1 Introduction

This briefing paper presents a structured overview of potential quality improvement areas for metastatic spinal cord compression. It provides the Committee with a basis for discussion and prioritising quality improvement areas for developing quality statements and measures, which will be drafted for public consultation.

Structure

The structure of this briefing paper includes a brief overview of the topic followed by a summary of each of the suggested quality improvement areas followed with supporting information.

Where relevant, guideline recommendations selected from the key development source below are presented to aid the Committee when considering specific aspects for which statements and measures should be considered.

Development source

Unless otherwise stated, the key development source referenced in this briefing paper is as follows:

Where relevant, guideline recommendations from the key development source are presented alongside each of the suggested areas for quality improvement within the main body of the report.

2 Overview

2.1 Focus of quality standard

This quality standard will cover the diagnosis and management of metastatic spinal cord compression in adults and the prevention of metastatic spinal cord compression in adults at risk.

2.2 Definition

Metastatic spinal cord compression (MSCC) is defined as spinal cord or cauda equina compression by direct pressure and/or induction of vertebral collapse or

---

1 Unless referenced in the body of the text sections 2.1 to 2.4 are taken from Metastatic spinal cord compression: diagnosis and management of adults at risk of and with metastatic spinal cord compression. NICE Clinical Guideline 75 (2008) & the National Collaborating Centre for Cancer full guideline (2008).
instability by metastatic spread or direct extension of malignancy that threatens or causes neurological disability.

Lung, breast and prostate cancers are the commonest malignancies causing metastatic spinal cord compression and account for over 50% of cases. In 7% of patients the site of primary tumour may remain unidentified.

### 2.3 Incidence and prevalence

The true incidence of metastatic spinal cord compression in England and Wales is unknown because cases are not systematically recorded. However, post mortem evidence indicates that it is present in 5–10% of patients with advanced cancer. Evidence from an audit carried out in Scotland between 1997 and 1999 and from a published study from Canada, also suggests that the incidence may be up to 80 cases per million people every year. This equates to approximately 4000 cases each year in England and Wales, or more than 100 cases per cancer network each year.

It is likely that the incidence of metastatic spinal cord compression will increase in the future with improving cancer treatments resulting in better survival rates and outcomes.

The median age at the time of metastatic spinal cord compression diagnosis is 65 years. Audit data suggests that 77% of patients diagnosed with metastatic spinal cord compression had an established diagnosis of cancer whereas 23% presented with metastatic spinal cord compression as the first presentation of malignancy.

Metastatic spinal cord compression occurs when there is pathological vertebral body collapse or direct tumour growth causing compression of the spinal cord or cauda equina. Irreversible neurological damage ensues with resulting paraplegia. Once paraplegia develops it is usually irreversible and can affect the quality of life of both the patient and their carers. These patients often need 24 hour nursing care either in hospital or in the community setting, which has major resource implications on the National Health Service (NHS).

When deciding the most appropriate treatment option for a patient it is important to consider quality of life issues. A number of the clinical symptoms and signs of metastatic spinal cord compression can have a significant impact on quality of life.

The two important groups of symptoms are pain from instability and neurological compromise. The painful paralysis, with or without instability and double incontinence, associated with spinal cord compression from metastases, spinal myeloma or lymphoma, is a common complication in patients with these cancers.²

---

² NHS Spinal Task Force (2013) [Commissioning Spinal Services - Getting the service back on track](https://www.nice.org.uk/guidance/csg17).
2.4 Management

Those responsible for organising clinical services for patients with metastatic spinal cord compression face particular challenges as there is no common pathway of entry into the secondary care system. Patients may present acutely with metastatic spinal cord compression under a variety of different specialists unlikely to be members of the oncology multi-disciplinary team (MDT) responsible for the management of the primary disease or its spinal consequences.

Studies have consistently demonstrated that metastatic spinal cord compression is diagnosed late and that the ability to walk after treatment is directly associated with the ability to walk at time of diagnosis. Recovery of mobility is unlikely if paraplegia has become established at the time of diagnosis and this may require 24 hour nursing care and prolonged hospitalisation for the remainder of the patient’s illness. ³

The key investigation for the diagnosis of metastatic spinal cord compression is magnetic resonance imaging (MRI) of the whole spine. Once a diagnosis has been made, the treatment goals include pain relief, restoration of neurological status, prevention of further neurological damage and stabilisation.

See appendix 2 for key priority for implementation recommendations from NICE clinical guideline 75.

### 3 Summary of suggestions

#### 3.1 Responses

In total 10 stakeholders responded to the 2-week engagement exercise 21 May – 5 June 2013. Suggestions were also provided by specialist committee members.

### Table 1 Summary of suggested quality improvement areas

Stakeholders were asked to suggest up to 5 areas for quality improvement. These have been merged and summarised in the table below for further consideration by the Committee (incorporating stakeholder and specialist committee member suggestions). The full detail of the suggestions is provided in appendix 3 for information.

