

## Diabetes in pregnancy

Management of diabetes and its complications  
from preconception to the postnatal period

*NICE guideline 3*

*Appendix H: Evidence tables*

*Wednesday February 25th, 2015*

*Final*

*Commissioned by the National Institute for  
Health and Care Excellence*

**Disclaimer**

Healthcare professionals are expected to take NICE clinical guidelines fully into account when exercising their clinical judgement. However, the guidance does not override the responsibility of healthcare professionals to make decisions appropriate to the circumstances of each patient, in consultation with the patient and/or their guardian or carer.

## Contents

Appendix H: Evidence tables .....	5
H.1 What is the effectiveness of oral oestrogen-containing or progestogen-containing contraceptives in women with diabetes compared with women without diabetes? .....	5
H.2 Blood glucose targets in the pre-conception period .....	36
H.3 What is the target value for HbA1c in women with type 1 or type 2 diabetes who are planning pregnancy? .....	37
H.4 Ketone monitoring in the pre-conception period.....	50
H.5 What is the effectiveness of specialist teams for pregnant women with diabetes compared with separate obstetric and endocrinology teams? .....	51
H.6 What are the target ranges for blood glucose in women with type 1, type 2 or gestational diabetes during pregnancy? .....	64
H.7 What is the target value for HbA1C in women with type 1, type 2 or gestational diabetes during pregnancy? .....	74
H.8 What is the effectiveness of blood glucose monitoring in predicting adverse outcomes in women with type 1, type 2 or gestational diabetes during pregnancy? .....	80
H.9 HbA1C monitoring during pregnancy .....	100
H.10 Ketone monitoring during pregnancy.....	101
H.11 What is the effectiveness of continuous glucose monitoring in pregnant women .....	
H.12 Screening for gestational diabetes in the first trimester .....	114
H.13 Gestational diabetes – second trimester screening .....	125
H.14 Diagnostic criteria for gestational diabetes .....	149
H.15 Interventions for gestational diabetes .....	160
H.16 Timing of birth .....	242
H.17 Diagnostic accuracy and timing of postnatal testing .....	252

## Appendix A: Evidence tables

### A.1 What is the effectiveness of oral oestrogen-containing or progestogen-containing contraceptives in women with diabetes compared with women without diabetes?

A structured interview was used to determine whether the women had ever taken birth control pills, and if they had, the names and duration of use of the medications. Grading of retinopathy took place at the University of Wisconsin Fundus Photograph Reading Centre using the Early Treatment Diabetic Retinopathy Study adaptation of the modified Airlie House classification of diabetic retinopathy, which was further adapted in-house. The level of retinopathy was determined by the most severely involved eye. For each eye, the maximum grade in any of the seven standard photographic fields was determined for each of the lesions and used in defining the retinopathy levels. The scale ranged from no retinopathy to the most severe retinopathy (including severe vitreous hemorrhage, phthitisis bulbi, or enucleation). Hypertension is defined as ≥ 160 mmHg systolic and/or ≥95 mmHg diastolic for women aged 25 years or older, and ≥ 140 mmHg systolic and/or ≥</p>	<p><b>Results</b> The authors of the paper state that the 'mild to minimal' and 'moderate to severe' categories of diabetic retinopathy are nonproliferative.</p> <p>Never used birth control pills* No diabetic retinopathy= 31/214 (14%) Mild to minimal diabetic retinopathy= 88/214 (41%) Moderate to severe retinopathy= 43/214 (20%) Proliferative retinopathy= 52/214 (24%)</p> <p>Ever used birth control pills No diabetic retinopathy= 14/170 (8%) Mild to minimal diabetic retinopathy= 77/170 (45%) Moderate to severe retinopathy= 37/170 (22%) Proliferative retinopathy= 42/170 (25%)</p> <p>≤ 1 year of use of birth control pills (excluding never used) No diabetic retinopathy= 6/62 (10%) Mild to minimal diabetic retinopathy= 25/62 (40%) Moderate to severe retinopathy= 16/62 (26%) Proliferative retinopathy= 15/62 (24%)</p> <p>2 to 4 years of use of birth control pills No diabetic retinopathy= 4/59 (7%) Mild to minimal diabetic retinopathy= 33/59 (56%) Moderate to severe retinopathy= 10/59 (17%) Proliferative retinopathy= 12/59 (20%)</p>	<p><b>Limitations</b> NICE guidelines manual. Study details	Participants	Interventions	Methods	Outcomes and results	Comments
					December 1996, only those with risk factors for gestational diabetes (including family history of diabetes, personal history of gestational diabetes, prior delivery of a stillborn, malformed or macrosomic neonate) were screened for gestational diabetes. From January 1997 all pregnant women were routinely screened for gestational diabetes between 24 and 28 weeks, however, only women who also had risk factors for gestational diabetes were included in this study to minimise selection bias.

