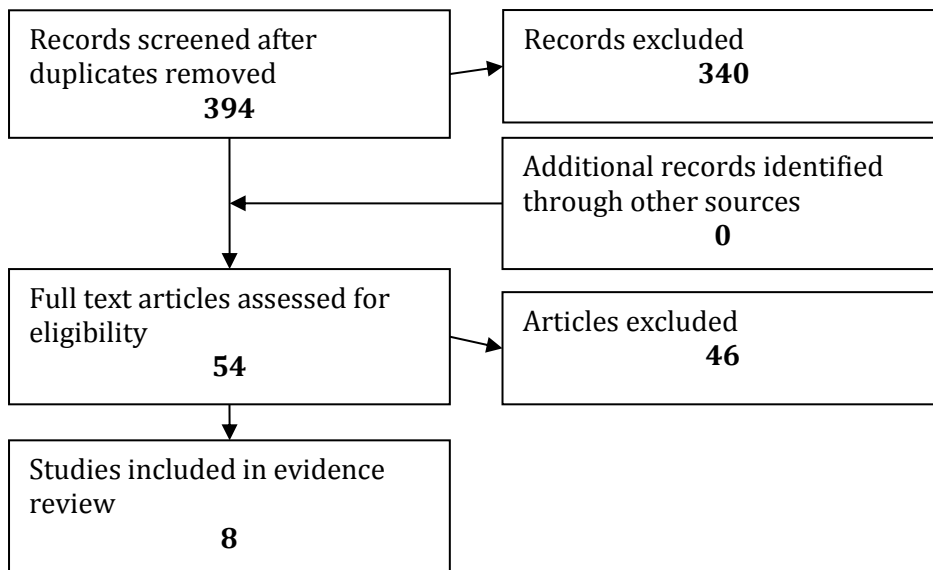

Additional Comments on PICO

Note for each study how risk is defined (early/low risk, advanced/high risk)
 Endemic Burkitt out due to no standard treatment, prevalence predominately sub-Saharan Africa.
 DLBC-Burkitt may crop up due to diagnostic uncertainty
 Where noted categorise by MYC in results
 exclude papers which only have HIV BL populations. Only include papers where population has some sporadic BL.
 Include non-comparative studies for interventions for which no comparative evidence was found (SFOP, Da-epoch-r).The following criteria were applied for non comparative studies:

- Modern diagnostic criteria
- Sufficient information reported on diagnosis to assess diagnostic criteria
- Publication date: >2006

Summary Tables

Figure 1. Study flow diagram

Additional non-comparative study search:

105 non-comparative studies in the database

- Exclusion N=91 at abstract and title sift:
 - o 41/105: published \leq 2006
 - o 50/105: interventions with comparative evidence already appraised, retrospective reviews, conference abstracts with no diagnostic criteria provided, wrong population (e.g. children, endemic etc.)
- Ordered N=7
 - o Exclusion N=6 at full paper review:
 - o No diagnostic details provided, interventions not included

Non Hodgkin's Lymphoma: diagnosis and management

Evidence Statements

Evidence came from one randomised controlled trial and seven cohort studies (one prospective).

Comparison of interventions

Five retrospective cohort observational studies including 650 patients reported comparisons of treatment regimens (HyperCVAD, CODOX-M/IVAC, CALGB9251, BFM and CHOP/CHOEP/MEVA/other). Overall survival rates were highest in the patient groups receiving HyperCVAD (82.8%), BFM (77.8-81.7%) and CODOX-M/IVAC (68.6-74.5%) and lowest in the patient groups receiving CHOP/CHOEP/mmCHOP/MEVA/Other regimens (35.5-38.8%). From the two observational studies reporting adverse events, the CHOP-like regimens reported lower rates of adverse events (treatment related mortality, neutropenia, nadir fever) but higher rates of CNS progression compared to the other treatment regimens (HyperCVAD, CODOX-M/IVAC, CALGB9251, BFM).

Overall survival

Three observational studies (Wästerlid *et al.*, 2013; Walewski *et al.*, 2001; Wang *et al.*, 2000) including 376 patients provided very low quality evidence of overall survival rates on the effectiveness of CODOX-M/IVAC compared to CHOP/CHOEP/MEVA/other. Reporting overall survival (range 1-2 years; follow-up median 37.5 months) rates of 68.6-79% in the CODOX-M/IVAC group compared to 30-42% in the CHOP/CHOEP/MEVA/other group. Walewski *et al.* (2001) reported that difference in overall survival was significant in their population ($p=0.0003$).

Two observational studies (Wästerlid *et al.*, 2013; Smeland *et al.* 2004) including 200 patients provided very low quality evidence of overall survival rates on the effectiveness of BFM compared to CHOP/CHOEP/mmCHOP. Overall survival (range 2-5 years, follow-up 13-247 months) rates ranged from 65-81.7% in the BFM group and from 23-38.8% in the CHOP/CHOEP/mmCHOP group. Wästerlid *et al.* (2013) reported that the difference between BFM and CHOP/CHEOP was significant at the univariate level ($p<0.001$) but did not remain significant at the multivariate analyses ($p=0.1$).

The Wästerlid *et al.* (2013) study also provided very low quality evidence of overall survival rates when comparing BFM to HyperCVAD and CODOX-M/IVAC, reporting that patients receiving BFM had a two year survival rate of 81.7% compared to 82.8% of patients receiving HyperCVAD and 68.6% of patients receiving CODOX-M/IVAC. The authors reported that these differences were not significantly different.

Complete remission and adverse events

One observational study (Smeland *et al.*, 2004) including 49 patients comparing BFM to mmCHOP provided very low quality evidence of higher complete remission rates (73.7% versus 53.8%), higher rates of event free survival (73.7% versus 30.8%) and no events of central nervous system progression (0% versus 30.8%) in the BFM group. However, the BFM group reported more treatment related mortality (10.5% versus 0%) and higher rates of febrile neutropenia (52.6% versus 0%) compared to the mmCHOP group.

One observational study (Wang *et al.*, 2000) including 38 patients comparing CODOX-M/IVAC to other treatment regimens (>60% CHOP) provided very low quality evidence of higher complete remission rates (8% versus 41.2%). The patients receiving CODOX-M/IVAC reported higher rates of neutropenia (95.2% versus 64.7%) and Nadir fever (90.5% versus 58.8%) compared to the patients receiving other treatment regimens (>60% CHOP). The author did not report significance level of these differences.

Role of rituximab

The role of adding rituximab to treatment regimens (HyperCVAD, CODOX-M/IVAC, CALGB 9251, BFM, CHOP/CHOEP, B-NHL86, LMBA) was assessed in four retrospective cohort observational studies (Wildes *et al.*, 2014; Wästerlid *et al.*, 2013; Dujmovic *et al.*, 2012; Barnes *et al.*, 2011) including 393 patients and one randomised control trial (Ribrag *et al.* 2012) including 257 patients.

Overall survival

The four observational studies provided very low quality evidence of an overall survival (range 2-5 years; follow-up mean 29.4 months) range of 70.2-83% in the chemotherapy plus rituximab group versus 29.4-66% in the chemotherapy alone. The RCT assessed the addition of rituximab to LMBA reporting very low quality evidence of 3-year overall survival (follow-up median 38 months) of 82% compared to 71.33% in the group treated with LMBA only. Three of the four observational studies and the RCT reported a significant benefit of the addition of rituximab to chemotherapy in overall survival (in all studies $p < 0.05$). The fourth observational study reported a trend in favour of the addition of rituximab. However, the addition of rituximab to chemotherapy failed to remain significant in three observational studies that reported multivariate analyses (Wildes *et al.*, 2014; Wåsterlid *et al.*, 2013; Barnes *et al.*, 2011). Age, performance ≥ 2 and central nervous system involvement were all factors that remained significant at the multivariate level.

Event free survival

Three of the four observational studies (Wildes *et al.*, 2014; Dujmovic *et al.*, 2012; Barnes *et al.*, 2011) and the RCT provided very low quality evidence of higher event free survival (range 3-5 years) in the patients receiving chemotherapy plus rituximab (60.6-83% [observational studies]; 75.8% [RCT]) compared to the patients receiving chemotherapy alone (29.4-61% [observational], 64.3% [RCT]). One of the three observational studies and the RCT reported that the difference in event free survival was significant ($p < 0.05$). However, neither of these papers reported multivariate statistical analyses.

Complete remission

Three of the four observational studies (Wildes *et al.*, 2014; Dujmovic *et al.*, 2012; Barnes *et al.*, 2011) provided very low quality evidence of higher rates of complete remission (follow-up mean 29.7 months) in the chemotherapy plus rituximab group (83.3-94.4%) compared to the chemotherapy alone group (37.5-85%). Only one of these studies reported that this difference was significant ($p = 0.035$; Dujmovic *et al.*, 2012). This study did not report multivariate statistical analyses.

Adverse events

The addition of rituximab to the regimens was associated with very low quality evidence of lower incidence of tumour lysis syndrome reported in two of the observational studies (5.8% versus 14.6%: Dujmovic *et al.*, 2012; Barnes *et al.*, 2011) but a higher incidence of sepsis (12.5% versus 7.5%) reported in one observational study (Barnes *et al.*, 2011). Very low quality evidence of higher rates of treatment related mortality in the chemotherapy plus rituximab group were reported in one observational study (10% versus 5%; Barnes *et al.*, 2011) and the RCT (7% versus 5.4%). No statistical information was provided by the studies regarding these reported differences.

Da-Epoch-R

No comparative evidence was found for the use of Da-epoch-R. One prospective non-comparative study including 30 patients using the WHO 2008 modern diagnostic criteria (Dunleavy *et al.* 2013) provided very low quality evidence for the rate of freedom from progression of disease at medium follow up of 95% (confidence interval [CI]: 75-99%) in the Da-epoch-r group and 100% (CI: 72-100%) in the Sc-epoch-rr group and overall survival rates of 100% (CI: 82-100%) and 90% (CI: 60-98%), respectively. No treatment related deaths were reported but in 19% of the treatment cycles there was fever and neutropenia resulting in hospital admission. In addition, 17% of the patients experienced a neurological sensory impairment after treatment and 7% experienced a neurological motor impairment.

GRADE Tables

GRADE profile 1: Chemotherapy plus Rituximab versus Chemotherapy

¹Smeland et al. (2004) reported a follow-up range of 13-247 months. Wasterlid et al. (2013) reported a median follow-up of 58 months.

²Smeland et al. (2004) population included BL and BLL.

³Wästerlid et al. (2013) data includes patients that received Rituximab but authors did not provide a breakdown by intervention.

⁴Confidence interval for the effect estimate includes both no effect and appreciable benefit or harm.

Non Hodgkin's Lymphoma: diagnosis and management

GRADE profile 7: CODOX-M/IVAC versus CHOP/CHOEP/MEVA/Other

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Event CODOX-M/IVAC	Event CHOP/CHOEP/MEVA/Other	Effect		
									Relative (95% CI)	Absolute	
Complete remission (Follow-up median 17 months^{1,2})											
1	Observational study	Serious limitations ⁴	No serious inconsistency	Serious indirectness ⁵	Serious imprecision ⁷	None	17/21 81%	7/17 41.2%	RR 1.97 (1.07 to 3.60)-	399 more per 1000 (from 29 more to 1000 more)	⊕○○○ Very Low
Overall survival (follow-up median 37.5 months³)											
3	Observational studies	Serious limitations ⁴	No serious inconsistency	Serious indirectness ⁵	Serious imprecision ⁶	None	Range 69% to 79% (N=98)	Range 30% to 42%(N=101)	Not reported	Not estimable-	⊕○○○ Very Low
Neutropenia (Follow-up median 17 months^{1,2})											
1	Observational study	Serious limitations ⁴	No serious inconsistency	Serious indirectness ⁵	Serious imprecision ⁷	None	20/21 95.2%	11/17 64.7%	RR 1.47 (1.02 to 2.12)	304 more per 1000 (from 13 more to 725 more)	⊕○○○ Very Low
Nadir fever (Follow-up median 17 months^{1,2})											
1	Observational study	Serious limitations ⁴	No serious inconsistency	Serious indirectness ⁵	Serious imprecision ⁷	None	19/21 90.5%	10/17 58.8%	RR 1.54 (1.01 to 2.34)-	318 more per 1000 (from 6 more to 788 more)	⊕○○○ Very Low

¹Wang et al. (2000) compared CODOX-M/IVAC to other chemotherapy regimens with 11/17 (65%) patients treated with CHOP.

²Wang et al. (2000) reported a follow-up range of 0-107 months.

³Waleski et al. (2001) did not report follow-up. Wasterlid et al. (2013) reported a median follow-up as did Wang et al. (2000). Wang et al. (2000) reported a range of 0-107 months follow-up.

⁴Wang et al. (2000) Limitations (risk of bias) due to no information provided on sample selection, demographics. Waleski et al. (2001) limitations (risk of bias) due to no information provided on sample selection, demographics.

⁵Wang et al. (2000) Indirectness due to no information provided on classification so unclear if population matches PICO. Waleski et al. (2001) Indirectness due to population including BL and BLL.

⁶ Wasterlid et al. (2013) data includes patients that received Rituximab but authors did not provide a breakdown by intervention. Low number of events

⁷Serious imprecision due to low number of events.

Excluded studies

Study	Reason for exclusion
Afanas, N et al. [Burkitt lymphoma]. [Portuguese]. <i>Acta Medica Portuguesa</i> 2011; 24(5): 735-738.	Not in PICO Population: <16 years old
Barnes, BA et al. Rituximab added to CODOX-M/IVAC has no clear benefit compared to CODOX-M/IVAC alone in adult patients with Burkitt lymphoma. <i>Blood</i> 2009; 114(22)	Same dataset as Barnes et al. (2011) included paper.
Bernasconi, C et al. Burkitt lymphoma/leukemia: a clinicopathologic study on 24 adult patients. <i>Leukemia</i> 1991; 5: Suppl-4.	Not in PICO No comparison of interventions Population: age 12-50 years N = 13
Biggar, RJ et al. Very late relapses in patients with Burkitt lymphoma: Clinical and serologic studies. <i>Journal of the National Cancer Institute</i> 1981; 66(3): 439-444.	Not in PICO Population: endemic BL, <16 years old
Bowcock, SJ et al. Elderly very poor performance status patients with aggressive B cell lymphomas can gain long term remissions with intensive chemotherapy with encouraging response rates and overall survival (OS). <i>Blood</i> 2010; 116(21)	Not in PICO Only one patient with BL, no comparison of interventions
Brecher, ML, Gardner, R, and Ettinger, LJ. Intensive chemotherapy for treatment of advanced Burkitt lymphoma. <i>Proceedings of the American Association for Cancer Research</i> 1981; Vol.: C-291.	Not in PICO No comparison of interventions Population: age 11 months – 17 ½ years old N = 13
Castillo, JJ. Population-based prognostic factors for survival in patients with Burkitt lymphoma: An analysis from the Surveillance, Epidemiology, and End Results database. <i>Cancer</i> 2013; 119(20): 13672-3679.	Not in PICO No comparison of interventions No data on interventions, aim was to assess prognostic factors
Costa, LJ et al. Trends in survival of patients with burkitt lymphoma diagnosed in the USA: An analysis of 3691 cases. <i>Blood</i> 2012; 120(21)	Not in PICO No comparison of interventions No data on interventions, aim was to assess prognostic factors
Dujmovic, D et al. Addition of rituximab to high-dose methotrexate-based chemotherapy improves outcomes in adult burkitt lymphoma patients. <i>Haematologica</i> 2010; 95: 625-626.	Same dataset as Dujmovic et al. (2012) included paper. Conference Abstract, limited data available.
Dunleavy, K et al. Low-intensity therapy in adults with Burkitt lymphoma. <i>New England Journal of Medicine</i> 2013; 369(20): 1915-1925.	Not in PICO. No comparison of interventions. All the sporadic BL patients received the same intervention. Comparison was BL versus HIV-BL
Dunleavy, K et al. Rituximab is associated with prolonged immunoglobulin deficiency in newly diagnosed patients with aggressive B-cell lymphoma receiving immunochemotherapy. <i>Blood</i> 2010; 116(21)	Not in PICO Population DLBCL and BL with >80% DLBCL so results not representative
Durodola, JI. Burkitt lymphoma in Ibadan: response to various chemotherapeutic agents and long term survivors. <i>Journal of the National Medical Association</i> 1976; 68(4): 294-299.	Not in PICO Population: 98% ≤14 years old Possibly endemic BL
Jost, LM et al. Short-term weekly chemotherapy followed by high-dose therapy with autologous bone marrow transplantation for lymphoblastic and Burkitt lymphomas in adult patients. <i>Annals of Oncology</i> 1995; 6(5): 445-451.	Not in PICO Population: Burkitts type lymphoblastic lymphoma
Kelly, JL et al. Outcomes of patients with Burkitt lymphoma older than age 40 treated with intensive chemotherapeutic regimens. <i>Clinical Lymphoma & Myeloma</i> 2009; 9(4): 307-310.	Systematic review, re-analysis of number of included studies including patients ≥40 years old

Non Hodgkin's Lymphoma: diagnosis and management

Kojima, Y et al. Feasibility of highly intensive chemotherapy for AIDS-related Burkitt lymphoma. <i>Journal of Clinical Oncology</i> 2013; 31(15 SUPPL. 1)	Conference abstract. Not enough data presented to extract.
Magrath, IT and Ziegler, JL. Failure of BCG immunostimulation to affect the clinical course of Burkitt lymphoma. <i>British Medical Journal</i> 1976; 1(6010): 615-618.	Not in PICO All patients received the same intervention Population: Endemic BL Age ≤16 years old Intervention: BCG
Magrath, IT, Ziegler, JL, and Bluming, AZ. Preliminary results of a randomized trial of BCG immunotherapy in Burkitt lymphoma. <i>Recent Results Cancer Res (Berl)</i> 1974; 47: 461-465.	Not in PICO Population: Endemic BL Age ≤16 years old Intervention: BCG
Maruyama, D et al. Modified cyclophosphamide, vincristine, doxorubicin, and methotrexate (CODOX-M)/ifosfamide, etoposide, and cytarabine (IVAC) therapy with or without rituximab in Japanese adult patients with Burkitt lymphoma (BL) and B cell lymphoma, unclassifiable, with features intermediate between diffuse large B cell lymphoma and BL. <i>International Journal of Hematology</i> 2010; 92(5): 732-743.	Not in PICO Population: Only 4/15 had BL of which ¾ had previously received treatment.
Mascres, C, Katongole-M'Bidde, E, and Vauclair, R. Burkitt lymphoma. Survey and up to date data. [French]. <i>Revue de Stomatologie et de Chirurgie Maxillo-Faciale</i> 1988; 89(6): 348-356.	Not in PICO No comparison of included interventions.
Matsuki, E et al. Chemo-immunotherapy with Hyper-CVAD/MA and rituximab for B-cell lymphomas leads to prolonged immune suppression compared to conventional treatment with R-CHOP. <i>Blood</i> 2013; 122(21).	Not in PICO All patients received the same intervention (4/21 BL in sample)
Morel, P et al. Comparison of two high-dose cyclophosphamide, doxorubicin, vincristine, and prednisone derived regimens in patients aged under 60 years with low/intermediate risk aggressive lymphoma: A final analysis of the multicenter LNH93-2 protocol. <i>Leukemia and Lymphoma</i> 2010; 51(9): 1668-1677.	Not in PICO Only 40/652 patients with BL, intervention data not presented by subtype
Nagai, H et al. Poorer prognosis of intermediate BL/DLBCL compared to burkitt lymphoma in rituximab era: A retrospective analysis with clinical and pathological features. <i>Haematologica</i> 2010; 95: 632.	Abstract: limited information, no breakdown by intervention and BL type
Nkrumah, FK and Perkins, IV. Burkitt lymphoma. A clinical study of 110 patients. <i>Cancer</i> 1976; 37(2): 671-676.	Not in PICO Population: Endemic BL, age range 2½ years – 16 years, intervention data not presented by age
Nkrumah, FK, Perkins, IV, and Biggar, RJ. Combination chemotherapy in abdominal Burkitt lymphoma. <i>Cancer</i> 1977; 40(4): 1410-1416.	Not in PICO Population: <16 years old
Nomura, Y et al. High-grade mature B-cell lymphoma with Burkitt-like morphology: results of a clinicopathological study of 72 Japanese patients. <i>Cancer Science</i> 2008; 99(2): 246-252.No	Not in PICO Population: BL and BLL, also >70% of the comparison group were ≤15 years old
Oji, C and Ike, I. [Burkitt lymphoma. Study of 110 patients]. [German]. <i>Mund-, Kiefer- und Gesichtschirurgie</i> 1999; 3(4): 220-224.	Not in PICO Population: <16 years old
Olweny, CL et al. Cerebrospinal irradiation of Burkitt lymphoma. Failure in preventing central nervous system relapse. <i>Acta radiologica: therapy, physics, biology.</i> 1977; 16(3): 225-231.	Not in PICO Population: <16 years old
Olweny, CL et al. Treatment of Burkitt lymphoma: randomized clinical trial of single-agent versus combination chemotherapy. <i>International journal of cancer.Journal international du cancer</i> 1976; 17(4): 436-440.	Not in PICO Intervention not included in PICO (CTX versus COM)
Ostronoff, M et al. Burkitt lymphoma in adults: a retrospective study of 46 cases. [Review] [28 refs]. <i>Nouvelle Revue Francaise d Hematologie</i> 1992; 34(5): 389-397.	Not in PICO All but one intervention not included in PICO. In addition only stage IV patients received LMB86 so no comparator.
Prica, A et al. Rituximab improves overall survival in patients treated with CODOX-M/IVAC for burkitt lymphoma (BL) and B-cell lymphoma, unclassifiable, with features intermediate between diffuse large B-cell	Not in PICO Population: All BL received the same intervention.

Non Hodgkin's Lymphoma: diagnosis and management

lymphoma and BL: A single center experience and review of the literature. <i>Blood</i> 2013; 122(21).	Conference abstract N for BL = 21
Schmitz, N et al. Conventional chemotherapy (CHOEP-14) with rituximab or high-dose chemotherapy (MegaCHOEP) with rituximab for young, high-risk patients with aggressive B-cell lymphoma: An open-label, randomised, phase 3 trial (DSHNHL 2002-1). <i>The Lancet Oncology</i> 2012; 13(12): 1250-1259.	Not in PICO Only 1/232 patients with BL, no comparison of interventions
Squire, RA. Burkitt lymphoma--a comparative study. <i>National Cancer Institute monograph</i> 1969; 32: 297-300.	Not in PICO No comparison of interventions. Animal study
Steinke, B et al. Clinic and therapy of Burkitt lymphoma in adults. A review on the basis of 14 cases. [German]. <i>Tumor Diagnostik und Therapie</i> 1984; 5(1): 1-6.	Not in PICO Population: Burkitt-like NHL
Tauro, S et al. Dose-intensified treatment of Burkitt lymphoma and B-cell lymphoma unclassifiable, (with features intermediate between diffuse large B-cell lymphoma and Burkitt lymphoma) in young adults (<50 years): a comparison of two adapted BFM protocols. <i>American Journal of Hematology</i> 2010; 85(4): 261-263.	Not in PICO Population includes B-cell ALL which is excluded from the scope
Thomas, DA et al. Chemo-immunotherapy with hyper-CVAD plus rituximab for adult Burkitt and Burkitt type lymphoma (BL) or acute lymphoblastic leukemia (B-ALL). <i>Blood</i> 2005; 106(11): 47A-47A.	Not in PICO. Population includes B-ALL with no breakdown by subtype and intervention.
Thomas, DA et al. Hyper-CVAD and rituximab for de novo burkitt lymphoma/leukemia. <i>Blood</i> 2011; 118(21).	Not in PICO. Population includes B-ALL with no breakdown by subtype and intervention. Same data as Thomas et al. (2005).
Thomas, DA et al. Long-term outcome after hyper-CVAD and rituximab chemoimmunotherapy for burkitt (BL) or burkitt-like (BLL) leukemia/lymphoma and mature B-cell acute lymphocytic leukemia (B-ALL). <i>Blood</i> 2007; 110(11): 831A-831A.	Not in PICO. Population includes B-ALL with no breakdown by subtype and intervention.
Walewski, J. Burkitt lymphoma - Break-through in outcome of chemotherapy after three decades of evolution. A review of previous approaches to treatment and comparative efficacy analysis of CODOX-M+IVAC and MEVA/CHOP regimens in the experience of the Maria Sklodowska-Curie Memorial Cancer Center - Institute of Oncology in Warsaw. [Polish]. <i>Nowotwory</i> 2001; 51: 1-45.	<i>Article in Polish, abstract reports same data as the Walewski et al. (2001) abstract included in the review.</i>
Wasterlid, T et al. Population based study of prognostic factors and treatment in adult Burkitt lymphoma: a Swedish Lymphoma Registry study. <i>Leukemia & Lymphoma</i> 2011; 52(11): 2090-2096.	Same dataset used as Waserlid et al (2013)
Wildes, TM et al. Hyper-CVAD and rituximab-hyperCVAD in Burkitt lymphoma (BL): A multi-institutional experience. <i>Journal of Clinical Oncology</i> 2011; 29(15 SUPPL. 1).	Same dataset used as Wildes et al (2011)
Ziegler, JL and Magrath, IT. BCG immunotherapy in Burkitt lymphoma: preliminary results of a randomized clinical trial. <i>National Cancer Institute monograph</i> . 1973; 39: 199-202.	Not in PICO Population: Endemic BL Age ≤16 years old Intervention: BCG
Ziegler, JL et al. Burkitt lymphoma--a model for intensive chemotherapy. <i>Seminars in Oncology</i> 1977; 4(3): 317-323.	Not in PICO Population: Relapsed patients
Ziegler, JL. Chemotherapy of Burkitt lymphoma. <i>Cancer</i> 1972; 30(6): 1534-1540.	Not in PICO Population: Endemic BL
Ziegler, JL, Magrath, IT, and Deisseroth, AB. Combined modality treatment of Burkitt lymphoma. <i>Cancer Treatment Reports</i> 1978; 62(12): 2031-2034.	Not in PICO Intervention not in PICO
Ziegler, JL et al. Intensive chemotherapy in patients with generalized Burkitt lymphoma. <i>International Journal of Cancer</i> 1972; 10(2): 254-261.	Not in PICO Population: Endemic BL
Zinzani, PL et al. Adult Burkitt lymphoma: clinical and prognostic evaluation of 20 patients. <i>Leukemia & Lymphoma</i> 1994; 14(5-6): 465-470.	Not in PICO. Intervention: not included in PICO (LSA versus L-MACHOP)

Evidence tables

Dunleavy, K et al. (2013). Low-intensity therapy in adults with Burkitt lymphoma. New England Journal of medicine, 369; 1915-25.																																																																																																																																																																																													
Pub year: 2013		Patient Characteristics						Intervention	Comparison	Outcome																																																																																																																																																																																			
Country	United States	November 2000 through December 2009, 30 consecutive patients with untreated Burkitt lymphoma <i>Inclusion criteria:</i> – Patients with who had not received systemic chemotherapy previously – Adequate organ function apart from organ function affected by disease – Among women with childbearing potential a negative pregnancy test was required Pathological findings were reviewed and confirmed by study pathologists, in compliance with the 4 th edition of the World Health Organisation (WHO, 2008) classification. Immunohistochemical studies and Epstein-Barr virus (EBV)-encoded RNA (EBER) in situ hybridization were performed as indicated. Fluorescence in situ hybridization or conventional karyotype analyses were performed to identify a translocation of MYC in available tissue samples.						DA-EPOCH-R HIV-negative patients SC-EPOCH-RR HIV-positive patients	N/A	Complete response Time to progression Treatment toxicity Overall survival <i>Date of enrolment until death or the last follow-up visit</i> Freedom from progression of disease <i>Date of enrolment until the date of progression or the last follow-up visit</i>

Note. ECOG: Eastern Cooperative Oncology Group: 0-5 with 0 indicating no symptoms and full activity and higher scores indicating increasing levels of disability. LMB: Lymphomes malins B risk groups, defined as follows: A includes patients with low-risk disease (resected stage I or abdominal stage II cancer), group B includes those with intermediate-risk disease (patients not in group A or C) and group C includes those with high risk disease (central nervous system involvement, at least 25% blasts in bone marrow, or both characteristics).

Table 2. Disease progression rates and overall survival according to treatment regimen

Event	DA-EPOCH-R n=19	95% CI	SC-EPOCH-RR n=11	95% CI
Rate of freedom from progression of disease at median follow-up	95	75-99	100	72-100
Overall survival	100	82-100	90	60-98

Note. CI: Confidence interval.

Among the patients with immune-deficiency-associated Burkitt lymphoma, the rates of freedom from progression and overall survival were both 92%

None of the patients in either group had a recurrence of disease or died from Burkitt lymphoma. However, one patient with primary immunodeficiency-associated Burkitt lymphoma did not have a pathological complete response and received localised radiotherapy. Acute myeloid leukemia developed in one HIV-positive patient 2.5 years after the completion of SC-EPOCH-RR, and the patient died 4 months later.

CALGB 9251	7	5/7	71.4	0/0	0	5/7	71.4	N/A	2/5	40

Note. Chemotherapeutic regimen was determined by the regimen received for the majority of cycles, allowing that some patients received their first cycle of chemotherapy prior to final confirmation of histology because of rapidly progressive disease and deteriorating clinical status.

Event-free survival and overall survival:

	Total sample	R-Chemo	Chemo	p value
5-year Event Free survival	50.3%	60.6%	29.4%	0.095
5-year Overall survival	60%	70.2%	29.4%	0.040

Multivariate analysis of predictors of death: On univariate analysis, poor performance status, CNS involvement and not receiving rituximab with chemotherapy were associated with inferior survival. On multivariate analysis, poor performance status or CNS involvement predicted a significantly greater risk of death.

	Univariate HR	p value	Adjusted HR (CI)	p value
Age	1.02	0.34	-	-
Race: Black/other-white	0.82	0.85	-	-

Year of diagnosis (2004-2008 versus 1998-2003)	0.46	0.11	-	-

Note. HR: Hazard Ratio. LDH: Lactate dehydrogenase. CNS: central nervous system. IPI: International Prognostic Index. CI: Confidence interval.

Comments

Complete response: CR was defined using the international working group response criteria (Cheson et al, 1999) taking into consideration that many patients did not undergo positron emission tomography (PET) scanning. Those patients who achieved a complete response unconfirmed (Cru) who did not relapse for at least 1 year were considered in retrospect to have achieved a CR
 The median year of diagnosis for patients who received rituximab was 2007 (2001-2008) and for those who did not receive rituximab was 2000 (1998-2004)
 8 patients (22.9%) underwent autologous stem cell transplantation (1 as salvage therapy and 7 as part of initial therapy) and 4 (11.4%) underwent allogeneic stem cell transplantation as salvage therapy
 The medical record of each patient was reviewed to obtain demographic information, staging information, laboratory data, chemotherapy, response to therapy, relapse and survival. Lactate dehydrogenase (LDH) and uric acid values obtained prior to initiation of chemotherapy were included for analysis
 - Improvement in OS over the observation period of the study among younger patients (up to 65 years) but not among elderly patients (>65 years)

Non Hodgkin's Lymphoma: diagnosis and management

Wästerlid, T et al. (2013). Impact of chemotherapy regimen and rituximab in adult Burkitt lymphoma: a retrospective population-based study from the Nordic Lymphoma Group. Annals of Oncology, 24: 1879-1886.																																																																												
Pub year: 2013			Patient Characteristics						Intervention		Comparison		Outcome																																																															
Country	Sweden and Denmark		All adult patients diagnosed with BL from January 2000 through 31 st December 2009 in Sweden and Denmark. Since 2007 detailed data on treatment have been added to the Swedish Lymphoma registry. To collect data on treatment of Swedish patients added to the registry before 2007, a retrospective review of medical records was carried out. Detailed data on response and relapse was not available for all patients <i>Inclusion criteria:</i> – Diffuse infiltrate of medium-sized cells of B-cell germinal centre immunophenotype, negative for terminal deoxynucleotidyl transferase (TdT) and with >95% expression of Ki-67, with or without demonstrable MYC aberration Baseline Characteristics:						HyperCVAD CODOX/M-IVAC CHOP/CHOEP Other		BFM		2-year overall survival

	Note. *Data on use of rituximab was available for 163 of the 205 patients for whom chemotherapy data was available. No significant differences according to chemotherapy regimen and use of rituximab, WHO performance status, LDH, BM and CNS involvement. Significant age difference among patients receiving the various chemotherapy regimens. As expected, more intensive regimens (e.g. BFM, CODOX-M/IVAC) were more frequently applied to younger patients and less intensive ones (CHOP, CHOEP) to elderly patients. Patients receiving CHOP/CHEOP or no treatment more frequently presented with WHO PS>1 and elevated S-LDH. High age was the only parameter associated with impaired OS at both univariate and multivariate levels. Poor performance status, elevated S-LDH, presence of B symptoms, and bone marrow involvement were all associated with inferior survival at univariate level, but did not retain prognostic value in the multivariate analysis. Gender, Ann Arbor stage, number of extranodal sites and presence of bulky disease (>10cm) had no significant prognostic impact (data not provided by authors).																																																																											

Non Hodgkin's Lymphoma: diagnosis and management

Wästerlid, T et al. (2013). Impact of chemotherapy regimen and rituximab in adult Burkitt lymphoma: a retrospective population-based study from the Nordic Lymphoma Group. *Annals of Oncology*, 24: 1879-1886.