4 Suggested improvement area: Service configuration

4.1 Summary of suggestions

Stakeholders highlighted that a multidisciplinary team (MDT) within a spinal centre should be available 24 hours a day. It was also suggested that any hospital providing surgical services for metastatic spinal cord compression should have a defined multi-disciplinary decision making process in place with 24 hour availability. More specifically, in relation to the membership of the MDT, stakeholders raised the importance of the provision of an MSCC co-ordinator and their role in co-ordinating urgent and emergency spinal assessment and care.

Stakeholders highlighted the establishment of local networks and relationships between spinal surgical centres and their catchment areas as important for driving improvement in this area. Common audit and governance across the whole care pathway was raised as an essential area for quality improvement. Stakeholders specifically highlighted the need for improved communication including handover of patient information including scans.

Stakeholders suggested that there should be an on call spinal surgery service in each region based on surgeons trained in spinal reconstructive surgery.

Stakeholders highlighted the importance of continuing external peer review of services for spinal metastases and metastatic spinal cord compression.

Stakeholders suggested that spinal stability and mobility should be documented in patient’s notes within 12 hours of diagnosis. This was raised as stakeholders felt it is important for the patient and staff to know what is considered safe with regards to moving and handling.

The following specific areas for quality improvement and potential development by the QSAC were highlighted, shown in the table below alongside recommendations that have been provisionally selected from the development source to support potential statement development.

### 4.2 Selected recommendations from development source

Recommendations from the development source relating to the suggested improvement areas have been provisionally selected and are presented below in inform QSAC discussion.

**MDT/ MSCC coordinator**

**NICE CG75 Recommendation number 1.1.2.1**

Each centre treating patients with MSCC should identify or appoint individuals responsible for performing the role of MSCC coordinator and ensure its availability at all times.

**NICE CG75 Recommendation number 1.1.2.2**

Each centre treating patients with MSCC should have a single point of contact to access the MSCC coordinator who should provide advice to clinicians and coordinate the care pathway at all times.

**NICE CG75 Recommendation number 1.1.2.3**

The MSCC coordinator should:

- provide the first point of contact for clinicians who suspect that a patient may be developing spinal metastases or MSCC
- perform an initial telephone triage by assessing requirement for, and urgency of, investigations, transfer, and treatment
- advise on the immediate care of the spinal cord and spine and seek senior clinical advice, as necessary
- gather baseline information to aid decision-making and collate data for audit purposes
- identify the appropriate place for timely investigations and admission if required
- liaise with the acute receiving team and organise admission and mode of transport.

NICE CG75 Recommendation number 1.1.2.4

The optimal care of patients with MSCC should be determined by senior clinical advisers (these include clinical oncologists, spinal surgeons and radiologists with experience and expertise in treating patients with MSCC), taking into account the patient's preferences and all aspects of their condition, with advice from primary tumour site clinicians or other experts, as required.

NICE CG75 Recommendation number 1.1.2.5

Every centre treating patients with MSCC should ensure 24-hour availability of senior clinical advisers to give advice and support to the MSCC coordinator and other clinicians, inform the decision-making process and undertake treatment where necessary.

Local networks with pathway audit and governance

NICE CG75 - Recommendation 1.1.1.1

Every cancer network should have a clear care pathway for the diagnosis, treatment, rehabilitation and ongoing care of patients with metastatic spinal cord compression (MSCC).

NICE CG75 - Recommendation 1.1.1.2 (key priority for implementation)

Every cancer network should ensure that appropriate services are commissioned and in place for the efficient and effective diagnosis, treatment, rehabilitation and ongoing care of patients with MSCC. These services should be monitored regularly through prospective audit of the care pathway.

NICE CG75 - Recommendation 1.1.1.4

Every cancer network should have a network site specific group for MSCC. The group should include representatives from primary, secondary and tertiary care and should have strong links to network site specific groups for primary tumours.

On call service

NICE CG75 Recommendation number 1.1.2.4

The optimal care of patients with MSCC should be determined by senior clinical advisers (these include clinical oncologists, spinal surgeons and
radiologists with experience and expertise in treating patients with MSCC), taking into account the patient's preferences and all aspects of their condition, with advice from primary tumour site clinicians or other experts, as required.

NICE CG75 - Recommendation 1.1.2.5

Every centre treating patients with MSCC should ensure 24-hour availability of senior clinical advisers to give advice and support to the MSCC coordinator and other clinicians, inform the decision-making process and undertake treatment where necessary.

External peer review

External peer review is not directly covered in NICE clinical guideline 75 and no recommendations are presented relating to the suggested quality improvement area.

Timely documentation

Timely documentation is not directly covered in NICE clinical guideline 75 and no recommendations are presented relating to the suggested quality improvement area.