Previously known diabetic patients were excluded from the study. For women with FPG <math>\geq 7.00</math> mmol/L at the first prenatal visit, medical care for diabetes was provided; for those with FPG <math>&lt; 7.00</math> mmol/L, no interventions were made until women returned at 24 and 28 weeks in the fasting state for repeat testing, and this time a 75-g OGTT was performed. Venous blood samples were collected at 0, 1, and 2 h after a 75-g glucose load. iagnosis of gestational diabetes can be made when any one of the following values is met or exceeded in the 75-g OGTT: 0 h (fasting), <math>\geq 5.10</math> mmol/L; 1 h, <math>\geq 10.00</math> mmol/L; and 2 h, <math>\geq 8.50</math> mmol/L. Data of FPG at the first prenatal visit</p>	<p><b>Results</b> Incidence of gestational diabetes</p> <p>Incidence gestational diabetes using IADPSG 75g OGTT in 2nd trimester = 3002/17186 (17.4%)</p> <p>Diagnostic accuracy of FPG at 13.4 <math>\pm</math> 3.5 weeks to detect gestational diabetes at 24-28 weeks using IADPSG criteria using 2 hour 75g OGTT</p> <p>FPG Threshold at 4.1mmol/l TP: 2816 FP: 12432 FN: 186 TN: 1752 Sensitivity,% (95% CI): 93.8 (92.9 - 94.6)* Specificity, % (95% CI): 12.4 (12.2 - 12.5)* LR+ (95% CI): 1.07 (1.06 - 1.08)* LR- (95% CI): 0.50 (0.43 - 0.58)*</p> <p>FPG Threshold at 4.6mmol/l TP: 1944 FP: 6259 FN: 1058 TN: 7935 Sensitivity,% (95% CI): 64.8 (63.2 - 66.3)* Specificity, % (95% CI): 55.9 (55.6 - 56.3)* LR+ (95% CI): 1.47 (1.42 - 1.52)* LR- (95% CI): 0.63 (0.60 - 0.66)*</p> <p>FPG Threshold at 5.1mmol/l TP: 779 FP: 1180 FN: 2223 TN: 13004 Sensitivity,% (95% CI): 25.9 (24.7 - 27.2)* Specificity, % (95% CI): 91.7 (91.4 - 92.0)* LR+ (95% CI): 3.12 (2.87 - 3.38)* LR- (95% CI): 0.81 (0.79 - 0.82)*</p>	<p><b>Limitations</b> NICE guidelines manual 2009: Appendix G: the QUADAS tool for studies of diagnostic test accuracy</p> <ol style="list-style-type: none"> <li>1) Was the spectrum of participants representative of the patients who will receive the test in practice: Yes</li> <li>2) Were selection criteria clearly described: Yes</li> <li>3) Was the reference standard likely to classify the target condition correctly: Yes</li> <li>4) Was the period between performance of the reference standard and the index test short enough to be reasonably sure that the target condition did not change between the two tests: Unclear</li> <li>5) Did the whole sample or a random selection of the sample receive verification using the reference standard: The whole sample</li> <li>6) Did participants receive the same reference standard regardless of the index test result: Yes</li> <li>7) Was the reference standard independent of the index test i.e. the index test did not form part of the reference standard: Yes.</li> <li>8) Was the execution of the index test described in sufficient detail to permit its replication: Yes</li> <li>9) Was the execution of the reference standard described in sufficient detail</li> </ol>

**Inclusion Criteria**

Women who had a live singleton birth at ≥ 20 weeks gestation at the KPSC Bellflower Medical Centre within the study period, who had a prenatal 2 hour 75g OGTT with no prior 50g oral glucose challenge test, for whom pre-pregnancy and delivery anthropometric data were available and who did not receive treatment

**Exclusion criteria**

Women receiving any form of treatment during pregnancy (n = 488). Only data from the first birth were included for women who had more than one birth during the study period.