Consecutive versions (1990/1995/2004) of the BFM regimen were the most commonly used treatment schedules in this series.

Estimated 2-year survival and hazard ratio (HR):

Variables	2-yr overall survival (%)	Univariate analysis			Multivariate analysis		
		HR	95% CI	p-value	HR	95% CI	p-value

BM involvement	49.4	1.5	1.0-2.1	0.03	0.9	0.5-1.8	0.8
CNS involvement	45.5	1.5	0.8-2.6	0.2	1.4	0.6-3.2	0.5
B-symptoms	50.3	1.8	1.2-2.6	<0.01	1.6	0.8-3.6	0.2
Year of diagnosis							
2000-2004	52.6						
2005-2009	61.3	0.8	0.5-1.2	0.3	1.9	0.7-4.8	0.2
Rituximab							
No	55.8						
Yes	70.3	0.6	0.3-0.9	0.03	0.4	0.2-1.1	0.07
BFM	81.7	-	-	-	-	-	-
Hyper-CVAD	82.8	1.0	0.4-2.7	0.9	1.2	0.3-4.2	0.8
CODOX/M-IVAC	68.6	1.9	0.9-4.0	0.1	2.1	0.7-5.9	0.2
CHOP/CHOEP	38.8	4.2	2.3-7.8	<0.001	2.4	0.8-7.2	0.1
Other	33.3	5.2	2.5-10.8	<0.001	3.4	1.0-11	0.04

Inclusion of rituximab was associated with improved OS (HR=0.57, CI: 0.34-0.94, p=0.03) but only for the univariate analysis. When stratifying the study population into three age groups, the favourable effect of rituximab on outcome was restricted to the cohort aged 40-65 (HR=0.46, CI: 0.21-0.98, p=0.047). However, when adjusting for age and chemotherapy regimen the addition of rituximab failed to sustain significance (multivariate analysis). In addition, there was no significant effect of rituximab addition in the univariate analysis when examining the various regimens individually.

Multivariate analysis of overall survival with intensive chemotherapy regimens (BFM, hyper-CVAD and CODOX/M-IVAC) adjusted for age, performance status and use of rituximab:

	HR	95% CI	p-value
Age ^a	1.038	1.017-1.060	<0.01
Rituximab	0.979	0.573-1.720	0.98
BFM	-	-	-
Hyper-CVAD	0.671	0.217-2.077	0.49
CODOX/M-IVAC	2.124	0.879-5.133	0.24

Note. ^aContinuous variable

Comments

Cohort includes participants aged 15 years.

HyperCVAD introduced in 2005 and solely administered in Sweden, whereas use of CODOX-M/IVAC was restricted to some Danish centres.

- Advanced age the only prognostic factor remaining independent, CNS directed drugs incorporated in the high intensive chemo regimens are sufficient to eradicate CNS disease

- Low intensity regimens achieved 2 year OS of 38.8% confirming that CHOP and CHOP like regimens are inadequate for treatment of BL

Non Hodgkin's Lymphoma: diagnosis and management

Dujmovic, D et al. (2012). Addition of rituximab to high-dose methotrexate-based chemotherapy improves survival of adults with Burkitt lymphoma/leukemia. Acta Haematol, 127:115-117.																																																																		
Pub year: 2012		Patient Characteristics			Intervention	Comparison	Outcome																																																											
Country	Croatia	Between 2000 and 2011, 20 immunocompetent adult patients with newly diagnosed sporadic BL, stage II-IV were treated using a modification of the B-NHL 86 regimen (GMALL). From 2006 all patients in addition received rituximab. <i>Inclusion criteria:</i> BL diagnosed according to the REAL (1994) or WHO (2008) criteria <i>Exclusion criteria:</i> Patients with Burkitt-like lymphoma according to the REAL classification or grey-zone lymphoma according to the newer WHO criteria were not included in this analysis. Prior to treatment patients underwent routine staging, including CT scanning and bone marrow biopsy. Non Hodgkin's Lymphoma: diagnosis and management

Barnes, JA et al. (2011). Evaluation of the addition or rituximab to CODOX-M/IVAC for Burkitt lymphoma: a retrospective analysis. Annals of Oncology, 22:1859-1864.																																																																																																																																																																															
Pub year: 2011		Patient Characteristics										Intervention		Comparison		Outcome																																																																																																																																																															
Country	USA	All adult BL patients (N=104) diagnosed and treated at Massachusetts General Hospital and the Dana-Farber Cancer Institute from 1 December 1992 to 1 December 2009. <i>Inclusion criteria:</i> N=80: BL diagnosed and treated with modified CODOX-M/IVAC chemotherapy, with or without rituximab. <i>Exclusion criteria:</i> N=24: BL diagnosed and treated with other regimens. The pathological diagnosis of BL was based on review by expert hematopathologists using the current revised European-American Lymphoma (classification system) or WHO criteria at the time of diagnosis. Patients with low-risk disease (defined as a single focus of disease <10cm with a normal LDH level) received three cycles of CODOX-M +/-Rituximab. Patients with high risk disease received alternating CODOX-M and IVAC with or without rituximab for four cycles.										CODOX-M+/-IVAC		CODOX-M+/-IVAC +Rituximab		Overall survival (defined as time from initial diagnosis to death from any cause) Progression free survival (defined as time from initial diagnosis to progression or death) Overall response rate (ORR) (defined as the number of subjects with either complete response [CR] or partial response [PR]) Responses were assessed based on the original radiology reports

Non Hodgkin's Lymphoma: diagnosis and management

Barnes, JA et al. (2011). Evaluation of the addition of rituximab to CODOX-M/IVAC for Burkitt lymphoma: a retrospective analysis. *Annals of Oncology*, 22:1859-1864.

	N	CODOX-M+/-IVAC	CODOX-M+/-IVAC +Rituximab	p-value
N	80	40	40	
Death due to progressive disease after relapse	12	10	2	
Death due to primary refractory disease	7	4	3	
Death due to infectious complications	4	1	3	
Death due to therapy-related myelodysplastic syndrome	1	-	1	
Relapse	16	13	3	0.01
Second remission	4/16			

Note. No treatment related deaths in the low risk group.

	N	Low risk disease	High risk disease
N	80	33	67
Grade 4 neutropenia	72	6	66
Grade 4 thrombocytopenia	68	2	66
Tumour lysis syndrome resulting in renal failure	7	-	7
High risk disease, sepsis	8	-	8

Overall infection rates between groups not significantly different.

Concern over inclusion of R may impair marrow recovery and delay treatment cycles: Mean cycle lengths with the addition of rituximab versus not, and found no difference for either low-risk (19 versus 21 days) or high-risk (23 versus 22 days) patients. No difference in the number of patients able to complete all planned therapy (37 versus 34).

Multivariate Cox regression model for overall survival and progression-free survival

	Hazard Ratio	95% CL	p-value
Overall survival			
Treatment (Rituximab versus no rituximab)	0.56	0.23-1.38	0.21
Age group (>60 versus ≤60)	3.84		0.01
CNS involvement (positive versus negative)	3.03		0.02
HIV (positive versus negative)	1.58		0.44
Risk (high versus low)	3.81		0.08
Progression free survival			
Treatment (Rituximab versus no rituximab)	0.59		0.22
Age group (>60 versus ≤60)	3.04		0.02
CNS involvement (positive versus negative)	2.32		0.06
HIV (positive versus negative)	1.17		0.78

88% with Rituximab and 85% without Rituximab completed all planned therapy (no difference)

Comments Trend in favour of superiority of Rituximab in all efficacy end points 3 year PFS (74% versus 61%) and 3 year OS (77% versus 66%) and in addition fewer relapses (p=0.01).

Non Hodgkin's Lymphoma: diagnosis and management

Smeland, S et al. (2004). Treatment of Burkitt/Burkitt-Like lymphoma in adolescents and adults: a 20 year experience from the Norwegian Radium Hospital with the use of three successive regimens. Annals of Oncology, 15(7): 1072-1078.									
Pub year: 2004		Patient Characteristics			Intervention	Comparison	Outcome		
Country	Norway	<i>Inclusion criteria:</i> Patients who were referred for the first time to the Norwegian Radium Hospital in the period 1981-2001 and were diagnosed with BL/BLL with an age>15 years and <60years (70 years from 1995). All histological material from the cases included was reviewed and the diagnoses were established according to the WHO criteria (2001). No information on whether the diagnosis changed based on this review. 50 eligible but 1 patients lost to follow-up so final N= 49 Survival retrieved from the National Population Registry. All patients expect two received a purged graft (immunomagnetic purging and haemopoietic progenitor cell assessment) Patients treated after 1997 received growth factor support with filgrastim injections to alleviate neutropenia.			MmCHOP	Each other	5 year rates for survival Progression free survival (Projected 5 year BL/BLL free) Death (due to disease, unrelated to BL/BLL, early death) Alive Complete remission (CR) Initial tumour failure CNS progression or relapse		
Design, period	Retrospective cohort study 1981-2001								
N	49/50								
Follow-up	Median in months: Range in months: 13-247				MmCHOP+HDT				
Funding source	Not provided		MmCHOP	MmCHOP+HDT	BFM				
		N	13	17	19	N (Ann Arbor)	13	17	19
		Treatment period	1982-1987	1988-1994	1995-2001	Stage I	4	4	4
		Female	4	6	6	Stage II	1	3	7
		Male	9	11	13	Stage III	1	0	1
		Median age	20	31	36	Stage IV	7	10	7
		Age range	15-44	15-56	17-69	Bulky	5	7	8
		Age> 40 years old	3	6	9	Elevated LDH	9	11	11
		Follow-up (mths)	218	127	49	ECOG>2	4	6	8
		Follow-up range	190-247	71-179	13-80	IPI score <1	5	6	9
		BL	12	14	13	IPI score >1	8	7	10
		BLL	1	3	6				
		Note. MmCHOP+HDT is consolidation treatment. Patients who showed complete response or good partial response with mmCHOP were entered in to a trial to receive MmCHOP+HDT during 1988-1994							
Results	Outcome according to treatment period:								
		N	MmCHOP	MmCHOP+HDT	BFM				
	Treatment period	13	17	19					
		1982-1987	1988-1994	1995-2001					
	Overall survival, 5 years (%)	23.1	70.6	64.5					
	Projected 5-year BL/BLL-free survival (%)	30.8	70.6	73.2					
	Dead of disease	9	5	5					
	Alive	3	12	13					
	Complete remission obtained	7	12	14					
	Early death	0	0	2					
Initial tumour failure	6	5	3						
Death unrelated to BL/BLL	1	0	1						
CNS progression or relapse	4	1	0						
No difference amongst groups regarding any tumour or patient related factors. There was no difference in outcome between BL and BLL (74.0% and 66.7%, respectively). No treatment related deaths									

Non Hodgkin's Lymphoma: diagnosis and management

<p>Smeland, S et al. (2004). Treatment of Burkitt/Burkitt-Like lymphoma in adolescents and adults: a 20 year experience from the Norwegian Radium Hospital with the use of three successive regimens. <i>Annals of Oncology</i>, 15(7): 1072-1078.</p>	
	<p>For patients who were aged >40 years and treated after 1987 (n=16) the projected 5-year PFS was 62.5% Excluding patients treated with only MmCHOP, the projected 5-year PFS by IPI score was 87.5% for IPI≤1 and 60% for IPI score>1.</p>
<p>Comments</p>	<p>BL and BLL population Age starts at 15 years Very unclear if the MmCHOP group were those patients who did not achieve CR or PR in their induction treatment and therefore did not receive the HDT consolidation treatment which would explain their reduced OS and EFS compared to the other two groups. - MmCHOP+HDT as well as short intensive BFM based therapy without consolidation produce similar results with significant but feasible toxicity in patients with BL/BLL up to 60(70) years of age. Outcome in these groups are superior to the CHOP-based regimens</p>

Non Hodgkin's Lymphoma: diagnosis and management

Walewski, J et al. (2001). A major progress in outcome of Burkitt and Burkitt-like lymphoma in a single institution: Evaluation of CHOP/MEVA and CODOX-M/IVAC chemotherapy programs in 80 consecutive patients over 20 years. <i>Blood</i> , 98(11): 252B-252B.					
Pub year: 2001		Patient Characteristics	Intervention	Comparison	Outcome
Country	Poland	<p>CODOX-M/IVAC group: 45 patients with BL and BLL diagnosed in 1996, 20 patients were entered into the UK Lymphoma Group LY06 trial and subsequent 25 patients were treated identically after the trial closed.</p> <p>Reference group: 35 patients treated at the same institution between 1978-2000 with conventionally dosed regimens CHOP/MEVA All adult patients diagnosed with BL from January 2000 through 31st December 2009 in Sweden and Denmark.</p>	<p>CODOX/M-IVAC CHOP/MEVA</p>	<p>Each other</p>	<p>Failure free survival</p> <p>Treatment related mortality</p>
Design, period	Retrospective cohort study 1978-2000				
N	80				
Follow-up	Not provided				
Funding source	Not provided				
Results	<p>In the CODOX-M/IVAC group: 2-year survival free survival for the 45 patients treated was 79% (61-96%) In the CHOP/MEVA group: 2-year survival was 30% (12-48%)</p> <p>Difference in 2-years survival was significant (p=0.0003), greater in a subset of patients with bulky disease, bone marrow and CNS involvement.</p> <p>Treatment related mortality was less than 10% in both groups.</p>				
Comments	<p>BL and BLL patients Conference abstract, limited information provided No information on how statistics computed and if multivariate (no p values presented to show significance levels)</p>				

Non Hodgkin's Lymphoma: diagnosis and management

Wang, D et al. (2000). Intensive chemotherapy (CODOX-M/IVAC) compares favorably with other regimens for HIV positive and negative patients with Burkitt lymphoma (BL). Blood, 11:139.							
Pub year: 2000		Patient Characteristics			Intervention	Comparison	Outcome
Country	USA	Adults (N=38) diagnosed with new BL and treated at Memorial Sloan Kettering Cancer Center (MASKCC) from 1988 to 2000. <i>Inclusion criteria:</i> N=38: BL diagnosed and treated with either CODOX-M/IVAC chemotherapy, or other types of chemotherapy.			CODOX-M+/-IVAC	Other Including M-CHOP	Overall survival Complete remission Relapse Death (Disease related death, toxic)
Design, period	Retrospective cohort study 1988-2000						
N	38		Total	CODOX-M+/-IVAC	Other (including M-CHOP n=11)		
Follow-up	Median: 17 months Range: 0-107	N	38	21	17		
		Stage IV disease	22				
		BM involvement	16				
		CNS involvement	9				
Funding source	Not provided	HIV positive	14				
Note.							
Results	Trend toward improved survival seen in all patients treated with CODOX-M/IVAC versus other treatment.						
	Treatment-related neutropenia (95% versus 65%), nadir fever (91 versus 58%) and documented infection (67 versus 29%) were more common after CODOX-M/IVAC. However, equivalent rates of sepsis (24%) and toxic death (<10%) were seen in both groups.						
	Clinical outcomes:						
		Total		CODOX-M+/-IVAC		Other (including M-CHOP n=11)	
		N	%	n	%	n	%
	N	38	%	21	55	17	45
	CR	24	66	17	81	7	41.2
	Relapses	1	3	1	3	0	0
	Total deaths	16	42	6	28	10	59
	Disease-related deaths	11	29	2	9	9	53
	Toxic death	3	8	2	9	1	6
	Overall survival	22	58	15	72	7	42
Treatment related neutropenia (%)	-	-	20	95	11	65	
Nadir fever	-	-	19	91	10	58	
Documented infection	-	-	14	67	5	29	
Note 6/11 with either CNS or BM involvement achieved CR treated with CODOXM/IVAC versus 0/7 treated with other.							
Comments	Conference abstract, limited information presented No information on age of sample or gender No statistical analysis presented. No information provided on classification of remission. -Authors state that higher rates of CR with CODOX-M/IVAC and more long term survivors compared with patients treated with other regimens.						

4.6: T-Cell Lymphoma

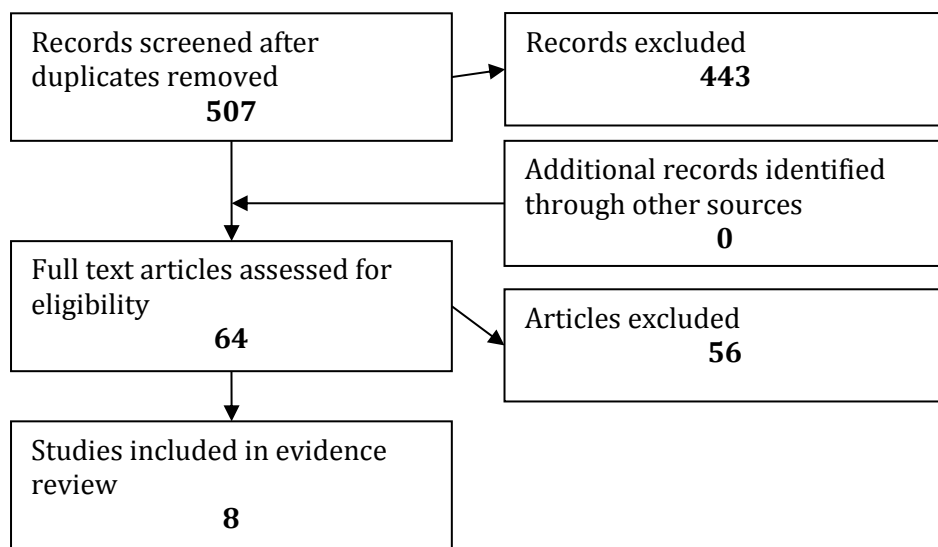

4.6.1: Review question: What is the most effective first-line treatment for people with peripheral T-cell lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
<p>Adults and young people (16 years and older) with new peripheral/mature T-cell non-Hodgkin's lymphoma.</p> <p>Include: Peripheral T-cell not otherwise specified (PTCL-NOS) Angio-immunoblastic</p>	<p>Chemotherapy CHOP Etoposide (CHOEP) Gemcitabine-based GEM-P PEGS ACVBP Mega CHOEP CHOP14</p> <p>Chemo-immunotherapy Alemtuzumab (Campath) (trials in progress)</p>	Each other	<p>Overall survival Overall response Complete response Disease free survival Progression free survival Treatment related mortality Treatment related morbidity Health-related quality of life</p>

Evidence Statements

Twenty three studies (two randomised control trials; two retrospective cohort studies, two phase II trials and 17 non-comparative studies [1 systematic review of 16 non-comparative studies]) reported evidence of the effectiveness of six chemotherapy regimens in 2,080 patients with peripheral T-cell lymphoma (PTCL). Of the comparative studies the five chemotherapy regimens were all compared to CHOP/CHOP like regimens.

Intensive chemotherapy versus CHOP/CHOP like

One retrospective cohort study (Xie *et al.* 2013) provided very low quality evidence of overall survival rates in 276 patients with peripheral T-cell lymphoma (56% PTCL-Not Otherwise Specified [PTCL-NOS] or Angioimmunoblastic T-cell lymphoma [AITL]). Overall survival was 38.9% in patients receiving intensive chemotherapy (ECHOP, Ara-C, Mesna, MINE, ESHAP, GDP, DHAP or Hyper-CVAD) compared to 16.7% in patients receiving CHOP/CHOP like chemotherapy ($p < 0.001$).

CHOEP versus CHOP

One retrospective cohort study of patients ≤ 60 years of age with either PTCL-U or AITL treated on protocols of the German High-Grade Non-Hodgkin Lymphoma Study Group between 1993 and 2007 provided low quality evidence of 3 year event free survival rates of 60.7% in patients receiving CHOEP compared to 48.3% in patients receiving CHOP ($p = 0.057$) (Schmitz *et al.* 2010). The 3-year overall and event free survival rates for the PTCL-U patients ($n = 70$) were 53.9% (95% confidence interval [CI]: 41.7-66.1) and 41.1% (CI: 29.5-52.7), respectively. The 3-year overall and event free survival rates for the AITL patients ($n = 28$) were 67.5% (CI: 50.1-84.9) and 50.0% (CI: 31.6-68.4), respectively.

VIP-rABVD versus CHOP

One randomised control trial (Simon *et al.* 2010) compared the effectiveness of VIP-rABVD to CHOP in patients with peripheral T-cell lymphoma (PTCL-NOS $n = 58$; AITL $n = 15$) provided moderate quality evidence of no overall survival benefit in patients in the VIP-rABVD arm compared to the patients in the CHOP arm (both 43 months survival rate) nor in the 2-year event free survival rate (45 ± 8 versus 41 ± 7 ; $p = 0.70$). Complete response rates in the VIP-rABVD and the CHOP arms (44% versus 33%) and number of deaths during follow-up ($n = 27$ versus 25) did not significantly differ, however, haematological toxicities were significantly higher in the VIP-rABVD arm with 23% versus 8% suffering grade 3-4 neutropenia ($p < 0.001$) and 20% versus 2% had grade 3-4 thrombocytopenia ($p < 0.001$). In addition, red blood cell and platelet transfusions were more frequent in the VIP-rABVD arm ($p < 0.001$). Finally, the overall proportion of cycles resulting in hospitalisation for toxicity were significantly higher in the VIP-rABVD arm compared to the CHOP arm (15% versus 8%, $p = 0.04$).

CycLOBEAP versus CHOP

One retrospective cohort study (Niitsu *et al.* 2008) provided very low quality evidence of 5-year overall survival in 101 patients with peripheral T-cell lymphoma (PTCL-U $n = 59$; AITL $n = 42$) of 61.7% in patients receiving CycLOBEAP compared to 25.7% in patients receiving CHOP. The 5-year progression free survival rate for the patients receiving CycLOBEAP was 59% compared to 22% in the CHOP group. The authors did not report whether the reported survival rates were significantly different. Niitsu *et al.* (2011) conducted a prospective non-comparative study of the effectiveness of CycLOBEAP in 84 patients with peripheral T-cell lymphoma. In the whole sample the 5 year overall and event free survival rates were 72% (CI: 66-79) and 61% (CI: 56-68), respectively, with a complete response rate of 92%. The 5-year overall survival rate for the PTCL-NOS sample ($n = 43$) was 63% and for the AITL sample ($n = 27$) 74%. The rates of grade 3-4 neutropenia, anaemia, grade 3-4 thrombocytopenia and non-haematological adverse events in the whole sample ($n = 84$) were 95%, 71%, 29% and 38%. There were no treatment related deaths (follow-up median: 82 months).

CMED versus CHOP

One randomised controlled trial (Avilés *et al.* 2008) compared the effectiveness of CMED to CHOP in 217 patients with peripheral T-cell lymphoma unspecified (PTCL-U) reporting moderate quality evidence of an increased overall survival benefit in patients in the CMED arm compared to the patients in the CHOP arm

Non Hodgkin's Lymphoma: diagnosis and management

(64% [CI: 68-79] versus 34% [CI: 31-46]; $p < 0.01$) and increased progression free survival (70% [CI: 58-70] versus 43% [CI: 21-32]; $p < 0.01$). The CMED arm had higher complete response rates compared to the CHOP arm (76% [CI: 77-94] versus 57% [CI: 57-69]; $p < 0.05$). There were no treatment related deaths. Grade 1 thrombocytopenia rates in the CMED arm were 16% compared to 12% in the CHOP arm. The rates of hospitalisation due to toxicity were similar in both arms (CMED: 9% versus CHOP: 10%). 4% of patients in the CMED group reported anaemia compared to none in the CHOP group. Finally, more patients in the CHOP group (23%) suffered from granulocytopenia compared to the CMED group (13%). The authors do not report if the numbers of adverse events differed significantly between the two arms.

Anthracycline-based chemotherapy

One systematic review (AbouYabis *et al.* 2011) reported 16 studies assessing the use of anthracycline-based chemotherapies in PTCL-NOS ($n=432$), AITL ($n=169$) and non-ALCL PTCL ($n=417$) patients. Pooled statistics for the AITL patients provided very low quality evidence of a 5-year overall survival rate of 32.1% (CI: 27.2-37.5%) and a complete response rate of 42.1% (CI: 33.9-50.9%). Due to heterogeneity the studies with PTCL-NOS or non-ALCL PTCL patients were not pooled. The range of 5 year overall survival rates in the PTCL-NOS sample were 32-45% for 3 retrospective non-comparative studies and for the non-ALCL PTCL sample were 26 (one retrospective study)-35% (one prospective study). Complete response rates in patients with PTCL-NOS ranged from 17.1-57.1% in three prospective studies and 47-69.6% in six retrospective studies. Complete response rates in patients with non-ALCL PTCL ranged from 41-49% in two prospective studies and 58-59% in two retrospective studies.

CHOP + Avastin

One prospective non-comparative study (Advani *et al.* 2012) provided very low quality evidence for cardiac related adverse events in 44 patients treated with CHOP + Avastin. On average 20% of patients reported cardiac events (CI: 9.1-35.7) with 17% stopping the trial early due to congestive heart failure (CI: 5.6-34.7).

GRADE Tables

Grade Profile 1: Intensive chemotherapy versus CHOP/CHOP like

Peripheral T-cell lymphoma subtypes: Not reported (Xie et al. 2013)

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Intensive chemo	CHOP/CHOP like	Effect		
									Relative (95% CI)	Absolute	
Overall survival (follow-up median: 23 months)											
1	Observational	None	None	Serious ¹	None	None	38.9% (N=135)	16.7% (N=72)	Not reported (Log rank P<0.001)	-	⊕○○○ VERY LOW

Note. N/A: Not applicable, no comparator

¹56% PTCL-NOS or AITL, data not provided by subtype of PTCL. Age range: 11-77

Grade Profile 2: CHOEP versus CHOP

Peripheral T-cell lymphoma subtypes: PTCL-U, AITL (Schmitz et al. 2010)

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	CHOEP	CHOP	Effect		
									Relative (95% CI)	Absolute	
3-year Event free survival in patients ≤60 years old (follow-up median: 43.8 months)											
1	Observational	None	None	None	None	None	60.7% (N=103)	48.3% (N=41)	-	-	⊕⊕○○ LOW

Note. Authors report limited data, and only present comparisons of the interventions in patients under the age of 60 years. No breakdown of interventions according to PTCL subtypes.

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 3: CHOP + Avastin

Peripheral T-cell lymphoma subtypes: PTCL-U, AITL (Advani et al. 2012)

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	CHOP + Avastin (95% CI)	N/A	Effect		
									Relative (95% CI)	Absolute	
Cardiac events (follow-up median: 23 months)											
1	Observational	None	None	Serious ¹	None	None	20% (9.1-35.7)	-	-	-	⊕○○○ VERY LOW
Congestive heart failure (follow-up median: 23 months)											
1	Observational	None	None	Serious ¹	None	None	17% (5.6-34.7)	-	-	-	⊕○○○ VERY LOW

Note. N/A: Not applicable, no comparator. NC: Non-comparative. CI: Confidence Interval

¹Non-comparative phase II trial.

Grade Profile 4: VIP-rABVD versus CHOP

Peripheral T-cell lymphoma subtypes: PTCL-NOS, AITL (Simon et al. 2010)

Quality assessment							Summary of findings				Quality

Non Hodgkin's Lymphoma: diagnosis and management

Advani RH et al. (2012). Cardiac toxicity associated with bevacizumab (Avastin) in combination with CHOP chemotherapy for peripheral t-cell lymphoma in ECOG 2404 trial. Leuk Lymphoma 53(4): 718-720.						
Pub year: 2012		Patient Characteristics		Intervention	Comparison	Outcome
Country	United States	Untreated PTCL patients older than 18 years with baseline cardiac left ventricular ejection fraction (EF) >50% were eligible.		Bevacizumab (15 mg/kg) and standard dose CHOP chemotherapy administered every 21 days for 6-8 cycles and those who achieved a complete response, partial response or stable disease received maintenance therapy with bevacizumab every 3 weeks for 4 cycles	N/A	Adverse events in patients completing at least 6 cycles of A-CHOP
Design, period	Non-comparative study Phase II clinical trial 2006-2011	<i>Exclusion criteria:</i> Clinically significant cardiovascular disease or peripheral vascular disease, including myocardial infarction, unstable angina (within 6 months prior to registration), NYHA Grade II or greater congestive heart failure, uncontrolled hypertension or a history of stroke within 6 months Between July 2006 and March 2009, 44 patients were treated on protocol				
N	44	Median age: 59 years (19-81 years)				
Follow-up	Median: 23 months Range: 1-79 months	30/44 received at least 6 cycles of A-CHOP (17/30 received maintenance bevacizumab)				
Funding source	– Public Health service Grants and the National cancer institute, National institutes of health and the department of health and human services					
Results	8 cardiac events were reported in 6/30 (20%) patients (90% CI: 9.1-35.7%) 1 patients developed grade 2 ventricular tachycardia after 8 cycles Congestive heart failure (CHF), defined as grade 2-4 left ventricular dysfunction (LVD) reported in 5/30 (17%) patients (90% CI: 5.6-34.7%) (all these patients were taken off the study). Medical management of CHF was required in all patients, including a ventricular assist device in one patient with concomitant grade 4 arrhythmia.					
Comments	Authors state that their observation supports the emerging body of literature that the concurrent administration of the combination of the angiogenesis inhibitor bevacizumab with anthracycline is associated with increased risk of LVD, albeit reversible.					

Non Hodgkin's Lymphoma: diagnosis and management

	IPI 2-5	35	81	33	73				
	Note. *Two cases (one NK nasal type and one other angiocentric lymphoma) were not introduced in any of the three principal entities described								
	Figure 1. CONSORT diagram is available								
	Note. Reproduced from the article PDF (page 161)								
Results	77-79% of the CHOP and VIP rABVD planned cycles respectively, were delivered								
	Haematological toxicities significantly higher in the VIP-rABVD arm with 23% versus 8% suffering grade 3-4 neutropenia (P<0.001) and 20% versus 2% had grade 3-4 thrombocytopenia (p<0.001).								
	Red blood cell and platelet transfusions were more frequent in the VIP-rABVD arm (p<0.001)								
	Proportion of cycles leading to hospitalisation for toxicity was significantly higher in the VIP-rABVD arm (15% versus 8%, p=0.04)								
	Number of delayed cycles higher in the VIP-rABVD arm (21% versus 4%, p<0.001)								
	Treatment related mortality similar in both arms (9% in VIP-rABVD versus 7% in CHOP)								
	Table 2. Toxicities according to the WHO scale per number of cycles for each treatment arm

Non Hodgkin's Lymphoma: diagnosis and management

Simon A., et al. (2010). Upfront VIP-reinforced-ABVD (VIP-rABVD) is not superior to CHOP/21 in newly diagnosed peripheral T-cell lymphoma. Results of the randomized phase III trial GOELAMS-LTP95. *British Journal of Haematology* 151; 159-166.

	CR	19		15		-
	PR	6		15		
	NR	18		15		
	Number of deaths during follow-up	27		25		ns
	2-year Event free survival	45%	±8%	41%	±7%	0.70
	Overall survival	42 months		42 months		
	Regardless of treatment arm, the CR rate was significantly higher in the ALCL than in other groups (64% fo ALCL vs 53% for AITL vs 29% for PTCL-nos, p=0.04)					
	In multivariate analysis with an ascendant cox model, Ann arbour stage I-II remained an independent prognostic value for EFS (Hazard ratio: 2.27, 95% CI: 1.02-5.08; p=0.044). ALCL was also independent prognostic value for EFS.					
	Treatment type was not an independent factor (HR: 0.99, 95% CI: 0.58-1.69, p=0.9777)					
Comments	Mixed population Authors state that study outcome demonstrates no difference in term of ORR and CR rates between the two treatment arms. The 2 year EFS and OS were also not statistically different. Furthermore more toxic events were reported in the experimental arm					

Niitsu N., et al. (2008). Clinico-pathologic features and outcome of Japanese patients with peripheral T-cell lymphomas. *Hematological Oncology* 26; 152-158.