4.3 Current UK practice

A study by Vaqas et al\textsuperscript{4} (2011) highlighted that a clearly specified MSCC co-ordinator as a single point of referral is not being employed. The study involved retrospective identification of patients referred with metastatic spinal cord compression to a hospital during a 12 month period. The time from presentation to imaging and neurosurgical or oncological intervention was calculated. Results showed that 87 patients with metastatic spinal cord compression were referred to the neurosurgical registrar on call (MSCC co-ordinator). Over 95% of these patients had an MRI of the whole spine within 24 hours of presentation. 16 of these patients were operated on for spinal cord decompression within a median time of 3 days (range 1-7) but of these the majority were referred via an alternative route.

The Patient Safety function of the NHS Commissioning Board has produced a Signal\textsuperscript{5} report concerning the harm associated with failure to rapidly diagnose and treat spinal cord compression and poor handling of patients where it is suspected or diagnosed. Following a serious incident and a letter of concern from a GP cancer lead, 334 relevant incident reports were identified in the National Reporting and Learning System (NRLS). There were two reports of patient death, 33 of severe harm and 60 relating to moderate harm. Delayed diagnosis or treatment was identified in 193 cases and poor handling was identified in 30 cases. In 25 cases there was difficulty in the identification of the team responsible for the management

of the patient. For patients with cancer there were also transport issues in relation to radiotherapy treatment at a different hospital and 43 of these incidents occurred following the publication of the NICE guidance.
5  **Suggested improvement area: Early detection**

### 5.1  Summary of suggestions

Stakeholders raised the issue of education for patients as an area for quality improvement. Provision of written, accessible information on symptoms and signs of cord compression to all patients with cancer was highlighted as important in encouraging early presentation.

Stakeholders highlighted the importance of education, training and raising awareness amongst health professionals. Stakeholders mentioned health care professionals in general and also specifically: primary care teams, GPs, oncologists, MSCC co-ordinators and hospital doctors. Spinal surgical training was raised in addition to general training in this area.

The following specific areas for quality improvement and potential development by the QSAC were highlighted, shown in the table below alongside recommendations that have been provisionally selected from the development source to support potential statement development.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Education &amp; training of health care professionals</td>
<td>Not directly covered in NICE clinical guideline 75 and no recommendations are presented.</td>
</tr>
</tbody>
</table>

### 5.2  Selected recommendations from development source

Recommendations from the development source relating to the suggested improvement areas have been provisionally selected and are presented below in inform QSAC discussion.

**Patient education**

**NICE CG75 Recommendation number 1.3.1.1 (key priority for implementation)**

Inform patients at high risk of developing bone metastases, patients with diagnosed bone metastases, or patients with cancer who present with spinal pain about the symptoms of MSCC. Offer information (for example, in the form of a leaflet) to patients and their families and carers which explains the symptoms of MSCC, and advises them (and their healthcare professionals) what to do if they develop these symptoms.
NICE CG75 Recommendation number 1.3.1.2

Each centre treating patients with MSCC should have a single point of contact to access the MSCC coordinator who should provide advice to clinicians and coordinate the care pathway at all times.

Education & training of healthcare professionals

Education and training of healthcare professionals is not directly covered in NICE clinical guideline 75 and no recommendations are presented relating to the suggested quality improvement area.

5.3 Current UK practice

Hutchison et al\(^6\) (2012) undertook a study with the aim of determining patient and staff views on the provision of relevant information to patients with a diagnosis of or considered to be at high risk of developing metastatic spinal cord compression. A total of 56 patients with metastatic spinal cord compression were interviewed. These patients had been admitted to a large regional cancer centre in Scotland over a 6-month period. Fifty members of staff working in the cancer centre were also surveyed using similar questions. Results showed that:

- 4% of staff reported giving written information about metastatic spinal cord compression to patients with a confirmed diagnosis.

- 54% of staff reported giving prophylactic information about metastatic spinal cord compression to patients, although the majority of the patients (86%) said they would have wanted this information.

- 20% of patients said they received written information about metastatic spinal cord compression and 77% said they wanted it.

- Patients generally did not access additional information about MSCC and were dependent on the limited amount provided by the health-care team.

A study by Sweeney\(^7\) (2011) involved the completion of a retrospective audit of all patients with metastatic spinal cord compression treated in Taunton with radiotherapy between May 2009 and September 2010. Staff also completed a short questionnaire, which was adapted from the NICE Audit Tool, and these results were also analysed. Results demonstrated that patients at risk of developing metastatic spinal cord compression were not being informed of the risk and what to do regarding symptom onset.