<p><b>Wendland, E.M., Torloni, M.R., Falavigna, M., Trujillo, J., Dode, M.A., Campos, M.A., Duncan, B.B., Schmidt, M.I., Gestational diabetes and pregnancy outcomes - a systematic review of the World Health Organization (WHO) and the International Association of Diabetes in Pregnancy Study Groups (IADPSG) diagnostic criteria, BMC Pregnancy and Childbirth, 12, 2012. Article Number, -, 2012</b></p> <p><b>Ref Id</b> 179445</p> <p><b>Country/ies where the study was carried out</b> Brazil</p> <p><b>Study type</b> Systematic review</p> <p><b>Aim of the study</b> To summarise the association between gestational diabetes (as defined by World Health Organization (WHO) and International Association of Diabetes and Pregnancy Study Groups (IADPSG) criteria) and adverse pregnancy outcomes in untreated women and evaluate the applicability of the IADPSG criteria beyond the setting of the Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study</p> <p><b>Study dates</b> Searches were run to identify study reports published prior to 15 March 2011</p> <p><b>Source of funding</b> Financial support was received from the World Health Organization</p>	<p><b>Sample size</b> Nine publications pertaining to eight cohort studies were identified and in total these studies included 44,829 women. Of relevance to this review question are results from two of the included studies, the Brazilian Study of Gestational Diabetes (EBDG 2001) and the HAPO study (HAPO 2008)</p> <p><b>Characteristics</b> Of the eight included studies, one study was performed in the USA, one in Asia, two in the Middle East, one in Europe, two in Latin America (one of which was EBDG 2001) and one was a multi-country study (HAPO 2008). All but one study used venous plasma glucose based on the oral glucose tolerance test (OGTT) to diagnose gestational diabetes</p> <p>EBDG 2001 Ethnicity White 44.9% Mixed 41.4% Black 13.6% Other 0.4%</p> <p>HAPO 2008 Ethnicity White 48.3% Black 11.6% Hispanic 8.5% Asian 29.0% Other 2.6%</p> <p><b>Inclusion criteria</b> Prospective or retrospective</p>	<p>The relative incidences of several maternal and neonatal outcomes were compared in women with and without gestational diabetes on the basis of diagnosis according to WHO 1999 criteria or IADPSG criteria</p> <p>The WHO 1999 criteria used diagnostic cut points for gestational diabetes that encompassed impaired glucose tolerance and diabetes (fasting plasma glucose <math>\geq 7</math> mmol/l ; 2 hour plasma glucose <math>\geq 7.8</math> mmol/l)</p> <p>The IADPSG criteria used the following diagnostic cut points for gestational diabetes: a fasting plasma glucose of <math>\geq 5.1</math> mmol/l, or a 1 hour result of <math>\geq 10.0</math> mmol/l, or a 2 hour result of <math>\geq 8.5</math> mmol/l</p>	<p>Ten electronic databases (MEDLINE, EMBASE, LILACS, the Cochrane Library (CENTRAL), CINAHL, WHO-Afro library, IMSEAR, EMCAT, IMEMR and WPRIM) were searched without language or country restrictions. Classical review articles and reference lists of studies retrieved in full text were also searched for potentially relevant studies. All identified citations were entered into an electronic database and duplicates removed. Two investigators independently screened titles and abstracts of potentially relevant studies. Discrepancies were discussed until consensus was reached</p> <p>Two independent investigators reviewed extracted data using a standardised form. Disagreements were discussed and resolved in a consensus meeting. When raw</p>	<p><b>Results</b> Eight studies in nine publications were included: Aberg 2001, Black 2010, EBDG 2001, Forsbach 1997, HAPO 2008, HAPO 2010, Khan 1994, Shirazian 2008, Sugaya 2000</p> <p>Relative incidence of maternal and neonatal outcomes in women with and without gestational diabetes</p> <p>Caesarean section Data from 2 studies were included EBDG 2001 WHO criteria, women with gestational diabetes = 151/321 IADPSG criteria, women with gestational diabetes = 309/801 Total number of untreated women tested = 4345</p> <p>HAPO 2008 WHO criteria, women with gestational diabetes = 564/2314 IADPSG criteria, women with gestational diabetes = 813/3338 Total number of untreated women tested = 20,732</p>	<p><b>Limitations</b> Appendix B: Methodology checklist: systematic reviews and meta-analyses</p> <ol style="list-style-type: none"> <li>1) The review addresses an appropriate and clearly focused question that is relevant to the guideline review question: Yes</li> <li>2) The review collects the type of studies you consider relevant to the guideline review question: Yes</li> <li>3) The literature search is sufficiently rigorous to identify all the relevant studies: Yes</li> <li>4) Study quality is assessed and reported: Yes</li> <li>5) An adequate description of the methodology used is included, and the methods used are appropriate to the question: No : details of data extraction for HAPO 2008 study are inadequate, for the large for gestational age outcome - denominators of the total numbers of women tested for gestational diabetes are different for IADPSG and WHO criteria and the statistical significance of the outcome findings cannot be assessed appropriately for this review question</li> </ol> <p><b>Other information</b> This systematic review investigated a universal screening strategy</p>