Pub year: 2008		Patient Characteristics				Intervention	Comparison	Outcome																																																															
Country	Japan	1545 patients with NHL treated in the Adult Lymphoma Treatment Study Group (ALTSG) in Japan from 1998-2005. 215 (13.9%) newly diagnosed, previously untreated and had T-cell or NK cell lymphoma				CHOP	CycloBEAP	Progression free survival (PFS) Date of beginning chemotherapy to the date of progression or relapse or to the date of the last contact																																																															
Design, period	Retrospective cohort study	101/215 included in the analyses because the clinical features of and treatment modality for the other types of T- and NK -cell lymphoma were considerably heterogeneous Authors conducted an agreement rate of diagnosis analysis and stated that a consensus diagnosis could not be reached for seven PTCL-U cases but it is unclear what happened to these patients						Overall survival (OS) Date of beginning chemotherapy to the date of death from any cause or to the date of the last contact

Non Hodgkin's Lymphoma: diagnosis and management

Schmitz N., et al. (2010). Treatment and prognosis of mature T-cell and NK-cell lymphoma: an analysis of patients with T-cell lymphoma treated in studies of the German High-Grade Non-Hodgkin Lymphoma Study Group. Blood 116: 3418-3425.														
Pub year: 2010		Patient Characteristics										Intervention	Comparison	Outcome
Country	Germany	Between October 1993 and May 2007, 343 patients with mature nodal or extranodal T-cell or NK-cell lymphoma were treated on protocols of the DSHNHL										CHOEP	CHOP	Event free survival (EFS) Time from randomisation or start of therapy to disease progression, start of salvage therapy, further (unplanned) treatment (excluding first-line chemo and radiotherapy), relapse or death from any cause
Design, period	Retrospective review of a series of trials 1993-2007	Mandatory reference pathology performed, diagnosis according to the current World Health Organisation classification.												
N	242/320 Included analyses removed ALK +	320/343 patients included 23/343 excluded from the analysis because the ALK status of some ALCO patients remained unknown (n=11) or the T-cell lymphoma subtype could not be confirmed for technical (n=3) or other reasons (n=9) 242/320 Exclusion of ALK+ patients – for all the analyses included in the table the ALK+ patients have been removed												
Follow-up	Median: 43.8 months (Whole sample n=320) Visit study site every 3 months for first 2 years, every 6 months in years 3-5 and annually thereafter	Table 1. Origin of patients in trials												
Funding source	Funding: – Deutsche Krebshilfe – Kompetenznetz Maligne Lymphome Conflict of interests: – Members of Roche advisory board, research support from Roche	Trial	N	%	ALK +		ALK -		PTCL U		AITL

Note. LDH: Lactate dehydrogenase

Results	Table 3. Survival rates for the included subtypes of the review				
		PTCL U n=70	%	AITL n=28	95% CI
	3-year EFS	41.1	29.5-52.7	50.0	31.6-68.4
	3-year OS	53.9	41.7-66.1	67.5	50.1-84.9
	Note. CI: Confidence interval				
	Table 4.				
		CHOEP	CHOP	P value	
	≤60 years of age				
	3-year EFS	60.7	48.3	0.057	
	Cox modelling: Patients with ALK-negative ALCL, PTCLU or AITL significant survival impact if the IPI is low (≤1). When ALK-positive ALCL excluded, patients with IPI ≥2 show poor EFS (3 year EFS ≤34%) and OS.				
	Authors note that no treatment was significantly better than 6 courses of CHOP given every 3 weeks in patients older than 60 years (they note the small sample sizes).				
Comments	Mixed sample Authors state that all attempts to improve treatment results for younger patients by escalating standard doses of cyclophosphamide, doxorubicin, etoposide and prednisone failed				

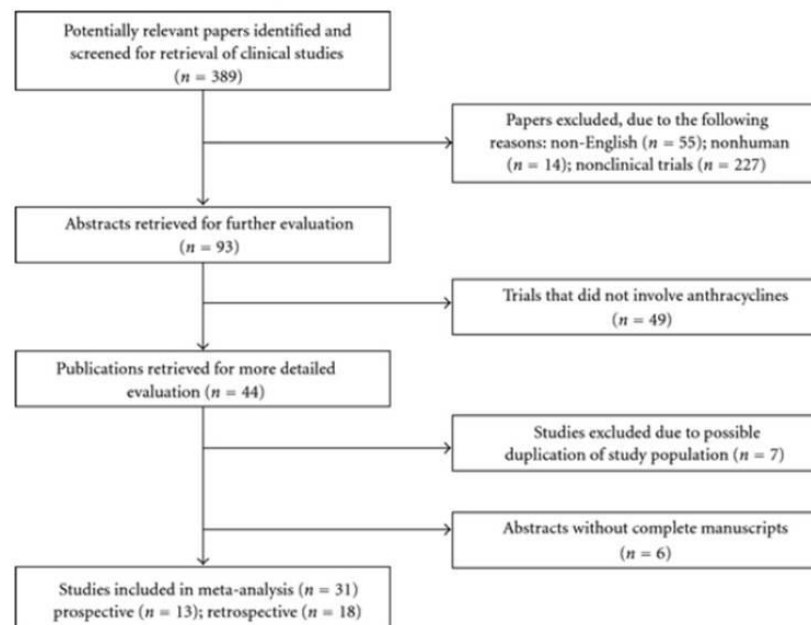

Non Hodgkin's Lymphoma: diagnosis and management

AbouYabis AN, et al. (2011). A systematic review and meta-analysis of front-line anthracycline-based chemotherapy regimens for peripheral T-cell lymphoma. International Scholarly Research Network Hematology. Doi: 10.5402/2011/623924

Objective of review: Elucidate the role of anthracyclines and examine the complete response and OS rates associated with anthracycline-based regimens

Complete response (CR): When combining studies to estimate CR, the P value for the Cochran's Q test was <0.01 and the I² statistic was 59% indicating substantial heterogeneity, therefore the authors did not calculate a pooled estimate of the CR rate for all PTCL patients. AITL demonstrated no evidence of heterogeneity (I²<50%) and was pooled for subtype-specific meta-analysis. PTCL-NOS and non-ALCL PTCL were not pooled due to heterogeneity
Pooled CR rate:
AITL: 42.1% (95% CI: 33.9-50.9%)

5-year Survival rates (OS): Only two studies reporting 5 year survival rates were prospective studies, the P value for the Cochran's Q test was <0.01 and the I² statistic was 78% indicating substantial heterogeneity, therefore the authors did not calculate a pooled estimate of the CR rate for all PTCL patients. AITL demonstrated no evidence of heterogeneity (I²=0%) and was pooled for subtype-specific meta-analysis. PTCL-NOS and non-ALCL PTCL were not pooled due to heterogeneity
Pooled 5-year OS rate:
AITL: 32.1% (95% CI: 27.2-37.5%)

Note. NR: Not reported

Tests indicated that there was no clear evidence of publication bias. Further, tests for publication bias repeated after inclusion of abstracts showed that adding abstracts did not add any significant informational value.

Meta-regression: Age >60 (p=0.03), stage III/IV (p=0.46) and presence of B symptoms (p=0.12) all predictors of complete response rate (prospective studies only, all patients)

Comments

4.6.2: Review question: What is the effectiveness of high-dose consolidation of first-line therapy with autologous or allogeneic transplantation in people with peripheral T-cell lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
<p>Adults and young people (16 years and older) who have undergone first-line treatment for peripheral/mature T-cell non-Hodgkin's lymphoma.</p> <p>Include: Peripheral T-cell not otherwise specified (PTCL-NOS) Angio-immunoblastic</p> <p>Subgroups: Response to first-line treatment PTCL subtypes</p>	<p>Autologous transplantation</p> <p>Allogeneic/allogeneic/reduce intensity transplantation</p>	<p>No transplantation Expectant observation (Clinic appointments, scans)</p> <p>Each other</p>	<p>Overall survival Disease free survival Progression free survival Treatment related mortality Treatment related morbidity Health-related quality of life</p>

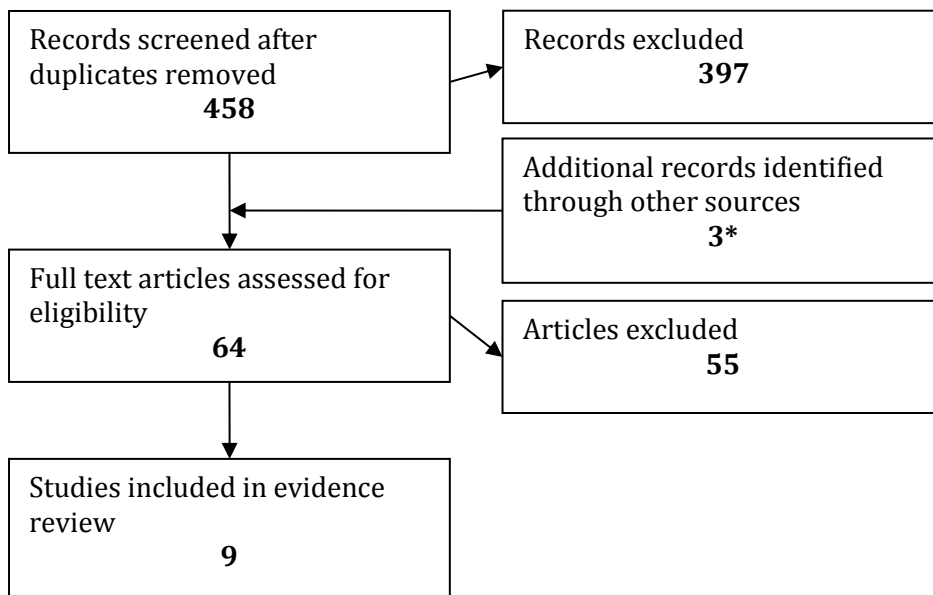

Additional Comments on PICO

Look at stage after appraisal of evidence
mature and peripheral are the same terms
most studies look at all PTCL subtypes. Anaplastic lymphoma kinase (ALK) positive Anaplastic large cell lymphoma (ALCL) has a relatively good prognosis so inclusion of these patients is likely to bias results in favour of the treatment intervention. Some studies specifically exclude these patients. These studies also have a bias towards young people. Exclude papers that only include ALK + ALCL but make note when papers have these populations included in the populations included in PICO (could use GRADE to downgrade evidence in these circumstances).

22.07.14:
Following on from GDG 4 the following criteria was applied to the database:
Exclude meeting abstracts due to limited data available to appraise
Exclude "aggressive NHL" only include PTCL
Exclude pre 2000
Sample size ≥40 (single arm trials)

Evidence Statements

Twenty studies (thirteen observational comparative studies [1 systematic review of 8 studies] and 7 non-comparative studies [1 systematic review of 5 non-comparative studies]) reported evidence of the effectiveness of consolidation therapy using stem-cell transplantation in 1,480 patients with peripheral T-cell lymphoma (PTCL).

Autologous transplantation versus chemotherapy alone

One systematic review (Yin *et al.* 2013) provided very low quality evidence of 3-year overall survival rates from two studies (PTCL-NOS and AITL, n=93) comparing patients who received either an autologous transplantation or chemotherapy alone after first line therapy finding no statistically significant difference between the two groups (Hazard ratio [HR]: 0.60; 95% confidence interval [CI]: 0.05-6.94). Six non-comparative studies of patients receiving consolidation therapy in first response (Mounier *et al.* 2004; 5 reported in Yin *et al.* 2013) provided very low quality evidence of 5-year overall survival rates between 52-62%. Finally Mounier *et al.* (2004) reported a 5 year disease free survival rate of 44% in patients receiving autologous transplantation.

One retrospective comparative observational study (Mehta *et al.* 2013) provided very low quality evidence of overall survival rates in 53 patients with peripheral T-cell lymphoma receiving consolidation therapy after first line therapy. In 32 patients with PTCL-Not Otherwise Specified (PTCL-NOS) the 4 year overall survival and progression free survival rates were 75% and 64.3% in the autologous group compared to 12.5% and 6.3% in the patients who received only chemotherapy. In 21 patients with angioimmunoblastic T-cell lymphoma [AITL] the 4 year overall survival and progression free survival rates were 62.8% and 48.2% in the autologous group compared to 66.7% and 33.3% in the patients who received only chemotherapy.

Complete response versus non-complete response

Very low quality evidence came from one systematic review (Yin *et al.* 2013) included three studies (n=149) comparing complete first response to non-complete first response prior to autologous transplantation. There was uncertainty about the difference in the overall survival of the two groups (HR: 3.17; 95% CI: 0.92-5.42). Three other studies (number of patients not provided by authors) compared complete response to partial response prior to autologous transplantation finding no statistically significant difference between the two groups (HR: 0.73; 95% CI: 0.36-1.48).

Allogeneic transplantation versus chemotherapy alone

Very low quality evidence about overall survival came from one retrospective cohort study (Mehta *et al.* 2013) in five patients with peripheral T-cell lymphoma receiving allogeneic consolidation therapy after first line therapy. In 4 patients with PTCL-NOS the 4 year overall survival and progression free survival rates were 100% and 50% in the allogeneic group compared to 12.5% and 6.3% in the patients who received only chemotherapy (n=26). One patient with AITL received an allogeneic transplantation but did not survive.

One non-comparative study (Le Gouill *et al.* 2008) provided very low quality evidence about complete response rates in PTCL-NOS (n=27) and AITL (n=11) patients receiving allogeneic transplantation of 22% and 9%, respectively and 5-year overall survival rates of 63% and 80%. The Le Gouill *et al.* (2008) study contained patients receiving consolidation therapy after more than one line of therapy although the exact numbers were not reported.

Allogeneic or autologous transplantation versus chemotherapy alone

One retrospective comparative study (Broussais-Guillaumot *et al.* 2013) compared peripheral T-cell lymphoma patients (PTCL-U n=81; AITL n=52; 19.7% complete first response) who had received either an autologous or allogeneic transplantation (n=75) to patients who received chemotherapy alone (n=133). Very low quality evidence from this study indicated median overall survival of 51 months in the transplantation group compared to 15 months in the chemotherapy alone group.

Allogeneic versus autologous transplantation

One prospective comparative observational study (Corradini *et al.* 2014) of 61 patients with peripheral T-cell lymphoma (n=33 PTCL-NOS and n=14 AILT), of which 23 received an allogeneic stem cell transplant and 14 received an autologous stem cell transplant provided very low quality evidence about four-year overall and progression free survival rates of 92% and 70% in the autologous group versus 69% and 69% in the allogeneic group. The authors reported that there were no significant differences between transplant types.

One retrospective comparative observational study (Mehta *et al.* 2013) provided very low quality evidence about overall survival rates in five patients with peripheral T-cell lymphoma receiving allogeneic consolidation therapy after first line therapy compared to 34 patients receiving autologous consolidation therapy. In 32 patients with PTCL-Not Otherwise Specified (PTCL-NOS) the 4 year overall survival and progression free survival rates were 75% and 64.3% in the autologous group compared to 12.5% and 6.3% in the patients who received only chemotherapy. In 17 patients with AILT the 4 year overall survival and progression free survival rates were 62.8% and 48.2% in the autologous group (n=16) compared to 0% in the one patient who received allogeneic transplantation.

Very low quality evidence came from one retrospective comparative observational study (Smith *et al.* 2013) including 241 patients with peripheral T-cell lymphoma (PTCL-U n=102, AILT n=27), of which 24% were receiving transplantation in their first complete response. In 102 PTCL-U patients the one and three year progression free survival rates for the autologous transplantation group (n=39) were 60% (CI: 43-74%) and 29% (CI: 14-47) compared to the allogeneic group (n=63) 40% (CI: 28-52) and 33% (CI: 22-45). The one and three year overall survival rates for the autologous transplantation group (n=39) were 64% (CI: 46-77%) and 45% (CI: 27-62) compared to the allogeneic group (n=63) 52% (CI: 38-64) and 42% (CI: 30-55). The non-relapse mortality rates at one and three years in the autologous group were 3% (CI: 0-12) and 3% (CI: 0-12) compared to 16% (CI: 8-26) and 28% (CI: 17-39) in the allogeneic group. The three year chronic GVHD rate was 43% in the allogeneic group.

In 27 AILT patients the one and three year progression free survival rates for the autologous transplantation group (n=15) were 53% (CI: 26-74%) and 47% (CI: 21-69) compared to the allogeneic group (n=12) 67% (CI: 34-86) and 67% (CI: 34-86). The one and three year overall survival rates for the autologous transplantation group (n=15) were 60% (CI: 35-82%) and 51% (CI: 26-76) compared to the allogeneic group (n=12) 92% (CI: 70-100) and 83% (CI: 56-98).

The 3 year progression free survival rate for patients in their first complete response (n=40) was 58% with a one and three year overall survival rate of 80% and 70%, respectively.

Allogeneic transplantation versus high dose methotrexate

One retrospective comparative observational study (Iriyama *et al.* 2013) provided very low quality evidence about 3 and 5 year relapse rates in 28 patients with peripheral T-cell lymphoma (PTCL-NOS n=13, AILT n=11) receiving autologous transplantation (n=18) or high dose Methotrexate (n=10) consolidation therapy after first line therapy. The 3 and 5 year relapse rates were 68% and 53% versus 58% and 40%

GRADE Tables

Grade Profile 1a: Autologous stem cell transplantation versus Chemotherapy alone: Peripheral T-cell lymphoma subtypes: *PTCL-NOS and AITL (Yin et al. 2013; Mounier et al. 2004)*

Quality assessment							Summary of findings				Quality
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	Autologous	Chemotherapy alone	Effect

	%	P value
40 months median follow-up OS		
PTCL-NOS	47	n.s.
ALK negative	36	

Results

Non Hodgkin's Lymphoma: diagnosis and management

Corradini P., et al. (2014). Intensified chemo-immunotherapy with or without stem cell transplantation in newly diagnosed patients with peripheral T-cell lymphoma. Leukemia, published online Feb 2014.

AILD	50	
40 months median follow-up PFS		
PTCL-NOS	50	n.s.
ALK negative	54	
AILD	50	
4 year OS		
Autologous	92	P=0.10
Allogeneic	69	
4 year PFS		
Autologous	70	P=0.92
Allogeneic	69	

Note. CI: Confidence Interval

For Clinic A: In multivariate analysis the achievement of CR maintained for at least 6 months had a dominant effect on PFS and OS, regardless of the patient's age, IPI or extranodal involvement. Patients who received a transplant had an advantage in OS (hazard ratio [HR]: 0.04; 95% CI: 0.01-0.37, P=0.004 for autologous; HR: 0.22; 95% CI: 0.007-0.67, p=0.008 for allogeneic.

For Clinic B: In multivariate analysis the achievement of CR maintained for at least 6 months was the factor associated with the longest PFS (p=0.0038) and OS (p=0.009)

Table 4. Non-relapse mortality rates according to study

	Clinic A		Clinic B	
	n	%	n	%
NRM	8	13	3	12

			0, 1	34	17						
			≥2	174	83						
Note. LDH: Lactate dehydrogenase; ECOG: Easter Cooperative Oncology Group; IPI: International Prognostic Index; WHO: World Health Organisation.											
Results	In all auto transplanted patients (n=51) 35 patients were alive and free of disease, while 21 relapsed in a median time of 5 months (2-80) and died from progression of disease.										
	Overall response rate to first-line therapy:		69% (48% CR, 21% PR)								
	Overall response rate to first-line therapy for PTCL-U:		59%								
	Overall response rate to first line therapy for AILT:		67%								
	Median survival time (months)		Transplanted (whole sample)			51			No transplant (whole sample)		
								15			
Comments	Authors state that factors influencing this survival were a performance status ≥2 at diagnosis, lack of response to chemotherapy and refractory status. Authors state that this noticeable difference can be explained by the overall better health condition and controlled disease (CR/PR) in patients selected for transplant.										
	Numbers do not add up, different numbers presented at different points of the manuscript for the sample sizes for the treatment groups, unclear which number to report.										
	Mixed population of patients receiving first and second line treatment Mixed population of patients achieving first or second remission Mixed population of patients with PTCL

Non Hodgkin's Lymphoma: diagnosis and management

Iriyama N., et al. (2013). Efficacy of a dose-intensified CHOP (Double-CHOP) regimen for peripheral T-cell lymphomas. <i>Oncology Reports</i> , 29; 805-811.			
	No treatment related mortality cases following HDMTX or ASCT		
	Table 3. Relapse free survival rates (RFS, %)		
		≤65 ASCT	>65 HDMTX
	3 year RFS	68	58
	5 year RFS	53	40
No significant difference in RFS rates according to type of treatment. The HDMTX group tended to relapse earlier than those receiving ASCT (not significantly different)			
Comments	Age starts at 15 Unclear as to whether the prior CHOP received by 23 patients would be considered within first-line therapy Mixed population of patients with PTCL		

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2013		Patient Characteristics – consolidate initial therapy			Intervention	Comparison	Outcome																																																																																																																																													
Country	France	Between 2001 and 2011 all patients with PTCL-NOS, AITL, and ALK-negative ALCL who were treated with the intention to receive a transplant via HD-ASCT or in selected cases allo-HSCT as part of consolidation of initial therapy. Decision to consolidate was made by the treating physician. However, at the institution to recommend upfront HD-ASCT patients had to meet the following criteria: <ul style="list-style-type: none"> – Age ≤70 years – Eastern Cooperative Oncology Group (ECOG) performance status ≤2 or poor performance status attributed to disease – Low level of comorbidities that would make them high risk candidates for transplantation – Patients who are older than 70 years are considered for HD-ASCT if they have a low level of comorbidities and acceptable performance status. 			High Dose Autologous stem cell transplantation (HD-ASCT) Allogeneic Hematopoietic stem cell transplantation (Allo-HSCT)	Each other No transplant	Progression free survival (PFS) <i>Time from initiation of therapy to the time of documented progression, death or last follow-up</i> Overall survival (OS) <i>Date of start of treatment to the date of death or loss to follow-up</i>

Non Hodgkin's Lymphoma: diagnosis and management

Mehta N., et al. (2013). A retrospective analysis of peripheral T-cell lymphoma treated with the intention to transplant in the first remission. *Clinical Lymphoma, Myeloma and Leukemia*, 13(6); 664-670.

Patients treated with either CHOP-like therapy or CHOP-ICE therapy did similarly with regard to PFS or OS (P=0.916, P=0.749). However, those who received CHOP-like therapy were significantly older than those who received CHOP-ICE therapy with a median age of 63 years versus 56.5 years (p=0.004) and had a higher median IPI score of 3 compared to 2 in the CHOP-ICE group. The 3 patients treated with pentostatin/cyclophosphamide had a median OS of 2.9 months and a median PFS of 2.9 months, which was significantly lower than in those treated with CHOP-like or CHOP-ICE therapy (P<0.003 and <0.001, respectively)

Table 2. Survival rates according to PTCL subtype

	N	Overall survival at 4 years %	Progression free survival at 4 years %
PTCL-NOS			
All patients	32	46.2	31.8
Allo-HSCT	4	100	50
HD-ASCT	12	75	64.3
No transplant	16	12.5	6.3
AITL			
All patients	21	57.5	42.6
Allo-HSCT	1	0	0
HD-ASCT	16	62.8	48.2
No transplant	4	66.7	33.3

Following numbers include the 12 patients with ALK negative ALCL:

- The median PFS and OS for patients who received HD-ASCT were 73.2 months and 103.5 months, respectively which were significantly greater than 6.4 and 8.3 months for those who did not proceed to transplantation (both p<0.001)
- The patients receiving allo-HSCT had a median PFS of 30.6 months, and the median OS was not reached and showed a difference in OS when compared with patients with no transplant (P=0.42), but not in PFS (P=0.193)

Note. CI: Confidence Interval

Authors note that when excluding paediatric patients from the overall NRM, PFS and OS at 1 year and 3 years were similar to those for the entire group (data not shown)

Table 4. Cause of death by transplantation modality for all PTCL subtypes (N=241)

	Auto N=115		Myeloblastic N=74		NST/RIC N=45	
	n	%	n	%	n	%
Number of deaths	51	44.3	45	60	24	53
Cause of death						
Primary disease	37	73	18	40	11	46
Infection	4	8	2	4	3	13
Interstitial pneumonitis	0	0	4	9	2	8
Acute respiratory disease syndrome	2	4	2	4	0	0
Organ failure	4	8	10	22	3	13
Accidental death	1	2	0	0	0	0
Graft failure	1	2	0	0	0	0
Haemorrhage	0	0	3	7	1	4
GVHD	0	0	3	7	2	8
Pulmonary toxicity	0	0	2	4	0	0
Vascular (cardiac or cerebral)	0	0	1	2	1	4
Other, not specified	2	4	0	0	1	4

Progressive lymphoma leading to death in all three groups was significantly higher in the autologous cohort (p=0.0036)

In multivariate models alloHCT or two or more pretransplantation chemo regimens were strongly predictive of worse NRM, with no improvement in relapse/progression. Chemo therapy resistant disease doubled the risk of relapse/progression.

Comments

Age range includes children <16 years, as young as 4 years old. 13.7% ≤20 years old.
 Mixed population of patients receiving first and second line treatment
 Mixed population of patients achieving first or second remission
 Mixed population of patients with PTCL although authors provided OS, PFS and NRM for PTCL and AITL which could be extracted

Studies included	21	Table 2. Retrospective studies included in the review																							
Study designs	15 retrospective: - 12 interventional - 3 comparative 6 prospective: - 6 interventional	<p>Overall survival up-front transplantation: 5 studies provided summary estimated 5-year probabilities of OS of patients who transplanted as front-line therapy was 62% (95% CI 0.44-0.80).</p> <p>Overall survival up-front transplantation versus conventional chemotherapy alone: 4 studies (n=606) reported a comparison between the group of patients treated with up-front HDT/ASCT and with conventional chemotherapy alone (in the Niitsu et al. paper they reported on a subgroups of patients treated with either CHOP or CycloBEAP groups and a comparison was drawn respectively resulting in 5 sets of data). The random effect estimate of the HR for OS for the 4 studies was 0.81 (95% CI: 0.31-2.13, I² 77%). Using the published data the meta-analyses was re-run excluding the two articles that used populations of patients with NK/T-cell nasal Lymphoma (Lee et al 2008 and Kim et al 2006). The HR for the OS for the three remaining sets of data was 0.60 (95% CI: 0.05-6.94).</p> <p>Overall survival up-front transplantation depending on remission status: 3 studies with 149 PTCL patients were used to compare overall survival between patients in CR and in non-CR at transplantation. Summary estimated HR for OS was 3.17 (95% CI: 0.92-5.42, I² 0.0%). Authors state that the patients in CR at transplantation showed a definite survival advantage compared with patients in non-CR at transplantation (p=0.004). The estimated HR for OS extracted from 3 different studies in patients in CR compared to patients in PR at transplantation was 0.73 (95% CI: 0.36-1.48, I² 0.0%) indicating that patients in CR at transplantation did not obtain better outcomes than patients in PR.</p>

5: Patient Information Needs

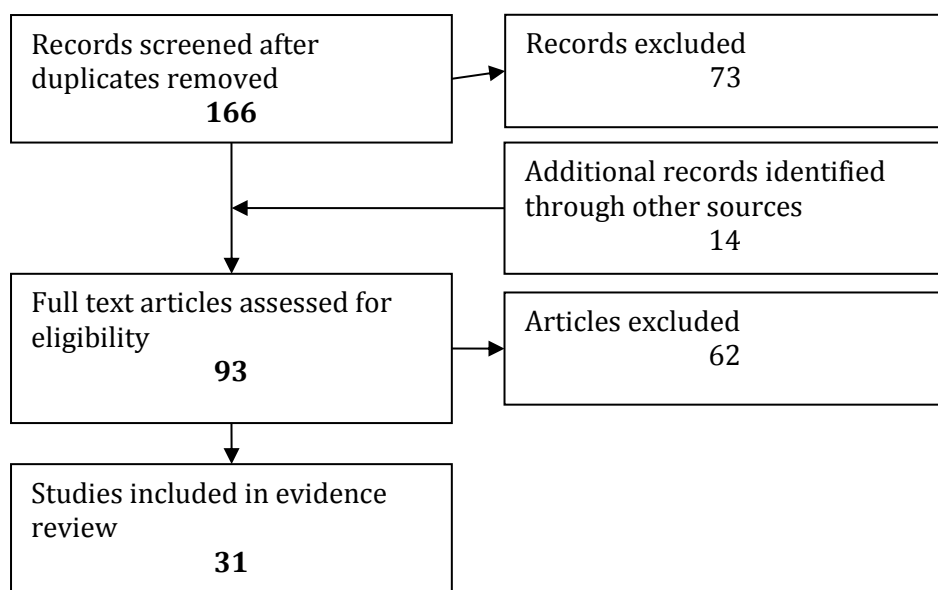

5.1 Review question: What are the information and support needs of patients with a diagnosis of non-Hodgkin's lymphoma and their carers?

PICO Table

Population	Intervention	Comparison	Outcomes
<p>Adults and young people (16 years and older) with NHL (<i>see included subtypes below</i>) and their carers:</p> <p>At diagnosis During treatment After treatment At point of consideration of palliative care</p>	<p>Information, communication and support needs associated with NHL cancer diagnosis and treatment <i>e.g.</i> <i>psychological difficulties; living with watch and wait/observation; therapeutic decision making.</i></p>	<p>Note. Watch and wait/observation, fertility issues.</p>	<p>Patient reported themes including:</p> <ul style="list-style-type: none"> • Health Related Quality of Life • Patient satisfaction/ experience • Treatment decision making • Social/psychological impact • Informed decision making
<p>Additional Comments on PICO</p> <p>Evidence by subtype of NHL when there are differences background text suggests that treatment may be influenced by age and co-morbidities, LB asked for clarification from the GDG and had the following response: Concern is both age and fitness of the patient, also there is lack of willingness to give radiotherapy in certain areas due to higher risk of secondary cancers in under 25 year olds Sifting update: excluded articles where either the sum of the NHL patients was less than 50% of the total sample and/or when the study did not provide results broken down according to NHL and other malignancies (so NHL sample could be extracted).</p>			

Evidence Quality

Figure 1. Study flow diagram

Non Hodgkin's Lymphoma: diagnosis and management

Study	Study type	Population	Methods	Analysis	Relevance to guideline population	Other comments	Overall quality
Arora et al. 2013	Cross sectional. Quantitative – Self-reported questionnaire	Well reported	Well reported	Well reported	– USA – Intermediate- or high-grade NHL	– Cross-sectional – Sample size = 374 – 54.8% response rate but no statistics on differences of non-responders – Validated measures – No reliability analyses of scales – Not clear if the experiences were hypothetical or personal experiences faced by the participants – Only participants who completed the paper version received all the questionnaires reducing the response rate – Items grouped into dichotomous variables, for example physician spends enough time during visits – never, sometimes, usually versus always grouped into never or other	–
Beckjord et al. 2011	Cross sectional. Quantitative – Self reported questionnaire	Well reported	Well reported	Well reported	– USA – NHL intermediate or high grade	– Cross-sectional – Sample size = 222 – 70% response rate – No non-responder analyses reported – Validated measures – Reliability of scales reported – Sample could have been larger but 159 eligible participants who returned surveys did not respond to the questions concerning sexual health issues – No information on sexual function prior to cancer diagnosis/treatment	–
Campbell et al. 1999	Cross sectional. Qualitative – Constant comparative analysis	Well reported	Well reported	Well reported	– UK – Type of cancer not reported	– Cross-sectional – Small sample size (n=5)	–
El-Banna et al. 2004	Cross sectional. Quantitative – Self reported Questionnaire	Unclear	Well reported	Well reported	– USA – NHL – 3 (11%) had Hodgkin's lymphoma	– Prospective (5 time points) – Small sample size (n=27) – Invite and response rates were not reported – Validated measures	–

Non Hodgkin's Lymphoma: diagnosis and management

Study	Study type	Population	Methods	Analysis	Relevance to guideline population	Other comments	Overall quality
Forsythe et al. 2014	Cross sectional. Quantitative – Self reported questionnaire – Surveillance Epidemiology, and End Results registry	Well reported	Well reported	Well reported	– USA – Aggressive (intermediate or high grade) NHL – Free of cancer at time of survey completion	– Cross-sectional – Sample size = 363 – 48% response rate – Non-responder analyses reported – Validated measures – Reliability of scales for one measure	–
Friedman et al. 2004	Cross sectional. Quantitative – Self-reported questionnaire – Duke Comprehensive Cancer Centre Tumour Registry	Well reported	Well reported	Well reported	– USA – DLBCL	– Cross-sectional – Physicians: 22 (29% response rate) – Survivors: 67 (41% response rate) – Non-responders analyses reported – Authors developed questionnaire so not externally validated – No reliability of scales	–
Glaser et al. 2013	Cross sectional. Quantitative – Self-reported questionnaire	Well reported	Well reported	Well reported	– UK – NHL	– Cross-sectional – Sample size = 778 – 62% response rate – Some validated measures others made specific for the survey – No reliability of scales	–
Glover et al. 2011	Case series Quantitative – Retrospective case review of social worker interview	Well reported	Well reported	Poor – Small sample size and lots of analyses	– USA – NHL – 32 (27%) had Hodgkin's lymphoma	– Retrospective case review – Sample size = 119 – Invite and response rates were not reported – Study did not take in to account other reasons for delay (clinician, hospital, follow-up care) – No psychological measures to assess whether patients found the support valuable or whether they wanted more/less support and whether it contributed to their treatment decision making about transplantation	–
Greaves et al. 2013	Cross sectional. Quantitative – Self-reported questionnaire	Well reported	Well reported	Well reported	– UK – NHL (FL, DLBCL and other)	– Cross-sectional – Sample size = 326 – Response rate not provided by cancer type	–

Evidence Statements

Evidence came from 27 cross-sectional studies, four prospective cohort studies and one retrospective case series. Two studies were qualitative in design the remainder were quantitative survey studies of patients with NHL. The overall quality of the evidence was moderate.