---

\(^7\) Sweeney J (2011) The smart route to a NICE future; introducing a smartcard for patients at risk of metastatic spinal cord compression has the potential to improve quality of life and save up to 17.5 million nationally. European Journal of Cancer 47: (Supplement 1) S300.
Similar results were found by Sweeney & Fitzpatrick\textsuperscript{8} (2011) when they undertook a small retrospective audit of patients treated with radiotherapy and analysed the results in comparison with the NICE guideline. The results showed that patients at risk were not being alerted to signs and symptoms of metastatic spinal cord compression and what action to take should they occur. Results also showed there were gaps and delays in detection, diagnosis and treatment due to methods of referral identified in the current pathway.

To explore the patient perspectives of care of metastatic spinal cord compression in England and Wales the Guideline Development Group (GDG) for NICE clinical guideline 75\textsuperscript{9} wrote to all relevant patient/carer organisations and charities whose members and contacts included patients with metastatic spinal cord compression and their carers and families. Individuals were invited to describe their experience of the condition and their interaction with health services. Several themes emerged including patients’ unawareness of early symptoms, general practitioner’s lack of awareness of early symptoms and signs, delays in diagnosis and treatment, lack of supportive and rehabilitative care, and ineffective communication throughout.

A Scottish audit\textsuperscript{10} also showed that there were significant delays from the time when patients first develop symptoms to when general practitioners and hospital doctors recognise the possibility of metastatic spinal cord compression and make an appropriate referral.

The Mount Vernon Cancer Network’s (2012) Acute Oncology Group (NAOG) commissioned an audit\textsuperscript{11} of patients diagnosed with metastatic spinal cord compression via MRI across their network to measure current practice against NICE guidance (2008). The audit includes patients who were diagnosed with metastatic spinal cord compression between June 2010 and November 2011. There was little evidence found of the provision of written information for patients particularly given that 59% of patients (22 of 37) had known bone metastases and high numbers of patients came in with neurological symptoms (94% - 35 of 37 patients).

\textsuperscript{8} Sweeney J, Fitzpatrick C (2011) Local and wider implications of implementing NICECG75 in a newly opened radiotherapy department. Clinical Oncology 23: (3) S55.

\textsuperscript{11} Mount Vernon Cancer Centre (2012) Metastatic spinal cord compression audit.
6  Suggested improvement area: Imaging

6.1  Summary of suggestions

Stakeholders highlighted the importance of appropriate imaging for diagnosis and management of metastatic spinal cord compression. It was suggested that written protocols for investigative imaging and referral of suspected metastatic spinal cord compression will streamline patient management and provide a framework for staff to use.

Timely access to diagnostic imaging was highlighted as an area for quality improvement. It is suggested that there should be access to MRI scanning 24 hours a day in spinal centres undertaking management of metastatic spinal cord compression.

The following specific areas for quality improvement and potential development by the QSAC were highlighted, shown in the table below alongside recommendations that have been provisionally selected from the development source to support potential statement development.

<table>

</tr>
</tbody>
</table>

6.2  Selected recommendations from development source

Recommendations from the development source relating to the suggested improvement areas have been provisionally selected and are presented below in inform QSAC discussion.

Choice of imaging modality

NICE CG75 Recommendation number 1.4.1.1

MRI of the spine in patients with suspected MSCC should be supervised and reported by a radiologist and should include sagittal T1 and/or short T1 inversion recovery (STIR) sequences of the whole spine, to prove or exclude the presence of spinal metastases. Sagittal T2 weighted sequences should also be performed to show the level and degree of compression of the cord or cauda equina by a soft tissue mass and to detect lesions within the cord itself.
Supplementary axial imaging should be performed through any significant abnormality noted on the sagittal scan.

**NICE CG75 Recommendation number 1.4.1.2**

Contact the MSCC coordinator to determine the most appropriate method of imaging for patients with suspected MSCC in whom MRI is contraindicated and where this should be carried out.

**Timing of imaging assessment**

**NICE CG75 - Recommendation 1.1.1.3**

Cancer networks should ensure that there is local access to urgent magnetic resonance imaging (MRI) within 24 hours for all patients with suspected MSCC. This service should be available outside normal working hours and with 24-hour capability in centres treating patients with MSCC.

**NICE CG75 – Recommendation 1.4.3.1**

Imaging departments should configure MRI lists to permit time for examination of patients with suspected MSCC at short notice during existing or extended sessions (by moving routine cases into ad hoc overtime or to alternative sessions, if overtime is not possible).

**NICE CG75 - Recommendation 1.4.3.3 (key priority for implementation)**

Perform MRI of the whole spine in patients with suspected MSCC, unless there is a specific contraindication. This should be done in time to allow definitive treatment to be planned within 1 week of the suspected diagnosis in the case of spinal pain suggestive of spinal metastases, and within 24 hours in the case of spinal pain suggestive of spinal metastases and neurological symptoms or signs suggestive of MSCC, and occasionally sooner if there is a pressing clinical need for emergency surgery.