Bibliographic details	Participants	Tests	Methods	Outcomes and results	Comments
	<p>cohort studies which included women of any race, parity, age, body weight or other sociodemographic characteristics were considered for inclusion if they provided sufficient information to estimate the associations of the WHO and/or the IADPSG criteria with related perinatal and maternal outcomes</p> <p>Only studies that applied a 2 hour 75 g OGTT performed during the 2nd or the 3rd trimesters universally (in all study participants) and which provided results for a diagnosis based on at least the 2 hour post-load glucose were included. Studies based on capillary glucose measurements were also included</p> <p>Perinatal outcomes examined were large for gestational age births, macrosomia (as defined by the authors) and perinatal mortality (fetal death and early neonatal death). Maternal outcomes that were analysed were caesarean delivery and pre-eclampsia (as defined according to individual studies). Only results for women who were untreated were analysed</p> <p>Exclusion Criteria Studies applying the OGTT only in women with certain clinical risk factors (such as family history, obesity,</p>		<p>quantitative data were not reported, approximate values were obtained from the figures or calculated from percentages. The methodological quality of included studies was assessed by examining factors that might affect the strength of the association between glucose levels and outcomes. The following factors were assessed in each study: i) adequate selection of participants - consecutive recruitment from antenatal clinics; ii) adequate standardisation of the glucose tolerance test (pre-analytic factors such as anhydrous glucose, plasma immediately separated or kept with glycolytic inhibitors and kept refrigerated until centrifugation; and analytic factors such as enzymatic method of measurement and laboratory quality control); iii) adequate reporting of losses to follow up; iv) medical staff blinded to OGTT results</p> <p>EBDG 2001 study quality assessment</p>	<p>Large for gestational age (birthweight <math>\geq</math> 90th centile for gestational age) Data from 2 studies were included EBDG 2001 WHO criteria, women with gestational diabetes = 45/294 Total number of untreated women tested using WHO criteria = 3924 IADPSG criteria, women with gestational diabetes = 87/772 Total number of untreated women tested using IADPSG criteria = 3974</p> <p>HAPO 2008 WHO criteria, women with gestational diabetes = 361/2642 Total number of untreated women tested using WHO criteria = 23,027 IADPSG criteria, women with gestational diabetes = 605/3738 Total number of untreated women tested using IADPSG criteria = 23,217</p> <p>Perinatal mortality (foetal death and early neonatal death) Data from 1 study were included EBDG 2001 WHO criteria, women with gestational</p>