Analysis of the subgroup of 2530 patients with non-Hodgkin's lymphoma included in the 2014 Cancer Patient Experience Survey suggested the following (see Appendix H):

Whilst similar to all cancer patient reports from the survey, there are potential areas where patient needs may warrant further attention around diagnosis, particularly to ensure patients fully understand their test results, have their diagnosis explained fully and are given the opportunity/choice to have a friend/relative present.

Approximately 70% of patients with NHL reported that their views were taken account and were involved in decisions regarding their treatment and care; similar to all cancer patients. However, the findings suggest an unmet need around information given on longer-term side effects for patients with NHL.

Ensuring easy access to a CNS for all patients is warranted given the high endorsement that CNS's listened to, and provided understandable answers to their patient's questions all or most of the time.

There may be unmet needs in informing patients of and allowing access to participation in clinical trials.

Patients should be assessed on their individual needs to receive information/advice on work/education and choice given to participate in support groups.

Attention to ensuring easy to understand written information both before and after procedures is relevant and important area to address.

Approximately 80% of patients expressed satisfaction with their hospital doctors; an unmet need for patients with NHL may be ensuring their carer/relative/friend has sufficient opportunity to ask questions.

Over 75% of patients with NHL stated positively on the way they were treated by doctors and nurses.

Ensuring patients are given opportunity to discuss worries and fear when wanted by the individual patient warrants further consideration.

Whilst the majority of patients with NHL were given information on what to do and whom to contact, a potential unmet need is the information provided to relatives/friend on how to care for him/her at home.

The majority of patients with NHL reported positive endorsement of their care given to control side-effects but further attention may be needed to ensure patients have access and opportunity to receive emotional support.

There are no obvious differences between sub-types, length of treatment, treatment pathway (e.g. in active treatment or follow up).

What do patients with non-Hodgkin's lymphoma need during diagnosis and treatment?

Participants reported moderate levels of satisfaction (~60%) with the information they were given during their treatment (Husson *et al.* 2013, Netherlands; Oerlemans *et al.*, 2012, Netherlands), with the majority of participants (71%) reporting that their physician always spent enough time during their visits and appointments (Arora *et al.* 2013, USA).

Feeling involved

Participant's information needs were individualistic. Whilst, the majority of participants (59%) reported that they considered their treatment decision making to be collaborative (whereby the doctor and they shared responsibility for any decisions; Poe *et al.*, 2012) and felt that they were at the heart of the communication process and information exchanges made (Wall *et al.*, 2011, UK) there were some participants (13%) who preferred for their doctor to make all their treatment decisions (Poe *et al.*, 2012, USA), actively avoided seeking out information for fear of further upset to themselves or their family (Wall *et al.* 2011, UK).

Informed decision making

Feeling informed and possessing adequate knowledge about investigations and treatments being undertaken was vital to coping with the process.

Non Hodgkin's Lymphoma: diagnosis and management

Participants reported using previous practical knowledge to make sense of what was happening, probably due to their experience undergoing similar investigations (e.g. ultrasounds, blood tests) or from other people's accounts of such investigations (Wall *et al.* 2011, UK).

Patients undergoing protective isolation as a consequence of receiving high-dose chemotherapy, who felt well-informed for the need for the protective environment, appeared to cope better with the experience, with knowledge having an mediating effect on the experience which was viewed as 'something that I have to do if I want to get well' (Campbell *et al.* 1999, USA). Knowledge of the remission length and levels of treatment toxicity were important attributes considered by patients with follicular lymphoma when deciding whether or not to go for transplantation, with participants requiring 0.6 years absolute increase in progression-free survival or a 6% absolute increase in 5-year progression-free survival in order to accept the toxicity of autologous stem cell transplantation (relative to chemotherapy) but 3.9 years increase in progression-free survival or a 39% increase in 5-year progression-free survival in order to accept the toxicity of allogeneic stem cell transplantation (relative to chemotherapy) (Shafey *et al.* 2011, Canada).

Knowing who they can discuss issues with

Whilst the majority of participants were willing to discuss any physical functioning issues (93.9%), daily functioning issues (81.6%) and emotional functioning issues (75.5) they may have or had with their doctor, less than half of participants were willing to discuss social (42.8%) or sexual (48.9%) functioning issues with their doctor with the majority of the remaining participants stating that they would prefer not to discuss these issues with their doctor. Participants believed that it was not their doctor's job to discuss these issues (47% social functioning issues, 30% sexual functioning issues) with almost 30% stating that they would not feel comfortable discussing these issues with their doctor. However, less than 20% of participants reported that they felt nothing could be done to help with social (11%) or sexual (16%) functioning issues, suggesting that they may like to access help with these issues but are either unsure whether their doctor is the correct person to discuss these issues with (Arora *et al.*, 2013, USA).

Information needs

Around 30% of patients and survivors would have wanted more information provision during treatment (Husson *et al.* 2013; Oerlemans *et al.*, 2012; Jonker-Pool *et al.*, 2004, Netherlands), with 22% still reporting an unmet information need one year after the completion of their initial survey (Jonker-Pool *et al.*, 2004, Netherlands).

Patients currently receiving treatment wanted more information concerning financial issues and emotional health compared to patients not actively in treatment and those experiencing a recurrence reported significantly higher unmet needs regarding financial concern, access and continuity of care and emotional health compared to participants without recurrence (or unsure if they have a recurrence, $p < 0.05$: Hall *et al.* 2014, Australia).

28.8% of survivors of adolescent and young adult NHL reported a need for additional information on how to talk about cancer with their family and friends and half wanting additional information on ways to help them meet other adolescents or young adult cancer patients/survivors (Kent *et al.* 2013).

28% of adult survivors of aggressive NHL wanted more information about factors associated with sexual functioning after a cancer diagnosis and 13% wanted more information about fertility issues, with the greatest reported need for more fertility-related information from younger participants (23-40 years old, $p < 0.01$), non-white-race participants ($p < 0.01$) and participants that perceived their quality of care received as less-than excellent ($p < 0.05$; Hammond *et al.* 2008, USA). Male participants ($p < 0.05$) and participants who had received a bone marrow/stem-cell transplantation ($p < 0.05$) reported a greater need for more sexual function-related information.

Just over half of participants would have liked to have received exercise counseling and would have felt able to participate in tailored exercise programme. With 80% expressing interest in exercise programmes designed specifically for NHL patients. However, the majority (56.3%) would have preferred to start an exercise programme after treatment was complete (Vallance *et al.* 2005a, Canada).

Non Hodgkin's Lymphoma: diagnosis and management

30% of participants reported that they had not been offered an appointment to attend a fertility clinic during their cancer treatment with only 8% of those offered reporting that they attended a fertility clinic at some point during or after their treatment (Greaves *et al.*, 2013, UK).

Strategies to cope with treatment

Patients undergoing protective isolation as a consequence of receiving high-dose chemotherapy appreciated having a natural view (which made them feel less shut out from the outside world), being involved in a nurse-led routine (providing an incentive to do things such as get up for bed-making) and felt that having a clock in the room was useful, enabling them to plan their day ahead. The geographical location of the bedrooms was significant to the patients not feeling alone ("I can't see them [nurses and doctors] from here and I can't hear them, and at times it feels as if it's the Marie Celeste [laughing]...nothing happens"). Whilst visitors were instrumental in providing support, many discouraged family and particularly friends from visiting so as to protect themselves from infection. Whilst face-to face contact was discouraged telephone and media were important ways that the patients could maintain contact with the outside world (Campbell *et al.* 1999). Finally, those who had previously received treatment on the ward where they were in isolation valued the familiarity that they felt towards the nurses, who were commonly portrayed as friends, serving to ameliorate the anxiety associated with the isolation experience (Campbell *et al.* 1999, UK).

Supportive needs

Support from others: Almost half of male NHL participants surveyed reported that they had received insufficient support (48%) during their treatment, although when measured again one year later after treatment, participants no longer reported any unmet additional support (Jonker-Pool *et al.*, 2004, Netherlands). Participants reported that the major emotional support provided to them during decision making came from their family (83.2%; Glover *et al.*, 2011, USA). Informational and instrumental support needs mainly came from nurses (79%) with only 12.6% of participants reporting that this support came from the physician (Glover *et al.*, 2011, USA). Over 90% of participants reported receiving no formal peer or group support during treatment decision making, and whilst it was not reported whether participants wanted to receive support from these avenues, access to a formal peer support group significantly reduced the time between treatment decisions in patients with relapsed Follicular lymphoma considering undergoing stem cell transplantation ($p=0.045$; Glover *et al.*, 2011, USA).

Psychological impact of treatment decision making: Whilst participants did not report significant conflict or regret surrounding their last treatment decision, they did report that treatment decision making was associated with psychological distress (mild: 57% sample, moderate: 33% sample), anxiety (57% sample) and severe levels of cancer specific distress (37% of the sample scored above average for: avoidance subscale and 27% of the sample scored above average: intrusive subscale, Poe *et al.*, 2012, USA).

Psychological impact of treatment: Undergoing treatment for non-Hodgkin's lymphoma was associated with poorer overall health related quality of life compared to age-matched norms ($p<0.01$), with patients reporting higher levels of fatigue, dyspnea, sleeping problems, appetite loss and financial problems compared to age-matched norms ($p<0.05$; Oerlemans *et al.* 2014, Netherlands). Certain treatments were associated with poorer physical health and mental well-being, with participants treated with R-CHOP14 reporting significantly more often tingling in hands and feet ($p<0.05$), lower global health status/quality of life ($p<0.05$), higher levels of fatigue ($p<0.01$) and a feeling of being slowed down ($p<0.05$) compared to patients treatment with R-CHOP21 (Oerlemans *et al.* 2014, Netherlands). Levels of psychological distress (fatigue and depression) increased and health related quality of life decreased (measured over 56 weeks, Jerkeman *et al.* 2001, Norway) during chemotherapy, with patients receiving CHOP reporting significantly higher levels of fatigue on day 10 compared to day 21 of the treatment cycle and baseline levels ($p<0.01$; Menshadi *et al.*, 2013, Israel) and patients receiving any chemotherapy reporting significantly higher levels of fatigue and depression on day 7 of the treatment cycle compared to baseline ($p<0.05$, El-Banna *et al.*, 2004, USA). However, increased levels of fatigue and depression returned to baseline levels two weeks post chemotherapy treatment (Menshadi *et al.*, 2013, Israel [only fatigue measured] El-Banna *et al.*, 2004, USA [fatigue and depression]) and varied during treatment depending on individual coping strategies, with patients who had high levels of learned resourcefulness (use of problem-solving strategies, ability to delay gratification and general belief in one's own ability to regulate internal events) reporting significantly lower

Non Hodgkin's Lymphoma: diagnosis and management

levels of treatment-related fatigue (no p-values reported, Menshadi *et al.*, 2013). Health related quality of life scores (except role function) measured at the 56th week of the treatment cycle in the majority of patients returned to baseline levels, comparable to an age-matched population (Jerkeman *et al.* 2001, Norway).

Vallance *et al.* (2005b, Canada) reported on patients' levels of exercise engagement during treatment, finding that quality of life and well-being did not differ depending on level of engagement when considering demographic and clinical characteristics.

What do patients with non-Hodgkin's lymphoma need after treatment?

The majority (>60%) of participants reported that their follow-up care they had received to date was excellent (Forsythe *et al.* 2014; Arora *et al.* 2013, USA).

Information needs

Most survivors reported moderate to low levels of need for additional health information (Forsythe *et al.*, 2014, USA) about cancer treatment information provision, financial concerns, access and continuity of care, relationships and emotional health (measured levels of unmet needs in the past month; Hall *et al.*, 2014, Australia). However, younger participants (<60 years old) reported significantly higher unmet needs ($p<0.001$: Hall *et al.*, 2014, Australia).

When considering what they would want for their longer-term follow-up care/survivorship care, participants reported that continued screening for a possible return of cancer was their most important factor, with monitoring overall health, nutrition and exercise support, insurance and adequate money to afford such monitoring also important (compared to physicians needs) (Friedman *et al.* (2010, USA). Participants rated psychosocial issues as less important compared to medical issues, with male survivors rating sexuality and fertility health issues as more important than women ($p=0.004$) and younger patients at diagnosis (<60 years old at time of diagnosis) rated having their overall health monitored and have care that took into account sexually and fertility, mental health services and financial issues as more important compared to patients who were over 60 years old at diagnosis (all $p<0.05$). The majority of participants (63%) would want an oncologist and a primary care physician to co-manage their survivorship/longer-term follow-up care.

Support needs

The majority of participants reported that they were not as interested in sex and that their sex life was less satisfying now compared to prior to their cancer diagnosis, with 30% reporting that they attributed these low satisfaction rates due to their cancer diagnosis (Greaves *et al.*, 2013, UK). Beckjord *et al.* (2011, USA) reported that survivors with a lower than average health status were less satisfied with their sex life compared to participants reporting an above average health status.

Psychological support: Health related quality of life varied across studies with some reporting that the majority of survivors reported medium/high levels of quality of life (Glaser *et al.*, 2014, UK; Smith *et al.*, 2013, USA; Vissers *et al.*, 2013, Netherlands, Tchen *et al.*, 2002, France) and others reporting lower levels of quality of life, general health perceptions and high levels of psychological distress compared to age-matched normative samples (Van der poel *et al.*, 2014; Oerlemans *et al.*, 2014, Netherlands; Smith *et al.*, 2009, USA; Mols *et al.*, 2007, Netherlands; Tchen *et al.*, 2002, France). One study reported that survivor's reported mental health status was comparable to population norms but their physical function was lower (Jensen *et al.*, 2014, USA). Two follow-up studies reported that 25.5% of survivors report a worsening of health related quality of life (measured at least 7 years post diagnosis) and between 20-33% of survivors report persistent symptoms and worries concerning their health and quality of life (measured at least 1 year after diagnosis, mean: 2.6 years) (Oerlemans *et al.*, 2014, Netherlands; Smith *et al.*, 2013, USA).

Health related quality of life varied in survivors according to the following factors

Coping strategies

Jensen *et al.* (2014, USA) reported that health related quality of life varied according to participants cognitive health appraisal competencies (Perceived Health Competence Scale and Perceived Personal Control) with participants reporting low levels of health competencies reporting lower levels of physical and mental component summary scores and higher levels of anxiety, depression and fatigue compared to participants who reported high levels of health appraisal competency ($p < 0.001$). Meaningful differences were also identified between survivors with low and medium levels of health competency across all health related quality of life outcomes except mental component summary scores. With the exception of physical component summary scores, greater perceptions of personal control was associated with significantly better quality of life outcomes ($p < 0.01$).

Age

Older participants scored significantly lower on the physical functioning items compared to younger participants ($p < 0.05$ Mols *et al.*, 2007, Netherlands) and reported reduced perceptions of cancer having positively impacted on one's life (Smith *et al.*, 2013, USA). Younger survivors (18-59 years old) reported higher physical functioning scores ($p < 0.01$), higher global health status scores ($p < 0.05$), higher levels of financial problems ($p < 0.01$), lower levels of appetite loss ($p < 0.01$) and lower levels of constipation ($p < 0.05$) compared to older survivors (76-85 years old) with survivors aged between 60-75 years reporting higher global health status scores ($p < 0.05$) and low levels of appetite loss ($p < 0.01$) compared to survivors aged between 76-85 years old (Van der Poel *et al.*, 2014, Netherlands). Finally, Kourkoukis *et al.* (2004, Canada) reported that older survivors (>65 years) reported more concern about how they consider their appearance to others ($p < 0.05$), more impact of general toxicity ($p < 0.01$) and the importance of their faith ($p < 0.01$) compared to younger patients (≤ 65 years). Younger patients reported more concern about sex/intimacy issues compared to older patients ($p < 0.01$). However, the authors doubted the differences reflected true differences in quality of life due to multiple comparisons increasing the likelihood of finding spurious differences.

Comorbidity

Greater number of comorbidities was a significant predictors of lower physical component scores measured at follow-up ($p < 0.01$) (Smith *et al.*, 2013, USA). In addition, compared to participants with no additional long-term conditions, the presence of one or two or more long-term conditions was significantly associated with lower quality of life scores, poorer outcomes on the social difficulties inventory (SD) and the functional assessment of cancer therapy (lymphoma items: $p < 0.001$: Glaser *et al.*, 2013, UK), poorer physical functioning ($p < 0.05$) and more pain ($p < 0.01$: Mols *et al.*, 2007, Netherlands).

Type of treatment

Survivors who reported a greater negative impact on their life at follow-up were more likely to have undergone a transplant (Smith *et al.*, 2013, USA), whereas survivors who had received chemotherapy were more likely to report lower scores on psychological well-being, social well-being and total quality of life ($p < 0.01$; Mols *et al.*, 2007, Netherlands).

Current employment

Participants who were employed reported being more vital and had better mental well-being scores compared to participants not working ($p < 0.01$: Mols *et al.*, 2007, Netherlands).

Time since diagnosis

Longer time since diagnosis was positively associated with social ($p < 0.01$) and psychological well-being ($p < 0.05$: Mols *et al.*, 2007, Netherlands).

Social support

Survivors who report good levels of social support were more likely to report greater perceptions of cancer having positively impacted on one's life at follow-up (Smith *et al.*, 2013, USA).

Recurrence/active disease

Compared to participants in remission, participants currently in active treatment, experiencing a recurrence or who were not sure about their disease status had increased odds of reporting lower quality of life and poorer outcomes on the social difficulties inventory (SD) and the functional assessment of cancer therapy (lymphoma items) ($p < 0.001$: Glaser *et al.*, 2013, UK).

Physical activity

Higher levels of reported physical activity were associated with increased quality of life in survivors, with each additional day of physical activity reducing the odds of lower quality of life score by 9% (Glaser *et al.*, 2013, UK). However, Vallance *et al.* (2005b, Canada) reported that survivors post treatment exercise levels were not associated with health related quality of life when considering demographic and clinical factors.

Evidence Tables

Wall, C et al. (2011). Experiences prior to diagnosis of non-Hodgkin lymphoma: a phenomenological study. Journal of Advanced Nursing, 67(11); 2363-2372.					
Pub year: 2011		Patient Characteristics	Method	Questionnaire/interview structure	Outcome
Country	UK	Purpose sampling was used to recruit patients diagnosed with NHL who were willing to talk about their experiences (it is important to ensure that those chosen for research are familiar with the phenomenon of interest and willing to reflect upon it; Morse & Richards, 2002). Recruited and interviewed over an 18-month period through two sources: – N=16: Hospital in North West of England, where the Clinical Haematology Nurse mailed details of the proposed study to patients identified from the hospital NHL database – N=15: Lymphoma association support group coordinator, who briefed support group members about the proposed research and gave the information sheet and contact details to those interested. 15 male 16 female Mean age: 56 years (29-79) They knew their diagnosis and had been diagnosed for not less than 2 months	Descriptive phenomenological approach – Enables the discovery of the essential characteristics or essences of the experience as lived by the participants (Husserl 1962, Moustakas 1994). – Key feature: entering the epoché, with the suspension of the researcher's natural attitude; our everyday attitudes, knowledge and biases, through the process of bracketing. This involves putting all presuppositions on hold by placing them in imaginary brackets to enable the phenomenon to be examined from a clear and fresh perspective. To maintain this, the researcher maintained a reflective diary throughout the study. Data analysis: – Guided by Colaizzi's (1978) method. – Transcripts were read and sentences related to the pre-diagnosis experience extracted. – Formulated meanings were described for each of these important statements. – Procedure repeated for all transcripts, and the resulting formulated meanings were organised into themes; those were then integrated into an exhaustive description of the essences of the experience. – NVivo data analysis software used to assist in organisation of data – Formulated meanings initially stored in unstructured free-node areas and, as conceptual groups emerged, these were transferred to structured tree-node areas, where sub-themes and themes were eventually identified. Rigour: – Process was checked by two independent researchers – Emerging themes and textual and structural descriptions compared against individual transcripts – Analysis was returned to participants, and eight responded and stated that it reflected their experiences	Patients were asked to reflect back to the period when they first became aware of a problem with their health, and to describe in depth what it was like for them during the period leading up to the diagnosis. Further open-ended questions were used as appropriate (for example, Can you tell me what that was life for you? How did that make you feel?) Interviews lasted between 45-60 minutes.	Patient experience
Design, period	Qualitative 2003-2005

Follow-up	N/A				
Funding source	PhD funding from Liverpool John Moores University No conflict of interest declared by authors				
Results	<u>Overriding theme:</u> Creating a pathway towards hearing the diagnosis of non-Hodgkin lymphoma – Pathway of experience spanning from initial symptom awareness to point of diagnosis – Essential structures of time and motion determined the speed of the patient journey – For some pathway was short and straightforward – For some prolonged and complicated journey – Key essences bound its route and all participants had experienced emotional disharmony and created various attributions and help-seeking behaviour during this time				

Non Hodgkin's Lymphoma: diagnosis and management

Wall, C et al. (2011). Experiences prior to diagnosis of non-Hodgkin lymphoma: a phenomenological study. *Journal of Advanced Nursing*, 67(11); 2363-2372.

Other themes:

Perceiving individual health perspective and onward movement

- Common essence was the identification of health deviation where participants either detected symptoms or were alerted to something unusual by others
- All felt emotional disharmony as they tried to make sense of their unfolding situation

Experiencing symptoms

- Some obvious, such as swellings or acute illness, many less indicative, including long-term illness and lethargy
- Not all immediately recognised significance of symptoms, and for some a dawning realisation occurred over time
 - *"Erm well, one day when I was working, well I actually worked out and about with my job, and it was one of my customers, who was actually a doctor's receptionist, said 'What have you done to your neck?' I felt this big lump in my neck. Now, I don't remember seeing it there in the morning when I shaved"*
 - *"Well, at the time I was working in secondary schools...and then I started to have a series of seemingly unrelated problems - various things...urinary infection, erm migraines, but worse, far worse. You know, a whole variety of things, over probably two or three years"*

Managing symptoms

- Essential characteristic was symptom management
- Active managing involved varying on as normal, but unpleasant physical effects required more stringent managing through practical or psychological ways of coping
- Interviewees described bathing in the middle of the night to relieve severe itching, being proposed up with extra pillows to alleviate breathlessness, and changing wet bedclothes as a result of night sweats
- Passive support from family and friends was recognised and welcomed, and involved reassurance, companionship and prayer
 - *"...and it was so bad; I actually used to sleep on the quilt, because it was painful. I couldn't sleep on my side because (pause)...my spleen was double the size"*
 - *"I used to have a lot of worries with my husband and I used to think, 'I can't worry about that tonight, I'll have to have a right good worry at it in the morning, but I need my sleep tonight.' So I'd empty my mind, I'd go to sleep and I'd wake up in the morning and half of the worries had stopped anyway"*

Moving symptoms into cognitive and emotional awareness

- Participants created attributions in an attempt to understand what was happening
- Participants often ascribed symptoms to environmental or lifestyle changes rather than illness:
 - *"Christmas came and we went to my mum's. He (husband) managed to get four days off and we went down from Christmas. Then my legs started itching at night. I thought, 'Gosh, I wonder if my mum's using different soap powder?"*
- In contrast, others made immediate attribution of possible malignancy for neck swelling:
 - *"Well you know yourself, there are so many, every magazine there's always things on cancer. Now there's a hundred and one different types, but it was the first thing that crossed my mind"*
- Many patients who had sudden illness or swellings described anxiety, fear and panic
 - *"In the morning, I was getting ready to go to work, and I felt warm. Quite hot. I panicked and start to think, 'Oh it may be breast cancer'"*
- Long-term and vague symptoms elicited different emotions. Here, participants felt generally uneasy about their health rather than experiencing anxiety or panic.
 - *"It was all a bit puzzling really... I wasn't unduly concerned really because it was just that, I didn't quite know what it was. Even before I got the pain in my chest I sort of went through March, from January, feeling there was something strange, not knowing what it was"*

Developing drives for accessing healthcare services

- Eventually developed motivational drive to seek help. Actual trigger for help-seeking behaviour was individual to each participant's situation.
 - *"Then what triggered me going to the doctor was that we had a church barbeque, and I went along to the barbeque and I was talking to this chap, he was a doctor, a GP...I was talking to him and he said, 'Erm excuse me, I hope you don't mind me saying this, but I can see this lump here on your neck, and I'm a GP and if I were you I would go to your won GP and get it checked out"*

Penetrating communication processes and investigations

Permeating healthcare boundaries

- Period of accessing healthcare services was an important part of the pre-diagnosis journey. Some participants were immediately referred for further investigation. Here, doctors alerted to the need for a prompt referral. Others had to make multiple appointments because of persistent or deteriorating symptoms until the need for referral was eventually recognised.
 - *"So he (GP) said that I should be seen by the oral surgery people as a matter of urgency, and so he rang there and then"*
 - *"It wasn't painful (referring to breast swelling), and that was on the Monday, and he (GP) phoned the doctor at the hospital. On the Tuesday there was a phone call, and I sent up there on the Wednesday, and they said they'd do a syringe biopsy"*
 - *"The only thing is that it could have been diagnosed earlier. I mean, going for 12 months (to GP) and having the same symptoms for 12 months" (Gastrointestinal problems and weight loss)*

Living through diagnostic investigations

- Presented participants with challenges in form of unfamiliar blood tests, scans and biopsies
- Common essence was participants' application of knowledge for understanding and coping with their particular investigations

Non Hodgkin's Lymphoma: diagnosis and management

Wall, C et al. (2011). Experiences prior to diagnosis of non-Hodgkin lymphoma: a phenomenological study. *Journal of Advanced Nursing*, 67(11); 2363-2372.

- Some used previous experiential knowledge to make sense of what was happening
 - This type of knowledge may have arisen from their experience undergoing similar investigations or from other people's accounts of such investigations. Participants also used knowledge of their own particular ways of coping with situations, including using humour or remaining detached from the situation
 - *"Oh that was funny. I don't think the person who took the ultrasound had a sense of humour like me. I was lying on the bed, you know, with the stuff on (meaning gel on abdomen). I said to the fella, 'I don't want to know when I will have the baby, I just want to know how many'"* (Male patient)
 - *"I am able to protect myself from things. I am able to deal with things in a very sort of remote way. That's the way I dealt with it."* (referring to scan)
- Engaging in communications and interactions*
- Participants were at the heart of communications process and information exchanges
 - Many were active players in the self-pursuit of information about symptoms and possible diagnosis, using the Internet, media and information from friends and family. Information was used to deal with uncertainty at various points: to assign meaning to symptoms, to acquire a possible diagnosis, or to check up on information given by a healthcare professional.
 - Information was avoided by some for fear of further upset to themselves or family. The important role of healthcare professionals as communicators of information is evident in two extracts, in which information was helpful in one instance and disbelieved in another:
 - *"Well, she was talking (the sister) and she was explaining about the blood and the lymph nodes, and I understand now, and the lymphatic fluid, because I have read all about that. She was very, very good"*
 - *"Some of the things, the initial consultant that I saw, I asked her if there was anything in my diet that I could change, and she said, 'No, no, just go away and live your life normally' So...I thought, 'I don't believe you. So I went away and I researched diets, vitamin supplements and exercise on the Internet and found that there were hundreds of things on the subject"*
- Advancing towards focusing on the non-Hodgkin lymphoma diagnosis**
- Initial perceptions of important events surrounding the diagnosis and how they interpreted its meaning.
 - Two sub-themes:
 - Attending to initial perspectives surrounding diagnosis
 - Bringing the diagnosis into sharper focus
- Attending to initial perspectives surrounding the diagnosis*
- Common factor was how the diagnosis was portrayed.
 - Some participants were told that it was the best type of NHL to have in terms of favourable treatment outcomes
 - For others, it was disclosed as bad news – worse than expected or difficult to treat
 - *"And he said (hospital doctor) 'Well, the bad news is, it might be lymphoma', cancer of the lymphatics. Well lymphoma I think he said, or cancer of the lymphatic system. But then straight away he said, 'But the good news is that if you're going to get cancer, it's the best one'"*
 - *"It was high grade. (Name of consultant) did actually tell me that it was actually better to have the high grade because it is easier to treat. So I had never even heard of non-Hodgkin lymphoma"*
- Bringing the diagnosis into sharper focus*
- Participants reflected on diagnosis and considered its significance for their lives
 - Some felt shock, panic or even relief at eventually finding out what was wrong
 - Others focused on how they were going to cope with the diagnosis: by using humour, keeping it private or adopting a fighting spirit
 - *"I mean, it was such a shock, a complete shock, it was a terrible existence for about the next 4-5 weeks, because you hear different things. People tell you different things"*
 - *"You have got to look at the funny side of things, or you start looking at the down-side of things. Well I've had a few down days, I get my down days now, but my aim is to be the longest living lymphoma cancer patient ever"*
- Conclusions:**
- Patients created symptom attributions, experienced emotional disharmony and developed motivational drives for seeking help. Through communicating with others and using information, they tried to understand their unfolding situation until the actual NHL diagnosis was revealed.
 - Findings support Andersen and Cacioppo (1990) and Andersen et al. (1995) who state that individuals are generally optimistic in their evaluations, adopting innocuous and self-correcting labels as opposed to more serious explanations for symptoms.
 - Examples of patients experiencing panic and anxiety when suddenly detecting symptoms (supports research which suggests such emotions arise when unexpected symptoms such as swellings are identified)
 - Information needs were individualistic: Variation in the amount and type of information patients wanted and received, and this was used in different ways. Some actively engaged in their own search for information, whereas others simply relied on whatever information was given by healthcare professionals.
 - Findings indicate the need for healthcare professionals to be alert to the information needs of patients at key points in the pre-diagnosis period and to be involved in communicating the right type and amount to meet individual requirements

Non Hodgkin's Lymphoma: diagnosis and management

Wall, C et al. (2011). Experiences prior to diagnosis of non-Hodgkin lymphoma: a phenomenological study. *Journal of Advanced Nursing*, 67(11); 2363-2372.

Comments

Authors note that some participants may have had problems recalling their symptom experiences accurately.
Possible selection bias: North West of England only

Menshadi, N et al. (2013). The relationship between learned resourcefulness and cancer-related fatigue in patients with non-Hodgkin lymphoma. *Oncology Nursing Forum*, 40(2); 133-138.