### 6.3 **Current UK practice**

Research by Vaqas et al\(^\text{12}\) (2011) found that, out of a sample of 87 patients with metastatic spinal cord compression, over 95% of patients had an MRI of the whole spine within 24 hours of presentation.

However, Bhamber et al\(^\text{13}\) (2013) found significantly different results when they undertook a retrospective audit that aimed to find if a tertiary spinal surgery unit was compliant with guidelines recommending whole spine MRI within one week of presentation.

---

suspected metastases. Forty-eight patients with suspected spinal metastases and a subsequent request for urgent MRI scan were identified from November 2010 to April 2011. Although all 48 patients met the criteria for obtaining an MRI scan within 1 week, time to obtain MRI on average was 22 days.

Woolf et al\textsuperscript{14} (2012) undertook research involving an audit of 85 patients treated with radiotherapy for metastatic spinal cord compression at a tertiary referral centre between January 2008 and September 2009. Results showed that the mean time from date of admission to imaging was 2.2 days (0 to 19 days). The data illustrates that significant potential delays remain in the treatment of metastatic spinal cord compression, especially in the diagnosis and in access to confirmatory imaging. The greatest delay occurs in the referring hospital and this is mainly composed of access to MRI scanning for which NICE guidance is not currently being met.

The Mount Vernon Cancer Network’s (2012) Acute Oncology Group (NAOG) commissioned an audit\textsuperscript{15} of patients diagnosed with metastatic spinal cord compression via MRI across their network to measure current practice against NICE guidance (2008). The audit includes patients who were diagnosed with metastatic spinal cord compression between June 2010 and November 2011. As part of the audit the time between requesting a scan for patients with suspected metastatic spinal cord compression and the scan being undertaken was calculated. Of the 37 patients included 29 were given an MRI on the same day as it was requested, 5 were given it on the next day, 1 patient waited longer than 48 hours (but had no neurological symptoms) and there was no data for 2 of the patients.

\textsuperscript{15} Mount Vernon Cancer Centre (2012) \textit{Metastatic spinal cord compression audit}. 
7 Suggested improvement area: Treatment

7.1 Summary of suggestions

Stakeholders emphasised that interventional radiology (biopsy, percutaneous cement reinforcement, embolisation) must be available in spinal centres. The importance of minimal access vertebral augmentation for spine surgical management was also specifically highlighted.

Stakeholders emphasised the importance of timely treatment to facilitate optimal outcomes.

Stakeholders suggested that low dose radiation therapy for metastatic spinal cord compression in myeloma and breast cancer is an area for quality improvement.

Stakeholders highlighted the need for access to spinal surgery for patients with good prognosis.

The following specific areas for quality improvement and potential development by the QSAC were highlighted, shown in the table below alongside recommendations that have been provisionally selected from the development source to support potential statement development.

7.2 Selected recommendations from development source

Recommendations from the development source relating to the suggested improvement areas have been provisionally selected and are presented below in inform QSAC discussion.

Interventional radiology

NICE CG75 Recommendation number 1.5.1.8

Consider vertebroplasty or kyphoplasty for patients who have vertebral metastases and no evidence of MSCC or spinal instability if they have:
• mechanical pain resistant to conventional analgesia, or
• vertebral body collapse.

NICE CG75 Recommendation number 1.5.1.9

Vertebroplasty or kyphoplasty for spinal metastases should only be performed after agreement between appropriate specialists (including an oncologist, interventional radiologist, and spinal surgeon), with full involvement of the patient and in facilities where there is good access to spinal surgery.

NICE CG75 Recommendation number 1.5.4.9

Consider vertebral body reinforcement with cement for patients with MSCC and vertebral body involvement who are suitable for instrumented decompression but are expected to survive for less than 1 year.

Timely intervention

NICE CG75 - Recommendation 1.5.1.10

Urgently consider patients with spinal metastases and imaging evidence of structural spinal failure with spinal instability for surgery to stabilise the spine and prevent MSCC.

NICE CG75 - Recommendation 1.5.3.1 (key priority for implementation)

Start definitive treatment, if appropriate, before any further neurological deterioration and ideally within 24 hours of the confirmed diagnosis of MSCC.

NICE CG75 - Recommendation 1.5.5.1 (key priority for implementation)

Ensure urgent (within 24 hours) access to and availability of radiotherapy and simulator facilities in daytime sessions, 7 days a week for patients with MSCC requiring definitive treatment or who are unsuitable for surgery.

Low dose radiation therapy

NICE CG75 - Recommendation 1.5.5.8

If patients have further radiotherapy, the total dose should be below a biologically equivalent dose of 100 Gy, where possible. Discuss the possible benefits and risks with the patient before agreeing a treatment plan.