<p><b>Country/ies where the study was carried out</b> United States of America</p> <p><b>Study type</b> Randomised controlled trial.</p> <p><b>Aim of the study</b> To determine whether treatment of women with mild gestational diabetes reduces perinatal and obstetric complications.</p> <p><b>Study dates</b> October 2002 to November 2007.</p> <p><b>Source of funding</b> Supported by grants from the Eunice Kennedy Shriver National Institute of Child Health and Human Development., the General Clinical Research Centers and the National Center for Research Resources.</p>	<p><b>Exclusion criteria</b> Pre-existing diabetes, an abnormal result on a glucose screening test before 24 weeks' gestation, prior gestational diabetes, a history of stillbirth, multifoetal gestation, asthma or chronic hypertension, corticosteroid treatment or if imminent/pre-term delivery was likely because of maternal or foetal conditions. To capture only mild GDM women with an OGTT &gt; 5.3mmol/l (95mg/dl) were excluded and their care provider informed.</p>		<p>Hypoglycaemia Hyperbilirubinaemia Neonatal hyperinsulinaemia Birth trauma</p> <p>Hyperinsulinaemia was defined as cord-blood C-peptide &gt; 95th percentile. Neonatal hypoglycaemia was defined as glucose &lt; 1.9mmol/l (35mg/dl) two hours after birth and before feeding. Hyperbilirubinaemia was defined as serum bilirubin &gt; 95th percentile. Birth trauma was defined as brachial plexus palsy or clavicular, humeral or skull fracture.</p> <p>Secondary neonatal outcomes: Birth weight &gt; 4000g (macrosomia) Large for gestational age (&gt; 90th percentile) Admission to the neonatal care unit</p> <p>Secondary maternal outcomes: Caesarean delivery Labour induction Shoulder dystocia (defined clinically)</p> <p><b>Statistical analysis</b> Based on a literature review it was assumed that outcome rates would be between 20 and 30% in the control group. A composite outcome rate of 25% was assumed in the control group. Sample size was calculated to be 950 for a power of 80% to detect a 30% difference in the composite outcome with</p>	<p>RR not calculable.</p> <p>Treatment failure Treatment: 37/476 Control: 2/455 RR = 17.68 (95% CI 4.29 to 72.93)*</p> <p>*Calculated by the NCC-WCH technical team.</p>	<p>Unclear - no p-values reported.</p> <p>B. Performance bias B1: The comparison groups received the same care apart from the intervention(s) studied. Unclear</p> <p>B2: Participants receiving care were kept 'blind' to treatment allocation. Unclear</p> <p>B3: Individuals administering care were kept 'blind' to treatment allocation. No - blinded to diagnosis status of controls only.</p> <p>C. Attrition bias C1: All groups were followed up for an equal length of time (or analysis was adjusted to allow for differences in length of follow-up). Unclear</p> <p>C2: a. How many participants did not complete treatment in each group? None</p> <p>b. The groups were comparable for treatment completion. Yes</p> <p>C3: a. For how many participants in each group were no outcome data</p>

Study details	Participants	Interventions	Methods	Outcomes and results	Comments															
			<p>treatment. Type 1 error was set at 5%. This sample size provided 85% power to detect a 30% reduction in rates of large for gestational age births and births &gt; 4000g.</p> <p>Analyses were carried out according to the intention to treat principle.</p> <p>Categorical variables were compared using X2 or Fisher's exact tests. Continuous variables were analysed using the Wilcoxon ranksum test.</p> <p>An external data monitoring committee was used for four interim analyses. Adjusted type 1 error was calculated using the Lan-DeMets generalisation of the O'Brien-Fleming boundary. In final analyses p-values &lt; 0.032 were considered significant, providing 97% confidence intervals for relative risks.</p>		<p>available? Unclear - missing data but numbers and/or group not reported.</p> <p>b. The groups were comparable with respect to the availability of outcome data. Unclear</p> <p>D. Detection bias D1: The study had an appropriate length of follow-up. Unclear D2: The study used a precise definition of outcome. Yes D3: A valid and reliable method was used to determine the outcome. Yes D4: Investigators were kept 'blind' to participants' exposure to the intervention. No D5: Investigators were kept 'blind' to other important confounding and prognostic factors. Unclear</p>