Pub year: 2013		Patient Characteristics	Questionnaire/interview structure	Outcome																																																								
Country	Israel	Hospitalised patients with NHL were recruited from two large medical centres, one in Israel's central region and the other in the northern region.	Time 1: – Day 1 of chemotherapy cycle (prior to treatment) participants completed questionnaires on learned resourcefulness and fatigue	Psychological impact																																																								
Design, period	Prospective repeated measures study	Inclusion: Fluency in Hebrew and having been prepared for one of the first three chemotherapy cycles of CHOP	Time 2: – Day 10 fatigue questionnaire																																																									
N	46/48	Exclusion: Having more than one co-morbidity, which could affect fatigue All 48 patients who met inclusion criteria were invited by the department head nurse to participate in the study.	Time 3: – Day 21 fatigue questionnaire Completed at home and returned at their next chemotherapy course. Researchers called them at home to remind them to complete the questionnaires. Compliance rate was 96%																																																									
Follow-up	3 time points: At 1, 10 and 21 days	Table 1. Sample characteristics (N=46)	Instruments:

Non Hodgkin's Lymphoma: diagnosis and management

Menshadi, N et al. (2013). The relationship between learned resourcefulness and cancer-related fatigue in patients with non-Hodgkin lymphoma. Oncology Nursing Forum, 40(2); 133-138.					
				– Cronbach alpha: 0.97, 0.97, 0.96 for fatigue at time 1, 2, and 3, respectively.	
Results	Results of the ANOVA showed significant differences in levels of fatigue at the three measurement points ($F(2,78)=24.87$, $p<0.01$, $n^2=0.39$). Bonferroni a posteriori testing showed that the mean levels of fatigue reported at time 1 and time 3 differed significantly from time 2 (No statistics provided, or P values for the follow-up tests)				
	Table 2. Correlation matrix of learned resourcefulness (LR) and fatigue at time points				
	Variable	Learned resourcefulness	Time 1 Day 1	Time 2 Day 10	Time 3 Day 21
	Learned resourcefulness	1			
	Time 1 Day 1	-0.67***	1		
	Time 2 Day 10	-0.6***	0.5***	1	
	Time 3 Day 21	-0.72***	0.71***	0.71***	1
	Note. *** $p<0.001$				
	– Measurement of fatigue at time 1 correlated more strongly with fatigue at time 2 than at time 2				
	– High negative correlations between fatigue and learned resourcefulness at all three time points were found				
Because of the high correlation among the three measurements of fatigue, the correlation between learned resourcefulness and fatigue after treatment could merely reflect the effect of learned resourcefulness on fatigue in patients with cancer, and not specifically the effect of learned resourcefulness on fatigue following chemotherapy. To determine whether learned resourcefulness specifically affected chemotherapy-related fatigue, a partial correlation was calculated between resourcefulness and time2, controlling for time 1. Controlled for the effect of learned resourcefulness on cancer-related fatigue, measured before the beginning of the chemotherapy. Authors state that a significant negative correlation demonstrates that, in addition to the effect of learned resourcefulness on cancer-related fatigue, learned resourcefulness affected fatigue related to chemotherapy ($r=-0.41$, $p=0.005$)					
Regression analysis: Step 1: demographic variables of gender (as a dummy variable), age, level of schooling, and length of illness Step 2: Fatigue at time 1, learned resourcefulness Dependant variable: Fatigue at time 2 – Learned resourcefulness predicted lower treatment-related fatigue ($b=-1.78$, standard error=0.46, $\beta=-0.6$, $\Delta R^2=0.18$, $t=3.86$) – no significance level provided					
Authors state that the negative correlations between fatigue at the three time points strengthened the assumption that learned resourcefulness helps patients cope with fatigue and that of all variables entered into the regression analysis, learned resourcefulness was the only predictor of fatigue.					
Author notes that teaching learned resourcefulness may be a possible intervention for future research.					
Authors note that during the first 1-0 days of CHOP, patients usually develop neutropenia, which subsequently resolves as the neutrophil level increases. Being multidimensional, the fatigue felt on day 10 also was likely to be associated with neutropenia (physiologic effect). In addition, fatigue at day 21 was measured before a subsequent chemotherapy course. The decrease in the level of fatigue between days 10 and 21 may have resulted from the reduced influence of the chemotherapy treatment during that period.					
Comments	Is the fatigue reported higher or lower than would be acceptable? Article does not provide the overall score for learned resourcefulness so it is not clear if the sample were high or low				

Non Hodgkin’s Lymphoma: diagnosis and management

<p>Campbell, T et al. (1999). Feelings of oncology patients about being nursed in protective isolation as a consequence of cancer chemotherapy treatment. Journal of Advanced Nursing, 30(2); 439-447.</p>							
<p>Pub year: 1999</p>		<p>Patient Characteristics</p>		<p>Questionnaire/interview structure</p>		<p>Outcome</p>	
<p>Country</p>	<p>England</p>	<p>Permission to approach potential informants granted from consultant haematologist, speciality manger and ward sister</p>		<ul style="list-style-type: none"> - Audio-taped, semi-structured interview, lasted half-to one hour - Tapes transcribed verbatim with attention given to the accurate representation of inflection, in order to provide a true portrayal of the tone and mood of the informant’s responses - Constant comparative analysis formed the basis of data analysis. Transcripts were read several times for the purpose of overview analysis. Ensuing line by line analysis resulted in the formation of substantive codes reflecting the essence of each line of text. Substantive codes were examined for potential emerging themes, which formed the basis of each subsequent interview. - Grounded theory approach - Transcripts sent to all informants with their consent for verification of the accurate interpretation of the interview. There was also an opportunity for informants to identify key themes that they noted within their transcripts - Reflective notes made and used in conjunction with transcripts and the literature for purpose of data analysis - Independent colleague verified that the transcripts were an accurate representation of the interviews by randomly listening to tapes and comparing corresponding transcripts. 		<p>Patient experience</p>	
<p>Design, period</p>	<p>Qualitative retrospective study</p>	<p>Five patients who had received high-dose chemotherapy and were being nursed in protective isolation recruited from a Cancer Centre in the south-west of England between May and November 1997.</p>				<p>Support needs</p>	
<p>N</p>	<p>5</p>	<p>Inclusion criteria:</p> <ul style="list-style-type: none"> - Age 18 years or over to enable legal informed consent - Patient must be of sound mind, that is there may not be any prevailing psychiatric disorders at the time of consent and participation - Patient must have read the information sheet and signed a consent form - Patient will have received high dose chemotherapy prior to isolation - Patient will have been isolated in a protective environment for a minimum of 7 days at the time of interview 					
<p>Follow-up</p>	<p>N/A</p>						
<p>Funding source</p>	<p>Not reported</p>						
<p>Results</p>		<ul style="list-style-type: none"> - Data collection continued until no new information was being offered in relation to the categories. - Knowledge gained from the data analysis and the results of a thorough literature review led to the development of a theoretical framework that displays the relationships between the categories and enables identification of the core variables: <p>The cancer experience: 8 categories identified from the interviews</p> <p>Four of the eight categories relate specifically to the informants’ feelings about being in the protective isolation and could therefore be construed as the primary product of the research:</p> <ol style="list-style-type: none"> 1. Being shut in 2. Coping with the experience 3. Being alone 4. Maintaining contact with the outside world <p>Other four categories relate to the whole cancer experience but nonetheless have a specific impact upon the feelings of the patient nursed in protective isolation:</p> <ol style="list-style-type: none"> 1. Having cancer 2. Suffering chemotherapy 3. Knowing what to expect 4. Developing relationships with the health professionals <p>The relationship between the eight categories clearly demands an integrative approach to assessing the needs of patients in protective isolation. Core variable, that inextricably links the eight categories is: <i>Something that I have to do</i></p> <p>Being shut in</p> <ul style="list-style-type: none"> - Without exception, patients were well informed about the reason for being in protective isolation - Knowledge regarding the purpose of the isolation appeared to have a mediating effect on the effect on the experience, which was consistently viewed as ‘something that I have to do’ if I want to get well. - Informants felt that the experience was ‘not too bad on the whole’ - Protective function of the isolation environment was a key theme with significant reference to infection and ‘keeping the germs out’ - Informant C, who was claustrophobic, felt compelled to get up and close the door when exiting staff failed to shut it. It appears that the drive for protection was of greater significance than the apparent distress caused by being shut in a room. 					

Non Hodgkin's Lymphoma: diagnosis and management

Campbell, T et al. (1999). Feelings of oncology patients about being nursed in protective isolation as a consequence of cancer chemotherapy treatment. *Journal of Advanced Nursing*, 30(2); 439-447.

- 'Keeping the germs out' was important to other informants too
- " Although the door's closed and people come in with a plastic apron on and wash their hands, it's not really isolation as such... people come in and breathe germs anyway... " (Informant E)
- One informant particularly enjoyed being in isolation since this rendered her free from the responsibilities associated with being around other people – explored in other interviews but consensus was that the experience was tolerable and not normally enjoyable
- All informants appreciated having a 'natural view' whether that was the harbour on one side of the ward, or trees on the other
- Some patients considered that having a view made them feel less shut out
- "They [nurses] have offered me the opportunity at night [to go up to the balcony for some fresh air]. I haven't gone yet...and I don't feel I want to until my levels are up. I have spent an, time, an awful lot of time... getting here, and I have no wish to knock myself back by picking up a bug. If it means I will stay here longer, I will stay here longer. I'm not going out that door until I can go out that door " (Informant C)
- The statement portrays a vivid picture of competing forces affecting the cancer patient in isolation. The main focus is clearly about recovery from cancer rather than release from isolation (Larson 1995)

Coping with the experience

- Themes within this category reflect the sentiment that 'this is something that I have to go through', a necessary step in the treatment process
- On whole, the isolation experience was found to be less traumatic than anticipated
- Various psychological coping strategies described by informants:
- "...the best way to explain it is just switching off...just to sort of drift..." (Informant E)
- Many considered that it was easier to copy if they didn't feel unwell
- 'Routines' featured consistently as useful resource for planning the day and for enabling orientation to time
- Nurse-led routines tended to provide an incentive for informants, i.e. to get up for bed-making
- No informant felt the desire to control their situation by 'organising' the nursing staff, rather they tried to minimise inconvenience to them
- All informants reported that having a clock in the room was useful, since this enable them to plan their day

Being alone

- Whilst some concluded that being alone was 'not enjoyable' others perceived that it had no effect upon them
- Four/five informants had previous experience of protective isolation and made reference to this as helpful factor in adapting to being alone
- General experience of spending time alone was considered to be helpful in adapting to the isolation environment
- "I'm used to being separated from my husband as well, which I think if you're used to a certain amount of separation it's not so traumatic" (Informant C)

- One informant made reference to the significance of her religiosity in relation to not 'being alone'
- "I think [religion] helps anyone, but then that's my personal thoughts. It's someone to talk to, your own God, Allah, God...whatever you care to call him...and it gives you strength. And I've asked for strength and I think I've got it. I would hate to do this on my own.... And I didn't feel I was alone. For me it's important. Yes, yes.... I'm never on my own. There's someone out there if I want them. And I do want them [smiling]." (informant C)
- Geographical location of each informant's bedroom was significant. One informant whose room was situated at the ward entrance stated that he liked to hear visitors chatting as they arrived whilst another like to see people walking along the corridor as it reminded her that 'life is going on out there'
- "I can't see them [nurses and doctors] from here and I can't hear anyone, and at times it feels as if it's the Marie Celeste [laughing]...nothing happens" [informant D]
- Many informants had no real wish to communicate or to be in the company of others whilst they felt unwell, although they appreciated company when they felt well

Maintaining contact with the outside world

- Key strategy for coping with the experience of isolation and for preparing informants to resume normal activities following intensive cancer treatment
- Visitors were instrumental in providing support; however, in some cases, family and particularly friends were discouraged from visiting during isolation by the informants, who were concerned to protect themselves from infection
- Telephone and media important to maintain contact with the outside world
- Humor and touch essential
- One informant valued the 'cuddles' provided by his daughters. Conversely, another informant let her husband kiss her only once, on the hand since she considered that kissing might pose an infection risk

Having cancer

Non Hodgkin's Lymphoma: diagnosis and management

<p>Campbell, T et al. (1999). Feelings of oncology patients about being nursed in protective isolation as a consequence of cancer chemotherapy treatment. <i>Journal of Advanced Nursing</i>, 30(2); 439-447.</p>	
	<ul style="list-style-type: none"> - Having cancer relates to being restricted by a diagnosis and by the effects of cancer - Treatment is clearly seen as something that has to be undertaken in order to achieve any hope of cure, or even temporary remission from cancer - Some informants missed aspects of their home life, but most commonly home was considered the final step of (hopefully) successful treatment - Going home was associated with recovery, with being well and with having personal freedom <p>Suffering chemotherapy</p> <ul style="list-style-type: none"> - Most informants approached the chemotherapy and its anticipated effects with a sense of dread, which was the result of past experience - Although some were very compromised physiologically as a result of the chemotherapy, others were pleasantly surprised at their reactions to it - "I'm not as ill as I thought I might be and as other people have been... so that was lucky for me. But you know, I'm pleased to have got through it, to be honest. That was my main aim" (informant C) <p>Knowing what to expect</p> <ul style="list-style-type: none"> - Informants had almost completed their active treatment phase and thus it could be hypothesized that they were experiencing less anxiety than at diagnosis, since they had a clearer understanding of what their treatment entailed. - Understanding what was happening to them helped to alleviate the anxiety associated with treatment - Information was an important sub-theme of knowing what to expect - Nurses and doctors were seen as instrumental in giving information - The need for information was commonly related to aspects of the disease rather than specific elements of the treatment, such as isolation <p>Developing relationships with the health professionals</p> <ul style="list-style-type: none"> - All but one of the informants had previously received treatment on the ward where they were in isolation and familiarity with both staff and the routines was a key theme - Familiarity with the nurses who were commonly portrayed as 'friends', served to ameliorate the anxiety associated with the isolation experience - "I was quite put out because they changed my antiemetics...without, the doctors didn't say anything to me about it...and I was quite put out about that... but I spoke to the doctor about it and they changed it...back again" (Informant D) - Need to control the situation - "When I was ill, I wanted them [nurses] to do something...obviously to get me feeling better... and then eventually I asked to see Dr X...one morning at the weekend. I was feeling so bad you know they brought him in and he a look at the drug chart and, erm, made a few changes" (Informant E) - Nurses consistently described in terms of their caring behaviours, conceptualised as 'being there' and knowing what they wanted before they did - "They're [nurses] very kind. You know they're very, they're there. I think they know what I want before I do" (informant C) <p>The core strategy - something that I have to do</p> <ul style="list-style-type: none"> - Core variables reflects each step within the experience of cancer treatment as something that the patient has to go through in order to receive any potential for cure from cancer - The core variable reflects evidence from early quantitative studies which concluded that disease and treatment issues were of greater significance to the patient than having to deal with being in protective isolation (Graubert & Edmonson, 1972; Holland et al. 1977; Kellerman et al. 1977)
Comments	No idea what type of cancer the patients had. The author mentions HL and NHL in the intro and the consultant was haematologist

Results	Of those receiving major emotional support, 83.2% was from immediate family members while in 57.1%, second major emotional support was provided by friends. 79% of clinician support was provided by nurses More than 90% of patients did not receive any support from formal peer support or group support programs. All patients had daily living needs (e.g. access to food, shelter and transportation) that were met																																																																																														

Non Hodgkin's Lymphoma: diagnosis and management

<p>Glover, R et al. (2011). Patterns of social support among lymphoma patients considering stem cell transplantation. <i>Social Work in Health Care</i>, 50:10; 815-827.</p>	
	<p>Predictors of treatment delay:</p> <ul style="list-style-type: none"> - 91/119 (76.5%) underwent SCT - Patients who were employed at the time of consultation were more likely to undergo SCT (p=0.009) - However, no statistically significant relationship between employment status and delay (p=0.964) - The median number of days from the consultation to transplantation was 32 days - Time from consultation and confirmation of relapse to transplantation was less than 12 weeks in 91% of the patients - Male gender significantly associated with treatment delay ≥ 60 days (OR=2.6, p=0.048) - No significant association between treatment delay and most emotional support variables - However, there was a statistically significant relationship between extended family as second major source of emotional support and delay (p=0.016) - No significant association between treatment delay and support from a clinician (p=0.833) or formal support group (p=0.742) (sources of information support) - Access to formal peer support significantly reduced treatment delay (p=0.045) - No significant association between treatment delay and the instrumental support variables included - Logistic regression of IV (age, gender, ethnicity, employment status, insurance status, marital status and children) as predictors of treatment delay showed that age at diagnosis 31-50 years, 51-70 years and divorced marital status were associated with treatment delay greater than 26 weeks (p-values of 0.025, 0.037 and 0.045 respectively)
Comments	<p>32 patients (27%) had Hodgkin's lymphoma</p> <p>Study does not seem to account for delays associated with external factors (clinician, hospital, follow-up care etc)</p> <p>No psychological measures to assess whether patients found the support valuable or whether they wanted the support</p>

El-Banna, MM et al. (2004). Fatigue and depression in patients with lymphoma undergoing autologous peripheral blood stem cell transplantation. <i>Oncology Nursing Forum</i> , 31(5), 937-944																																						
Pub year: 2004		Patient Characteristics			Questionnaire/interview structure			Outcome																														
Country	USA	Transplant unit in a Midwestern university National Cancer Institute-designated clinical cancer centre While undergoing chemo, transplantation and recovery, patients in this centre reside in a hotel-like suite in a cooperative care setting with a designated caregiver who is a member of the patient's family or a friend. Patients are in close contact with nurses and other healthcare team members. Cooperative care is an approach that allows patients and caregivers to play an active role in the treatment and recovery processes following transplantation. Caregivers assist in all aspects of the recovery process, including administering medications, monitoring health changes, and attending informational sessions. 27 patients who underwent autologous PBSCT agreed to participate Table 1. Demographic characteristics of the sample (N=27) <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th></th> <th>Mean/n</th> <th>SD/%</th> </tr> </thead> <tbody> <tr> <td>Age (mean, SD)</td> <td>49</td> <td>13.706</td> </tr> <tr> <td>Range</td> <td>19-71</td> <td></td> </tr> <tr> <td>Male</td> <td>15</td> <td>56</td> </tr> <tr> <td>Female</td> <td>12</td> <td>44</td> </tr> <tr> <td>Non-Hodgkin lymphoma</td> <td>24</td> <td>89</td> </tr> <tr> <td>Hodgkin lymphoma</td> <td>3</td> <td>11</td> </tr> <tr> <td>Treatment protocol</td> <td></td> <td></td> </tr> <tr> <td>BEAM</td> <td>24</td> <td>89</td> </tr> <tr> <td>BEAM with rituximab</td> <td>3</td> <td>11</td> </tr> </tbody> </table> Note. N	Patients: 81/98/180 Physicians: 48/252																																																																																																																																		
Follow-up	N/A																																																																																																																																		
Funding source	Funded by an unrestricted research grant from Glaxo-Smith-Kline, Canada Authors declare no conflict of interest	Sample size calculation: A reported heuristic is that 50 respondents required to allow estimation of a reliable choice model consisting of main effects only. Table 1. Patient and physician demographic and clinical characteristics	Discrete choice experiment: <ul style="list-style-type: none"> - Wanted to obtain preference information pertaining to the four major treatment options for relapsed follicular lymphoma: <ul style="list-style-type: none"> - Standard CT - RIT - High-dose therapy and auto-SCT - High-dose therapy and allo-SCT - The level for each attribute for individual treatment options was determined by reviewing the current literature on second and third-line treatment options for patients with relapsed follicular lymphoma - Four categorical levels were used to describe the various administration protocols and toxicities for each treatment option - Given three attributes with four levels and one attribute with two levels, 128 profiles were possible. The 17 choice sets were randomly ordered. For each choice set, respondents were asked to choose between two unlabeled treatment options (A or B). - DCE questionnaire independently reviewed for content accuracy and face validity by two members of the Calgary Hematology Tumor Group and was also examined for face readability and acceptability by a small group of five lymphoma patients and five medical oncologists in Calgary

Non Hodgkin's Lymphoma: diagnosis and management

Shafey, M et al. (2011). Preferences of patients and physicians concerning treatment options for relapsed follicular lymphoma: a discrete choice experiment. Bone Marrow Transplantation, 46; 962-969.

DV: choice
IVs: the attributes
Group variable: respondent

Patients: N=81
98/180 consented to the survey
81/180 completed questionnaire (45%)

Physicians: N=48
Of the 252 who were sent a questionnaire, 38 (15%) did not treat lymphoma, 1 declined the survey (0.4%) and 161 did not respond, resulting in an overall participation rate of only 19%

DCE:

- A total of 2193 choices (129 participants X 17 questions each) were posed in the DCE. Only 18/2193 were unanswered across 6 patients and one physician, resulting in a completion rate of 99.2%
- Five patients and no physician failed the dominant choice question, however, their data were retained in the DCE analysis

Table 2. Regression analysis for patients (N=81) and physicians (N=48)

P value	<0.0001	-	-	<0.0001	-	-

Note. CT: Chemotherapy; RIT: radioimmunotherapy

As shown in Table 2, the results of the regression analysis indicate that the model as a whole is statistically significant in that the attributes taken together have an effect on choice. Remission length, costs and toxicity of transplantation (relative to chemotherapy) were important attributes (p<0.001). The negative coefficient on toxicity of allo-SCT suggests that the described toxicities corresponding to this treatment in comparison with CT decreased the likelihood of choosing the treatment option. Neither toxicity of RIT nor auto-SCT was significant on influences on choice for either patients or physicians. Cost was an important negative influence on choice only for physicians.

Strength of preference:

- Strength of preference regarding toxicity of treatment was measured against survival free of relapse.
- Participants required 0.6 years absolute increase in PFS or a 6% absolute increase in 5-year PFS in order to accept the toxicity of auto-SCT (relative to CT), but 3.9 years increase in PFS or a 39% increase in 5-year PFS in order to accept the toxicity of allo-SCT (relative to CT)

Author conclusions:

Results

Non Hodgkin's Lymphoma: diagnosis and management

<p>Shafey, M et al. (2011). Preferences of patients and physicians concerning treatment options for relapsed follicular lymphoma: a discrete choice experiment. Bone Marrow Transplantation, 46; 962-969.</p>	
	<ul style="list-style-type: none"> - For both patients and physicians, survival free of relapse was an important positive influence on choice. - Toxicity of allo-SCT relative to standard CT was an important negative influence on choice - Somewhat surprising the toxicity of RIT relative to standard CT was not a significant positive influence on choice - Administration of treatment did not influence the choice in the study - Cost was a significant negative influence on choice only to physicians - When strength of preference for toxicity was measured against survival free of relapse, participants required a chance of remission or remission length close to seven times higher for allo-SCT compared with auto-SCT, clearly, participants placed tremendous value on survival free of relapse and toxicity of allo-SCT when making hypothetical treatment decisions - Study demonstrated that patients are willing to trade-off the toxicity associated with auto-SCT in order to benefit from increased survival free of relapse
Comments	<p>~25% of patients and 54% of physicians had prior experience with SCT, which could have biased their choices for or against 'administration' and 'side-effect' attributes associated with auto-SCT and allo-SCT</p> <p>Low response rates</p>

Non Hodgkin's Lymphoma: diagnosis and management

Oerlemans, S et al. (2014). Health-related quality of life and persistent symptoms in relation to (R-)CHOP14, (R-)CHOP21, and other therapies among patients with diffuse large B-cell lymphoma: results of the population-based PHAROS-registry . Ann Hematol, 93: 1705-1715.				
Pub year:		Patient Characteristics	Questionnaire/interview structure	Outcome
Country	Netherlands	Population-based Haematological Registry for Observational Studies (PHAROS), an extension of the Netherlands Cancer Registry (NCR). <ul style="list-style-type: none"> NCR was used to select all patients who were diagnosed with DLBCL as defined by the International Classification of Diseases for Oncology-3 codes (ICD)-3 between Jan 1, 2004 and December 31, 2010 in an area covering approximately 40% of the Dutch population. <ul style="list-style-type: none"> The NCR data (including date of diagnosis, morphology, gender, date of birth and stage) were replenished with details on treatment, adverse events and treatment outcomes from PHAROS A longitudinal population-based survey was set-up among DLBCL patients registered with the Eindhoven Cancer Registry (ECR) which fills about 15% of NCR. The database with patients diagnosed between January 1, 2004 and December 31, 2010 was linked with the database of the Central Bureau for Genealogy to exclude patients who were deceased. HRQOL and symptoms were collected within patient reported outcomes following initial treatment and long-term evaluation of survivorship (PROFILES). Normative population <ul style="list-style-type: none"> Selected from a reference cohort of 2,040 individuals from the general Dutch population (CentER panel) Set of questionnaires completed by this normative population in November 2011 included the EORTC QLQ-C30, SCQ and data on socio-demographics Cohort is considered as representative for the Dutch-speaking population in the Netherlands Based upon this normative population, an age- and sex-matched selection was made of 425 persons to compare HRQOL with the DLBCL patients For matching, 10 strata were formed using sex and age (5 categories). Within each stratum, a maximum number of persons from the reference cohort were randomly matched according to the "strata frequency distribution" of the patients. 425 matched cancer-free panel members for 256 patients 	Questionnaires sent out in batches, this was done at three time points: <ul style="list-style-type: none"> Time 1 <ul style="list-style-type: none"> May 2009, patients diagnosed between Jan 2004 and Jan 2009 were included in the study and received the first questionnaire November 2009 and May 201, patients newly diagnosed after the last inclusion date were subsequently invited to participate to include all patients up to December 31, 2010. Time 2 <ul style="list-style-type: none"> Patients received the subsequent questionnaire 1 year after T1 HRQOL: <i>Dutch-validated version of the European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30)</i> <ul style="list-style-type: none"> Answer categories range from one (not at all) to four (very much) All scales and single item measures range in score from 0-100 A higher score on function scales and global health and quality of life scale implies a better HRQOL, whereas for symptoms with a higher score refers to more symptoms Patients were determined to be fatigued with a QLQ-C30 fatigue score >21.9 (mean of age- and sex- matched normative population + small clinically important difference, i.e., five points) Disease and treatment-related symptoms and worries: <i>Dutch version of the EORTC CLL-16</i> <ul style="list-style-type: none"> Originally developed for patients with chronic lymphocytic leukaemia but authors state also applicable to lymphoma patients The symptom tingling in hands/feet was added as it appeared from the literature and interactions with patients that this might be a prevalence symptom Answer categories range from one (not at all) to four (very much) Comorbidity: <i>Adapted self-administered comorbidity questionnaire (SCQ)</i> Socio-demographic and clinical data: <ul style="list-style-type: none"> Marital status and educational level Clinical data obtained from the NCR and PHAROS If patients received more than one treatment line, the treatment category was based on the sum of treatments before completion of the questionnaire and was ordered from most to least expected impact on HRQOL: <ol style="list-style-type: none"> ASCT HDCT (R-)CHOP14 (R-)CHOP21 Other chemotherapy (CT), radiotherapy (RT) or no therapy 	HRQoL

Results

Non Hodgkin's Lymphoma: diagnosis and management

Oerlemans, S et al. (2014). Health-related quality of life and persistent symptoms in relation to (R-)CHOP14, (R-)CHOP21, and other therapies among patients with diffuse large B-cell lymphoma: results of the population-based PHAROS-registry . Ann Hematol, 93: 1705-1715.

Note. NA: not applicable

Non-response analysis

At baseline, non-respondents (N=48) and patients with unverifiable addresses (N=29) were more often female than respondents (60 and 66% vs 34%; $p<0.01$), and non-respondents were more often treated shorter than 12 months ago compared to respondents (48 vs 27%; $p=0.01$). No statistically significant differences between these groups were observed for age, time since diagnosis, stage, treatment, and number of treatment lines (data not shown in article)

No statistically significant differences were observed between patients who completed one and patients who completed two questionnaires for QLQ-C30 global health and QoL score (Mean=74.8 versus 72.9; $p=0.47$) or for sex, age, stage, (time since) treatment, co-morbidities, marital status and educational level (data not shown in article)

HRQoL and symptoms/worries in relation to treatment

- Patients treated with RCHOP14 reported significantly more often tingling in hands and feet compared to patients treated with RCHOP21 (42% versus 27%, $p=0.02$; adjusted for age, number of comorbidities, time since treatment and number of treatment cycles)
- Patients treated with RCHOP14 reported significantly lower global health status/quality of life compared to patients treated with RCHOP21 (71.9 versus 75.2, $p=0.04$; adjusted for age, number of comorbidities, time since treatment and number of treatment cycles)
- Patients treated with RCHOP14 reported significantly higher levels of fatigue compared to the RCHOP21 group (46% versus 35%, $p=0.003$; adjusted for age, number of comorbidities, time since treatment and number of treatment cycles)
- Patients treated with RCHOP14 often felt slowed down compared to patients treated with RCHOP21 (44% versus 37%, $p=0.03$ adjusted for age, number of comorbidities, time since treatment and number of treatment cycles)
- Numbers too small for the patients treated with HDCT, ASCT and other therapies to draw conclusions of differences in prevalence rates of symptoms and worries

HRQoL of DLBCL patients and the normative population

Note. Higher scores on functioning implies better HRQoL, higher scores on symptom refer to more symptoms.