Access to surgery

NICE CG75 - Recommendation 1.5.1.10

Urgently consider patients with spinal metastases and imaging evidence of structural spinal failure with spinal instability for surgery to stabilise the spine and prevent MSCC.
NICE CG75 - Recommendation 1.5.4.3

Patients with MSCC who have residual distal sensory or motor function and a good prognosis should be offered surgery in an attempt to recover useful function, regardless of their ability to walk.

7.3 Current UK practice

Woolf et al\textsuperscript{16} (2012) undertook research involving an audit of 85 patients treated with radiotherapy for metastatic spinal cord compression at a tertiary referral centre between January 2008 and September 2009. The mean time from MRI scan to transfer was 1.4 days (0 to 41 days). Mean time from arrival at the centre until the first fraction of radiotherapy was 0.9 days (0 to 6 days). The mean overall time taken from admission to hospital to first fraction of radiotherapy was 4.3 days (0 to 41 days). The data illustrates that significant potential delays remain in the treatment of metastatic spinal cord compression. The greatest delay occurs in the referring hospital and this is mainly composed of access to MRI scanning for which NICE guidance is not currently being met.

Berry et al\textsuperscript{17} (2011) conducted research for which the aim was to assess whether oncologists in a spinal centre were adhering to the NICE guidelines on metastatic spinal cord compression. All patients who received radiotherapy for metastatic spinal cord compression at the spinal centre from 1st June 2009 to 1st June 2010 were identified. The results of the study showed that, of the 34 patients who received radiotherapy for metastatic spinal cord compression, 15 patients were not referred to the spinal team prior to radiotherapy. When each individual case was reviewed it was found that 2 patients may have potentially benefited from surgical intervention. The conclusions made were that many patients are still not referred for spinal opinion. The vast majority of these patients would not have been suitable for surgery, however, a small number may have potentially benefited.

The full clinical guideline for Metastatic spinal cord compression\textsuperscript{18} presents a number of statistics relevant to this area for quality improvement. The statistics are presented by type of centre and those considered most relevant are as follows:

Cancer centres

In total, 19 centres (70%) report it is ‘easy’ or ‘very easy’ to contact the surgical team. On site surgical review is available in 10 centres (37%) and the average

\textsuperscript{18} National Collaborating Centre for Cancer (2008) Clinical Guideline 75 Metastatic spinal cord compression: diagnosis and management of adults at risk of and with metastatic spinal cord compression.
distance to a spinal unit is 10 miles (range 0 to 60 miles). Only a minority of patients are referred for review; in 18 centres (67%) less than 25% are assessed by the surgical team. Of those patients reviewed, 14 of the centres (52%) report that over 50% proceed to surgery.

**Spinal surgery units**

Sixteen units (76%) do not have a defined policy for selecting patients for surgery and 5 units (24%) use the Tokuhashi score. In 11 units (52%) over 75% of the patients referred for surgical review are not operated on. Only 4 units (19%) operated on more than half of the patients seen which is much lower than the surgical rates reported by cancer centres. Surgery is carried out within 72 hours of the decision to operate in all but one centre.

**Palliative care departments**

Surgery is an uncommon treatment for this group of patients, with 104 units (90%) reporting that 25% or less are operated on (9 or 8% of respondents were unsure). Sixty two centres (53%) report it is ‘easy’ or ‘very easy’ to contact the surgical team. The average distance to a Spinal Surgery Unit is 14.5 miles (range 0 to 100 miles).
8 Suggested improvement area: Supportive care and rehabilitation

8.1 Summary of suggestions

Stakeholders highlighted the importance of the co-ordination of rehabilitation and discharge planning. Specific comments highlighted rehabilitation of neurological deficits for this group of people. Pressure sores, bladder and bowel management were highlighted as the most problematic areas for this group. Stakeholders also highlighted the importance of timely and adequate access to community rehabilitation and equipment.

Stakeholders suggested that physiotherapy and occupational therapy treatment for people with metastatic spinal cord compression is an integral part of rehabilitation to promote independence and quality of life.

Stakeholders raised the issue that a proportion of patients presenting with metastatic spinal cord compression have an unknown primary. It is important that this group are given appropriate support and management.

The following specific areas for quality improvement and potential development by the QSAC were highlighted, shown in the table below alongside recommendations that have been provisionally selected from the development source to support potential statement development.

8.2 Selected recommendations from development source

Recommendations from the development source relating to the suggested improvement areas have been provisionally selected and are presented below in inform QSAC discussion.
Co-ordination of rehabilitation & discharge planning

NICE CG75 Recommendation number 1.1.1.7

Commissioners should establish a joint approach with councils responsible for local social services to ensure efficient provision of equipment and support, including nursing and rehabilitation services, to meet the individual needs of patients with MSCC and their families and carers.

NICE CG75 Recommendation number 1.6.5.1

Ensure that all patients admitted to hospital with MSCC have access to a full range of healthcare professional support services for assessment, advice and rehabilitation.