<p><b>diabetes.[Erratum appears in N Engl J Med. 2008 Jul 3;359(1):106], New England Journal of Medicine, 358, 2003-2015, 2008</b></p> <p><b>Ref Id</b> 145223</p> <p><b>Country/ies where the study was carried out</b> Australia</p> <p><b>Study type</b> Open-label, randomised controlled trial</p> <p><b>Aim of the study</b> The Metformin in Gestational Diabetes(MiG) Trial was designed to rule out a 33% increase in a composite of perinatal complications in infants of women treated with metformin as compared with insulin. The hypotheses were that perinatal outcomes would be similar for both treatments, that women would consider metformin a more acceptable treatment than insulin, and that metformin would improve markers of insulin sensitivity in</p>	<p><b>Characteristics</b> The two groups were similar at baseline for 21 characteristics including age, BMI, gestation length at enrollment, race/ethnic group, smoking, blood pressure, diagnostic test result and obstetric and family history parameters. However, more women in the metformin group than in the insulin group had had 3 or more pregnancy terminations or miscarriages (23.1% vs 16.8%, p = 0.03).</p> <p><b>Inclusion criteria</b> Women were eligible for inclusion if they were between 18 and 45 years of age, had received a diagnosis of gestational diabetes mellitus according to ADIPS 1998 criteria, were pregnant with a single fetus between 20 and 33 weeks of gestation, met the hospital's usual criteria for starting insulin treatment, and, after lifestyle intervention consisting of advice about diet and exercise, had more than one capillary blood glucose measurement above 5.4 mmol/l after an overnight fast or more than one 2-hour postprandial blood glucose measurement above 6.7 mmol/l.</p> <p><b>Exclusion criteria</b> Exclusion criteria were a prepregnancy diagnosis of diabetes, a contraindication to metformin, a fetal anomaly, gestational hypertension, preeclampsia, fetal growth restriction and ruptured membranes.</p>	<p>levels (fasting &lt;5.5 mmol/l; 2-hour postprandial &lt;7.0 mmol/l), several sites aimed for lower target levels.</p> <p>Metformin Local pharmacies supplied medications to women according to prescription.</p> <p>Metformin was supplied as Metomin [Pacific Pharmaceuticals] in New Zealand and as Diaformin Alphapharm and other nonspecified manufacturers] in Australia). The initial dose was 500 mg once or twice daily with food and was typically increased over 1 to 2 weeks, to meet glycemic targets up to a maximum daily dose of 2500 mg. If the targets were not achieved with metformin alone, insulin was added.</p> <p>Metformin was stopped if maternal contraindications (such as liver or renal impairment or sepsis) or fetal growth restriction developed.</p> <p>Insulin Insulin was prescribed according to usual practice.</p>	<p>phototherapy, 1.5% for birth trauma, &lt; 1% for Apgar scores below 7, and 15% for preterm delivery. The infants could meet one or more of the criteria. Two-tailed calculations were used to rule out a significant difference in either direction. For 80% power and a 5% significance level, 375 subjects were required in each group.