- DLBCL patients exhibited on average statistically significant and clinically relevant worse scores on QLQ-C30 physical, role, cognitive and social functioning compared to the matched norm
- DLBCL patients reported more fatigue, dyspnea, sleeping problems, appetite loss and financial problems compared to the matched norm (all $p<0.05$, small clinically important differences)

Prevalence of symptoms/worries

- Most frequently reported symptom/worry on T1 were worry about future health (53%), skin problems (itching and dry skin; 42%), feeling slowed down (40%), dry mouth (40%) and tingling in hands and feet (33%)
- The prevalence of symptoms/worries did not significantly differ per time since treatment category, except for skin problems which occurred more often among patients who received treatment more than 3 years ago
- Worry about future health and having a dry mouth seemed to occur more often among patients until 1 year after treatment

Factors associated with persistent symptoms/worries and the relation with HRQoL

Of the patients who completed the questionnaire again 1 year later (N=130), persistent symptoms/worries were reported by 20-33% of patients

- Multivariate logistic regression analyses showed that:
- Older patients and patients treated with RCHOP14 more often had persistent tingling in hands and feet compared to patients treated with RCHOP21 independently of the other characteristics (OR:1.08, 95% CI: 1.0-1.1, $p=0.02$)
- Persistent worry about future health and persistent slowed down feeling were reported more often by patients with comorbid disease (OR:4.44, 95% CI: 1.4-14, $p=0.01$ for persistent worry; OR:7.99, 95% CI: 1.6-40, $p=0.01$ for persistent slowed down feeling)
- Persistent skin problems more often occurred among patients diagnosed longer ago (OR:1.51, 95% CI: 1.1-2.1, $p=0.02$)
- Sex, disease stage and number of treatment cycles were not associated with any of the persistent symptoms/worries (OR:1.08, 95% CI: 1.0-1.1, $p=0.02$)
- Patients who reported to be persistently slowed down, worrying about future health, or having tingling hands or feet had statistically, significantly and clinically relevant lower EORTC global health status/HRQoL compared to patients without these persistent symptoms/worries (all $p<0.01$, data not shown)

Demographic and clinical variables (N=374)</p> <table border="1"> <thead> <tr> <th></th> <th>N</th> <th>%/SD</th> </tr> </thead> <tbody> <tr><td>Age <50</td><td>101</td><td>27</td></tr> <tr><td>Age 50-64</td><td>115</td><td>31</td></tr> <tr><td>Age ≥65</td><td>158</td><td>42</td></tr> <tr><td>Female</td><td>181</td><td>48</td></tr> <tr><td>Male</td><td>193</td><td>52</td></tr> <tr><td>NHL grade High</td><td>38</td><td>10</td></tr> <tr><td>NHL grade Intermediate</td><td>336</td><td>90</td></tr> <tr><td>No. of co-morbidities</td><td></td><td></td></tr> <tr><td>≥3</td><td>72</td><td>19</td></tr> <tr><td>1-2</td><td>179</td><td>48</td></tr> <tr><td>0</td><td>121</td><td>33</td></tr> <tr><td>Self-reported remission</td><td></td><td></td></tr> <tr><td>No</td><td>34</td><td>9</td></tr> <tr><td>Yes</td><td>331</td><td>91</td></tr> <tr><td>Physician specialty</td><td></td><td></td></tr> <tr><td>Oncology/ haematology</td><td>325</td><td>92</td></tr> <tr><td>Primary care/other</td><td>27</td><td>8</td></tr> <tr><td>Patient-physician sex match</td><td></td><td></td></tr> <tr><td>No</td><td>168</td><td>47</td></tr> <tr><td>Yes</td><td>187</td><td>53</td></tr> <tr><td>Length of relationship with physician (years)</td><td></td><td></td></tr> <tr><td><2</td><td>83</td><td>23</td></tr> <tr><td>≥2</td><td>278</td><td>77</td></tr> </tbody> </table>		N	%/SD	Age <50	101	27	Age 50-64	115	31	Age ≥65	158	42	Female	181	48	Male	193	52	NHL grade High	38	10	NHL grade Intermediate	336	90	No. of co-morbidities			≥3	72	19	1-2	179	48	0	121	33	Self-reported remission			No	34	9	Yes	331	91	Physician specialty			Oncology/ haematology	325	92	Primary care/other	27	8	Patient-physician sex match			No	168	47	Yes	187	53	Length of relationship with physician (years)			<2	83	23	≥2	278	77	<p><u>Socio-demographic, clinical and follow-up care-related variables</u> Age, sex, race/ethnicity, marital status, education, NHL grade, number of co-morbidities, current disease status, speciality of follow-up care physician, sex match between the survivor and physician, length of survivor-physician relationship, survivors' perception of the physician spending enough time during visits in the past 12 months (never, sometimes, usually, always) and survivors rating of the quality of their follow-up care in the past 12 months (poor, fair, good, very good, excellent)</p> <p><u>Discussion of HRQOL problems</u> Adapted items from existing study Detmar et al. (2000) to assess NHL survivors' willingness to discuss their HRQOL problems in five domains:</p> <ul style="list-style-type: none"> Physical functioning (symptoms such as pain, shortness of breath) Daily functioning (doing regular daily activities) Emotional functioning (sadness, anxiety, depression) Social functioning (relationships with partner, family members, or close friends) Sexual functioning <p>For each domain participants asked if they were to experience problems, "would you talk about them during a visit with the doctor you see most often for follow-up cancer care?"</p> <ul style="list-style-type: none"> The 374 survivors who received follow-up care in the past 12 months were provided with three response options: "yes, I would bring up this issue on my own"; "yes, but only if my doctor raises the issue"; and "no, preferably not". The latter two groups asked to select as many reasons as applicable for not wanting to initiate discussions about their problems. <p>Six patient-, physician-, and system-related factors were assessed:</p> <ol style="list-style-type: none"> I don't think anything can be done about these problems (patient factor) I'm not comfortable discussing these problems with my doctor (patient factor) I don't think my doctor is interested in discussing these problems (physician factor) I don't think it is my doctor's job to address these problems (physician factor) I would prefer to talk about these problems with some other doctor or healthcare professional I don't think my doctor has the time to discuss these problems (system factor) <p>For each domain, authors created a dichotomous variable that distinguished survivors who were willing to initiate discussion from those who either preferred to talk only if the doctor raised the issue or preferred to not discuss the issue at all.</p> <p><u>Current HRQOL - patients completing the telephone interview did not receive these questions</u> Identified an indicator of survivors' current HRQOL for each of the five domains.</p> <ul style="list-style-type: none"> For physical, daily, emotional, and social functioning used Short Form-36 (SF-36v2). Scores standardised on basis of 1999 US general population norms, with a mean of 50 (SD=10). To identify survivors experiencing greater HRQOL problems, dichotomized the social, physical and the mental component 	<p>HRQoL</p> <p>Patient satisfaction</p> <p>Treatment decision making</p>

	≥40	222	76							2.01	1.0-4.06	0.05			
	Sexual functioning	243													
	Any problem	131	54										REF		
	No problem	112	46										1.04	0.56-1.93	0.9

Note. All four logistic regression models adjusted for: age, race/ethnicity, marital status, education, non-Hodgkin lymphoma grade, number of co-morbidities, remission status, survivor-physician sex match, and length of the relationship with physician in years, adequacy of time spent with physician and ratings of quality of care. OR: Odds ratio

- Survivors with higher PCS scores were more willing to discuss problems with daily activities than survivors with lower scores
- Association between experience of problems and willingness to discuss them was not statistically significant for emotional, social or sexual functioning

Comments
 For each domain participants asked if they were to experience problems - Not therefore clear if these are problems participants actually faced or hypothetical
 Group items into dichotomous variables could be problematic, for example physician spends enough time during visits - never, sometimes, usually versus always, the grouping covers quite a range of opinions
 Only patients who completed the paper version of the survey received all the questions

Non Hodgkin’s Lymphoma: diagnosis and management

Smith, S et al. (2009). Health status and quality of life among non-Hodgkin lymphoma survivors. Cancer, 15: 3312-3323.				
Pub year:		Patient Characteristics	Questionnaire/interview structure	Outcome
Country	USA	Potential study participants identified through the Duck and University of North Carolina Tumor Registries and contacted by mail. Inclusion: Patients with NHL aged ≥19 years and 2 years post-diagnosis	<p><u>Health status and quality of life outcomes:</u> <i>Medical Outcomes Study Short Form (SF-36)</i></p> <ul style="list-style-type: none"> - General health measure of physical and mental health functioning - Used to allow for comparisons with general population-based norms - 36 items, 8 subscales and 2 summary scores <ul style="list-style-type: none"> - Physical Component Score (PCS) - Mental Component Score (MCS) - For purposes of comparison, a score of 50 (Standard deviation=10) represents the population mean - Reliability estimates ranged from $\alpha=0.84$ to $\alpha=0.95$ <p><i>Functional Assessment of Cancer Therapy-General (FACT-G)</i></p> <ul style="list-style-type: none"> - 27 items - Originally intended for patients who were receiving treatment but increasingly used with off-treatment samples <p><i>FACT-Lymphoma (FACT-LYM)</i></p> <ul style="list-style-type: none"> - 15 items - Reliability estimates for FACT-G and FACT-LYM ranged from $\alpha=0.77$ to $\alpha=0.93$ <p><i>Impact of Cancer (IOC)</i></p> <ul style="list-style-type: none"> - Assess respondent’s perceptions of positive and negative impacts of cancer in various aspects of their lives using 5 positive subscales, 5 negative subscales, and 2 summary scores (Positive Impact and Negative Impact) - Developed to assess certain aspects of survivorship that were not measured by other QOL measures (e.g. health worries, meaning of cancer, post-traumatic growth) - Reliability estimates for the IOC ranged from $\alpha=0.62$ to $\alpha=0.91$ <p>Higher scores on all outcome measures indicate better health status and QOL, except for the IOC Negative Impact score, for which a higher score indicates greater negative impacts</p> <p><u>Demographic and Clinical characteristics</u></p> <p><u>General Health:</u> <i>Self-administered Comorbidity Questionnaire</i></p> <ul style="list-style-type: none"> - Assess non-NHL health problems - Selected questions related to healthcare use were adapted from the Childhood Cancer Survivor Study survey <p><u>Psychosocial</u> <i>Medical Outcomes Study-Social Support survey</i></p> <ul style="list-style-type: none"> - 20-item - Perceived availability of social support - Range: 20-100 - $\alpha=0.97$ <p><i>Appraisal of Life Threat and Treatment Intensity Questionnaire</i></p> <ul style="list-style-type: none"> - 6-item - Assess extent to which cancer and its treatment were perceived as life-threatening and intense - Range: 6-30 - $\alpha=0.80$ <p><i>Cancer and Leukemia Group B research instrument</i></p> <ul style="list-style-type: none"> - 24-item - Employment-related and insurance-related situations and difficulties - Range: 0-24 - $\alpha=0.82$ 	HRQoL

Smith, S et al. (2009). Health status and quality of life among non-Hodgkin lymphoma survivors. Cancer, 15: 3312-3323.

Post-traumatic Stress:
PTS Disorder (PTSD) Checklist

- symptom checklist that closely mirrors criteria from the Diagnostic and Statistical Manual (4th Edition) for a formal diagnosis of PTSD
- Instrument was modified for current study, such that survivors were asked to rate each symptom in the past 4 weeks with respect to their diagnosis and treatment for lymphoma
- Continuous scoring method used
- Cronbach α ranged from 0.78 to 0.91

Employed	302	40.2	39	36.1	68	45.9	195	39.3	

Note. NA: Not applicable.

- Sample bias analyses using demographic information from the registries indicated that participating survivors were less frequently non-white and were older at diagnosis and study enrolment than non-participants (all P<0.001)
- Survivors who reported having active disease were more likely to be diagnosed with an indolent lymphoma, to receive biologic therapy, to have more recurrences and types of treatment, and to have PTS than disease-free survivors (all P<0.01)
- STS were younger at enrolment, less likely to have a secondary cancer, and had less comorbidity than those with active disease or LTS (all P<0.05)

Health status and quality of life in non-Hodgkin lymphoma survivors (n=761)

- Survivors who had active disease:
 - Demonstrated worse functioning compared with disease free survivors for physical (PCS) and mental (MCS) health (all P<0.01)
 - Demonstrated significantly worse QOL, as measured by the FACT-G and lymphoma-specific items, than both STS and LTS (all P<0.01)
 - Less positive impact and more negative impact (all P<0.01) on the IOC than those who were disease-free
- STS and LTS did not differ significantly in any of the outcomes measured
- Compared with general population-based norms (PCS and MCS scores: mean ±SD, 50±10), individuals with active disease scored lower in physical health (41.1±11.9) and mental health (45.4±11.5)
- Disease free survivors fared better, as expected but still seemed to have worse physical health cores (STS: 47.3±10.4; LTS: 45.7±9.9) compared to the general adult population
- Comparing to an age-stratified normed groupings the sample scored comparably (within ±1.8 points) on the PCS
- Disease-free survivors on the MCS (STS: 50.3±9.9; LTS: 49.3±11.4) were close to the general population norm; however, the sample scored lower (≤4.1 points) on the MCS than the corresponding age-stratified groups (except for the groups ages 35-44 years and ≥75 years), with the largest difference observed between the group ages 25-34 years

Regression results

- SF-36 Model I indicates that STS and LTS scored 6.2 and 4.6 points higher, respectively, than those with active disease before adjusting for covariates (p<0.001)
- Differences statistically non-significant, LTS reported lower health status and QoL than STS in all models
- All relationships reported in the models were lost once post-traumatic stress was included
- Disease-free survivorship was associated with better IOC positive impact scores (p<0.05)

Non Hodgkin's Lymphoma: diagnosis and management

Smith, S et al. (2009). Health status and quality of life among non-Hodgkin lymphoma survivors. <i>Cancer</i> , 15: 3312-3323.	
	Authors conclude that only one outcome measure continued to elucidate differences between those with and without active disease: the IOC positive impact scale (authors state that this may be because the IOC is the only QoL-related measure that contains items related to post-traumatic growth, hence more sensitive outcome measure for individuals who are disease-free and are more likely to report having benefited from their cancer experience)

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2013		Patient Characteristics	Questionnaire/interview structure	Outcome
Country	Netherlands	<p>Data from three large population-based surveys on survivors of thyroid cancer, colorectal cancer, and non-Hodgkin's and Hodgkin's lymphoma conducted between 2008-2010. Data from the survey was linked to Eindhoven Cancer Registry (ECR) which records data on all newly diagnosed cancer patients in the southern region of the Netherlands covering an area with 2.3 million inhabitants and 10 hospitals.</p> <ul style="list-style-type: none"> - All lymphoma patients diagnosed between 1999 and 2008 were eligible for participation in the surveys. All patients surveyed at least 6 months after their cancer diagnosis, in order to ensure that cancer treatment was completed at the time of the survey, and at most 10 years after cancer diagnosis. - Exclusion: deceased patients and patients deemed to have serious cognitive impairment or who were in transition to terminal care according to their treatment physicians were not invited to participate - Eligible patients received invitation letter with a login account and password to complete the survey online. If patients did not have access to internet or preferred to take the survey on paper, they could return a postcard, and they received the paper questionnaire within 1 week. 	<p><u>Clinical and socio-demographic characteristics:</u> ECR</p> <p><u>Health-related quality of life (HRQoL):</u> <i>European Organisation for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire Core 30 (QLQ-C30) (version 3.0)</i></p> <ul style="list-style-type: none"> - 30-item - Five function scales, measure of global health or quality of life, nine scales on symptoms and side effects - Four scales included <ul style="list-style-type: none"> - Physical function - Emotional function scale - Symptoms pain and fatigue - Response: 1 (not at all) to 4 (very much) - Score: 1-100 - Higher score on function domains = better quality of life - Higher score on symptom scales = more symptoms <p><u>Comorbidity:</u> <i>Self-administered comorbidity questionnaire</i></p> <ul style="list-style-type: none"> - Prevalence, hindrance in daily activity and treatment of 14 comorbidities including heart disease, stroke, high blood pressure, COPD/asthma, diabetes, stomach disease, kidney disease, liver disease, anaemia, depression, thyroid disease, osteoarthritis, back pain and rheumatoid arthritis - Only the number of prevalent comorbidities and not treatment and hindrance in daily activities was assessed in the survey due to concern about confounding effect of hindrance with the included measures of HRQoL - Score: 0-14 	HRQoL
Design, period	Cross-sectional study

Non Hodgkin's Lymphoma: diagnosis and management

Vissers, PAJ et al. (2013). The impact of comorbidity on health-related quality of life among cancer survivors: analyses of data from the PROFILES registry. *Journal of Cancer Survivorship*, 7:602-613

Table 1. Characteristics of the study population (N=716)

	Mean/n	SD/%
Age	64	12
Male	439	61
Female	277	39
Years after diagnosis	5	3
Tumour stage		
1	100	33
2	77	25
3	54	18
4	76	25
Treatment		
Surgery only	11	2
Surgery and radiotherapy	6	1
Surgery and chemotherapy	9	11
Surgery, radio and chemotherapy	10	11
Chemotherapy only	303	44
Radiotherapy only	62	9
Watchful waiting	187	27
Radio and chemotherapy	85	12
Stem cell transplantation	1	0
Stem cell transplantation and chemotherapy	22	3
Education level		
Medium or low	532	77
High	163	23

Note.SD: Standard deviation

Comorbidities: Stroke, stomach, kidney and liver diseases were prevalent in less than 5% of NHL patients and were excluded from further analyses

Table 2. Health related quality of life according to the QLQ-C30

QLQ-C30 Score range: 1-100	Mean	SD
Physical functioning	80	20
Emotional functioning	84	21
Pain	16	25
Fatigue	28	25

Note. SD: Standard deviation. Pain and fatigue scored in opposite direction with higher scores indicating more symptoms

- Having one and/or two or more comorbidities was significantly associated with lower physical and emotional function and higher levels of pain and fatigue
- Multivariate linear regression models showed that the number of comorbidities was strongly related to the studies subscales of the QLQ-C30 with a p value <0.01
- All standardised betas were in the expected direction with more comorbidities resulting in lower physical and emotional function
- Having more comorbidities was associated with higher levels of pain and fatigue
- These significant results were reported across all cancers, suggesting not unique to NHL

- Variance explained by number of comorbidities was higher compared with sociodemographic and cancer characteristics
- For NHL, variance in physical function was explained most by heart disease and back pain
- For NHL, variance in emotional function was explained most by depression
- For NHL, variance in pain was explained most by back pain
- Comorbidities were significantly higher among the elderly

Non Hodgkin's Lymphoma: diagnosis and management

<p>Vissers, PAJ et al. (2013). The impact of comorbidity on health-related quality of life among cancer survivors: analyses of data from the PROFILES registry. <i>Journal of Cancer Survivorship</i>, 7:602-613</p>	
	<ul style="list-style-type: none"> - Among elderly NHL patients, the number of comorbidities explained less while cancer characteristics explained more variance in all studies subscales compared to the total population <p>Authors state that they have showed that in comparison with socio-demographic and cancer characteristics, comorbidity explained more variance in physical function, emotional function, pain and fatigue. This was found regardless of cancer type. Difference in these patterns according to cancer type appeared when looking at patients' ≥70 years old with NHL patients' cancer characteristics seemed to have greater impact on HRQoL compared to the results for the total population. As hypothesised, the prevalence of comorbidity was higher among the elderly, but did not have a higher impact compared to socio-demographic and cancer characteristics among all cancer survivors.</p>
Comments	<ul style="list-style-type: none"> - ECR only collects data on the primary tumour and treatment therefore it cannot be ascertained that patients were disease-free at the time of the survey - Authors state that the EOI+RTC QLQ-C30 does not include an overall score of all scales, and in order to prevent multiple testing and avoid an associated type 1 error, the four most important or distinctive scales were selected – not clear how this was decided - Cross-sectional design – was self-reported comorbid conditions present before the cancer diagnosis or developed thereafter. In addition, questionable whether comorbidities measured in study are independent predictors of HRQoL, since they can interact with treatments or could be caused by cancer treatment and synergistically lower HRQoL

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2013		Patient Characteristics	Questionnaire/interview structure	Outcome																																																	
Country	USA	Analysis of data from the Experience of care and Health Outcomes of Survivors of non-Hodgkin Lymphoma (ECHOS-NHL) Inclusion: – Adult survivors of aggressive NHL who were selected in 2003 from the Cancer Surveillance Programme (Surveillance Epidemiology, and End Results [SEER] registry) for Los Angeles County who were diagnosed 2-5 years before the study (between June 1, 1998 – August 31, 2001) – Aged ≥20 years with a first-time diagnosis of either intermediate-grade or high-grade NHL Exclusion: – Diagnosed with another cancer within a year before their NHL diagnosis or subsequently – 89 patients who completed the telephone survey as they were not asked about HRQoL 744 eligible 408/744 (55%) completed the survey 319/408 full paper survey 89/408 brief telephone version (did not include HRQoL measures) Survivors who completed the brief survey did not differ from those who responded to the full survey on any of the socio-demographic or clinical variables, except that telephone responders were more likely to have been diagnosed earlier (3.8 years versus 3.5 years; p<0.01)	Mailed questionnaire with telephone follow-up for non-responders to the mailing, and also conducted a medical record abstraction to augment clinical data available from the SEER registry <u>Patient-level variables – some self reported and others from the SEER registry:</u> – Socio-demographic (age, sex, race/ethnicity, education, household income, insurance, marital status) – Clinical characteristics <u>Health-related quality of life outcomes:</u> Medical Outcomes Study (version 2) Short form health survey (SF-36) – 36-items – 8 sub-scales – Physical function – Role limitations because of physical health – Mental health – Role limitations because of emotional problems – Social function – Bodily pain – Vitality – General health perceptions – Scores from these subscales used to calculate 2 summary health scores: – Physical Component Summary (PCS) – Mental Component Summary (MCS) – Basis of norms from the 1999 general US population, standardised all scores on a T-score metric, such that a score of 50 represented the average score in the US general population with a standard deviation of 10 – Higher scores reflecting better HRQoL Hospital Anxiety and Depression Scale (HADS) – 14-item scale (7 for depression and 7 for anxiety) – 4-point (0-3) response format – Score range: 0-21 – 0-7: considered normal – 8-1:0 considered mild anxiety/depression – 11-14: considered moderate – 15-21: considered severe Fatigue symptom Inventory (FSI) – 7-item – Assess extent to which fatigue interfered during the past week with their general activity, ability to bathe and dress, normal work activity, ability to concentrate, relations with others, enjoyment of life and mood – 0 (no interference) – 10 (extreme interference) – Overall score by averaging scores on the 7 items, transformed to scale 0-100 – Higher score = greater fatigue interference	HRQoL

Other	38.38		44.39		-	-	5.58		32.56	
Adjusted R ²		0.28		0.12		0.08		0.11		12

Note. Gender, Education, race/ethnicity and treatment in the past 6 months were not significantly different.

Clinically meaningful differences:

- Differences in MCS, depression, anxiety and fatigue scores among survivors aged <50 years and those aged >65 years were large enough (effect sizes ≥0.5) to be considered clinically meaningful
- Differences in HRQoL among survivors with no comorbidities and those with ≥3 comorbid health conditions suggested clinically meaningful differences between these subgroups for these outcomes (effect sizes between 0.6-1.1)
- Differences in PCS scores were also clinically meaningful between survivors with no comorbidities and those with 1 or 2 comorbidities (effect size 0.6)
- NHL survivors who experienced a cancer recurrence also reported lower PCS scores (P<0.01) and higher levels of fatigue (P<0.05). The difference in the PCS score was 5.9 points,, suggesting clinically meaningful deficits in physical health were also present among survivors who had recurrent NHL compared with those who did not

Cognitive health appraisal and health-related quality of life

- HRQoL differences among NHL survivors who reported low levels and high levels of health competence far exceeded the threshold of clinically meaningful differences, with effect sizes between 0.8 and 1.0
- Meaningful differences also identified between survivors with low and medium health competence across all HRQoL outcomes except Mental Component Summary (MCS)
- With exception of Physical component summary (PCS) scores, greater perceptions of personal control also were associated with significantly better HRQoL outcomes (P<0.01), with differences in the range of medium to large effect sizes (≥0.5) identified between survivors with low and high levels of control

Sensitivity analyses:

- Conducted sensitivity analyses re-constructing regression models for only those survivors whose cancer did not recur and who were in remission at time of study
- Observed similar pattern of associations for all sociodemographic, clinical and cognitive appraisal variables
- In disease-free sample, men reported significantly better physical functioning than women (P=0.01)

Comments

- 2-5 years after diagnosis NHL survivors had MCS scores similar to those of the general US population, but their PCS scores were significantly lower, suggesting that many individuals in this population report deficits in physical functioning.
- 1 in 5 reported scores above the clinical threshold for depression or an anxiety disorder. Overall rates slightly higher than the general US population. Higher levels of reported Fatigue

Non Hodgkin's Lymphoma: diagnosis and management

Kourkoulis, CT et al. (2004). An Evaluation of age-related differences in quality of life preferences in patients with non-Hodgkin's lymphoma. Leukemia and Lymphoma 45(12); 2471-2476																																																																																																				
Pub year: 2004		Patient Characteristics			Questionnaire/interview structure		Outcome																																																																																													
Country	Canada	Consecutive patient with NHL attending an outpatient clinic at the Juravinski Cancer Centre, Hamilton, Canada were approached for participation if the clinic staff felt they were able to complete the self-administered questionnaire during their clinic visit and if the patient consented to filling out the questionnaire - 79 patients approached - 76/79 completed survey Table 1. Note. M: mean. SD: standard deviation.

Functional scales

- Compared to the reference population, baseline scores of physical, role and social functioning as well as global QoL were significantly lower, the differences were both clinically (>10) and statistically significant (p<0.01)
- Emotional and role functions were significantly improved at week 56 compared to baseline (p<0.001)
- At week 56, 8 (CHOP) and 11 weeks (MACOP-B), respectively, after completion of chemotherapy, role function was still depressed compared to the reference group. The other functional scores were not different from those of the reference population in terms of clinical significance
- These results were identical also when the analysis was restricted to the patients with complete baseline data

Symptom scales

- At baseline, appetite loss scores were significantly higher compared to the reference population
- At week 56, symptom scores were not significantly different from those of the reference population, but fatigue scores were significantly improved compared to baseline scores (p<0.01)
- 18 (29%) patients reported a global QoL below the pretreatment median value (65) at week 56. No association between clinical prognostic factors or chemotherapy regimen and post-treatment global QoL. When population divided according to the median pain score (15), 88% of patients reporting pain >15 at baseline, had a low global QoL (<65) at week 56, compared to 12% among patients with less pre-treatment pain (<15) (p<0.05)

Comments

Missing item imputations were performed in 0.4% of all calculations
Absolute difference of 10 or more on the 0-100 scale was considered clinically significant

Non Hodgkin's Lymphoma: diagnosis and management

Glaser, AW et al. (2013). Patient-reported outcomes of cancer survivors in England 1-5 years after diagnosis: a cross-sectional survey. BMJ Open, 3:e002317				
	Remission (R) versus Not sure	3.04	1.58-5.84	0.001
	Physical activity performed each week quantified according to the Chief Medical Officer of England's recommendations	0.91	0.84-0.98	0.001
	Index of multiple deprivation			
	1 (least deprived) (R) versus 2	1.06	0.67-1.69	0.80
	1 (R) versus 3	1.21	0.75-1.95	0.43
	1 (R) versus 4	1.64	0.97-2.76	0.07
	1 (R) versus 5 (most deprived)	1.19	0.65-2.21	0.57
	Ethnicity			
	White (R) versus Asian	2.78	0.28-27.7	0.38
	White (R) versus Black	0.68	0.29-1.59	0.38
	White (R) versus Mixed	0.91	0.33-2.49	0.85
	White (R) versus Other	0.61	0.09-4.39	0.62
	Note. R: reference standard. †Odds of reporting 'medium' or 'low' QoL EQ5D scores compared with 'high' QoL scores where 'High', '#medium' and 'low' QoL was defined as scores = 1, 0.5≤scores<1 and scores<0.5, respectively.			
	<ul style="list-style-type: none"> - Presence of one or two or more long-term conditions was significantly associated with lower QoL scores - Those currently being treated, experiencing a recurrence or who were not sure about their disease status had increased odds of reporting lower QoL scores compared with those in remission - These same factors were associated with poorer outcomes on the SDI and FACT-Lym items - Significant positive association between increasing physical activity and QoL was seen with each additional day of physical activity reducing the odds of lower QoL score by 9% - QoL seemed to improve with time from diagnosis for NHL but the trend was not significant (p=0.100) 			
Comments	Authors present QoL scores for Health survey for England (2008) and a GP population survey (with and without long term health conditions) reporting that high QoL ranged from 45.4 – 73.8%, medium: 25.2-45.6 and low QoL: 0.9-9.0.			

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2014		Patient Characteristics				Questionnaire/interview structure	Outcome																																																																																																																	
Country	Netherlands	Data from five large population-based cross-sectional surveys on survivors of Hodgkin lymphoma, non-Hodgkin lymphoma, myeloma, endometrial and colorectal cancer. <ul style="list-style-type: none"> - ECR compiles data of all individuals newly diagnosed with cancer in the southern part of the Netherlands, an area with 10 hospitals serving 2.3 million inhabitants - All individuals diagnosed with Diffuse Large B-cell lymphoma (DLBCL) between 1 January 1999 and 12 January 2010 - Inclusion: All patients with DLBCL as defined by the International Classification of Diseases for Oncology-3 codes (ICD-0-3) - Exclusion criteria: Participants aged ≥85 years because it was expected that they would have difficulty completing self-administered questionnaires without assistance. All patients who had died (according to the ECR, hospital records, and the Central Bureau for Genealogy that collects information on all deceased Dutch citizens via the civil municipal registries) 				EORTC QLQ-C30 <ul style="list-style-type: none"> - Self-report - Five scales - Physical - Role - Emotional - Cognitive - Social - Global health status/quality of life scale - Three symptom scales on fatigue, nausea and vomiting and pain - Six single items assessing dyspnea, sleeping problems, appetite loss, constipation, diarrhoea and financial problems - 1-not at all to 4-very much - Linear transformation all scales and single-item measures range in score from 0-100 - Higher score on the functional scales and global health and QoL scale = better HRQoL - Higher score on the symptom scales = more symptoms Self-administered Co-Morbidity Questionnaire (SCQ) – measure of co-morbidity Demographic and clinical characteristics	HRQoL

Non Hodgkin's Lymphoma: diagnosis and management

Hall, A et al. (2014). The survivor unmet needs survey (SUNS) for haematological cancer survivors: a cross-sectional study assessing the relevance and psychometric properties. BMC Health Services Research, 14(211); 1472-6963																																							
Pub year: 2014		Patient Characteristics	Questionnaire/interview structure	Outcome																																			
Country	Australia	Inclusion: Haematological cancer survivors, aged between 18-80 years selected from four Australian state population-based cancer registries	<i>Survivors Unmet Needs Survey (SUNS)</i> – Measures cancer survivors' unmet needs over the last month – 89 items – Five domains: – Financial concerns (11 items) – Emotional health (33 items) – Access and continuity of care (22 items) – Information (8 items) – Relationships (15 items) – Each item is scored from 0 (no unmet need) to four (very high unmet need) – Cronbach's alpha values >0.9 for all five domains <i>Depression Anxiety and Stress Scale (DASS-21)</i> – Self-report measure of depression, anxiety and stress over the past week – 3 subscales consisting of 7 items each – 0 (not at all) – 3 (very much) – Total subscale score calculated by summing all items in a subscale and multiplying by two – Higher scores = higher level of the emotional state – Calculation of subscale scores requires completion of at least six of the seven subscale items <i>Patient, disease and treatment characteristics</i> – Self report and cancer registries	Information provision Unmet needs																																			
Design, period	Cross-sectional study	Eligible survivors were contacted by the registries via mail unless their clinician had previously notified the registry not to contact their patient Non-responders were mailed a second questionnaire package approximately 4 weeks later, and contacted via telephone after a further 4 weeks																																					
N	676/1280/1957	1957 eligible survivors contacted 1280/1957 sent survey 715/1280 returned survey (37% eligible survivors and 56% of eligible survivors sent survey) 529/715 completed all 89 items of the SUNS 146/1280 mailed a second copy of the SUNS; of these, 125 returned a completed survey																																					
Follow-up

NHL	397	59																																					
Leukaemia	129	19																																					
Myeloma	108	16																																					
Other lymphoma	42	6.2																																					
Age at diagnosis																																							
15-39	54	8.0																																					
40-49	71	11																																					
50-59	179	26																																					
60-69	236	35																																					
70+	136	20																																					
Results	Responders and non-responders were statistically significantly different in regards to age-group at diagnosis and cancer type Floor effects were present for all five domains, indicating that most survivors were experiencing low levels of unmet needs across all five domains. The ability of the SUNS to detect improvements in haematological cancer survivors' unmet needs may be impaired and thus impacting on the responsiveness of the scale. May however, be an accurate reflection that many cancer survivors are in fact doing well and have few unmet needs.																																						
Comments	Participants aged 15 years old at diagnosis were included Numbers of included in the breakdown of those returning completed surveys (n=654) does not add up to that in the tables reported as included by the authors (n=715) or the numbers presented in the table (n=676)																																						

Non Hodgkin's Lymphoma: diagnosis and management

Kent, EE et al. (2013). Talking about cancer and meeting peer survivors: social information needs of adolescents and young adults diagnosed with cancer. Journal of adolescent and young adult oncology, 2(2), 44-52				
Pub year: 2013		Patient Characteristics	Questionnaire/interview structure	Outcome
Country	USA	<ul style="list-style-type: none"> - Adolescent and Young Adult Health Outcomes and Patient Experience (AYA HOPE) study is a population-based cohort study - Patients identified through seven Surveillance, Epidemiology and End Results (SEER) programmesites - Inclusion: <ul style="list-style-type: none"> - 15-39 year old Patients newly diagnosed between July 1, 2007 and October 31, 2008, with histologically confirmed, invasive first primary NHL, HL, germ cell cancer, acute lymphocytic leukaemia, or sarcoma (Ewing, osteosarcoma and rhabdomyosarcoma) - Residence in one of the study areas - Ability to read and write in English - Being alive at time of contact 	Social information needs <ul style="list-style-type: none"> - "At this time, do you feel you need more information about..." followed by a list of needs, including the following social information needs: <ul style="list-style-type: none"> - "how to talk about your cancer experience with family and friends" (labelled talk about cancer or TAC) - "meeting other adolescents or young adult cancer patients/survivors" (labelled meet peer survivors or MPS) - Response options were: I have enough information, I need some more information, I need much more information, does not apply - Analyses excluded individuals who responded 'does not apply' or left the response blank 	Unmet needs Information provisions
Design, period	Cross sectional study			
N	~118			
Follow-up	N/A			
Funding source	National Cancer Institute with support from the Lance Armstrong Foundation No competing financial interests			
Results	About 80% not on active treatment 71.2% of respondents indicated no need for information on how to talk about cancer with family and friends and 48.7% indicated no need for information on ways to meet other adolescents or young adult cancer patients/survivors. Note. No information provided on number of patients with each cancer type, for this question there were 118 responses to one part and 117 responses to the second part.

	Note. Higher scores = worse illness perception			
Comments	Authors analysed the scales by disease type and found significant differences in illness perception and satisfaction, therefore the multivariate analyses reported were not extracted as they were conducted on the whole sample and not by disease type			

Non Hodgkin's Lymphoma: diagnosis and management

Forsythe, LP et al. (2014). Role of oncologists and primary care physicians in providing follow-up care to non-Hodgkin lymphoma survivors within 5 years of diagnosis: a population-based study. Support Care Cancer, 22; 1509-1517.																																																																
Pub year: 2014		Patient Characteristics	Questionnaire/interview structure	Outcome																																																												
Country	USA	ECHOS-NHL study identified NHL survivors through the Los Angeles (LA) county Cancer Surveillance Program's Surveillance, Epidemiology and End Results (SEER) registry. <u>Inclusion:</u> - Diagnosed with aggressive NHL (i.e. intermediate or high grade) between June 1, 1998 and August 31, 2001 (2-5 years before study enrolment; mean time since diagnosis; 3.6 years) - Alive at time of recruitment - English speaking - No other cancer diagnoses Aggressive NHL determined based on NCI's Working Formulation for classification of NHL diagnoses. - 744/1025 survivors sampled through SEER - 408/744 returned questionnaires (54.8% of those eligible, 72.5% of eligible cases located) - 319 participants responded by mail - 89 completed an abbreviated telephone survey - 363 free of cancer at survey completion (this sample was used for analysis because authors state that those with recurrent NHL would have different care experiences from those receiving follow-up care) - 285/319 used to assess aim three as only the mail participants were asked to assess their follow-up care attitudes	Three aims: 1. Characteristics associated with high-frequency NHL follow-up care 2. Characteristics associated with receiving care from other physicians in addition to oncologists (PCPS and/or other specialists) 3. Attitudes towards follow-up care Demographic and clinic characteristics: - Self reported demographics, history of cancer recurrence, treatment, comorbidity burden index (13 possible conditions), symptom burden (26 possible problems experienced in the last 6 months) - NHL grade at time diagnosis and time since diagnosis (years) from SEER <u>Psychological factors:</u> - Worry about cancer recurrence using a Likert scale (never to all of the time) - Health information needs using a 16-item inventory by summing the number of 6 possible categories (e.g. tests and treatment, health promotion) with ≥1 need endorsed <u>Follow-up care characteristics:</u> - Assessed the primary physician seen for cancer-related follow-up, the number of visits in the last year with this physician for follow-up cancer care, the duration of the relationship with this physician, and the perceived quality of cancer follow-up care - Assessed additional physicians seen in the past year with questions developed by the ECHOS-NHL team - High-frequency follow-up was defined as ≥5 visits in the past year <u>Attitudes towards cancer follow-up care:</u> Cancer Patients' Attitudes Towards Follow-up survey - Two subscales adapted for study - Reassurance from follow-up care and negative anticipation towards follow-up care - Agreement with statements about follow-up care was assessed (Strongly agree – strongly disagree) - One item from the negative anticipation scale loaded more strongly on the reassurance factor than the negative anticipation factor in exploratory factor analysis and was excluded, resulting in two 4-item sub-scales - Internal consistency for negative anticipation: α=0.78 - Internal consistency for reassurance: α=0.67 - Score range: 0-100 - Higher scores reflect greater reassurance/negative anticipation	Psychological impact Treatment decision making

Non Hodgkin's Lymphoma: diagnosis and management

Forsythe, LP et al. (2014). Role of oncologists and primary care physicians in providing follow-up care to non-Hodgkin lymphoma survivors within 5 years of diagnosis: a population-based study. *Support Care Cancer*, 22; 1509-1517.