NICE CG75 Recommendation number 1.6.5.4 (key priority for implementation)

Discharge planning and ongoing care, including rehabilitation for patients with MSCC, should start on admission and be led by a named individual from within the responsible clinical team. It should involve the patient and their families and carers, their primary oncology site team, rehabilitation team and community support, including primary care and specialist palliative care, as required.

NICE CG75 Recommendation number 1.6.5.5

Ensure that community-based rehabilitation and supportive care services are available to people with MSCC following their return home, in order to maximise their quality of life and continued involvement in activities that they value.

NICE CG75 Recommendation number 1.6.5.6

Ensure that people with MSCC are provided with the equipment and care they require in a timely fashion to maximise their quality of life at home.

NICE CG75 Recommendation number 1.6.5.8

Clear pathways should be established between hospitals and community-based healthcare and social services teams to ensure that equipment and support for people with MSCC returning home and their carers and families are arranged in an efficient and coordinated manner.

Physiotherapy and occupational therapy

Physiotherapy and occupational therapy are not directly covered in NICE clinical guideline 75 and no recommendations are presented relating to the suggested quality improvement area.
Support and management of people with an unknown primary

NICE CG75 - Recommendation 1.5.3.2

Attempt to establish the primary histology of spinal metastases (including by tumour biopsy, if necessary) when planning definitive treatment.

8.3 Current UK practice

The full clinical guideline for Metastatic spinal cord compression\(^{19}\) presents a number of statistics relevant to this area for quality improvement. The statistics are presented by type of centre and those considered most relevant are as follows:

Cancer centres

Access to specialist physiotherapy is variable with only 13 centres (48%) providing this service (6 or 22% of respondents were unsure). Daily physiotherapy is available in 17 centres (63%) and 8 centres (30%) have a written policy on mobilisation. Occupational therapy is available in 25 centres (93%) (2 respondents were unsure). Referral to specialist rehabilitation services is available to patients in 17 centres (63%) (5 or 19% of respondents were unsure). An average of 5 patients per year (range 1 to 10) were referred for specialist rehabilitation in the 9 centres (30%) that provided this information.

Spinal surgery units

Access to specialist physiotherapy is available in 10 units (48%) (2 or 10% of respondents were unsure). Daily physiotherapy is available in 17 units (81%) and 5 units (24%) have a written policy on mobilisation (2 or 40% of respondents were unsure). Occupational therapy is available in 19 units (90%) (1 or 5% of respondents were unsure). Referral to specialist rehabilitation services is available to patients in 16 units (76%) (1 or 5% of respondents were unsure). An average of 5 patients per year (range 2 to 10) were referred for specialist rehabilitation in the 10 centres (48%) that provided this information.

Palliative care departments

Access to specialist physiotherapy is available in 65 departments (56%) (15 or 13% of respondents were unsure). Sixty nine departments (59%) reported that patients are assessed by a physiotherapist within 48 hours of referral. Fourteen departments reported waiting more than 72 hours for physiotherapy review (22 or 19% of respondents were unsure). One department has no inpatient physiotherapy service.

The Mount Vernon Cancer Network’s (2012) Acute Oncology Group (NAOG) commissioned an audit\(^{20}\) of patients diagnosed with metastatic spinal cord compression via MRI across their network to measure current practice against NICE guidance (2008). The audit includes patients who were diagnosed with metastatic spinal cord compression between June 2010 and November 2011. Results showed that there was not always evidence that a patient had been seen by either a physiotherapist or occupational therapist following diagnosis although this may be because patients were transferred to a different location for treatment. There was also a limited amount of information around patient discharge which made it very difficult to include much detail in this area in the report.

\(^{20}\) Mount Vernon Cancer Centre (2012) [Metastatic spinal cord compression audit.](#)
Appendix 1  Additional information

The Algorithms

Patient with symptoms suggestive of spinal metastases/metastatic spinal cord compression (MSCC)

Patient with prior diagnosis of cancer (should have info card)  
Patient without prior cancer diagnosis

Symptoms suggestive of spinal metastases  
Symptoms suggestive of spinal metastases plus neurological symptoms or signs suggestive of MSCC

Non-specific low back pain

Suspicious spinal pain +/- mild stable neurological symptoms/signs  
Non-specific spinal pain +/- mild stable neurological symptoms/signs

Contact MSCC coordinator within 24 hours

Contact MSCC coordinator immediately

Standard back care (outside remit of guideline)

Standard back care or cancer pathway (outside remit of guideline)

Standard back care (outside remit of guideline)

MRI within 1 week

MRI within 24 hours (sooner if paralysis imminent and emergency surgery proposed)

Continued frequent observation for symptom progression. If symptoms persist or progress refer via pathway 1 or 2

MSCC coordinator role +/- senior clinical adviser

Negative investigations or other diagnosis. Treat or refer appropriately (outside remit of guideline)

Treatment planning
- Presumptive or proven histology (including biopsy if required)
- Tumour staging, patient assessment and preferences
- Treatments for pain relief and preventing MSCC
- Definitive treatments for MSCC always prior to further deterioration (and ideally within 24 hours)

Immobilisation, mobilisation, desensitisation, supportive care and discharge planning

Rehabilitation and care at home

Palliative care

Thromboprophylaxis, pressure ulcers, cardiopulmonary problems

Limiting and managing complications

Commence, cardiorespiratory problems
Appendix 2  Key priorities for implementation recommendations (CG75)

Key priorities for implementation recommendations which have been referred to in the main body of this report are highlighted in grey.