</p> <p>Block randomisation was performed with stratification according to site and gestational age (from 20 to 27+6 weeks or from 28 to 33+6 weeks).</p> <p>The primary outcome was a composite of the following neonatal complications: neonatal hypoglycemia (two or more neonatal glucose values &lt;2.6 mmol per litre), respiratory distress (need for at least 4 hours of respiratory support with supplemental oxygen, continuous positive airway pressure, or intermittent positive-pressure ventilation during the first 24 hours after delivery), need for phototherapy, birth trauma (injury to the baby at delivery, documented as mild if bruises or abrasions were present at birth but resolved before 6 weeks post partum; more serious injuries were also recorded), 5-minute Apgar score below 7, or premature birth (&lt;37 weeks of gestation).</p> <p>The component complications were chosen to reflect important adverse effects of fetal exposure to maternal hyperglycemia that might be modified by</p>	<p>(36.1%) Insulin group = 142 (38.4%) (P = 0.52) Emergency cesarean section Metformin group = 55 women (15.2%) Insulin group = 63 (17.0%) (P = 0.49) Treatment failure Supplemental insulin was required in 168 women (46.3%) in the metformin group. Metformin treatment was stopped in 27 women (7.4%) before delivery (Fig. 1). Treatment was stopped in 11 of these women in accordance with the trial protocol (9 women had obstetrical complications, 1 had sepsis, and 1 had worsening abnormal liverfunction test results); treatment was stopped in 7 women (1.9%) because of gastrointestinal side effects; 5 women chose to stop metformin; and 4 women were advised to stop by other health professionals who were not involved in the trial.</p> <p>Metformin doses were reduced because of gastrointestinal side effects in 32 women (8.8%); all but 1 of these women were able to maintain a dose of at least 1000 mg per day.</p> <p>Results of questionnaire regarding acceptability of treatment How often did you forget to take your medication? p &lt; 0.001 Never or rarely: Metformin Group = 231/333 (69.4%) Insulin Group = 267/331 (80.7%) 1-3 times/wk: Metformin Group = 81/333 (24.3%) Insulin Group = 52/331 (15.7%) 4-6 times/wk: Metformin Group = 12/333 (3.6%) Insulin Group = 2/331 (0.6%) &gt;6 times/wk: Metformin Group = 9/333 (2.7%) Insulin Group =</p>	<p>concealment: Unclear Groups comparable at baseline: Yes except for one point of obstetric history Groups received the same care (apart from the intervention): Yes Participants kept 'blind' to allocation: No Care givers kept 'blind' to allocation: No Follow up equal for groups: Yes How many participants did not complete treatment in each group?: Metformin group =27, Insulin Group = 0 Were the groups were comparable for treatment completion: Only repotred for metformin group For how many participants in each group were no outcome data available?: Data after randomization were not available for 10 women in the metformin group and 8 in the insulin group. The groups were comparable with respect to the availability of outcome data: Yes Appropriate length of follow-up: Yes Precise outcome definitions used: Yes Outcome determined using valid and reliable methods: Yes Investigators kept 'blind' to allocation: No</p>