Private insurance	243	66.9
Education		
High school or less	107	29.5
Some college	117	32.2
College graduate or more	136	37.5

Note. Missing data so percentages may not sum to 100. SD: Standard deviation

Non-responders: more likely to be younger, male and Hispanic but no significant differences on demographics or NHL grade between respondents and located non-respondents

Table 2. Psychological and follow-up care characteristics

	Mean	SD	Median	Range
Comorbidity burden (maximum score 13)	1.62	1.50	1	0-8
Symptom burden (maximum score 26)	5.97	4.38	6	0-20
Worry about recurrence (maximum score 5)	2.34	1.0	2	1-5
Health information needs (maximum score 6)	3.12	2.23	4	0-6

Note. SD: Standard deviation

Table 3. Quality of follow-up care and duration of relationship with primary physician (N=363)

	n	%
Cancer-related follow-up in the past year	334	92.0
Followed-up by oncologist	297	88.9
>1 visit	272	91.6
≥5 visits	46	15.5
Followed-up by a PCP	23	7.0
Followed-up by another type of provider	-	<1%
Most frequently endorsed reasons for lack of follow-up in the past year:		
"I feel I didn't need to see one anymore" or "another doctor told me I didn't need to see one anymore"	16	4.4%
"Costs too much" or "Insurance didn't cover it"	6	1.7%
"Didn't know I needed it"	3	0.8%
Quality of follow-up care		
Less than excellent	115	34.4
Excellent	213	63.8
Duration of relationship with primary follow-up care physician		
≤2 years	70	21.0
>2 years	259	77.5

89% (n=264) of survivors followed up by an oncologist reported on additional care beyond main cancer follow-up:

- 88.6% saw ≥1 additional provider (mean 2.30, SD=1.33)
- Nearly three quarters (71.2%) reported having seen a PCP in the last year
- Survivors were most likely to be seen by oncologists alone if they reported a recurrence history (OR=4.38, 95% CI: 1.84-10.43), radiation (OR=4.02; 95% CI: 1.80-9.0) or BMT/SCT (OR=3.24; 95% CI: 1.35-7.77)

Table 4. Multivariable logistic regression: likelihood of high-frequency follow-up care and visits with PCP

	High frequency follow-up care (N=273) (≥5 visits in 12 months)			Visit with PCP in the past year (N=260)		
	OR	95% CI	P	OR	95%	P
Education						
High school or less (ref) versus College graduate or more	5.40	1.57-18.50	0.007			
Time since diagnosis (years)	0.46	0.27-0.79	0.005			

Results

Non Hodgkin's Lymphoma: diagnosis and management

Forsythe, LP et al. (2014). Role of oncologists and primary care physicians in providing follow-up care to non-Hodgkin lymphoma survivors within 5 years of diagnosis: a population-based study. *Support Care Cancer*, 22; 1509-1517.

History of recurrence						
No/unknown (ref) versus Yes	10.25	3.17-33.14	<0.0001	0.37	0.15-0.94	0.04
Comorbidity burden	1.44	1.09-1.91	0.01			
Symptom burden	1.12	1.00-1.26	0.045	1.13	1.04-1.22	0.004
Health information needs				1.16	1.00-1.33	0.048
Quality of cancer follow-up						
Less than excellent (ref) versus Excellent				2.04	1.10-3.77	0.02
Duration of relationship with primary cancer follow-up care provider						
<2 years (ref) versus >2 years	0.34	0.13-0.88	0.03			

Note. Model included predictors significant at $p < 0.20$ in bivariate tests. Gender, marital status, race, insurance status, history of bone marrow or stem cell transplant were not significantly associated with likelihood of high-frequency follow-up care (all $p > 0.05$). Gender, history of radiation, education, duration of relationship with primary cancer follow-up care provider, history of bone marrow or stem cell transplant and frequency of cancer follow-up care in the past year was not significantly associated with likelihood of visiting a PCP in the past year (all $p > 0.05$).

Table 5. Multivariable logistic regression: Attitudes towards follow-up care

	High reassurance (N=233)			High negative anticipation (N=211)		
	OR	95% CI	P	OR	95%	P
Female (ref) versus Male	0.44	0.25-0.78	0.005	0.83	0.43-1.60	0.57
Time since diagnosis (years)	1.52	1.08-2.13	0.02			
Worry about recurrence				2.75	1.85-4.10	<0.001
Health information needs				1.27	1.07-1.50	0.007
Quality of cancer follow-up care						
Less than excellent (ref) versus Excellent	1.99	1.09-3.63	0.03			
Visit with PCP(s), past year						
No versus Yes				0.45	0.21-0.95	0.04

Note. Model included predictors significant at $p < 0.20$ in bivariate tests. Age at interview, marital status, Education, health information needs were not significantly associated with likelihood of reporting high levels of reassurance (all $p > 0.05$). Age at interview, gender, race, insurance status and quality of cancer follow-up care were not significantly associated with likelihood reporting high negative anticipation (all $p > 0.05$).

- As shown in table 5, among survivors followed up primarily by an oncologist, female gender, longer time since diagnosis, and perceived excellent quality of care were associated with high reassurance
- Lesser worry about cancer recurrence, fewer health information needs, and having a PCP were associated with low negative anticipation

Comments Authors note that history of chemotherapy and NHL grade at diagnosis were not examined due to lack of variation (96.1% reported chemotherapy, 89% had intermediate grade NHL)

Non Hodgkin's Lymphoma: diagnosis and management

Oerlemans, S et al. (2012). Perceived information provision and satisfaction among lymphoma and multiple myeloma survivors – results from a Dutch population-based study. Ann Hematol, 91:1587-1595																																																																																																																																		
Pub year: 2012		Patient Characteristics			Questionnaire/interview structure	Outcome																																																																																																																												
Country	Netherlands	<ul style="list-style-type: none"> – Longitudinal population-based survey among lymphoma and multiple myeloma survivors registered within the Eindhoven Cancer Registry (ECR) of the Comprehensive Cancer Centre South and is embedded in Population-Based Haematological Registry for Observational studies. ECR records data on all patients who are newly diagnosed with cancer in the southern part of the Netherlands. – Data collection took place in 2009 using PROFILES (Patient Reported Outcomes Following Initial treatment and Long-term Evaluation of Survivorship – PROFILES registry for the study of the physical and psychosocial impact of cancer and its impact of cancer and its treatment from a dynamic, growing population-based cohort of both short-and long-term cancer survivors – Inclusion: <ul style="list-style-type: none"> – All patients who were diagnosed with NHL, HL and MM between January 1, 1999 and January 1, 2009. All subtypes of indolent (including chronic lymphocytic leukaemia-like) and aggressive B-cell NHL, HL and MM as defined by the International Classification of Diseases for Oncology-3 codes – In May 2009, patients between 1 and 10 years after diagnosis were included and received first questionnaire. In November 2009, patients diagnosed between May and November 2009 were invited to participate – Exclusion: Deceased patients 1448 lymphoma and MM survivors sent questionnaire 1135/1448 (78%) completed survey Table 1. Sociodemographic and clinical characteristics of cancer survivors			European Organisation for Research and Treatment of Cancer (EORTC) QLQ-INFO25	Patient satisfaction																																																																																																																												
Design, period	Cross-sectional study				– Evaluate the perceived level of and satisfaction with information among NHL, HL and MM patients	– 25-item	– 4 subscales:	Unmet needs																																																																																																																										
N	818/113/14485				– Perceived receipt of information about the disease ($\alpha=.75$)	– Medical tests ($\alpha=.88$)	– Treatment ($\alpha=.88$)																																																																																																																											
Follow-up	N/A				– Other care services ($\alpha=.82$)	– Several single items on receiving written information or information on CD or tap/video and items on the satisfaction with and helpfulness of the received information	– Answer categories range from one (not at all) to four (very much), except for four items which had two-point scales

Non Hodgkin's Lymphoma: diagnosis and management

Vallance, JKH et al. (2005^a). Exercise preferences among a population-based sample of non-Hodgkin's lymphoma survivors. *European Journal of Cancer Care*, 15;34-43

Would you be able to participate in an exercise programme designed for persons with NHL (n=427)		
Yes	226	52.9
No	66	15.5
Maybe	135	31.6
Would you be interested in an exercise programme designed for persons with NHL (n=424)		
Yes	235	55.4
No	80	18.9
Maybe	109	25.7
Who would you prefer to exercise with (n=409)		
Alone	126	30.8
With other cancer survivors	52	12.7
With friends	57	13.9
With family	35	8.6
No preference	139	34.0
Where would you prefer to exercise (n=404)		
At home	172	42.6
At a community fitness	70	17.3
At a cancer fitness centre	51	12.6
No preference	111	27.5
What time of day would you prefer to exercise (n=407)		
Morning	168	41.3
Afternoon	71	17.4
Evening	76	18.7
No preference	92	22.6
When would you prefer to start an exercise programme (n=343)		
Before treatment	95	27.7
During treatment	55	16.0
3-6 months after treatment	131	38.2
At least 1 year after treatment	62	18.1
What intensity would you prefer your exercise programme to be (n=411)		
Low intensity	95	23.1
Moderate intensity	255	62.0
High intensity	40	9.7
No preference	21	5.1
What types of activities would you like to perform (n=383)		
Same activity each session	149	38.9
Different activities each session	234	61.1
How would you prefer to perform these exercises (n=390)		
Supervised/instructed	162	41.5
Unsupervised/self-paced	228	58.8
How would you prefer the structure of your exercise programme (n=393)		
Spontaneous/flexible	177	45.0
Scheduled (i.e. specific days/times)	216	55.0

Note. Numbers may not equal 431 due to missing data

- The majority of participants (55%) listed walking as their preferred choice of exercise.
- Resistance training was the second most commonly preferred exercise (11%)

Non Hodgkin's Lymphoma: diagnosis and management

Vallance, JKH et al. (2005 ^a). Exercise preferences among a population-based sample of non-Hodgkin's lymphoma survivors. European Journal of Cancer Care, 15;34-43	
	<ul style="list-style-type: none"> - Logistic regression analyses indicated that meeting public health exercise guidelines was associated with... <ul style="list-style-type: none"> - ... being able (i.e. yes or maybe) to participate in an exercise programme designed for NHL survivors (OR=4.20, 95% CI=1.23-14.27, p<0.05) - ... preferring a moderate-to-high intensity exercise programme (OR=2.76, 95% CI=1.36-3.60, p<0.01) - ...engaging in different types of activities (OR=1.99, 9% CI=1.14-3.48, p<0.05) - ...and scheduled exercise sessions (OR=1.70, 95% CI=1.02-2.92, p<0.05) - Being female was associated with... <ul style="list-style-type: none"> - ...preferring to be counselled about exercise at some point after their NHL diagnosis (i.e. yes/maybe) (OR=1.99, 95% CI=1.13-3.52, p<0.05) - ...engaging in different types of activities (OR=2.07, 95% CI=1.30-3.34, p<0.01) - ...scheduled exercise sessions (OR=1.76, 95% CI=1.11-2.78, p<0.005) - ...negatively associated with preferring unsupervised exercise sessions (OR=0.40, 95% CI=0.25-0.64, P<0.001) - Being overweight and obese were both negative associated with <ul style="list-style-type: none"> - ...being able (i.e. yes or maybe) to participate in an exercise programme designed for NHL (overweight: OR=0.43, 95% CI=0.19-0.98, p<0.05; obese: OR=0.39, 95% CI=0.19-0.95, p<0.05) - Having a uni/college education was associated with <ul style="list-style-type: none"> - ...being interested in an exercise programme designed for NHL survivors (OR=3.30, 95% CI=1.4-8.0. p<0.01) - ...preferring to receive exercise counselling at some point (OR=2.92, 95% CI=1.5-5.6, p<0.01) - ...preferring a moderate-to-high intensity exercise programme (OR=2.41, 95% CI=1.32-4.40, p<0.01) - ...negatively associated with preferring unsupervised exercise sessions (OR=0.45, 95% CI=0.26-0.77, p<0.01) - Receiving some form of treatment(s) for NHL was associated with preferring to start an exercise programme at least 3 months into the post-treatment/rehabilitation phase of the cancer experience (OR=2.57, 95% CI=1.37-4.84, p<0.01) - Being married was associated with preferring to exercise with others (OR=2.01, 95% CI=1.05-3.86, p<0.05) - Being employed (either full or part time) was negatively associated with preferring to exercise in the morning (OR=0.45, 95% CI=0.26-0.78, p<0.01) - Preferring to engage in different types of activity was negatively associated with being over the age of 60 years (OR=0.49, 95% CI=0.27-0.88, p<0.05)
Comments	

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2005		Patient Characteristics	Questionnaire/interview structure	Outcome																																											
Country	Canada	Alberta Cancer Registry used to identify eligible NHL survivors residing in Alberta Canada diagnosed between April 1994 and December 2001	<p>Demographic Information:</p> <ul style="list-style-type: none"> – Self report socio-demographic variables and weight and height – Clinical variables extracted from the Alberta Cancer Registry <p>Exercise behaviour:</p> <p><i>Leisure Score Index (LSI)</i></p> <ul style="list-style-type: none"> – Godin Leisure Time Exercise Questionnaire (GLTEQ) – 3-items – Average frequency of mild, moderate and strenuous exercise during free time in a typical week <p>Exercise preferences:</p> <ul style="list-style-type: none"> – Drawn from work by Jones and Courneya (2002a), Courneya and Hellsten (1998) and Denmark-Wahnfried et al. (2000) – “would you be able to participate in an exercise programme designed for persons with NHL” – “would you be interested in participating” – One item addressed preference for exercise counselling at some point after cancer diagnosis – Open ended question to indicate what type of exercises they would be most interested in 	HRQOL																																											
Design, period	Cross-sectional study	Survey conducted between Jan 2004 and March 2004																																													
N	438/830	Each individuals oncologist of family physician was required to provide approval to contact their patient(s) before any mailouts occurred. Of the 162 available oncologists 74 (46%) provided approval to contact 1000 survivors																																													
Follow-up	N/A	Each participant was sent a questionnaire package and asked to return one copy. Multiple reminders were used, postage paid envelopes, personalised cover letters, coloured paper, assurances of confidentiality and university/institution sponsorship.																																													
Funding source	Authors received studentships /scholarships and Chair programs from Alberta Heritage Foundation for Medical research, Canadian Institutes of Health Research and from the National Cancer Institute of Canada	<ul style="list-style-type: none"> – 1000 questionnaires sent out – 318/1000 not returned – 280/318 returned unopened (60 deceased and 110 returned to sender) – 512/830 returned (62%) – 32/512 were incomplete – 27/512 unable to complete the questionnaire – 7/512 reported never having NHL – 5/512 ill – 3/512 mentally unstable – 438/830 final response (53%) <p>Table 1. Note. ^a Sample size for the on treatment analysis is reduced given that some survivors were on observation (n=75), did not receive any treatment (n=7), or refused treatment (n=2) and could not be included in any on treatment analyses. MANOVA for on treatment periods: Wils' λ = 0.973, F(4,348)=1.613, p<0.143, η =0.03. MANOVA for off treatment periods: Wils' λ = 0.929, F(4,433)=8.264, p<0.001, η =0.07.

- On treatment covariates: When MANCOVA conducted using age, gender, income, employment status, education, months since diagnosis, Ann Arbor stage and treatment received as covariates the AS scale changed from being statistically significant to non-significant (p=0.25)
- Off treatment covariates: When MANCOVA conducted using age, gender, income, employment status, education, months since diagnosis, Ann Arbor stage and treatment received as covariates the functional well-being changed to non-significant (p=0.07)
- Survivors meeting public health exercise guidelines have a slightly higher annual family income than survivors not meeting the guidelines. However, a large number of participants did not report their annual family income (n=54).

Non Hodgkin's Lymphoma: diagnosis and management

Greaves, P et al. (2013). Fertility and sexual function in long-term survivors of haematological malignancy: using patient-reported outcome measures to assess a neglected area of need in the late effects clinic. *British Journal of Haematology*, 164; 526-535.

- I am bothered that my body cannot do what it could before having cancer
- Having cancer has made me feel old
- Likert scale

- Rates of missing data from the questionnaire components analysed in the study were people 1 and 7%
- No significant differences with respect to gender, age at diagnosis, stage at diagnosis and primary treatment when comparing the respondents to the non-respondents. NHL patients who died prior to study commencement were significantly different from NHL patients who completed the survey in terms of age at diagnosis, stage at diagnosis and primary treatment

Table 1. Respondent characteristics

Characteristic	n	%
Female	150	46
Male	176	54
Age at diagnosis (years)		
<15	1	0.3
15-21	10	3
22-34	55	17
35-50	157	48
50+	101	31
Mean (SD)	45.0	13.0
Current age (years)		
20-39	10	3
40-59	117	36
60+	119	61
Mean (SD)	61.8	11.8
Years since diagnosis		
5-9	88	27
10-19	130	40
20-29	85	26
30+	23	7
Mean (SD)	16.8	8.5
Era of diagnosis		
Pre-1990	101	31
Post-1990	225	69
Primary treatment		
RT only	49	15
CT only	264	81
CMT	0	0
Transplant	0	0
Surgery	13	4

Note. The numbers were generated from the percentage provided in the article and the age at diagnosis group numbers does not add-up to 326 (n=324)

- 80% of the total respondents (N=718) reported having partners at the time of the survey
- 26% of patients with NHL reported that they were not offered an appointment to attend a clinic (61/236)
- No ovarian tissue was stored in any patients

Non Hodgkin's Lymphoma: diagnosis and management

<p>Greaves, P et al. (2013). Fertility and sexual function in long-term survivors of haematological malignancy: using patient-reported outcome measures to assess a neglected area of need in the late effects clinic. <i>British Journal of Haematology</i>, 164; 526-535.</p>	
	<ul style="list-style-type: none"> - At univariate analysis: NHL more likely to report not having a child after treatment compared to HL (OR: 2.42, p<0.001) <ul style="list-style-type: none"> - After adjusting for age at diagnosis, gender, whether patients had myeloablative therapy and era of diagnosis this difference was not significant - In the whole sample: Adjusted logistic regression showed significant effects of age at diagnosis (OR: 1.09, p<0.001) suggesting that with 1-year increase in age at diagnosis patients have a 9% higher likelihood of reporting childlessness - In the whole sample: Having had myeloablative therapy also increased the likelihood of childlessness (OR: 2.48, p=0.004) - At univariate analysis: Low proportion of NHL patients reported attending a fertility clinic (8%) compared to patients with HL (17%, p=0.005) <ul style="list-style-type: none"> - After adjusting for age at diagnosis, era of diagnosis and gender no longer significant - In the whole sample: older patients at diagnosis and female patients were less likely to attend a fertility clinic (OR:0.91, p<0.001; OR: 0.56, p=0.04, respectively) - In the whole sample: patients diagnosed post-1990 4 times more likely to have reported attending a fertility clinic (OR:4.05, p<0.001) - At univariate analysis: higher proportion of men with HL and AL stored their sperm compared to patients with NHL (p=0.04) <ul style="list-style-type: none"> - After adjusting for age at diagnosis and era of diagnosis no longer significant - In the whole sample: every year increase in age, the odds of a patient storing sperm decreased (OR:0.93, p<0.001, or 7% per year) - Among the patients with NHL the most frequent reason provided for reasons not to store sperm was 'did not intend to have any children after treatment (55%) - At univariate analysis: HL patients reported higher proportion of fertility problems compared to NHL patients (p<0.001) <ul style="list-style-type: none"> - After adjusting for gender, current age and era of diagnosis no longer significant - In the whole sample: Older patients less likely to report being told that they were infertile and/or having fertility problems as a result of treatment (OR:0.96, p<0.001) but those diagnosed before 1990 were more likely to report such problems (OR:1.83, p=0.001) - In the whole sample: Male patients significantly higher rates of reporting fertility problems after cancer compared to female patients (OR:1.77, p=0.001) - In univariate analysis: patients surviving NHL were more likely compared to patients with HL to report a loss of interest in (28% versus 20%; p=0.02) or satisfaction from sex (34% versus 22%, p=0.01) following diagnosis <ul style="list-style-type: none"> - After adjusting for age, gender, years since diagnosis and use of anti-depressants the univariate association was lost - In the whole sample: women were more than twice as likely as men to have lost interest in sex following their diagnosis (OR:2.20, p<0.001) - In the whole sample: Older patients were 3% more likely to have lost interest in sex (OR: 1.03, 95% CI: 1.01-1.04) and 4% were more likely to be less satisfied with sex since diagnosis (OR:0.98, 95% CI: 0.96-0.99) - In the whole sample: more women than men reported anti-depressant use (24% versus 16%, p=0.01) and patients on anti-depressants experienced a significantly higher negative impact on cancer on sexual function (p≤0.01) - Analysis based on age at diagnosis instead of current age produced identical results - Bonferroni correction for multiple testing (three questions of sexual function) did not change the observed significant relationships <p>For the whole sample (N=718)</p> <ul style="list-style-type: none"> - 3-way ANOVA suggested that there was a significant association between sexual function and patients' scores in the negative IOC questions, specifically 'Body change Concerns' domain (p<0.03 for satisfaction in sex and effect on cancer diagnosis on their sex life) and 'Appearance Concerns' domain (p<0.03 for effect of cancer diagnosis on their sex life) - Bonferroni-corrected post-hoc analysis showed that patients who reported that their sex life is not as satisfying had a significantly higher mean score on 'Body Change Concerns' (p<0.001) compared to those who were as satisfied as before their cancer diagnosis - Respondents who reported that the cancer diagnosis and treatment for it has had an effect on their sex life also had significantly higher concerns of body change (p<0.001) and appearance (p=0.001)
Comments	Some patients (<10%) aged <16 years old

Pub year: 2011		Patient Characteristics	Questionnaire/interview structure	Outcome																																																												
Country	USA	<ul style="list-style-type: none"> Experience of Care and Health Outcomes of Survivors of Non-Hodgkin Lymphoma (ECHOS-NHL) study assessed quality of care and health-related quality of life among 408 adult NHL survivors identified via the Los Angeles County Cancer Surveillance Program. Inclusion: All survivors diagnosed with intermediate or high-grade lymphomas two - five years prior to the study (mean=3.54, SD=0.84) Participation rate for eligible respondents able to be located was 73% <p>About 20% of those who initially refused to complete the mailed survey completed an abbreviated version of the survey by phone (n=89) but this did not include the measures of sexual well-being (author states due to sensitive nature of questions). Therefore baseline population for current study was 319.</p> <ul style="list-style-type: none"> 222/319 completed 68/319 missing data on whether they had participated in sexual activity or on items assessing satisfaction with their sex life 29/319 missing data on independent variables <ul style="list-style-type: none"> These 97 participants excluded and when compared they were older (by about 4.3 years, p<0.01) and were less likely to be married or partnered (p<0.01) 160/222 reported data on the specific outcome of sexual function, therefore analyses of this outcome exclude the 62 survivors with missing sexual function data <ul style="list-style-type: none"> These 62 participants were older (by about 7.7 years), were more likely to be women, and were less likely to have attended college (all, p<0.01) <p>Table 1. Non Hodgkin's Lymphoma: diagnosis and management

Beckjord, EB et al. (2011). Sexual well-being among survivors of non-Hodgkin lymphoma. *Oncology Nursing Forum*, 38(5), E351-E359.

- Survivors who had participated in sexual activity reported better satisfaction and function than those who had not ($t=3.9$ for function; $t=-2.78$ for satisfaction) and survivors who reported better satisfaction reported better sexual function ($r=0.42$), (all $p<0.01$; data not shown in article)

Table 2. Response to sexual activity and function in the past four weeks

	n	%
Participation in sexual activity		
Did you engage in any sexual activity either alone or with a partner		
Yes	154	69
No	68	31
Satisfaction with sex life		
How satisfied were you with your sex life		
Not at all	56	25
A little or somewhat	82	37
Very or completely	84	38
How satisfied were you with the frequency of your sexual activity		
Not at all	51	23
A little or somewhat	82	37
Very or completely	89	40
How big a problem did you consider your sexual functioning to be		
No problem	98	44
Very small or small	66	30
Moderate or big	58	26
Sexual function (N=160)		
How often did you experience a lack of sexual desire		
Never	40	25
Sometimes	74	46
Usually or always	46	29
How often did you experience a lack of sexual arousal		
Never	56	35
Sometimes	63	40
Usually or always	41	26
How often did you experience difficulty reaching orgasm		
Never	72	45
Sometimes	50	31
Usually or always	38	24

Note. Because of rounding, not all percentages total 100.

Bivariate analysis:

- Factors associated with higher probability of having engaged in sexual activity ($p<0.01$):
 - Younger age
 - Male gender
 - Being married or partnered
- Factors associated with better reported sexual function ($p<0.05$):
 - Younger age
 - Longer time since diagnosis
 - Never having experienced a recurrence
 - Reporting pre-or perimenopausal status (for women)

Results

Non Hodgkin's Lymphoma: diagnosis and management

Beckjord, EB et al. (2011). Sexual well-being among survivors of non-Hodgkin lymphoma. *Oncology Nursing Forum*, 38(5), E351-E359.

- Perceived health status associated with all three indices of sexual well-being:
- Survivors who reported at or above average MCS or PCS function were ($p < 0.01$; $p = 0.06$ for association between participation and MCS):
 - more likely to have participated in sexual activity
 - more satisfied with their sexual experiences
 - more likely to report better sexual function

Multivariate analyses:

Comments

159 participants did not complete or missed parts of questionnaire addressing sexual health issues.
No information on sexual function prior to NHL

Non Hodgkin's Lymphoma: diagnosis and management

Hammond, CTC et al. (2008). Non-Hodgkin's lymphoma survivors' fertility and sexual function-related information needs. Fertility and Sterility, 90(4), 1256-1258.					
Pub year: 2008		Patient Characteristics		Questionnaire/interview structure	Outcome
Country	USA	Adult survivors of aggressive NHL (intermediate and high grades of NHL) at 2-5 years after diagnosis selected from Los Angeles County Cancer Surveillance Program Inclusion: age 20 years or older, alive at the time of the study, primary cancer diagnosis of NHL, ability to read and write in English 1025 cases 282/1025 deemed ineligible after contact (e.g., deceased, having had another cancer) 319/1025 offered and completed the full-version of the questionnaire by mail 69/319 excluded because of missing data on one or more of the variables of interest		<ul style="list-style-type: none"> - information needs of 16 different cancer-related issues, 2 of which were about fertility and sexual function and focus of article - Fertility and sexual function information need items were dichotomized (no information needed vs. Some or much more information needed) - Socio-demographic, medical history/treatment, and quality of life factors also examined 	Unmet information needs Impact
Design, period	Cross-sectional				
N	250/319/1025				
Follow-up	N/A				
Funding source	California Department of Health Services				
Results	Non-respondents did not differ from respondents with complete data on gender, age, education or time since diagnosis, but they were more likely to be African American [$\chi^2(2\text{ df})=7.07, p<0.05$]				
Comments	<ul style="list-style-type: none"> - Survivors with fertility-related information needs were more likely to report sexual function information needs [$\chi^2(1\text{ df})=3.92, p<0.05$] - Factors associated with a need for more fertility-related information: <ul style="list-style-type: none"> - Younger age: $\chi^2(2\text{ df})=89.79, p<0.01$ - Non-white race/ethnicity: $\chi^2(2\text{ df})=14.09, p<0.01$ - Fewer comorbid conditions: $\chi^2(2\text{ df})=14.79, p<0.01$ - Better physical function: $\chi^2(1\text{ df})=6.21, p<0.05$ - Less-than-excellent perceived quality of care received $\chi^2(1\text{ df})=6.56, p<0.05$ - Factors associated with a need for more sexual function-related information: <ul style="list-style-type: none"> - Being male: $\chi^2(1\text{ df})=3.95, p<0.05$ - History of bone marrow/stem-cell transplantation (possibly due to age covariate) : $\chi^2(2\text{ df})=6.99, p<0.05$ - Education, income, marital status, time since diagnosis, health status and mental functioning were not associated with fertility or sexual function information needs - Multivariate analyses (logistic regressions not shown owing to small sample size, but results were consistent?): <ul style="list-style-type: none"> - Results consistent with the bivariate results except that comorbid health conditions and physical functioning were no longer associated with fertility information needs 				

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2004		Patient Characteristics	Questionnaire/interview structure	Outcome
Country	Netherlands	<ul style="list-style-type: none"> - Medical records of male patients, treated since 1977 at the University Medical Center Groningen (UMCG) for malignant testicular germ cell tumour (TC) or for malignant lymphoma (ML) - Inclusion: Patients who were alive, without signs of recurrence, aged between 17-70 years - Exclusion: >70 years old to reduce bias due to the risk of including patients with physical or mental co-morbidity or bereavement due to old age - Malignant lymphoma: <ul style="list-style-type: none"> - Hodgkin's disease treated with RT (stages I-IIA), or PCT (all other stages) - NHL treated only with PCT (dependent on stage: three courses combined with involved field radiotherapy 30-40 Gy for stage I; six-eight courses for stages II-IV) - Author notes that age-effects have to be considered, because the age at diagnosis in case of non-Hodgkin lymphoma generally is higher (between 50 and 75 years) than in Hodgkin's disease (15-45 years). - 58 patients (response rate 72.5% of a sample of 80 patients) returned the questionnaire - 8/58 excluded: 6 were treated before 1977; 1 suffered from a brain tumour; 1 patient received a non-standard combination of treatments - 24/50 malignant lymphoma patients had NHL 	<ul style="list-style-type: none"> - Sexual functioning using an adapted questionnaire (Weijmar et al. 1986; Caffo et al. 1999) - Added four times concerning information and support: two items were about information and support received from the medical staff during the treatment period (sufficient - not sufficient, 4-point scale) - Two others assessed the current need for information or support (yes or no) 	Unmet needs
Design, period	Cross-sectional study			
N	24/50/58/80			
Follow-up	N/A			
Funding source	Dutch Cancer Society			
Results	Note. Authors state that there were no statistical differences between sub-groups but that it was hard to establish, due to low numbers per sub-group (n=8 HD-RT, n=18 HD-PCT, n=24 NHL-PCT)			
Comments				

6: Follow-up

6.1: Review question: In patients in remission after treatment with curative intent for non-Hodgkin's lymphoma, what are the optimal method(s), frequency and duration of follow-up?

PICO Table

Population	Intervention	Comparison	Outcomes
<p>Adults and young people (16 years and older) in complete remission (i.e., complete response) after firstline treatment with curative intent for DLBCL.</p> <p>Exclude: Allograft People who were treated for non-Hodgkin's lymphoma below the age of 16 years</p>	<p>Follow-up protocol of tests including: Blood test: Full blood count (FBC) Complete blood count (CBC) Haemoglobin/haemoglobin White blood count/leukocyte count Platelets/platelet count</p> <p>Serum biochemistry: Lactate dehydrogenase (LDH) Liver function tests (LFTs) Renal/kidney function tests</p> <p>CT scan X-ray PET scan or PET-CT scan</p> <p>Medical history (review of symptoms) and physical examination</p> <p>Patient reported symptoms</p>	<p>No follow-up</p> <p>Presentation with symptoms</p> <p>Each other (including frequency and duration of follow-up, setting of follow-up)</p>	<p>Recurrence Overall survival Disease progression Disease-specific survival Test related complications Health-related quality of life Patient experience Patient preference Number of scans</p>

Additional Comments on PICO

Present outcomes by NHL subtypes included in scope.
Question is assessing which tests, when, how often and how long follow-up should be.
Discussion on PICO at GDG meeting 26.01.15:
- GDG decided to limit population to patients in complete remission after first-line treatment for DLBCL
- Do not include results that compare the different blood tests listed under interventions in the PICO above (e.g., full blood count versus platelets only)
(26.01.15):
- Follow up starts at the end of the last cycle of chemotherapy
- Follow up ends at relapse or death. Late effects/survivorship (topic R) is separate from follow up and runs alongside follow up.
- Outcomes are all clinical outcomes, thus no sensitivity and specificity to be reported.