Service configuration and urgency of treatment

• Every cancer network should ensure that appropriate services are commissioned and in place for the efficient and effective diagnosis, treatment, rehabilitation and ongoing care of patients with MSCC. These services should be monitored regularly through prospective audit of the care pathway. [1.1.1.2]

Early detection

• Inform patients at high risk of developing bone metastases, patients with diagnosed bone metastases, or patients with cancer who present with spinal pain about the symptoms of MSCC. Offer information (for example, in the form of a leaflet) to patients and their families and carers which explains the symptoms of MSCC, and advises them (and their healthcare professionals) what to do if they develop these symptoms. [1.3.1.1]

• Contact the MSCC coordinator urgently (within 24 hours) to discuss the care of patients with cancer and any of the following symptoms suggestive of spinal metastases:
  • pain in the middle (thoracic) or upper (cervical) spine
  • progressive lower (lumbar) spinal pain
  • severe unremitting lower spinal pain
  • spinal pain aggravated by straining (for example, at stool, or when coughing or sneezing)
  • localised spinal tenderness
  • nocturnal spinal pain preventing sleep. [1.3.2.1]

• Contact the MSCC coordinator immediately to discuss the care of patients with cancer and symptoms suggestive of spinal metastases who have any of the following neurological symptoms or signs suggestive of MSCC, and view them as an oncological emergency:
  • neurological symptoms including radicular pain, any limb weakness, difficulty in walking, sensory loss or bladder or bowel dysfunction
  • neurological signs of spinal cord or cauda equina compression. [1.3.2.2]

Imaging

• Perform MRI of the whole spine in patients with suspected MSCC, unless there is a specific contraindication. This should be done in time to allow definitive treatment to be planned within 1 week of the suspected diagnosis in the case of spinal pain suggestive of spinal metastases, and within 24 hours in the case of spinal pain suggestive of spinal metastases and neurological symptoms or signs suggestive of MSCC, and occasionally sooner if there is a pressing clinical need for emergency surgery. [1.4.3.3]
Treatment of spinal metastases and MSCC

- Patients with severe mechanical pain suggestive of spinal instability, or any neurological symptoms or signs suggestive of MSCC, should be nursed flat with neutral spine alignment (including ‘log rolling’ or turning beds, with use of a slipper pan for toilet) until bony and neurological stability are ensured and cautious remobilisation may begin. [1.5.2.1]

- Start definitive treatment, if appropriate, before any further neurological deterioration and ideally within 24 hours of the confirmed diagnosis of MSCC. [1.5.3.1]

- Carefully plan surgery to maximise the probability of preserving spinal cord function without undue risk to the patient, taking into account their overall fitness, prognosis and preferences. [1.5.4.6]

- Ensure urgent (within 24 hours) access to and availability of radiotherapy and simulator facilities in daytime sessions, 7 days a week for patients with MSCC requiring definitive treatment or who are unsuitable for surgery. [1.5.5.1]

Supportive care and rehabilitation

- Discharge planning and ongoing care, including rehabilitation for patients with MSCC, should start on admission and be led by a named individual from within the responsible clinical team. It should involve the patient and their families and carers, their primary oncology site team, rehabilitation team and community support, including primary care and specialist palliative care, as required. [1.6.5.4]

**Additional Comments**

SCM04 suggested the following statements:

1. Patients at risk at risk should be clearly informed of the symptoms which could occur with MSCC.

2. There should be a rapid referral pathway to ensure patients suspected of MSCC are seen by the appropriate specialist/s
3. There should be a MSCC Co-ordinator available at all times in each centre which delivers the service.

4. Patients suspected of MSCC should have a MRI scan within 24 hours of referral.

5. Patients should be informed of a contact person who will be available to link with the key facilities delivering care.

6. Patients with MSCC who are able to walk at presentation need to be prioritised for urgent treatment within 24 hours.

7. Surgical Intervention should be delivered in appropriate (Neuroscience or Spinal Surgery) centres by Specialists with experience in the interventions.

8. Radiotherapy facilities should be available within 24 hours as primary treatment and/or later as an adjunct to surgical management.

9. Pain management expertise must be available to support the treatment programme.

10. Rehabilitation facilities must be available as part of the ongoing care.