Study details	Participants	Interventions	Methods	Outcomes and results	Comments																																																												
One author was supported by the National Institute of Child Health and Human Development	<p><b>Inclusion criteria</b> Women were identified from California Vital Statistics Birth Certificate Data linked with the California Patient Discharge Data as well as Vital Statistics Death Certificate Data and Vital Statistics Fetal Death File. 193,028 deliveries were to women with a diagnosis of gestational diabetes identified from maternal medical records using ICD-9 codes: 648.8, 648.80, 648.81, 648.82, 648.83 and 648.84.</p> <p><b>Exclusion criteria</b> Women with a diagnosis of pre-pregnancy (Type 1 or Type 2) diabetes mellitus were excluded (using ICD-9 codes: 648.0, 648.01, 648.02, 648.03, and 648.04). Multiple gestations and births with congenital anomalies as determined by diagnosis codes on the birth certificate and the infant's medical record (ICD-9 codes Q00-Q99) were also excluded.</p> <p>The mother/infant pair was excluded from analysis if the date of last menstrual period was missing or was nonsensical, as this was needed to calculate the length of gestation</p>		<p>that gestational age per 1000 deliveries.</p> <p>Infant mortality at each gestational age was defined as the number of infants born at this gestational age who die within one year of life per 10,000 live births at that same gestational age.</p> <p>Calculations relied on the following assumptions: 1. The risk of infant death has a uniform distribution throughout the week of gestation. 2. When estimating the risk of delivering at a particular gestational age, the fetus is not at risk for stillbirth beyond that gestational age, therefore their mortality risk in that week is equal only to the risk of infant death. 3. The composite risk associated with expectant management is the sum of the risk of stillbirth during the week of gestation plus the risk of infant death in the following week of gestation.</p>	<table border="1"> <tr> <td>41</td> <td>15,717</td> <td>3.2 (1.0 - 7.4)</td> <td>509749</td> <td>3.6 (3.1 - 4.2)</td> <td>0.88 (0.36 to 2.14)*</td> </tr> <tr> <td>42</td> <td>6,285</td> <td>6.4 (1.7 - 16.3)</td> <td>168769</td> <td>4.7 (3.7 - 5.8)</td> <td>1.36 (0.50 to 3.72)*</td> </tr> </table> <p>Incidence of Infant death</p> <table border="1"> <thead> <tr> <th>GA</th> <th>GDM Deliveries</th> <th>GDM Infant death/10,000 live births (95% CI)</th> <th>No GDM Deliveries</th> <th>No GDM Infant death/10,000 live births (95% CI)</th> <th>RR (95% CI) of Infant death</th> </tr> </thead> <tbody> <tr> <td>36</td> <td>10445</td> <td>19.3 (11.8 - 29.8)</td> <td>155597</td> <td>22.9 (20.6 - 25.4)</td> <td>0.84 (0.54 - 1.32)</td> </tr> <tr> <td>37</td> <td>22,157</td> <td>14.0 (9.5 - 19.9)</td> <td>340,239</td> <td>18.4 (17.0 - 19.9)</td> <td>0.76 (0.53 - 1.1)</td> </tr> <tr> <td>38</td> <td>44,487</td> <td>10.6 (7.8 - 14.1)</td> <td>736,413</td> <td>13.3 (12.5 - 14.2)</td> <td>0.80 (0.59 - 1.06)</td> </tr> <tr> <td>39</td> <td>56,085</td> <td>8.7 (6.5 - 13.2)</td> <td>1,105,279</td> <td>10.7 (10.1 - 11.4)</td> <td>0.82 (0.61 - 1.08)</td> </tr> <tr> <td>40</td> <td>37,819</td> <td>9.5 (6.7 - 13.2)</td> <td>981,106</td> <td>11.6 (10.9 - 12.3)</td> <td>0.82 (0.59 - 1.14)</td> </tr> <tr> <td>41</td> <td>15,739</td> <td>11.5 (6.8 - 18.1)</td> <td>510,292</td> <td>12.8 (11.9 - 13.9)</td> <td>0.89 (0.56 - 1.4)</td> </tr> <tr> <td>42</td> <td>6,296</td> <td>9.5 (3.5 - 20.8)</td> <td>168,999</td> <td>14.0 (12.3 - 15.9)</td> <td>0.68 (0.3 - 1.5)</td> </tr> </tbody> </table> <p>* Calculated by NCC-WCH</p>	41	15,717	3.2 (1.0 - 7.4)	509749	3.6 (3.1 - 4.2)	0.88 (0.36 to 2.14)*	42	6,285	6.4 (1.7 - 16.3)	168769	4.7 (3.7 - 5.8)	1.36 (0.50 to 3.72)*	GA	GDM Deliveries	GDM Infant death/10,000 live births (95% CI)	No GDM Deliveries	No GDM Infant death/10,000 live births (95% CI)	RR (95% CI) of Infant death	36	10445	19.3 (11.8 - 29.8)	155597	22.9 (20.6 - 25.4)	0.84 (0.54 - 1.32)	37	22,157	14.0 (9.5 - 19.9)	340,239	18.4 (17.0 - 19.9)	0.76 (0.53 - 1.1)	38	44,487	10.6 (7.8 - 14.1)	736,413	13.3 (12.5 - 14.2)	0.80 (0.59 - 1.06)	39	56,085	8.7 (6.5 - 13.2)	1,105,279	10.7 (10.1 - 11.4)	0.82 (0.61 - 1.08)	40	37,819	9.5 (6.7 - 13.2)	981,106	11.6 (10.9 - 12.3)	0.82 (0.59 - 1.14)	41	15,739	11.5 (6.8 - 18.1)	510,292	12.8 (11.9 - 13.9)	0.89 (0.56 - 1.4)	42	6,296	9.5 (3.5 - 20.8)	168,999	14.0 (12.3 - 15.9)	0.68 (0.3 - 1.5)	<p>than those without gestational diabetes</p> <p>6) The statistical analysis is appropriate for the design of the study, limiting potential for the presentation of invalid results: Y</p> <p>Other information</p>