Summary Tables

Figure 1. Study flow diagram

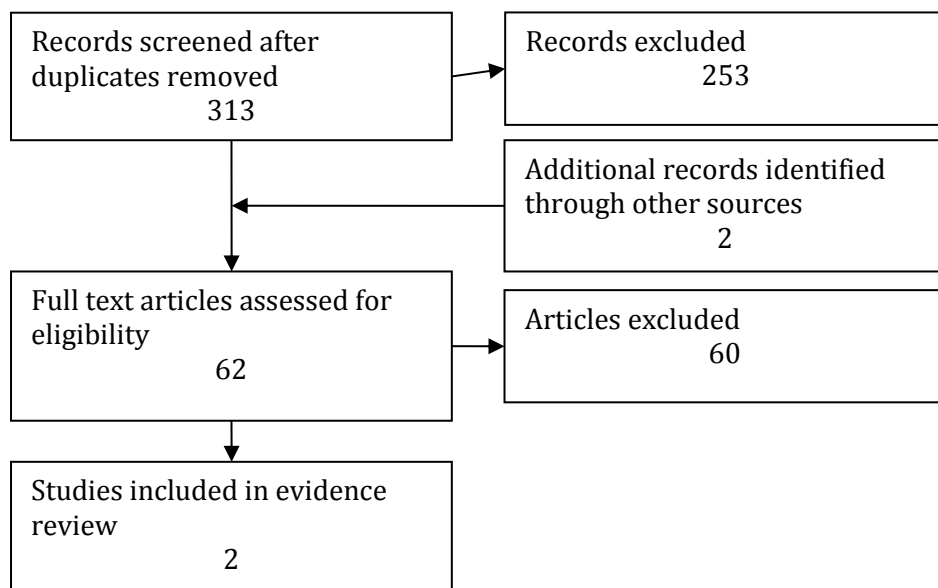

Table 1. Summary of findings

Treatment options and comparisons			Studies	N	Outcome
Planned follow up visits	Vs.	Unplanned, early follow up visits	1	106	<p>3-year event-free survival and overall survival = 86.4% and 93.6%, respectively.</p> <ul style="list-style-type: none"> - 501 visits were planned with routine imaging; 407 CT and 168 PET-CT. 3 relapses detected on routine imaging - 322 visits were planned without routine imaging. 1 relapse detected. - 33 visits were unplanned early patient-initiated visits due to abnormal signs/symptoms. 11 relapses detected. - There was a strong association between early visits and the detection of relapse (11/33) compared to planned visits (with or without clinical symptoms/signs; 4/823; $p < 0.001$)
Clinic-based follow up	Vs.	NA (non-comparative)	1	162 (94 had CR)	<ul style="list-style-type: none"> - All patients (N = 162): 5-year freedom from progression and overall survival rates = 80.8% and 81.2%, respectively - 17/18 patients who ultimately experienced relapse after initial response to therapy had received surveillance imaging, with 9/18 relapses initially suspected by surveillance imaging (8 PET, 1 CT), and 9 clinically suspected (5 by patient-reported symptoms and 4 by both symptoms and physical examination). - No relapses were detected by surveillance LDH. - Median (range) time from treatment initiation to relapse was 14.3 (7.8-121.1) months for patients with relapses suspected by imaging, and 59.8 (9.3-123.3) months for patients with Clinically suspected relapses ($p = 0.077$). - There was also no significant difference in survival from the date of relapse ($p = 0.2$) and from the date of initial therapy ($p = 0.12$) between patients whose relapse was suspected by imaging or clinically.

Evidence Statements

Evidence came from a retrospective case series and a retrospective cohort study.

Routine versus patient-initiated follow up for disease relapse

Very low quality evidence from one study with 106 patients (Hong *et al*, 2014) suggests that more relapses were detected during unplanned patient-initiated visits (11/33 visits) than during routine visits (4/823 visits) and the 3-year event-free and overall survival were 86.4% and 93.6%, respectively.

Clinic-based follow up for disease relapse

Very low quality evidence from one study of 162 patients (Hiniker *et al*, 2015) reported 5-year freedom from progression and overall survival rates = 80.8% and 81.2%, respectively. 18 patients ultimately experienced relapse. No relapses were detected by surveillance LDH. Similar time from treatment initiation to relapse for patients with relapses suspected by imaging and clinically. Similar survival from the date of relapse or of initial therapy between patients whose relapse was suspected by imaging or clinically.

GRADE Tables

Grade Profile 1: Should routine or patient-initiated follow up be used for monitoring for disease relapse for people with DLBCL and complete response (CR)?

Settings: Republic of Korea

Quality assessment							Summary of findings			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect	Quality
							Routine	Unplanned		
Detection of relapse										
1	observational study ¹	Serious limitations ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	823 visits	33 visits	Unplanned visits (11/33) > routine visits (4/823)	⊕ ○ ○ ○ Very low
Survival										
1	observational study ¹	nSerious limitations ²	no serious inconsistency	no serious indirectness	No serious imprecision	none	All patients: N = 106		3-year event-free survival and overall survival = 86.4% and 93.6%, respectively.	⊕ ○ ○ ○ Very low

¹ Hong et al. (2014) – retrospective cohort study

² Low number of events.

Grade Profile 2: Should clinic-based follow up be used for monitoring for disease relapse for people with DLBCL and complete response (CR)?

Settings: USA

Quality assessment							Summary of findings		
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients	Effect	Quality
							Clinic-based follow up		
5 year overall survival									
1	observational non-comparative study ¹	serious limitations ²	no serious inconsistency	serious indirectness ³	serious imprecision ⁴	none	162 (94 had CR)	81.2%,	⊕○○○ Very low
5 year progression free survival									
1	observational non-comparative study ¹	serious limitations ²	no serious inconsistency	serious indirectness ³	serious imprecision ⁴	none	162 (94 had CR)	80.8%	⊕○○○ Very low
Relapses detected by surveillance LDH tests									
1	observational non-comparative study ¹	serious limitations ²	no serious inconsistency	serious indirectness ³	serious imprecision ⁴	none	162 (94 had CR)	18 relapses in total but none were detected by surveillance LDH;	⊕○○○ Very low
Time from treatment initiation to relapse									
1	observational non-comparative study ¹	serious limitations ²	no serious inconsistency	serious indirectness ³	serious imprecision ⁴	none	162 (94 had CR)	Similar time from treatment initiation to relapse for patients with relapses suspected by imaging and clinically;	⊕○○○ Very low

¹ Hiniker et al. (2015)

² Non-comparative study – did not compare clinic based follow-up with another strategy but noted the pattern of disease relapse

³ Only 94/162 patients had confirmed complete response.

⁴ Low number of events.

Evidence Tables

Hiniker et al (2015) Value of Surveillance Studies for Patients With Stage I to II Diffuse Large B-Cell Lymphoma in the Rituximab Era. <i>International Journal of Radiation Oncology, Biology, Physics</i> , 92: 99-106.								
Pub year: 2015		Patient Characteristics				Intervention (non-comparative study)		Outcome
Country	USA	Inclusion: Patients with histologically proven DLBCL, stage I or II according to the Ann Arbor staging system, including patients with bulky disease, treated with chemotherapy, radiation therapy, or both during the rituximab era. Patient treatment was at the discretion of the treating physician. Exclusion: Patients with primary mediastinal lymphoma, primary central nervous system lymphoma, or transformed follicular lymphoma. Patients (N=162): Age: Median (range) = 60 (25-92) years; >60 years: N = 82; 102 males/60 females; ECOG PS 0-1/>1: N = 136/26; Elevated lactate dehydrogenase: N = 49; Stage I/II: N = 81/81; Extranodal disease: N = 98; Bulky disease (>7.5 cm): N = 17; Stage-modified IPI 0-1/>1: N = 95/67; Chemotherapy CHOP/R-CHOP/R-CEOP/R + other chemotherapy: N = 16/110/12/19; Therapy modality chemotherapy alone/radiotherapy alone/combined chemotherapy and radiation: N = 42/2/118.				Follow up in the clinic every 3 months for the first 2 years, then every 4 to 6 months until year 5, with annual visits afterwards. Surveillance scans were defined as any routinely scheduled scans occurring after end-of-treatment scans, not prompted by clinical signs or symptoms. Surveillance imaging, incl CT, PET, and MRI, was performed at the discretion of the treating physician.		Relapse rate
Design, period	Retrospective cohort study 2002-2013							Overall survival
N	162							Freedom from progression
Follow-up	Median: 56 months							Relapse detection rate
Funding source	Not reported							
Results	Please note that not all patients had CR - 124/162 patients had a post-treatment PET; 94 of these had a metabolic CR (22 patients had PR, 2 patients had SD and 6 patients had PD). 20/124 patients with post-treatment PET ultimately experienced progression; 12/94 with a metabolic CR ultimately progressed. - All patients (N = 162): 5-year freedom from progression and overall survival rates = 80.8% (95% CI 74.4-87.8%) and 81.2% (95% CI 74.7-88.3%), respectively - 17/18 patients who ultimately experienced relapse after initial response to therapy had received surveillance imaging, with 9/18 relapses initially suspected by surveillance imaging (8 PET, 1 CT), and 9 clinically suspected (5 by patient-reported symptoms and 4 by both symptoms and physical examination). - No relapses were detected by surveillance LDH. - Median (range) time from treatment initiation to relapse was 14.3 (7.8-121.1) months for patients with relapses suspected by imaging, and 59.8 (9.3-123.3) months for patients with clinically suspected relapses (p = 0.077). There was also no significant difference in survival from the date of relapse (p = 0.2) and from the date of initial therapy (p = 0.12) between patients whose relapse was suspected by imaging or clinically.							
		Months after completion of treatment						
		3	6	9	12	18	24	>24
	Patients undergoing surveillance PET-CT	124	115	104	99	95	78	45
	Relapses detected by surveillance	1	4	1	0	1	1	0
Relapses detected clinically	0	2	1	0	1	1	4	

Non Hodgkin's Lymphoma: diagnosis and management

Hiniker et al (2015) Value of Surveillance Studies for Patients With Stage I to II Diffuse Large B-Cell Lymphoma in the Rituximab Era. *International Journal of Radiation Oncology, Biology, Physics*, 92: 99-106.

Comments

- Retrospective observational study - High risk
- Patient selection bias? Low risk
- Performance bias? Unclear
- Detection bias (blinding of outcome assessor)? Unclear
- Attrition bias (missing data)? Low risk
- Reporting bias? Unclear
- Other bias? Unclear risk

Non Hodgkin's Lymphoma: diagnosis and management

Hong et al (2014) Symptom-oriented clinical detection versus routine imaging as a monitoring policy of relapse in patients with diffuse large B-cell lymphoma. <i>Leukemia & Lymphoma</i> , 55: 2312-2318.					
Pub year: 2014		Patient Characteristics	Intervention	Comparison	Outcome
Country	Republic of Korea	<p>Inclusion criteria: Patients with DLBCL diagnosed according to the WHO (2008) criteria, aged ≥ 20 years, with CR as demonstrated by FDG PET-CT (according to the 2007 Revised criteria) after receiving R-CHOP with or without consolidative theraoies (such as radiotherapy or autologous stem cell transplant), who had ≥ 1 outpatient department follow up visit for relapse monitoring and a complete set of clinical data for anlysis.</p> <p>Patients (N=106): Age: Median (range) = 54 (22-85) years; >60 years: N = 37; 53 males/53 females; ECOG PS 2-4: N = 12; Elevated lactate dehydrogenase: N = 36; ≥ 2 extranodal sites: N = 18; Ann Arbor stage III-IV: N = 39; Standard IPI low/low-intermediate/high-intermediate/high: N = 63/23/13/7; Bone marrow involvement: N = 7; Hans classification GCB/non-GCB/not classified: N = 31/48/27; Consolidative therapy involved field radiotherapy/autologous stem cell transplant: N = 36/7.</p>	<p>Planned outpatient department visits for monitoring disease status after CR: Every 2-3 months for the first 2 years, then every 4-6 months for the following 3 years, and then annually.</p> <p>Each visit: History taking, physical examination, complete blood cell count.</p> <p>Short-term (< 2 months) follow up visits with any suspicion of early disease relapse were considered part of a further investigation of the previous visit and not a new independent visit.</p> <p>Routine imaging "defined as a CT or FDG-PET/CT scheduled by a physician at least 2 months prior to the actual scan for routine surveillance of lymphoma (i.e. without any symptoms or signs f relapse). There was no specific institutional policy for routine imaging and the attending physician decided whether to perform routine imaging during the next visit while</p>	<p>Unplanned early visits (any visit occurring earlier than the next planned visit initiated by the patient due to abnormal symptom/sign)</p> <p>Each visit: History taking, physical examination, complete blood cell count.</p>	<p>Relapse rate</p> <p>Relapse detection</p>
Design, period	Retrospective cohort study, 2004-2012				
N	106				
Follow-up	Median = 38.1 months from diagnosis and 30 months from CR				
Funding source	Not reported				

Non Hodgkin's Lymphoma: diagnosis and management

Hong et al (2014) Symptom-oriented clinical detection versus routine imaging as a monitoring policy of relapse in patients with diffuse large B-cell lymphoma. *Leukemia & Lymphoma*, 55: 2312-2318.

considering the patient's opinion."

3-year event-free survival and overall survival = 86.4% and 93.6%, respectively.
15/106 patients relapsed (confirmed by biopsy)

856 outpatient department visits were analysed for the 106 patients (median per patient? = 6, range = 1-25)

- 501 visits were planned with routine imaging (median per patient? = 4, range = 0-15; mean = 4.8); 407 CT and 168 PET-CT. 3 relapses detected on routine imaging

- 322 visits were planned without routine imaging (median per patient? = 2, range = 0-14; mean = 3). 1 relapse detected.

- 33 visits were unplanned early patient-initiated visits due to abnormal signs/symptoms. 11 relapses detected.

- There was a strong association between early visits and the detection of relapse (11/33) compared to planned visits (with or without clinical symptoms/signs; 4/823; $p < 0.001$)

	823 planned visits			33 unplanned visits
	501 visits with routine imaging		322 visits without routine imaging	
	407 CT scans	168 PET-CT scans		
Symptom+/Relapse+	1 scan	1 scan	1 visit	11
Symptom+/Relapse-	7 scans	2 scans	5 visits	22
Symptom-/Relapse+	2 scans	2 scans	0 visits	
Symptom-/Relapse-	397 scans	163 scans	316 visits	

Results

All patients: PET-CT (A patients may have 2 or more false positive results):

	No relapse	Relapse
Normal	142 visits	0 visits
Abnormal	23 visits	3 visits

"If there was any area with a score of 4 or 5 according to the Deauville criteria [11], a 5-point visual assessment system, the FDG-PET/CT was considered abnormal. Indeterminate scans were classified as either normal or abnormal after discussion by two investigators".

All patients: CT (A patients may have 2 or more false positive results):

	No relapse	Relapse
Normal	397 visits	0 visits
Abnormal	7 visits	3 visits

"An abnormal CT finding was defined as any newly developed nodal enlargement or extranodal lesion that could not be seen in a normal human body and that significantly raises the concern of relapse." "Indeterminate scans were classified as either normal or abnormal after discussion by two investigators".

Patients with IPI of ≥ 3 : PET-CT (N = 20):

	No relapse	Relapse
Normal	22 visits	0 visits
Abnormal	6 visit	2 visits

Non Hodgkin's Lymphoma: diagnosis and management

Hong et al (2014) Symptom-oriented clinical detection versus routine imaging as a monitoring policy of relapse in patients with diffuse large B-cell lymphoma. <i>Leukemia & Lymphoma</i> , 55: 2312-2318.			
	Patients with IPI of ≥ 3: PET-CT (N = 20):		
		No relapse	Relapse
	Normal	76 visits	0 visits
	Abnormal	1 visit	2 visits
Comments	<ul style="list-style-type: none"> - Patient selection bias (randomisation sequence, allocation concealment)? High risk – non-randomised - Performance bias (blinding of patients, personnel)? High risk – No blinding - Detection bias (blinding of outcome assessor)? High risk – No blinding - Attrition bias (missing data)? Low risk - Reporting bias? Unclear risk - Other bias? Unclear risk 		

7: Survivorship

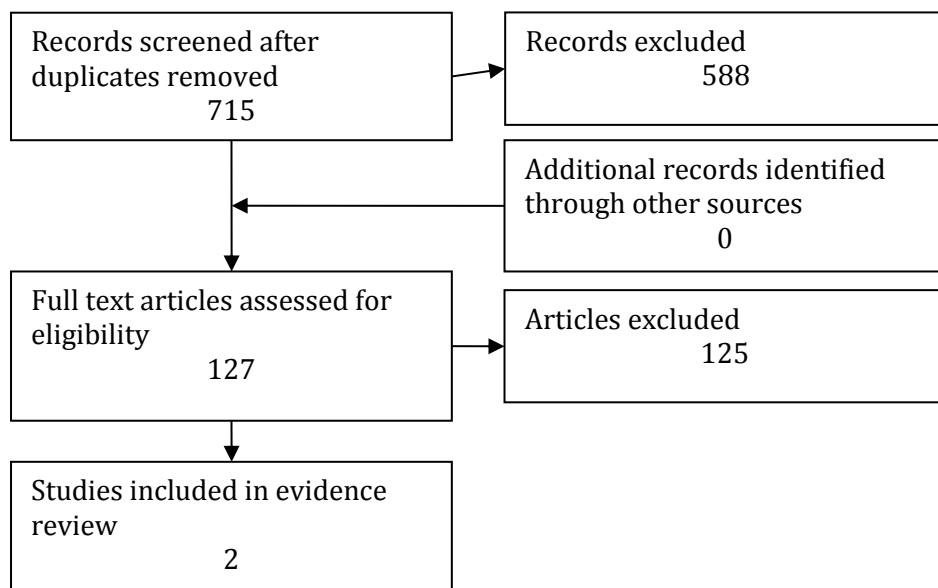

7.1: Review question: What is the effectiveness of surveillance protocols for late adverse effects of treatment in people with non-Hodgkin's lymphoma?

PICO Table

Population	Intervention	Comparison	Outcomes
Adults and young people (16 years and older) treated for non-Hodgkin's lymphoma Subgroups: Type of treatment Risk of relapse Co-morbidity Exclude: People who were treated for non-Hodgkin's lymphoma below the age of 16 years	Surveillance programs specific to NHL: Immuno-deficiency/infection Cardiac Disease (including heart failure, coronary artery disease) Fertility issues Secondary cancers Follow-up setting: General Practice Specific hospital clinics	None Each other	Overall survival Late-event rate Cause-specific survival Treatment related morbidity Health related quality of life Patient satisfaction Patient preference Psychological well-being
Additional Comments on PICO			
Record where reported the results by subgroups presented in the PICO Record number of relapses (for risk of relapse subgroups in PICO) Record incidence of heart failure and coronary cardiac/artery disease separately.			

Summary Tables

Figure 1. Study flow diagram

Non Hodgkin’s Lymphoma: diagnosis and management

Table 1. Summary of findings

Treatment options and comparisons			Studies	N	Outcome
Nurse-led	Vs.	Medic-led	1	120; 50	Waiting times: Average reduced from 65 min (medic-led) to 10 min (nurse-led) Patient satisfaction: Better or similar in nurse-led compared to medic-led
Phone/in person-based follow up	Vs.	NA (non-comparative)	1	957	<ul style="list-style-type: none"> - 75/957 patients had new diagnosis of cardiovascular disease (validated in 57/71 patients: 18 heart failures, 9 myocardial infarctions, 21 arrhythmia, 2 pericarditis, and 10 valvular heart disease. - Cumulative incidence of cardiovascular disease at 1, 3, 5, and 7 years was 1.3%, 3.7%, 5.2%, and 7.4%, respectively. - Older age associated with increased risk of overall cardiovascular disease. - Gender, radiation therapy, and anthracycline treatment not associated with the incidence of overall cardiovascular disease. - anthracycline use associated with development of heart failure and arrhythmia. - Radiation associated with development of arrhythmia. - older age associated with development of heart failure and arrhythmia.

Evidence Statements

Evidence came from a prospective case series and retrospective cohort study.

Nurse-led versus medic-led survivorship care

Very low quality evidence from one study suggested that waiting times (n=120) were reduced from 65 min (medic-led) to 10 min (nurse-led) and patients satisfaction (n=50) was either higher or similar for nurse-led compared to medic-led survivorship care).

Phone/in person-based follow up for cardiovascular disease

Very low quality evidence from one study with 957 patients reported 75/957 patients had new diagnosis of cardiovascular disease (validated in 57/71 patients: 18 heart failures, 9 myocardial infarctions, 21 arrhythmia, 2 pericarditis, and 10 valvular heart disease. Cumulative incidence of cardiovascular disease at 1, 3, 5, and 7 years was 1.3%, 3.7%, 5.2%, and 7.4%, respectively. Older age was associated with increased risk of overall cardiovascular disease. Gender, radiation therapy, and anthracycline treatment were not associated with the incidence of overall cardiovascular disease. Anthracycline use was associated with development of heart failure and arrhythmia. Radiation was associated with development of arrhythmia. Older age was associated with development of heart failure and arrhythmia.

GRADE Tables

Grade Profile 1: Should a nurse-led vs. medic-led clinic be used for monitoring survivorship issues for people treated for non-Hodgkin's lymphoma?

Settings: UK

Quality assessment							Summary of findings			
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients		Effect	Quality
							Nurse-led	Medic-led		
Waiting times (patient reported waiting time for appointment in clinic)										
1	observational study ¹	serious limitations ³	no serious inconsistency	serious indirectness ²	No serious imprecision	none	Mean 10 minutes (N=60)	Mean 65 minutes (N=60)	55 minutes shorter with nurse-led	⊕○○○ Very low
Patient satisfaction (measured using questionnaire)										
1	observational study ¹	serious limitations ³	no serious inconsistency	serious indirectness ²	No serious imprecision	none	(N=25)	(N=25)	Better or the same in nurse-led compared to medic-led.	⊕○○○ Very low

¹ John et al. (2013) – case series

² For the waiting times outcome, unclear how many patients had NHL. 17/50 patients had Hodgkin's lymphoma for the patient satisfaction outcome.

³ Low number of events.

Non Hodgkin's Lymphoma: diagnosis and management

Grade Profile 2:: Should phone/in person-based follow up be used for monitoring for cardiovascular disease for people treated for non-Hodgkin's lymphoma?

Settings: US

Quality assessment							Summary of findings		
No of studies	Design	Limitations	Inconsistency	Indirectness	Imprecision	Other considerations	No of patients	Effect	Quality
							Phone/in person-based		
Cardiovascular disease (CVD) as a whole									
1	observational non-comparative study ¹	serious limitations ^{2,3}	no serious inconsistency	no serious indirectness	No serious imprecision	none	75/957	-75 patients (8%) had new diagnosis of CVD	⊕ ○ ○ ○ Very low
Arrhythmia									
1	observational non-comparative study ¹	serious limitations ^{2,3}	no serious inconsistency	no serious indirectness	No serious imprecision	none	957	- anthracycline use associated with development of heart failure and arrhythmia; - Radiation associated with development of arrhythmia; - older age associated with development of heart failure and arrhythmia.	⊕ ○ ○ ○ Very low

¹ Thompson et al. (2011) – case series

² Non-comparative study – does not report effectiveness of surveillance but the incidence of late CVD in those treated for NHL

³ Low number of events.

⁴ - Cumulative incidence of CVD at 1, 3, 5, and 7 years was 1.3%, 3.7%, 5.2%, and 7.4%, respectively;- Older age associated with increased risk of overall CVD.

- Gender, radiation therapy, and anthracycline treatment not associated with the incidence of CVD.

Evidence Tables

Pub year: 2013		Patient Characteristics	Intervention	Comparison	Outcome
Country	UK	<p>"The service development took place in a large, central London teaching hospital with 1100 beds that treats over 800,000 patients each year. It has a large haematology department, with over 800 patients in the lymphoma service. With the growing incidence of lymphoma, the rising age of the population and prolonged survival of cancer patients, it is expected that these numbers will rise each year, as patients are not currently discharged from the clinic.</p> <p>The purpose of this service development project was to develop a nurse-led follow-up clinic for patients with lymphoma that provides high-quality survivorship care. Objectives of the service were to:</p> <ul style="list-style-type: none"> - Undertake holistic assessment of patients' medical, emotional, practical and financial needs. - Monitor for disease relapse and detect new cancers. - Ensure lymphoma patients are monitored for treatment lateeffects and undergo appropriate investigations. - Provide high-quality written information on a wide range of topics. - Actively engage patients in their own health management and promote self-care behaviour. Provide late-effect surveillance and documentation of late effects data. - Provide a point of contact for lymphoma patients who have completed treatment and rapid access to specialist advice as necessary. - Improve patient experience and reduce waiting times." <p><i>Patients selected to attend the nurse-led clinic were 3 years post-treatment.</i></p> <p><u>Waiting times:</u> "Sixty patients from each clinic were asked to note the length of waiting times for their appointment, to provide evidence of the current patient experience and as a baseline comparison for the new service. Twenty patients were observed by the project manager to ensure the data were accurate." <i>No further information reported about these patients.</i></p> <p><u>Patient satisfaction questionnaire:</u> A convenience sample of 50 patients was required to undertake a meaningful analysis (25 patients from the nurse-led group and 25 from the medical-led group). Overall, 61 questionnaires were distributed and 50 returned.</p> <ul style="list-style-type: none"> - Nurse-led (N=25): Age: 16-50 years: N = 6; 51+ years: N = 19; 13 males/12 females; White/other: N = 16/9; living alone yes/no: N = 2/23; type of lymphoma Hodgkin's/other high-grade lymphoma/low-grade lymphoma: N = 9/11/5. 	<p>"The nurse-led survivorship service: <u>Clinic:</u> Run by two clinical nurse specialists who see patients on a fortnightly basis. Patients are reviewed at least annually. <u>Patients:</u> 3 years post completion of treatment for lymphoma and in clinical remission. <u>Intervention:</u> 30 min consultation, comprising of physical and psychological assessment using recognised tools. Clinical investigations e.g. blood tests, ECG's and X-rays to monitor for late-effects of treatment. Consequences of treatment and health promotion topics were addressed and patients provided with a leaflet on late effects of treatment, an 'information prescription' and clinical nurse specialist contact details. They are encouraged to discuss any other concerns and are directed to further support if required."</p>	<p>"At the time the project was undertaken, patients were offered annual medical follow-up in a busy clinic consisting of newly diagnosed patients, those receiving treatment, and follow-up patients. The clinic space was overcrowded and patients could wait up to three hours to see a clinician. The consultation focused on disease relapse, little attention was given to psycho-social issues and there was no provision for late-effect monitoring." Patients seemingly not provided with written information about survivorship/late effects.</p>	<p>Patient satisfaction: Assessed by questionnaire broken down into 15 sections with questions to be answered on 5-point likert scale from 1 (strongly disagree/poor) to 5 (strongly agree/excellent)</p>
Design, period	Propsective cohort study Unclear study year				
N	60 (waiting times); 50 (patient satirfaction)				
Follow-up	Unclear				
Funding source	Not reported				

Non Hodgkin's Lymphoma: diagnosis and management

John, C. (2013) Developing a nurse-led survivorship service for patients with lymphoma. <i>European Journal of Oncology Nursing</i> , 17: 521-527.				
		- Medic-led (N=25): Age: 16-50 years: N = 4; 51+ years: N = 20; 16 males/9 females; White/other: N = 18/7; living alone yes/no: N = 4/21; type of lymphoma Hodgkin's/other high-grade lymphoma/low-grade lymphoma: N = 8/7/10.		
Results	<p>Waiting times - The average waiting time reduced from 65 min per patient to 10 min in the new nurse-led clinic.</p> <p>Patient satisfaction questionnaire: <i>Despite having a lot of numerical data that could be presented, the following paragraph is the only results presented from the patients satisfaction questionnaire:</i> "Certain questions relating to respect, preventative care, contact information and the provision of educational resources, elicited a statistically significantly more positive response from the nurse-led patients. No questions demonstrated a more positive response from medic-led patients. Taken together, these implied that the nurse-led clinic was equal in satisfaction to the medic-led clinic and preferred in some areas. It was interesting to note that the response to the final question 'overall, what is your impression of the quality of care and services you have received?', which directly probed the impression of the clinic, did not provide any definitive evidence. This was most likely because of the high number of neutral responses from both the medic-led and the nurse-led patients (44% and 40% respectively). In conclusion, there is evidence show that patients are just as satisfied within the nurse-led service as the medical-led one, and that certain aspects of the nurse-led clinic scored higher. This questionnaire did not aim to detect whether the nurse-led clinic was preferred to the medic-led clinic because patients only attended one type of clinic, so direct comparisons could not be made." <i>Please note, just because the patients did not attend both clinics, this does not mean that the data can not be compared between the patient groups as might be implied by the authors.</i></p>			
Comments	<ul style="list-style-type: none"> - Patient selection bias (randomisation sequence, allocation concealment)? High risk – non-randomised - Performance bias (blinding of patients, personnel)? High risk – No blinding - Detection bias (blinding of outcome assessor)? High risk – No blinding - Attrition bias (missing data)? Unclear - Reporting bias? High risk – data not clearly reported - Other bias? Unclear risk 			

Non Hodgkin's Lymphoma: diagnosis and management

Pub year: 2011		Patient Characteristics	Intervention (non-comparative study)	Outcome
Country	USA	<p>Inclusion: "All patients were from the Mayo component of the Molecular Epidemiology Resource (MER) of the University of Iowa/Mayo Clinic Lymphoma Specialized Program of Research Excellence (SPORE). The MER offers enrollment to all consecutive patients with newly diagnosed NHL who are US residents and age >18 years."</p> <p>"1164 patients with NHL were enrolled into the MER at Mayo Clinic between 9/1/2002-2/28/2008. 646 were male (56%) and median age at diagnosis was 62 years (range 20-93)." Of these 207 patients were excluded due to CVD prior to the diagnosis of NHL (N = 131) or no follow up (N = 76). Thus 957 patients were included, but no further patient characteristics reported.</p>	<p>"Clinical data from the time of diagnosis and treatment data are abstracted from medical records using a standard protocol. Patients are prospectively contacted via telephone or in person per protocol every 6 months for the first 3 years from diagnosis and yearly afterwards to assess disease status and development of comorbid conditions."</p>	<p>"CVD events, including heart failure, myocardial infarction, arrhythmia, pericarditis, and valvular heart disease, occurring after diagnosis were identified during follow-up and validated against medical records. Heart failure was validated with the Cardiovascular Health Study Criteria and/or the Framingham Criteria. Myocardial infarction was validated using case definition standards of coronary heart disease, while arrhythmia, pericarditis, and valvular heart disease were validated using clinical definitions."</p>
Design, period	Prospective cohort study 2002-2008			
N	957			
Follow-up	Median: 59 months (range: 1-105)			
Funding source	Not reported			
Results	<ul style="list-style-type: none"> - 75/957 patients (7.8%) self-reported a new diagnosis of cardiovascular disease. 71 of these patients had available medical records, and in 57 of these 71 patients, the cardiovascular diagnosis was validated: 18 heart failures, 9 myocardial infarctions, 21 arrhythmia, 2 pericarditis, and 10 valvular heart disease. - Cumulative incidence of cardiovascular disease at 1, 3, 5, and 7 years was 1.3%, 3.7%, 5.2%, and 7.4%, respectively. - Median time from NHL diagnosis to cardiovascular disease was 26.5 months (range 1-84). - "Older age was associated with increased risk of overall cardiovascular disease (p-value<0.001)." - "Gender (p=0.59), radiation therapy (p=0.61), and anthracycline treatment (p=0.25) were not associated with the incidence of overall cardiovascular disease." - "Among types of CVD, <ul style="list-style-type: none"> - anthracycline use was associated with development of heart failure (HR=5.30; p-value=0.008) and arrhythmia (HR=2.68; p-value=0.04). - Radiation was associated with development of arrhythmia (HR=2.73; p-value=0.03), - while older age was associated with development of heart failure (HR=1.36 per 5 year increment; p-value=0.003) and arrhythmia (HR=1.25 per 5 year increment; p-value=0.02)."
